Similar to `getColumn`, the following expressions can be used to return column values from field wells or themes:

- `getColumnFromGroupBy` returns columns from the group by field. The second argument is the index of the column to return. For example, `["getColumnFromGroupBy", 0]` returns values of the first field as an array. You can pass multiple indices to get an array of arrays where each element corresponds to the field in the group by field well.
- `getColumnFromValue` returns columns from the value field well. You can pass multiple indices to get an array of arrays where each element corresponds to the field in the values field well.
- `getColorTheme` returns the current color palette of a Quick theme, shown in the following example.

```
{  
  "color": ["getColorTheme"]  
}
```

```
{  
  "color": ["getPaletteColor", "secondaryBackground"]  
}
```

14	1	2,831
15	1	2,601
16	1	3,198

Page size

500

<< < Page 1 > >>

getColumn can access any column from the table:

- ["getColumn", 0] - returns array [1, 2, 3, 4, 5, ...]
- ["getColumn", 1] - returns array [1, 1, 1, 1, 1, ...]

- ["getColumn", 2] - returns array [1674, 7425, 4371, ...]

getColumnFromGroupBy works similarly, but its index is limited to the columns in the group by field well:

- ["getColumnFromGroupBy", 0] - returns array [1, 2, 3, 4, 5, ...]
- ["getColumnFromGroupBy", 1] - returns array [1, 1, 1, 1, 1, ...]
- ["getColumnFromGroupBy", 2] - does not work, since there are only two columns in the group by field well

getColumnFromValue works similarly, but its index is limited to the columns in the value field well:

- ["getColumnFromValue", 0] - returns array [1, 2, 3, 4, 5, ...]
- ["getColumnFromValue", 1] - does not work, since there is only one column in the value field well
- ["getColumnFromValue", 2] - does not work, since there is only one column in the value field well

formatValue

Use the formatValue expression to apply Quick formatting to your values. For example, the following expression formats the x-axis label with the format value that is specified in the first field of Quick field wells.

```
"xAxis": {
  "categories": ["getColumn", 0],
  "labels": {
    "formatter": ["formatValue", "value", 0]
  }
}
```

Using histograms

Use a histogram chart in Amazon Quick to display the distribution of continuous numerical values in your data. Amazon Quick uses un-normalized histograms, which use an absolute count of the data points or events in each bin.

To create a histogram, you use one measure. A new histogram initially displays ten *bins* (also called *buckets*) across the X-axis. These appear as bars on the chart. You can customize the bins to suit your dataset. The Y-axis displays the absolute count of the values in each bin.

Make sure that you adjust the format settings so that you have a clearly identifiable shape. If your data contains outliers, this becomes clear if you spot one or more values off to the side of the X-axis. For information about how Amazon Quick handles data that falls outside display limits, see [Display limits](#).

Histogram features

To understand the features supported by histograms, use the following table.

Feature	Supported?	Comments	For more information
Changing the legend display	No		Legends on visual types in Quick
Changing the title display	Yes		Titles and subtitles on visual types in Quick
Changing the axis range	No	However, you can change the bin count or the bin interval width (range of distribution).	
Showing or hiding axis lines, grid lines, axis labels, and axis sort icons	Yes		Axes and grid lines on visual types in Quick
Changing the visual colors	Yes		Colors in visual types in Quick
Focusing on or excluding elements	No		
Sorting	No		

Feature	Supported?	Comments	For more information
Performing field aggregation	No	Histograms use only the count aggregation.	
Adding drill-downs	No		

Creating a histogram

Use the following procedure to create a histogram.

To create a histogram

1. On the analysis page, choose **Visualize** on the tool bar.
2. Choose **Add** on the application bar, and then choose **Add visual**.
3. On the **Visual types** pane, choose the histogram icon.
4. On the **Fields list** pane, choose the field that you want to use in the **Value** field well. A **Count** aggregate is automatically applied to the value.

The resulting histogram shows the following:

- The X-axis displays 10 bins by default, representing the intervals in the measure that you choose. You can customize the bins in the next step.
 - The Y-axis displays the absolute count of individual values in each bin.
5. (Optional) Choose **Format** on the visual control to change the histogram format. You can format the bins either by count or width, not both together. The count setting changes how many bins display. The width setting changes how wide or long of an interval each bin contains.

Formatting a histogram

Use the following procedure to format a histogram.

To format a histogram

1. Choose the histogram chart that you want to work with. It should be the highlighted selection. The visual controls display on the top right of the histogram.
2. Choose the cog icon on the visual control menu to view the **Format visual** options.
3. On the **Properties** pane, set the following options to control the display of the histogram:

- **Histogram** settings. Chose *one* of the following settings:
 - Bin count (option 1): The number of bins that display on the X-axis.
 - Bin width (option 1): The width (or length) of each interval. This setting controls the number of items or events to include in each bin. For example, if your data is in minutes, you can set this to 10 to show 10-minute intervals.
- With the following settings, you can explore the best way to format the histogram for your dataset. For example, in some cases, you might have a tall peak in one bin, while most of the other bins look sparse. This isn't a useful view. You can use the following settings individually or together:
 - Change the **Number of data points displayed** in the **X-axis** settings.

Amazon Quick displays up to 100 bins (buckets) by default. If you want to display more (up to 1,000), change the X-axis setting for **Number of data points displayed**.

- Enable **Logarithmic scale** in the **Y-axis** settings.

Sometimes your data doesn't fit the shape that you want and this can provide misleading results. For example, if the shape is skewed so far to the right that you can't read it properly, you can apply a log scale to it. Doing this doesn't normalize your data; however, it does reduce the skew.

- Display **Data labels**.

You can enable the display of data labels to see the absolute counts in the chart. Even if you don't want to display these in most cases, you can enable them while you're developing an analysis. The labels can help you decide on formatting and filtering options because they reveal counts in bins that are too small to stand out.

To see all the data labels, even if they overlap, enable **Allow labels to overlap**.

4. (Optional) Change other visual settings. For more information, see [Formatting in Amazon Quick](#).

Understanding histograms

Although histograms look similar to bar charts, they are very different. In fact, the only similarity is their appearance because they use bars. On a histogram, each bar is called a *bin* or a *bucket*.

Each bin contains a range of values called an *interval*. When you pause on one of the bins, details about the interval appear in a tooltip that shows two numbers enclosed in glyphs. The type of enclosing glyphs indicates if the numbers inside them are part of the interval that's inside the selected bin, as follows:

- A square bracket next to a number means that the number is included.
- A parenthesis next to a number means that the number is excluded.

For example, let's say that the first bar in a histogram displays the following notation.

$[1, 10)$

The square bracket means that the number 1 is included in the first interval. The parenthesis means that the number 10 is excluded.

In the same histogram, a second bar displays the following notation.

$[10, 20)$

In this case, 10 is included in the second interval, and 20 is excluded. The number 10 can't exist in both intervals, so the notation shows us which one includes it.

Note

The pattern used for marking intervals in a histogram comes from standard mathematical notation. The following examples show the possible patterns, using a set of numbers that includes 10, 20, and every number in between.

- $[10, 20]$ – This set is closed. It has hard boundaries on both ends.
- $[10, 21)$ – This set is half open. It has a hard boundary on the left and a soft boundary on the right.
- $(9, 20]$ – This set is half open. It has a soft boundary on the left and a hard boundary on the right.

- (9, 21) – This set is open. It has soft boundaries on both ends.

Because the histogram uses quantitative data (numbers) rather than qualitative data, there's a logical order to the distribution of the data. This is called a *shape*. The shape is often described the qualities the shape possesses, based on the count in each bin. Bins that contain a higher number of values form a *peak*. Bins that contain a lower number of values form a *tail* on the edge of a chart, and a *valley* between peaks. Most histograms fall into one of the following shapes:

- Asymmetrical or *skewed* distributions have values that cluster near the left or the right—the low or high end of the X-axis. The direction of skewness is defined by where the longer tail of the data is, not by where the peak is. It's defined this way because this direction also describes the location of the mean (average). In skewed distributions, the mean and the median are two different numbers. The different types of skewed distribution are as follows:
 - *Negatively skewed* or *left skewed* – A chart that has the mean to the left of the peak. It has a longer tail to the left and a peak to the right, sometimes followed by a shorter tail.
 - *Positively skewed* or *right skewed* – A chart that has the mean to the right of the peak. It has a longer tail to the right and a peak to the left, sometimes preceded by a shorter tail.
- Symmetrical or *normal* distributions have a shape that's mirrored on each side of a center point (for example, a bell curve). In a normal distribution, the mean and the median are the same value. The different types of normal distribution are as follows:
 - Normal distribution, or *unimodal* – A chart that has one central peak representing the most common value. This is commonly called a bell curve, or a Gaussian distribution.
 - Bimodal – A chart that has two peaks representing the most common values.
 - Multimodal – A chart that has three or more peaks representing the most common values.
 - Uniform – A chart that has no peaks or valleys, with a relatively equal distribution of data.

The following table shows how a histogram differs from a bar chart.

Histogram	Bar chart
A histogram displays the distribution of values in one field.	A bar chart compares the values in one field, grouped by dimension.

Histogram	Bar chart
A histogram sorts values into bins that represent a range of values, for example 1–10, 10–20, and so on.	A bar chart plots values that are grouped into categories.
The sum of all bins equals exactly 100% of the values in the filtered data.	A bar chart isn't required to display all of the available data. You can change display settings at the visual level. For example, a bar chart might show only the top 10 categories of data.
Rearranging bars detracts from the meaning of the chart as a whole.	Bars can be in any order without changing the meaning of the chart as a whole.
There are no spaces between the bars, to represent the fact this is continuous data.	There are spaces between the bars, to represent the fact that this is categorical data.
If a line is included in a histogram, it represents the general shape of the data.	If a line is included in a bar chart, it's called a combo chart, and the line represents a different measure than the bars.

Using image components

Use image components to upload static images from your desktop to a Quick analysis. Each Quick analysis sheet supports up to 10 image components. Image components are not included in the 50 visual per sheet limit. The file size of an image component can't exceed 1MB.

The following file formats are supported for image components:

- .bmp
- .jpg/.jpeg
- .png
- .tiff
- .webp

Use the following procedure to add an image component to a Quick analysis:

To add an image component to a Quick analysis

1. Open the [Quick console](#).
2. Open the Quick analysis that you want to add an image to.
3. Choose the **Add image** button in the toolbar at the top of the analysis.
4. The file selection of your desktop opens. Choose the file that you want to upload, and then choose **Open**. The file size of the image component can't exceed 1MB.
5. The image is uploaded to Quick and appears in the analysis.
6. (Optional) To add alt text or update the image scaling options, choose the **Properties** icon at the top right of the image to open the **Properties** pane.
7. (Optional) To add a [custom tooltip](#) to the image, open the **Properties** pane, choose **Interactions**, and then choose **Add action**. Filter actions are not supported for image components. You can also use the **Interactions** section to add custom navigation and URL actions to the image component.
8. (Optional) To duplicate or replace the image, choose the **More options** ellipsis (three dots) icon at the top right of the image, and then choose the action that you want to perform.

Using KPIs

Use a key performance indicator (KPI) to visualize a comparison between a key value and its target value.

A KPI displays a value comparison, the two values being compared, and a visual that provides context to the data that's displayed. You can choose from a set of predesigned layouts to suit your business needs. The following image shows an example of a KPI visual that uses a sparkline.

1. Choose **Add (+)** drop down in the **Visuals** pane.
2. Choose the KPI icon from Visual types menu.

KPI features

To understand the features supported by the KPI visual type in Amazon Quick, use the following table.

Feature	Supported?	Comments	For more information
Changing the title display	Yes		Titles and subtitles on visual types in Quick
Removing the title	Yes	You can choose not to display a title.	
Changing comparison method	Yes	By default, Amazon Quick automatically chooses a method. The settings are auto, difference, percent, and difference as percent.	
Changing the primary value displayed	Yes	You can choose comparison (default) or actual.	
Displaying or removing the progress bar	Yes	You can format the visual to either display (default) or not display a progress bar.	

For more information on KPI formatting options, see [KPI options](#).

Creating a KPI

Use the following procedure to create a KPI.

To create a KPI

1. Create a new analysis for your dataset.
2. In the **Visual types** pane, choose the KPI icon.
3. From the **Fields list** pane, drag the fields that you want to use to the appropriate field wells. You must use measure fields as indicated by the target field well. If you choose to use a dimension field as a measure, the **Count** aggregate function is automatically applied to it to create a numeric value.

To create a KPI, drag a measure to the **Value** field well. To compare that value to a target value, drag a different measure to the **Target value** field well.

4. (Optional) Choose formatting options by selecting the on-visual menu at the upper-right corner of the visual, then choosing **Format visual**.

Changing a KPI's layout

Use the following procedure to change the layout for a KPI.

To change the layout of a KPI

1. Navigate to the KPI visual that you want to change and choose **KPI layouts**.
2. In the **KPI Layouts** pane, choose the KPI layout that you want to use.

Using layer maps

Use layer maps to visualize data with custom geographic boundaries, such as congressional districts, sales territories, or user-defined regions. With layer maps, Quick authors upload GeoJSON files to Amazon Quick that shape layers over a base map and join with Quick data to visualize associated metrics and dimensions. Shape layers can be styled by color, border, and opacity. Quick authors can also add interactivity to layer maps through tooltips and custom actions.

The following image shows a layer map visual in Amazon Quick.

Creating a shape layer with layered maps

Use the procedure below to create a shape layer with layer map visuals in Amazon Quick.

1. Open the [Quick console](#).
2. Open the Quick analysis that you want to add a layer map to.
3. Choose **Add** on the application bar, and then choose **Add visual**.
4. On the **Visual types** pane, choose one of the layer map icon.
5. An empty map visual appears in the analysis and prompts you to continue configuring the layer. Choose **CONFIGURE LAYER** to continue configuring the layer map.
6. The **Layer properties** pane opens to the right. Navigate to the **Shape file** section, and then choose **UPLOAD SHAPE FILE**.

7. Choose the GeoJSON file that you want to visualize. The file must be in .geojson format and must not exceed 100 MB.
8. Navigate to the **Data** section.
9. For **Shape file key field**, choose the field that you want the shape to visualize.
10. (Optional) For **Dataset key field**, choose the dataset field that you want the shape to visualize. To assign color to the shapes, add a color field. If the color field is a measure, the shape uses gradient coloring. If the color field is a dimension, the shape uses categorical coloring. If a color field is not assigned to the shape, use the fill color option in the **Styling** section of the **Layer properties** pane to set a common color for all shapes.
11. (Optional) To change the layer name, navigate to the **Layer options** section and enter a name in the **Layer name** input.
12. (Optional) To change the fill or border colors, navigate to the **Styling** section and choose the color switch next to the object that you want to change. To adjust the opacity of the color, enter a percentage amount in the input located next to the eye icon. If you do not assign a color field to the **Dataset key field**, the fill color can be used to set a common color for all shapes.

Using line charts

Use line charts to compare changes in measure values over period of time, for the following scenarios:

- One measure over a period of time, for example gross sales by month.
- Multiple measures over a period of time, for example gross sales and net sales by month.
- One measure for a dimension over a period of time, for example number of flight delays per day by airline.

Line charts show the individual values of a set of measures or dimensions against the range displayed by the Y axis. Area line charts differ from regular line charts in that each value is represented by a colored area of the chart instead of just a line, to make it easier to evaluate item values relative to each other.

Because a stacked area line chart works differently than other line charts, simplify it if you can. Then the audience won't try to interpret the numbers. Instead, they can focus on the relationships of each set of values to the whole. One way to simplify is to remove the numbers down the left

side of the screen by reducing the step size for the axis. To do this, choose the **Options** icon from the on-visual menu. In **Format Options** under **Y-axis**, enter **2** as the **Step size**.

Each line on the chart represents a measure value over a period of time. You can interactively view the values on the chart. Hover over any line to see a pop-up legend that shows the values for each line on the **X axis**. If you hover over a data point, you can see the **Value** for that specific point on the **X axis**.

Use line charts to compare changes in values for one or more measures or dimensions over a period of time.

In regular line charts, each value is represented by a line, and in area line charts each value is represented by a colored area of the chart.

Use stacked area line charts to compare changes in values for one or more groups of measures or dimensions over a period of time. Stacked area line charts show the total value for each group on the x-axis. They use color segments to show the values of each measure or dimension in the group.

Line charts show up to 10,000 data points on the x-axis when no color field is selected. When color is populated, line charts show up to 400 data points on the x-axis and up to 25 data points for color. For more information about data that falls outside the display limit for this visual type, see [Display limits](#).

Line chart features

To understand the features supported by line charts, use the following table.

Feature	Supported?	Comments	For more information
Changing the legend display	Yes		Legends on visual types in Quick
Changing the title display	Yes		Titles and subtitles on visual types in Quick
Changing the axis range	Yes	You can set the range for the Y axis.	Range and scale on visual types in Quick
Showing or hiding axis lines,	Yes		Axes and grid lines on visual types in Quick

Feature	Supported?	Comments	For more information
grid lines, axis labels, and axis sort icons			
Adding a second Y-axis	Yes		Creating a dual-axis line chart
Changing the visual colors	Yes		Colors in visual types in Quick
Focusing on or excluding elements	Yes, with exceptions	You can focus on or exclude any line on the chart, except in the following cases: - You create a multi-dimension line chart and use a date field as the dimension for the line color. - You create a measure or multi-measure line chart and use a date field as the dimension for the X axis. In these cases, you can only focus on a line, not exclude it.	Focusing on visual elements Excluding visual elements
Sorting	Yes, with exceptions	You can sort data for numeric measures in the X axis and Value field wells. Other data is automatically sorted in ascending order.	Sorting visual data in Amazon Quick

Feature	Supported?	Comments	For more information
Performing field aggregation	Yes	You must apply aggregation to the field that you choose for the value, and can't apply aggregation to the fields you choose for the X axis and color.	Changing field aggregation
Adding drill-downs	Yes	You can add drill-down levels to the X axis and Color field wells.	Adding drill-downs to visual data in Quick Sight

Creating a line chart

Use the following procedure to create a line chart.

To create a line chart

1. On the analysis page, choose **Visualize** on the tool bar.
2. Choose **Add** on the application bar, and then choose **Add visual**.
3. On the **Visual types** pane, choose one of the line chart icons.
4. From the **Fields list** pane, drag the fields that you want to use to the appropriate field wells. Typically, you want to use dimension or measure fields as indicated by the target field well. If you choose to use a dimension field as a measure, the **Count** aggregate function is automatically applied to it to create a numeric value.
 - To create a single-measure line chart, drag a dimension to the **X axis** field well and one measure to the **Value** field well.
 - To create a multi-measure line chart, drag a dimension to the **X axis** field well and two or more measures to the **Value** field well. Leave the **Color** field well empty.
 - To create a multi-dimension line chart, drag a dimension to the **X axis** field well, one measure to the **Value** field well, and one dimension to the **Color** field well.
5. (Optional) Add drill-down layers by dragging one or more additional fields to the **X axis** or **Color** field wells. For more information about adding drill-downs, see [Adding drill-downs to visual data in Quick Sight](#).

Creating a dual-axis line chart

If you have two or more metrics that you want to display in the same line chart, you can create a dual-axis line chart.

A *dual-axis chart* is a chart with two Y-axes (one axis at the left of the chart, and one axis at the right of the chart). For example, let's say you create a line chart. It shows the number of visitors who signed up for a mailing list and for a free service over a period of time. If the scale between those two measures varies widely over time, your chart might look something like the following line chart. Because the scale between measures varies so greatly, the measure with the smaller scale appears nearly flat at zero.

If you want to show these measures in the same chart, you can create a dual-axis line chart. The following is an example of the same line chart with two Y-axes.

Sum of Free Sign Up and Sum of Mailing List Adds by Date

To create a dual-axis line chart

1. In your analysis, create a line chart. For more information about creating line charts, see [Creating a line chart](#).
2. In the **Value field well**, choose a field drop-down menu, choose **Show on: Left Y-axis**, and then choose **Right Y-axis**.

Or you can create a dual-axis line chart using the **Properties** pane:

- a. On the menu in the upper-right corner of the line chart, choose the **Format visual** icon.
- b. In the **Properties** pane that opens, choose **Data series**.
- c. In the **Data series** section, choose the **Show on right axis** icon for the value that you want to place on a separate axis. Use the search bar to quickly find a value if you need to.

The icon updates to indicate that the value is being shown on the right axis. The chart updates with two axes.

The **Properties** pane updates with the following options:

- To synchronize the Y-axes for both lines back into a single axis, choose **Single Y-axis** at the top of the **Properties** pane.
- To format the axis at the left of the chart, choose **Left Y-axis**.
- To format the axis at the right of the chart, choose **Right Y-axis**.

For more information about formatting axis lines, see [Axes and grid lines](#). For more information about adjusting the range and scale of an axis, see [Range and scale](#).

Creating maps and geospatial charts

You can create two types of maps in Quick: point maps and filled maps. *Point maps* show the difference between data values for each location by size. *Filled maps* show the difference between data values for each location by varying shades of color.

Important

Geospatial charts in Quick currently aren't supported in some AWS Regions, including in China.

For help with geospatial issues, see [Geospatial troubleshooting](#).

Before you get started creating maps, do the following:

- Make sure that your dataset contains location data. *Location data* is data that corresponds to latitudinal and longitudinal values. Location data can include a column for latitude and a column for longitude in your dataset. It can also include a column with city names. Quick can chart latitude and longitude coordinates. It also recognizes geographic components such as country, state or region, county or district, city, and ZIP code or postal code.
- Make sure that your location data fields are marked as geospatial data types.
- Consider creating geographic hierarchies.

For more information about working with geospatial data, including changing field data types and creating geospatial hierarchies, see [Adding geospatial data](#).

To learn more about creating maps in Quick, see the following.

Topics

- [Creating point maps](#)
- [Creating filled maps](#)
- [Interacting with maps](#)

Creating point maps

You can create point maps in Quick to show the difference between data values for each location by size. Each point on this type of map corresponds to a geographic location in your data, such as a country, state or province, or city. The size of the points on the map represents the magnitude of the field in the **Size** field well, in relation to other values in the same field. The color of the points represents the values in the **Color** field well. The field values in the **Color** field well display in the legend, if you choose a field for color.

Use the following procedure to create a point map in Quick.

To create point maps in Quick, make sure that you have the following:

- One geospatial field (such as country, state or region, county or district, city, or ZIP code or postal code). Or you can use one latitude field and one longitude field.

- One numeric field (measure) for size.
- (Optional) A categorical field (dimension) for color.

For information on formatting geospatial maps, see [Map and geospatial chart formatting options](#).

Creating point maps

To create a point map

1. Add a new visual to your analysis. For more information about starting analyses, see [Starting an analysis in Quick Sight](#). For more information about adding visuals to analyses, see [Adding a visual](#).
2. For **Visual type**, choose the **Points on map** icon. It looks like a globe with a point on it.
3. Drag a geographic field from the **Fields list** pane to the **Geospatial** field well, for example **Country**. You can also choose a latitude or longitude field.

A point map appears with a point for each location in your data.

If the field is part of a geographic hierarchy, the hierarchy displays in the field well.

4. Drag a measure from the **Fields list** pane to the **Size** field well.

The points on the map update to show the magnitude of values for each location.

5. (Optional) Drag a dimension from the **Fields list** pane to the **Color** field well.

Each point updates to show a point for each categorical value in the dimension.

Creating filled maps

You can create filled maps in Quick to show the difference between data values for each location by varying shades of color.

Use the following procedure to create a filled map in Quick.

To create filled maps in Quick, make sure that you have the following:

- One geospatial field (such as country, state or region, county or district, or ZIP code or postal code).
- (Optional) A numeric field (measure) for color.

Creating filled maps

To create a filled map

1. Add a new visual to your analysis. For more information about starting analyses, see [Starting an analysis in Quick Sight](#). For more information about adding visuals to analyses, see [Adding a visual](#).
2. For **Visual type**, choose the **Filled map** icon.
3. Drag a geographic field from the **Fields list** pane to the **Location** field well, for example **Country**.

A filled map appears with each location in your data filled in by the number of times they appear in your dataset (the count).

If the field is part of a geographic hierarchy, the hierarchy displays in the field well.

4. (Optional) Drag a measure from the **Fields list** pane to the **Color** field well, for example **Sales**.

Each location updates to show the sum of sales.

Interacting with maps

When you view a map visual in an Quick analysis or published dashboard, you can interact with it to explore your data. You can pan, zoom in and out, and autozoom to all the data.

By default, map visuals are always zoomed based on the underlying data. When you pan around in the map or zoom to a different level, the zoom to data icon appears above the zoom in and out icons at bottom right of the map. Using this option, you can quickly zoom back to the underlying data.

To pan in a map visual

- Click anywhere on the map visual and drag your cursor in the direction that you want to pan the map.

To zoom in or out in a map visual

- On the map visual, choose the plus or minus icons at bottom right. Or you can double-click the map to zoom in, and shift-double-click to zoom out.

To zoom back to all the data

- On the map visual, choose the zoom to data icon. This icon appears when you pan or zoom in on a map.

Using small multiples

Use this feature when you need to set multiple comparative visuals in a row. When you activate the *small multiples* feature, Amazon Quick creates a container or shelf of small visuals, presented side-by-side. Each copy of the visual contains a one view of the data. Using small multiples is a way to get a holistic view of your business, in an efficient and interactive way.

Small multiples aren't listed in the palette visualization icons. Instead, the option to create small multiples appears as a field well, in the visuals that support it.

To add small visuals to your analysis

1. On a line, bar, or pie charts, add a field to the **Small multiples** field well.
2. To see your small multiples, you need to enlarge the container that holds them, so you can see all of them at once.
3. To format the set of small multiples, choose Format visual (the pencil icon) from the menu on the visual. You can adjust the following settings:

- **Layout**

- **Visible rows**
- **Visible columns**
- **Number of panels**
- Panel title options (toggle)
 - Font size and color
 - Font weight
 - Text alignment
- **Panel order options (toggle)**

Line thickness, style, and color

- **Panel gutter (toggle)**

Spacing

- **Panel background** (toggle)

Background color

Using pie charts

Use pie charts to compare values for items in a dimension. The best use for this type of chart is to show a percentage of a total amount.

Each wedge in a pie chart represents one item in the dimension. Wedge size represents the proportion of the value for the selected measure that the item represents compared to the whole for the dimension. Pie charts are best when precision isn't important and there are few items in the dimension.

To create a donut chart, use one dimension in the **Group/Color** field well. With only one field, the chart displays the division of values by row count. To display the division of dimension values by a metric value, you can add a metric field to the **Value** field well.

Pie charts show up to 20 data points for group or color. For more information about how Amazon Quick handles data that falls outside display limits, see [Display limits](#).

Pie chart features

To understand the features supported by pie charts, use the following table.

Feature	Supported?	Comments	For more information
Changing the legend display	Yes		Legends on visual types in Quick
Changing the title display	Yes		Titles and subtitles on visual types in Quick
Changing the axis range	Not applicable		Range and scale on visual types in Quick
Showing or hiding axis labels.	Yes		Axes and grid lines on visual types in Quick

Feature	Supported?	Comments	For more information
Changing the visual colors	Yes		Colors in visual types in Quick
Focusing on or excluding elements	Yes, with exceptions	You can focus on or exclude a wedge in a pie chart, except when you are using a date field as a dimension . In that case, you can only focus on a wedge, not exclude it.	Focusing on visual elements Excluding visual elements
Sorting	Yes	You can sort on the field that you choose for the value or the group or color.	Sorting visual data in Amazon Quick
Performing field aggregation	Yes	You must apply aggregation to the field that you choose for the value, and can't apply aggregation to the field that you choose for group or color.	Changing field aggregation
Adding drill-downs	Yes	You can add drill-down levels to the Group/Color field well.	Adding drill-downs to visual data in Quick Sight

Creating a pie chart

Use the following procedure to create a pie chart.

To create a pie chart

1. On the analysis page, choose **Visualize** on the tool bar.
2. Choose **Add** on the application bar, and then choose **Add visual**.
3. On the **Visual types** pane, choose the pie chart icon.

4. From the **Fields list** pane, drag the fields that you want to use to the appropriate field wells. Typically, you want to use dimension or measure fields as indicated by the target field well. If you choose to use a dimension field as a measure, the **Count** aggregate function is automatically applied to it to create a numeric value.

To create a pie chart, drag a dimension to the **Group/Color** field well. Optionally, drag a measure to the **Value** field well.

5. (Optional) Add drill-down layers by dragging one or more additional fields to the **Group/Color** field well. For more information about adding drill-downs, see [Adding drill-downs to visual data in Quick Sight](#).

Using pivot tables

Use pivot tables to show measure values for the intersection of two dimensions.

Heat maps and pivot tables display data in a similar tabular fashion. Use a heat map if you want to identify trends and outliers, because the use of color makes these easier to spot. Use a pivot table if you want to analyze data on the visual.

To create a pivot table, choose at least one field of any data type, and choose the pivot table icon. Amazon Quick creates the table and populates the cell values with the count of the column value for the intersecting row value. Typically, you choose a measure and two dimensions measurable by that measure.

Pivot tables support scroll down and right. You can add up to 20 fields as rows and 20 fields as columns. Up to 500,000 records are supported.

Using a pivot table, you can do the following:

- Specify multiple measures to populate the cell values of the table, so that you can see a range of data
- Cluster pivot table columns and rows to show values for subcategories grouped by related dimension
- Sort values in pivot table rows or columns
- Apply statistical functions
- Add totals and subtotals to rows and columns
- Use infinite scroll

- Transpose fields used by rows and columns
- Create custom total aggregations

To easily transpose the fields used by the rows and columns of the pivot table, choose the orientation icon

near the top right of the visual. To see options for showing and hiding totals and subtotals, formatting the visual, or exporting data to a CSV file, choose the Menu items icon at top right.

As with all visual types, you can add and remove fields. You can also change the field associated with a visual element, change field aggregation, and change date field granularity. In addition, you can focus on or exclude rows or columns. For more information about how to make these changes to a pivot table, see [Changing fields used by a visual in Amazon Quick](#).

For information on formatting pivot tables, see [Formatting in Amazon Quick](#).

For information on custom total aggregations for pivot tables, see [Custom total values](#).

Pivot table features

Pivot tables don't display a legend.

To understand the features supported by pivot tables, use the following table.

Feature	Supported?	Comments	For more information
Changing the legend display	No		Legends on visual types in Quick
Changing the title display	Yes		Titles and subtitles on visual types in Quick
Changing the axis range	Not applicable		Range and scale on visual types in Quick
Changing the visual colors	No		Colors in visual types in Quick
Focusing on or excluding elements	Yes, with exceptions	You can focus on or exclude any column or row, except when you are using a date field as one of the dimension s. In that case, you can only focus on the column or row that uses the date dimension , not exclude it.	Focusing on visual elements Excluding visual elements
Sorting	Yes	You can sort fields in the Rows or Columns field wells alphabetically or by a metric in ascending or descending order.	Sorting visual data in Amazon Quick Sorting pivot tables in Quick
Performing field aggregation	Yes	You must apply aggregation to the field or fields you choose for the value. You can't apply aggregation to the fields that you choose for the rows or columns. If you choose to create a multi-measure pivot table,	Changing field aggregation

Feature	Supported?	Comments	For more information
		you can apply different types of aggregation to the different measures. For example, you can show the sum of the sales amount and the maximum discount amount.	
Adding drill-downs	No		Adding drill-downs to visual data in Quick Sight
Showing and hiding totals and subtotals	Yes	You can show or hide totals and subtotals for rows and columns. Metrics automatically roll up to show subtotals when you collapse a row or column. If you use a table calculation, use aggregates to display roll-ups.	
Exporting or copying data	Yes	You can export all of the data to a CSV file. You can select and copy the content of the cells.	Exporting data from visuals
Conditional formatting	Yes	You can add conditional formatting for values, subtotals and totals.	Conditional formatting on visual types in Quick

Creating a pivot table

Use the following procedure to create a pivot table.

To create a pivot table

1. On the analysis page, choose the **Visualize** icon on the tool bar.
2. On the **Visuals** pane, choose **+ Add**, and then choose the pivot table icon.
3. From the **Fields list** pane, choose the fields that you want to include. Amazon Quick automatically places these into the field wells.

To change the placement of a field, drag it to the appropriate field wells. Typically, you use dimension or measure fields as indicated by the target field well. If you choose to use a dimension field as a measure, the **Count** aggregate function is automatically applied to it to create a numeric value.

- To create a single-measure pivot table, drag a dimension to the **Rows** field well, a dimension to the **Columns** field well, and a measure to the **Values** field well.
- To create a multi-measure pivot table, drag a dimension to the **Rows** field well, a dimension to the **Columns** field well, and two or more measures to the **Values** field well.
- To create a clustered pivot table, drag one or more dimensions to the **Rows** field well, one or more dimensions to the **Columns** field well, and a measure to the **Values** field well.

You can also select multiple fields for all of the pivot table field wells if you want to. Doing this combines the multi-measure and clustered pivot table approaches.

Note

To view roll-ups for calculated fields, make sure that you are using aggregates. For example, a calculated field with `field-1 / field-2` doesn't display a summary when rolled up. However, `sum(field-1) / sum(field-2)` does display a roll-up summary.

Choosing a layout

When you create a pivot table in Amazon Quick, you can further customize the way your data is presented with Tabular and Hierarchy layout options. For pivot tables that use a tabular layout, each row field is displayed in its own column. For pivot tables that use a hierarchy layout, all row fields are displayed in a single column. Indentation is used to differentiate row headers of different fields. To change the layout of a pivot table visual, open the **Format visual** menu of the pivot

table that you want to change and choose the layout option that you want from the **Pivot options** section.

Depending on the layout that you choose for your pivot table visual, different formatting options are available. For more information about formatting differences between tabular and hierarchy pivot tables, see [Table and pivot table formatting options in Quick](#).

Orienting pivot table values

You can choose to display a pivot table in a columnar or row-based format. Columnar is the default. When you change to a row-based format, a column with the value name is added to the right of the row header column.

To change a pivot table format

1. On the analysis page, choose the pivot table visual that you want to edit.
2. Expand the **Field wells** pane by choosing the field wells at the top of the visual.
3. On the **Values** field well, choose one of the following options:
 - Choose **Column** for a columnar format.
 - Choose **Row** for a row format.

Note

If you use only one metric, you can eliminate the repeated header by formatting the visual and styling it with the **Hide single metric** option.

Expanding and collapsing pivot table clusters

If you are using grouped columns or rows in a pivot table, you can expand or collapse a group to show or hide its data in the visual.

To expand or collapse a pivot table group

1. On the analysis page, choose the pivot table visual that you want to edit.
2. Choose one of the following:
 - To collapse a group, choose the collapse icon near the name of the field.

- To expand a group, choose the expand icon near the name of the field. The collapse icon shows a minus sign. The expand icon shows a plus sign.

In the following screenshot, Customer Region and the Enterprise segment are expanded, and SMB and Startup are collapsed. When a group is collapsed, its data is summarized in the row or column.

Revenue by Service Line, Customer Region, Customer Segment, and Consumption Channel

		Customer Segment > Service Line					
Customer Region	Consumption C...	Billed Amount	Enterprise			SMB	Startup
			Marketing	HR	Billing		
APAC	API	Billed Amount	104,350.34	132,225.58	127,772.08	98,977.33	854,403.2
	Mobile	Billed Amount	191,448.63	247,966.85	238,773.51	231,934.61	1,985,478.41
	Web	Billed Amount	282,733.31	370,020.33	340,658.32	329,184.75	2,854,727.09

	Mobile	Billed Amount	497,424.85	1,029,193.5	899,185.99	656,111.84	5,188,415.35
	Web	Billed Amount	714,712.03	1,466,952.72	1,284,108.35	928,394.53	7,381,337.62

Showing and hiding pivot table columns in Quick

By default, all columns, rows, and their field values appear when you create a pivot table. You can hide columns and rows that you don't want to appear in the pivot table without changing the pivot table values. When you have more than one measure in the pivot table, you can also hide values.

At any time, you can choose to show any hidden fields in the pivot table. When you publish the visual as part of a dashboard, anyone who subscribes to the dashboard can export the pivot table to a comma-separated value (CSV) or Microsoft Excel file. They can choose to export only the visible fields, or all fields. For more information, see [Exporting data from a dashboard to a CSV](#).

To hide a column or row in a pivot table

- In your analysis, select the pivot table visual that you want to work with.
- Choose the three-dot menu in the **Rows**, **Columns** or **Values** field wells, and then choose **Hide**.

To show all hidden fields in a pivot table

1. In your analysis, select the pivot table visual that you want to work with.
2. Choose any field in the **Fields well** and choose **Show all hidden fields**.

Sorting pivot tables in Quick

In Amazon Quick, you can sort values in a pivot table by fields in the **Rows** and **Columns** field wells or quickly by column headers in the pivot table. In pivot tables, you can sort rows and columns independently of each other in alphabetical order, or by a measure.

Note

You can't run Total, Difference, and Percent Difference table calculations when a pivot table is being sorted by a measure. For more information about using table calculations in pivot tables, see [Using table calculations in pivot tables](#).

Understanding sorting in pivot tables

When you have multiple panes in a pivot table, sorting is applied to each pane independently. For example, the Segment column in the pivot table on the left is being sorted in ascending order by Cost. Given that there are multiple panes, the sort starts over for each pane and the rows within each pane (for Segment) are ordered by lowest to highest cost. The table on the right has the same sort applied, but the sort is being applied across the entire table, as shown following.

Pivot Table: Segment sorted by Cost in ascending order

Customer Region	Segment	Cost
APAC	SMB	443,364.19
	Enterprise	1,360,766.43
	Startup	3,852,507.31
EMEA	SMB	961,547.22
	Startup	2,869,902.85
	Enterprise	4,054,584.77
US	SMB	1,191,778.64
	Enterprise	4,445,523.69
	Startup	9,499,922.96

Table: Segment sorted by Cost in ascending order

Customer Region	Segment	Cost
APAC	SMB	443,364.19
EMEA	SMB	961,547.22
US	SMB	1,191,778.64
APAC	Enterprise	1,360,766.43
EMEA	Startup	2,869,902.85
APAC	Startup	3,852,507.31
EMEA	Enterprise	4,054,584.77
US	Enterprise	4,445,523.69
US	Startup	9,499,922.96

When you apply multiple sorts to a pivot table, sorting is applied from the outside dimension to the inside dimension. Consider the following example image of a pivot table. The Customer Region column is sorted by Cost in descending order (as shown in orange). The Channel column is sorted by Revenue Goal in ascending order (as shown in blue).

Customer Region	Channel	Revenue Goal	Cost
US	API	\$3,308,145	\$2,359,267
	Mobile	\$7,445,681	\$5,291,181
	Web	\$9,718,851	\$7,486,778
	Subtotal	\$20,472,677	\$15,137,225
EMEA	API	\$2,023,046	\$1,344,824
	Mobile	\$3,660,777	\$2,933,557
	Web	\$4,895,932	\$3,607,654
	Subtotal	\$10,579,754	\$7,886,035
APAC	API	\$1,392,361	\$1,067,056
	Mobile	\$2,606,978	\$1,876,292
	Web	\$3,400,757	\$2,713,291
	Subtotal	\$7,400,096	\$5,656,638

Sorting pivot tables using row or column headers

Use the following procedure to sort a pivot table using Row or Column headers.

To sort values in a tabular pivot table using table headers

1. In a tabular pivot table chart, choose the header that you want to sort.
2. For **Sort by**, choose a field to sort by and a sort order.

You can sort dimension fields alphabetically a–z or z–a, or you can sort them by a measure in ascending or descending order.

Pivot Table: Segment sorted by Cost in ascending order

Customer Region	Segment	Cost
APAC	Enterprise	1,360,766.43
	SMB	443,364.19
	Startup	3,852,507.31
EMEA	Enterprise	4,054,584.77
	SMB	961,547.22
	Startup	2,869,902.85
US	Enterprise	4,445,523.69
	SMB	1,191,778.64
	Startup	9,499,922.96

Sorting pivot tables using value headers

Use the following procedure to sort a pivot table using value headers.

To sort a pivot table using value headers

1. In a pivot table chart, choose the value header that you want to sort.
2. Choose **Ascending** or **Descending**.

Customer Region	Segment	Revenue Goal	Cost
APAC	Enterprise	1,873,330.74	1,360,766.43
	SMB	523,381.34	443,364.19
	Startup	5,003,383.53	3,852,507.31
EMEA	Enterprise	5,450,312.56	4,054,584.77
	SMB	1,321,251.73	961,547.22
	Startup	3,808,189.88	2,869,902.85
US	Enterprise	6,353,745.66	4,445,523.69
	SMB	1,506,943.36	1,191,778.64
	Startup	12,611,988.15	9,499,922.96

Sorting by value headers in a pivot table also works on subtotals.

Sorting tabular pivot tables using the field wells

Use the following procedure to sort values in a tabular pivot table using the field wells.

To sort values in a tabular pivot table using the field wells

1. On the analysis page, choose the tabular pivot table that you want to sort.
2. Expand the **Field wells**.
3. In the **Rows** or **Columns** field well, choose the field that you want to sort, and then choose how you want to sort the field for **Sort by**.

You can sort dimension fields in the **Rows** or **Columns** field wells alphabetically from a–z or z–a, or you can sort them by a measure in ascending or descending order. You also have the option to collapse all or expand all rows or columns for the field you choose in the field well. You can also remove the field, or to replace it with another field.

- To sort a dimension field alphabetically, hover your cursor over the field in the **Rows** or **Columns** field well, and then choose the a–z or z–a sort icon.

Search fields

City

Contact Name

- To sort a dimension field by a measure, hover your cursor over the field in the **Rows** or **Columns** field well. Then choose a measure from the list, and then choose the ascending or descending sort icon.

The screenshot shows the Amazon QuickSight interface. On the left, the 'Visuals' pane is open, showing a 'Pivot table' visual. The 'ROWS' field well contains 'Segment' and 'Industry'. The 'VALUES' field well contains 'Sales (Sum)' and 'Quantity (Sum)'. A context menu is open over the pivot table, showing 'Sort by: Sales', 'Sort order: Ascending', and 'Format: Text'. A red box highlights the 'Sort options' menu, which includes 'Quantity', 'Sales' (selected), and 'Segment'. Below the pivot table, a table of data is visible:

Rows	Sales	Quantity
Enterprise	429,653.15	6,744
...	...	...
...	20,984.49	345

Or, if you want more control over how the sort is applied to the pivot table, customize the sort options.

To create a sort using the sort options

1. On the analysis page, choose the pivot table that you want to sort.
2. Expand **Field wells**.
3. Choose the field that you want to sort in the **Rows** or **Columns** field well, and then choose **Sort options**.
4. In the **Sort options** pane that opens at left, specify the following options:
 - a. For **Sort by**, choose a field from the drop-down list.
 - b. For **Aggregation**, choose an aggregation from the list.
 - c. For **Sort order**, select **Ascending** or **Descending**.
 - d. Choose **Apply**.

Sorting hierarchy pivot tables using the field wells

For tabular pivot tables, each field in the **Rows** field well has a separate title cell. For hierarchy pivot tables, all row fields are displayed in a single column. To sort, collapse, and expand these row fields, select the **Rows** label to open the **Combined row fields** menu and choose the option that you want. Each field in a hierarchy pivot table can be individually sorted from the **Combined row fields** menu.

Tables						
Jumbo Box	95.97		230,167.66			

More advanced formatting options such as **Hide** and **Remove** are available from the field well menus.

Using table calculations in pivot tables

You can use table calculations to apply statistical functions to pivot table cells that contain measures (numeric values). Use the following sections to understand which functions you can use in calculations, and how to apply or remove them.

The data type of the cell value automatically changes to work for your calculation. For example, say that you apply the **Rank** function to a currency data type. The values display as integers rather than currency, because rank isn't measured as currency. Similarly, if you apply the **Percent difference** function instead, the cell values display as percentages.

- [Ways to apply pivot table calculations](#)

Adding and deleting pivot table calculations

Use the following procedures to add, modify, and remove table calculation on a pivot table.

Topics

- [Adding a pivot table calculation](#)
- [Changing how a calculation is applied](#)
- [Removing a calculation](#)

Adding a pivot table calculation

Use the following procedure to add a table calculation to a pivot table.

To add a table calculation to a pivot table

1. Expand the **Field wells** pane by choosing the field wells near the bottom of the visual.
2. Choose the field in the **Values** well that you want to apply a table calculation to, choose **Add table calculation**, and then choose the function to apply.

Note

You can't run Total, Difference, and Percent Difference table calculations when a pivot table is being sorted by a measure. To use these table calculations, remove the sort from the pivot table.

Changing how a calculation is applied

Use the following procedure to change the way a table calculation is applied to a pivot table.

To change the way a table calculation is applied to a pivot table

1. Expand the **Field wells** pane by choosing field wells at the top of the visual.
2. Choose the field in the **Values** well that has the table calculation that you want to change, choose **Calculate as**, and then choose the way that you want the calculation applied.

Removing a calculation

Use the following procedure to remove a table calculation from a pivot table.

To remove a table calculation from a pivot table

1. Expand the **Field wells** pane by choosing the field wells near the bottom of the visual.
2. Choose the field in the **Values** well that you want to remove the table calculation from, and then choose **Remove**.

Functions for pivot table calculations

You can use the following functions in pivot table calculations.

Running total

The **Running total** function calculates the sum of a given cell value and the values of all cells prior to it. This sum is calculated as $Cell1=Cell1$, $Cell2=Cell1+Cell2$, $Cell3=Cell1+Cell2+Cell3$, and so on.

Applying the **Running total** function across the table rows, using **Table across** for **Calculate as**, gives you the following results.

Sum of Billed Amount by Date, Customer Region, Consumption Channel, and Service Line							
		Service Line > Consumption Channel					
Customer Region	Date	Billing			HR

Difference

The **Difference** function calculates the difference between a cell value and value of the cell prior to it. This difference is calculated as $Cell1=Cell1-null$, $Cell2=Cell2-Cell1$, $Cell3=Cell3-Cell2$, and so on. Because $Cell1-null = null$, the Cell1 value is always empty.

Applying the **Difference** function across the table rows, using **Table across** for **Calculate as**, gives you the following results.

Sum of Billed Amount by Date, Customer Region, Consumption Channel, and Service Line							
Service Line > Consumption Channel							
Customer Region	Date	Billing			HR

	2016		-\$643K	-\$893K	\$1,547K	-\$638K	-\$900K

Percentage difference

The **Percentage Difference** function calculates the percent difference between a cell value and the value of the cell prior to it, divided by the value of the cell prior to it. This value is calculated as $Cell1=(Cell1-null)/null$, $Cell2=(Cell2-Cell1)/Cell1$, $Cell3=(Cell3-Cell2)/Cell2$, and so on. Because $(Cell1-null)/null = null$, the Cell1 value is always empty.

Applying the **Percentage Difference** function across the table rows, using **Table across** for **Calculate as**, gives you the following results.

Sum of Billed Amount by Date, Customer Region, Consumption Channel, and Service Line

	2016		-29.48%	-58.06%	239.84%	-29.10%	-57.92%

Percent of total

The **Percent of Total** function calculates the percentage the given cell represents of the sum of all of the cells included in the calculation. This percentage is calculated as $\text{Cell1} = \text{Cell1} / (\text{sum of all cells})$, $\text{Cell2} = \text{Cell2} / (\text{sum of all cells})$, and so on.

Applying the **Percent of Total** function across the table rows, using **Table across** for **Calculate as**, gives you the following results.

Sum of Billed Amount by Date, Customer Region, Consumption Channel, and Service Line							
Service Line > Consumption Channel							
Customer Region	Date	Billing			HR		
		Web	Mobile	API	Web	Mobile	API
APAC	2014	21.47%	14.90%	6.83%	20.56%	13.64%	6.15%
	2015	20.54%	14.60%	6.48%	20.29%	14.06%	6.37%
	2016	20.40%	14.24%	6.47%	20.06%	13.65%	6.30%
EMEA	2014	20.00%	13.79%	6.49%	18.79%	13.24%	6.04%
	2015	19.07%	13.39%	6.77%	18.63%	12.97%	6.40%
	2016	19.31%	13.38%	6.71%	18.59%	12.98%	6.29%
US	2014	19.61%	13.72%	5.88%	20.17%	13.86%	6.00%
	2015	19.38%	13.49%	5.79%	19.59%	13.96%	5.79%
	2016	19.38%	13.66%	5.73%	19.48%	13.81%	5.81%

Rank

The **Rank** function calculates the rank of the cell value compared to the values of the other cells included in the calculation. Rank always shows the highest value equal to 1 and lowest value equal to the count of cells included in the calculation. If there are two or more cells with equal values, they receive the same rank but are considered to take up their own spots in the ranking. Thus, the next highest value is pushed down in rank by the number of cells at the rank above it, minus one. For example, if you rank the values 5,3,3,4,3,2, their ranks are 1,3,3,2,3,6.

For example, suppose that you have the following data.

Customer Region	Service Line		
	Marketing	HR	Billing
APAC	\$1,357K	\$3,023K	\$3,122K
EMEA	\$2,247K	\$3,788K	\$3,944K
US	\$4,657K	\$8,392K	\$8,282K

Applying the **Rank** function across the table rows, using **Table across** for **Calculate as**, gives you the following results.

Customer Region	Service Line		
	Marketing	HR	Billing
APAC	3	2	1
EMEA	3	2	1
US	3	1	2

Percentile

The **Percentile** function calculates the percent of the values of the cells included in the calculation that are at or below the value for the given cell.

This percent is calculated as follows.

$$\text{percentile rank}(x) = 100 * B / N$$

Where:

B = number of scores below x

N = number of scores

Applying the **Percentile** function across the table rows, using **Table across** for **Calculate as**, gives you the following results.

Sum of Billed Amount by Customer Region, Date, Consumption Channel, and Service Line							
		Service Line > Consumption Channel

Ways to apply pivot table calculations

You can apply table calculations in the ways described following. Table calculations are applied to only one field at a time. Thus, if you have a pivot table with multiple values, calculations are only applied to the cells representing the field that you applied the calculation to.

Topics

- [Table across](#)
- [Table down](#)
- [Table across down](#)
- [Table down across](#)
- [Group across](#)
- [Group down](#)
- [Group across down](#)
- [Group down across](#)

Table across

Using **Table across** applies the calculation across the rows of the pivot table, regardless of any grouping. This application is the default. For example, take the following pivot table.

		Consumption Channel		
Customer Region	Date	Web	Mobile	API
APAC	2014	\$599K	\$410K	\$186K
	2015	\$1,137K	\$795K	\$361K
	2016	\$1,997K	\$1,379K	\$638K
EMEA	2014	\$932K	\$646K	\$302K
	2015	\$1,511K	\$1,046K	\$531K
	2016	\$2,461K	\$1,702K	\$848K
US	2014	\$1,816K	\$1,257K	\$539K
	2015	\$3,230K	\$2,272K	\$963K
	2016	\$5,613K	\$3,971K	\$1,669K

Applying the **Running total** function using **Table across** gives you the following results, with row totals in the last column.

Sum of Billed Amount by Customer Region, Date, and Consumption Channel

		Consumption Channel		
Customer Region	Date	Web	Mobile	API
APAC	2014	\$599K	\$1,009K	\$1,195K
	2015	\$1,137K	\$1,932K	\$2,293K
	2016	\$1,997K	\$3,376K	\$4,014K
EMEA	2014	\$932K	\$1,578K	\$1,880K
	2015	\$1,511K	\$2,557K	\$3,088K
	2016	\$2,461K	\$4,163K	\$5,011K
US	2014	\$1,816K	\$3,074K	\$3,613K
	2015	\$3,230K	\$5,502K	\$6,465K
	2016	\$5,613K	\$9,584K	\$11,253K

Table down

Using **Table down** applies the calculation down the columns of the pivot table, regardless of any grouping.

Applying the **Running total** function using **Table down** gives you the following results, with column totals in the last row.

Sum of Billed Amount by Customer Region, Date, and Consumption Channel

Customer Region	Date	Consumption Channel		
		Web	Mobile	API
APAC	2014	\$599K	\$410K	\$186K
	2015	\$1,735K	\$1,205K	\$547K
	2016	\$3,733K	\$2,584K	\$1,185K
EMEA	2014	\$4,665K	\$3,230K	\$1,487K
	2015	\$6,176K	\$4,276K	\$2,017K
	2016	\$8,637K	\$5,978K	\$2,865K
US	2014	\$10,454K	\$7,235K	\$3,404K
	2015	\$13,684K	\$9,507K	\$4,367K
	2016	\$19,297K	\$13,478K	\$6,036K

Table across down

Using **Table across down** applies the calculation across the rows of the pivot table, and then takes the results and reapplies the calculation down the columns of the pivot table.

Applying the **Running total** function using **Table across down** gives you the following results. In this case, totals are summed both down and across, with the grand total in the lower-right cell.

Sum of Billed Amount by Customer Region, Date, and Consumption Channel

		Consumption Channel		
Customer Region	Date	Web	Mobile	API
APAC	2014	\$599K	\$1,009K	\$1,195K
	2015	\$2,332K	\$3,127K	\$3,488K
	2016	\$5,485K	\$6,864K	\$7,501K
EMEA	2014	\$8,433K	\$9,079K	\$9,381K
	2015	\$10,893K	\$11,939K	\$12,469K
	2016	\$14,931K	\$16,633K	\$17,480K
US	2014	\$19,297K	\$20,554K	\$21,093K
	2015	\$24,323K	\$26,595K	\$27,558K
	2016	\$33,171K	\$37,142K	\$38,811K

In this case, suppose that you apply the **Rank** function using **Table across down**. Doing so means that the initial ranks are determined across the table rows and then those ranks are in turn ranked down the columns. This approach gives you the following results.

Sum of Billed Amount by Customer Region, Date, and Consumption Channel				
Customer Region	Date	Consumption Channel		
		Web	Mobile	API
APAC	2014	21	24	27
	2015	13	18	25
	2016	6	11	20
EMEA	2014	16	19	26
	2015	10	14	23
	2016	4	8	17
US	2014	7	12	22
	2015	3	5	15
	2016	1	2	9

Table down across

Using **Table down across** applies the calculation down the columns of the pivot table. It then takes the results and reapplies the calculation across the rows of the pivot table.

You can apply the **Running total** function using **Table down across** to get the following results. In this case, totals are summed both down and across, with the grand total in the lower-right cell.

Sum of Billed Amount by Customer Region, Date, and Consumption Channel

		Consumption Channel		
Customer Region	Date	Web	Mobile	API
APAC	2014	\$599K	\$1,009K	\$1,195K
	2015	\$2,332K	\$3,127K	\$3,488K
	2016	\$5,485K	\$6,864K	\$7,501K
EMEA	2014	\$8,433K	\$9,079K	\$9,381K
	2015	\$10,893K	\$11,939K	\$12,469K
	2016	\$14,931K	\$16,633K	\$17,480K
US	2014	\$19,297K	\$20,554K	\$21,093K
	2015	\$24,323K	\$26,595K	\$27,558K
	2016	\$33,171K	\$37,142K	\$38,811K

You can apply the **Rank** function using **Table down across** to get the following results. In this case, the initial ranks are determined down the table columns. Then those ranks are in turn ranked across the rows.

Sum of Billed Amount by Customer Region, Date, and Consumption Channel				
		Consumption Channel		
Customer Region	Date	Web	Mobile	API
APAC	2014	21	24	27
	2015	13	18	25
	2016	6	11	20
EMEA	2014	16	19	26
	2015	10	14	23
	2016	4	8	17
US	2014	7	12	22
	2015	3	5	15
	2016	1	2	9

Group across

Using **Group across** applies the calculation across the rows of the pivot table within group boundaries, as determined by the second level of grouping applied to the columns. For example, if you group by field-2 and then by field-1, grouping is applied at the field-2 level. If you group by field-3, field-2, and field-1, grouping is again applied at the field-2 level. When there is no grouping, **Group across** returns the same results as **Table across**.

For example, take the following pivot table where columns are grouped by Service Line and then by Consumption Channel.

Sum of Billed Amount by Customer Region, Date, and Consumption Channel				
		Consumption Channel		
Customer Region	Date	Web	Mobile	API
APAC	2014	\$599K	\$410K	\$186K
	2015	\$1,137K	\$795K	\$361K
	2016	\$1,997K	\$1,379K	\$638K
EMEA	2014	\$932K	\$646K	\$302K
	2015	\$1,511K	\$1,046K	\$531K
	2016	\$2,461K	\$1,702K	\$848K
US	2014	\$1,816K	\$1,257K	\$539K
	2015	\$3,230K	\$2,272K	\$963K
	2016	\$5,613K	\$3,971K	\$1,669K

You can apply the **Running total** function using **Group across** to get the following results. In this case, the function is applied across the rows, bounded by the columns for each service category group. The Mobile columns display the total for both Consumption Channel values for the given Service Line, for the Customer Region and Date (year) represented by the given row. For example, the highlighted cell represents the total for the APAC region for 2012, for all Consumption Channel values in the Service Line named Billing.

Sum of Billed Amount by Customer Region, Date, Service Line, and Consumption Channel

Service Line > Consumption Channel

Customer Region	Date	Billing		Marketing	
		API	Mobile	API	Mobile
APAC	2012	\$23K	\$74K		
	2013	\$45K	\$153K	\$3K	\$11K
	2014	\$82K	\$260K	\$31K	\$100K
EMEA	2012	\$22K	\$78K		
	2013	\$50K	\$172K	\$4K	\$15K
	2014	\$122K	\$381K	\$66K	\$204K
US	2012	\$43K	\$140K		
	2013	\$114K	\$382K	\$14K	\$48K
	2014	\$213K	\$709K	\$110K	\$370K

Group down

Using **Group down** applies the calculation down the columns of the pivot table within group boundaries, as determined by the second level of grouping applied to the rows. For example, if you group by field-2 and then by field-1, grouping is applied at the field-2 level. If you group by field-3, field-2, and field-1, grouping is again applied at the field-2 level. When there is no grouping, **Group down** returns the same results as **Table down**.

For example, take the following pivot table where rows are grouped by Customer Region and then by Date (year).

Sum of Billed Amount by Customer Region, Date, and Consumption Channel

Customer Region	Date	Consumption Channel		
		Web	Mobile	API
APAC	2014	\$599K	\$410K	\$186K
	2015	\$1,137K	\$795K	\$361K
	2016	\$1,997K	\$1,379K	\$638K
EMEA	2014	\$932K	\$646K	\$302K
	2015	\$1,511K	\$1,046K	\$531K
	2016	\$2,461K	\$1,702K	\$848K
US	2014	\$1,816K	\$1,257K	\$539K
	2015	\$3,230K	\$2,272K	\$963K
	2016	\$5,613K	\$3,971K	\$1,669K

You can apply the **Running total** function using **Group down** to get the following results. In this case, the function is applied down the columns, bounded by the rows for each Customer Region group. The 2014 rows display the total for all years for the given Customer Region, for the Service Line and Consumption Channel represented by the given column. For example, the highlighted cell represents the total the APAC region, for the Billing service for the Mobile channel, for all the Date values (years) that display in the report.

Sum of Billed Amount by Customer Region, Date, Service Line, and Consumption Channel

Customer Region	Date	Service Line > Consumption Channel			
		Billing		Marketing	
		API	Mobile	API	Mobile
APAC	2012	\$23K	\$51K		
	2013	\$68K	\$159K	\$3K	\$8K
	2014	\$149K	\$337K	\$34K	\$77K
EMEA	2012	\$22K	\$56K		
	2013	\$72K	\$178K	\$4K	\$11K
	2014	\$194K	\$438K	\$70K	\$148K
US	2012	\$43K	\$97K		
	2013	\$157K	\$365K	\$14K	\$34K
	2014	\$370K	\$861K	\$124K	\$294K

Group across down

Using **Group across down** applies the calculation across the rows within group boundaries, as determined by the second level of grouping applied to the columns. Then the function takes the results and reapplies the calculation down the columns of the pivot table. It does so within group boundaries as determined by the second level of grouping applied to the rows.

For example, if you group a row or column by field-2 and then by field-1, grouping is applied at the field-2 level. If you group by field-3, field-2, and field-1, grouping is again applied at the field-2 level. When there is no grouping, **Group across down** returns the same results as **Table across down**.

For example, take the following pivot table where columns are grouped by Service Line and then by Consumption Channel. Rows are grouped by Customer Region and then by Date (year).

Sum of Billed Amount by Customer Region, Date, and Consumption Channel				
		Consumption Channel		
Customer Region	Date	Web	Mobile	API
APAC	2014	\$599K	\$410K	\$186K
	2015	\$1,137K	\$795K	\$361K
	2016	\$1,997K	\$1,379K	\$638K
EMEA	2014	\$932K	\$646K	\$302K
	2015	\$1,511K	\$1,046K	\$531K
	2016	\$2,461K	\$1,702K	\$848K
US	2014	\$1,816K	\$1,257K	\$539K
	2015	\$3,230K	\$2,272K	\$963K
	2016	\$5,613K	\$3,971K	\$1,669K

You can apply the **Running total** function using **Group across down** to get the following results. In this case, totals are summed both down and across within the group boundaries. Here, these boundaries are Service Line for the columns and Customer Region for the rows. The grand total appears in the lower-right cell for the group.

Sum of Billed Amount by Customer Region, Date, Service Line, and Consumption Channel

		Service Line > Consumption Channel			
Customer Region	Date	Billing		Marketing	
		API	Mobile	API	Mobile
APAC	2012	\$23K	\$201K		
	2013	\$68K	\$309K	\$3K	\$42K
	2014	\$149K	\$487K	\$34K	\$111K
EMEA	2012	\$22K	\$250K		
	2013	\$72K	\$372K	\$4K	\$81K
	2014	\$194K	\$632K	\$70K	\$219K
US	2012	\$43K	\$466K		
	2013	\$157K	\$734K	\$14K	\$157K
	2014	\$370K	\$1,231K	\$124K	\$418K

You can apply the **Rank** function using **Group across down** to get the following results. In this case, the function is first applied across the rows bounded by each Service Line group. The function is then applied again to the results of that first calculation, this time applied down the columns bounded by each Customer Region group.

Sum of Billed Amount by Customer Region, Date, Service Line, and Consumption Channel

		Service Line > Consumption Channel			
Customer Region	Date	Billing		Marketing	
		API	Mobile	API	Mobile
APAC	2012	6	4		
	2013	5	2	4	3
	2014	3	1	2	1
EMEA	2012	6	4		
	2013	5	2	4	3
	2014	3	1	2	1
US	2012	6	5		
	2013	4	2	4	3
	2014	3	1	2	1

Group down across

Using **Group down across** applies a calculation down the columns within group boundaries, as determined by the second level of grouping applied to the rows. Then Amazon Quick takes the results and reapplies the calculation across the rows of the pivot table. Again, it reapplies the calculation within group boundaries as determined by the second level of grouping applied to the columns.

For example, if you group a row or column by field-2 and then by field-1, grouping is applied at the field-2 level. If you group by field-3, field-2, and field-1, grouping is again applied at the field-2 level. When there is no grouping, **Group down across** returns the same results as **Table down across**.

For example, take the following pivot table. Columns are grouped by Service Line and then by Consumption Channel. Rows are grouped by Customer Region and then by Date (year).

		Consumption Channel		
Customer Region	Date	Web	Mobile	API
APAC	2014	\$599K	\$410K	\$186K
	2015	\$1,137K	\$795K	\$361K
	2016	\$1,997K	\$1,379K	\$638K
EMEA	2014	\$932K	\$646K	\$302K
	2015	\$1,511K	\$1,046K	\$531K
	2016	\$2,461K	\$1,702K	\$848K
US	2014	\$1,816K	\$1,257K	\$539K
	2015	\$3,230K	\$2,272K	\$963K
	2016	\$5,613K	\$3,971K	\$1,669K

You can apply the **Running total** function using **Group down across** to get the following results. In this case, totals are summed both down and across within the group boundaries. In this case, these are Service Category for the columns and Customer Region for the rows. The grand total is in the lower-right cell for the group.

Sum of Billed Amount by Customer Region, Date, Service Line, and Consumption Channel

		Service Line > Consumption Channel			
Customer Region	Date	Billing		Marketing	
		API	Mobile	API	Mobile
APAC	2012	\$23K	\$201K		
	2013	\$68K	\$309K	\$3K	\$42K
	2014	\$149K	\$487K	\$34K	\$111K
EMEA	2012	\$22K	\$250K		
	2013	\$72K	\$372K	\$4K	\$81K
	2014	\$194K	\$632K	\$70K	\$219K
US	2012	\$43K	\$466K		
	2013	\$157K	\$734K	\$14K	\$157K
	2014	\$370K	\$1,231K	\$124K	\$418K

You can apply the **Rank** function using **Group down across** to get the following results. In this case, the function is first applied down the columns bounded by each Customer Region group. The function is then applied again to the results of that first calculation, this time applied across the rows bounded by each Service Line group.

Sum of Billed Amount by Customer Region, Date, Service Line, and Consumption Channel

		Service Line > Consumption Channel			
Customer Region	Date	Billing		Marketing	
		API	Mobile	API	Mobile
APAC	2012	6	4		
	2013	5	2	4	3
	2014	3	1	2	1
EMEA	2012	6	4		
	2013	5	2	4	3
	2014	3	1	2	1
US	2012	6	5		
	2013	4	2	4	3
	2014	3	1	2	1

Pivot table limitations

The following limitations apply to pivot tables:

- You can create pivot tables with up to 500,000 records.
- You can add any combination of row and column field values that add up to 40. For example, if you have 10 row field values, then you can add up to 30 column field values.
- You can create pivot table calculations only on nonaggregated values. For example, if you create a calculated field that is a sum of a measure, you can't also add a pivot table calculation to it.
- If you are sorting by a custom metric, you can't add a table calculation until you remove the custom metric sort.
- If you are using a table calculation and then add a custom metric, you can't sort by the custom metric.
- Totals and subtotals are blank for table calculations on metrics aggregated by distinct count.

Pivot table best practices

It's best to deploy a minimal set of rows, columns, metrics, and table calculations, rather than offering all possible combinations in one pivot table. If you include too many, you risk overwhelming the viewer and you can also run into the computational limitations of the underlying database.

To reduce the level of complexity and reduce the potential for errors, you can take the following actions:

- Apply filters to reduce the data included in for the visual.
- Use fewer fields in the **Row** and **Column** field wells.
- Use as few fields as possible in the **Values** field well.
- Create additional pivot tables so that each displays fewer metrics.

In some cases, there's a business need to examine many metrics in relation to each other. In these cases, it can be better to use multiple visuals on the same dashboard, each showing a single metric. You can reduce the size of the visuals on the dashboard, and colocate them to form a grouping. If a decision the viewer makes based on one visual creates the need for a different view, you can deploy custom URL actions to launch another dashboard according to the choices made by the user.

It's best to think of visuals as building blocks. Rather than using one visual for multiple purposes, use each visual to facilitate one aspect of a larger business decision. The viewer should have enough data to make a well-informed decision, without being overwhelmed by the inclusion of all possibilities.

Using radar charts

You can use radar charts, which are also known as spider charts, to visualize multivariate data in Amazon Quick. In a radar chart, one or more groups of values are plotted over multiple common variables. Each variable has its own axis, and each axis is arranged radially around a central point. The data points from a single observation are plotted on each axis and connected to each other to form a polygon. Multiple observations can be plotted in a single radar chart to display multiple polygons, which makes it easier to spot outlying values for multiple observations quickly.

In Quick, you can organize a radar chart along its category, value, or color axes by dragging and dropping fields to the **Category**, **Value**, and **Color** field wells. How you choose to distribute fields among the field wells determines the axis that the data is plotted on.

The following image shows an example of a radar chart.

Radar chart features

To view the features supported by radar charts, use the following table.

Feature	Supported?	Comments	For more information
Changing the legend display	Yes		Legends on visual types in Quick

Feature	Supported?	Comments	For more information
Changing the title display	Yes		Titles and subtitles on visual types in Quick
Changing the axis range	Yes		Range and scale on visual types in Quick
Changing the visual colors	Yes		Colors in visual types in Quick
Focusing on or excluding elements	Yes		Focusing on visual elements Excluding visual elements
Sorting	Limited	You can only sort data fields that are in the Category and Color field wells.	Sorting visual data in Amazon Quick
Performing field aggregation	Yes		Changing field aggregation
Adding drill-downs	Not supported		Adding drill-downs to visual data in Quick Sight
Choosing size	Yes		Formatting in Amazon Quick
Showing totals	Not supported		Formatting in Amazon Quick

Creating a radar chart

Use the following procedure to create a radar chart.

To create a radar chart

1. On the analysis page, choose **Visualize** on the tool bar.
2. Choose **Add** on the application bar, and then choose **Add visual**.

3. On the **Visual types** pane, choose the radar chart icon.
4. From the **Fields list** pane, drag the fields that you want to use to the appropriate field wells. In most cases, you want to use dimension or measure fields as indicated by the target field well.

To create a radar chart, drag fields to the **Category**, **Value**, and **Group/Color** field wells. The axis that a radar chart is organized around is determined by the way that you organize fields into their respective field wells:

- In a radar chart that uses a **value axis**, dimension values are shown as lines and axes represent value fields. To create a radar chart that uses a value axis, add one category field to the **Color** field well and one or more values to the **Value** field well.
- In a radar chart that uses a **dimension axis**, group dimension values are shown as axes and value fields are shown as lines. All axes share a range and scale. To create a radar chart that uses a dimension axis, add one dimension to the **Group** field well and one or more values to the **Value** field well.
- In a radar chart that uses a **dimension-color axis**, group dimension values are shown as axes and color dimension values are shown as lines. All axes share a range and scale. To create a radar chart that uses a dimension-color axis, add one dimension to the **Category** field well, one value to the **Value** field well, and one dimension to the **Color** field well.

Using Sankey diagrams

Use Sankey diagrams to show flows from one category to another, or paths from one stage to the next.

For example, a Sankey diagram can show the number of people migrating from one country to another. A Sankey diagram can also show the path a web visitor takes from one page to the next on a company website, with possible stops along the way.

Data for Sankey diagrams

To create Sankey diagrams in Quick, your dataset should contain a measure and two dimensions (one dimension containing source categories and another containing destination categories).

The following table is a simple example of data for a Sankey diagram.

Dimension (Source)	Dimension (Destination)	Measure (Weight)
--------------------	-------------------------	------------------

Dimension (Source)	Dimension (Destination)	Measure (Weight)
A	W	500
A	X	23
A	Y	147

The following Sankey diagram is created when the dimensions and measure are added to the field well, with the A node on the left linking to the W, Y, and X nodes on the right. The width of each link between nodes is determined by the value in the Measure (Weight) column. The nodes are automatically ordered.

To create multilevel Sankey diagrams in Amazon Quick, your dataset should still contain a measure and two dimensions (one for source and one for destination), but in this case your data values differ.

The following table is a simple example of data for a multilevel Sankey diagram with two stages.

Dimension (Source)	Dimension (Destination)	Measure (Weight)
A	W	500
A	X	23
A	Y	147
W	Z	300
X	Z	5
Y	Z	50

The following Sankey diagram is created when the dimensions and measure are added to the field well. Here, the A node on the left links to the W, Y, and X nodes in the middle, and the W, Y, and X nodes then link to the Z node on the right. The width of each link between nodes is determined by the value in the Measure (Weight) column.

Working with cyclical data

Sometimes, the data that you use for a Sankey diagram contains cycles. For example, suppose that you're visualizing user traffic flows between pages on a website. You might discover that users who come to page A move to page E, and then come back to page A. An entire flow might look something like A-E-A-B-A-E-A.

When your data contains cycles, the nodes in each cycle are repeated in Quick. For example, if your data contains the flow A-E-A-B-A-E-A, the following Sankey diagram is created.

Preparing data for Sankey diagrams

If your dataset doesn't contain Source or Destination columns, prepare your data to include them. You can prepare data when creating a new dataset, or when editing an existing dataset. For more information about creating a new dataset and preparing it, see [Creating datasets](#). For more information about opening an existing dataset for data preparation, see [Editing datasets](#).

The following procedure uses an example table (illustrated in following) to demonstrate how to prepare your data for Sankey diagrams in Quick. The table includes three columns: Customer ID, Time, and Action.

Customer ID	Time	Action
1	9:05 am	Step 1
1	9:06 am	Step 2
1	9:08 am	Step 3
2	11:44 am	Step 1
2	11:47 am	Step 2

Customer ID	Time	Action
2	11:48 am	Step 3

To create a Sankey diagram in Quick using this data, first add Source and Destination columns to the table. Use the following procedure to learn how.

To add Source and Destination columns to your table

1. Add a Step Number column to the table to number or rank each row.

There are multiple ways to compute the Step Number column. If your data source is compatible with SQL and your database supports ROW_NUMBER or RANK functions, you can use custom SQL in Quick to order the rows in the Step Number column. For more information about using custom SQL in Quick, see [Using SQL to customize data](#).

Customer ID	Time	Action	Step Number
1	9:05 am	Step 1	1
1	9:06 am	Step 2	2
1	9:08 am	Step 3	3
2	11:44 am	Step 1	1
2	11:47 am	Step 2	2
2	11:48 am	Step 3	3

2. Add a Next Row Number column to the table with values equal to Step Number plus one.

For example, in the first data row of the table, the value for Step Number is 1. To compute the value for Next Step Number for that row, add 1 to that value.

$$1 + 1 = 2$$

The value for Step Number in the second data row of the table is 2; therefore, the value for Next Step Number is 3.

$$2 + 1 = 3$$

Customer ID	Time	Action	Step Number	Next Step Number
1	9:05 am	Step 1	1	2
1	9:06 am	Step 2	2	3
1	9:08 am	Step 3	3	4
2	11:44 am	Step 1	1	2
2	11:47 am	Step 2	2	3
2	11:48 am	Step 3	3	4

3. Join the table with itself:
 - a. For **Join type**, choose **Inner**.
 - b. For **Join clauses**, do the following:
 - i. Choose **Customer ID = Customer ID**
 - ii. Choose **Next Step Number = Step Number**

Joining the two tables creates two columns for Customer ID, Time, Action, Step Number and Next Step Number. The columns from the table at the left of the join are Source columns. The columns from the table at the right of the join are Destination columns.

For more information about joining data in Quick, see [Joining data](#).

4. (Optional) Rename columns to indicate sources and destinations.

The following is an example:

1. Rename the **Action** column on the left to **Source**.
2. Rename the **Action [copy]** column on the right to **Destination**.
3. Rename the **Time** column on the left to **Start Time**.
4. Rename the **Time [copy]** column on the right to **End Time**.

Your data is now ready to visualize.

Creating Sankey diagrams

Use the following procedure to create a Sankey diagram.

To create a Sankey diagram

1. On the analysis screen, choose **Visualize** on the left toolbar.
2. On the application bar, choose **Add**, and then choose **Add visual**.
3. On the **Visual types** pane, choose the Sankey diagram icon.
4. On the menu in the upper-right corner of the visual, choose the **Properties** icon.
5. In the **Properties** pane, choose either the **Source** or **Destination** section.

Customizing the number of nodes

Use the following procedure to customize the number of nodes that appear in a Sankey diagram. Quick supports up to 100 Source/Destination nodes.

To customize the number of nodes that appear in a Sankey diagram

1. On the analysis page, choose the Sankey diagram visual that you want to format.
2. On the menu in the upper-right corner of the visual, select the **Format Visual** icon.
3. In the **Properties** pane that opens, choose either the **Source** or **Destination** tab.
4. For **Number of nodes displayed**, enter a number.

The nodes in the diagram update to the number that you specified. The top nodes are automatically shown. All other nodes are placed in an **Other** category.

Note

Specifying the number of Source nodes controls how many Source nodes can appear overall in the diagram. Specifying the number of Destination nodes controls how many Destination nodes can appear per Source node. This means that if there is more than one Source node in your diagram, the overall number of Destination nodes will be higher than the number specified.

Quick supports up to 100 Source/Destination nodes.

For example, the following Sankey diagram has a limit of three source nodes (out of five), so the top three are shown in the diagram. The other two source nodes are placed in the Other category.

To remove the **Other** category from the diagram, select it in the view and choose **Hide “other” categories**.

Sankey diagram features

To understand the features supported by Sankey diagrams, use the following table.

Feature	Supported?	For more information	
Changing the legend display	No		
Changing the title display	Yes	Titles and subtitles on visual types in Quick	
Changing the axis range	No		
Changing the visual colors	No		
Focusing on or excluding elements	Yes	Focusing on visual elements	

Feature	Supported?	For more information	
		Excluding visual elements	
Sorting	No		
Performing field aggregation	Yes	Changing field aggregation	
Adding drill-downs	No		
Conditional formatting	No		

Using scatter plots

Use scatter plots to visualize two or three measures across two dimensions.

Each bubble on the scatter plot represents one or two dimension values. The X and Y axes represent two different measures that apply to the dimension. A bubble appears on the chart at the point where the values for the two measures for an item in the dimension intersect. Optionally, you can also use bubble size to represent an additional measure.

Scatter plots show up to 2500 datapoints in aggregated and unaggregated scenarios regardless of whether a color or label dimension is used in the visual. Due to the order of limit operations, there may be cases where fewer datapoints for a dataset are shown. For more information about how Amazon Quick handles data that falls outside display limits, see [Display limits](#).

Scatter plot features

To understand the features supported by scatter plots, use the following table.

Feature	Supported?	Comments	For more information
Changing the legend display	Yes, with exceptions	Scatter plots display a legend if you have the	Legends on visual types in Quick

Feature	Supported?	Comments	For more information
		Group/Color field well populated.	
Changing the title display	Yes		Titles and subtitles on visual types in Quick
Changing the axis range	Yes	You can set the range for both the X and Y axes.	Range and scale on visual types in Quick
Showing or hiding axis lines, grid lines, axis labels, and axis sort icons	Yes		Axes and grid lines on visual types in Quick
Changing the visual colors	Yes		Colors in visual types in Quick
Focusing on or excluding elements	Yes, with exceptions	You can focus on or exclude a bubble in a scatter plot, except when you are using a date field as a dimension . In that case, you can only focus on a bubble, not exclude it.	Focusing on visual elements Excluding visual elements
Sorting	No		Sorting visual data in Amazon Quick
Performing field aggregation	Yes	You must apply aggregation to the fields you choose for the X axis, Y axis, and size, and can't apply aggregation to the field that you choose for the group or color.	Changing field aggregation

Feature	Supported?	Comments	For more information
Displaying unaggregated fields	Yes	On the field context menu, choose None to display unaggregated X and Y axis values. If your scatter plot shows unaggregated fields, you can't apply aggregations to the field that is in the color or label field well. Mixed aggregation is not supported for scatter plots.	
Adding drill-downs	Yes	You can add drill-down levels to the Group/Color field well.	Adding drill-downs to visual data in Quick Sight

Creating a scatter plot

Use the following procedure to create a scatter plot.

To create a scatter plot

1. On the analysis page, choose **Visualize** on the tool bar.
2. Choose **Add** on the application bar, and then choose **Add visual**.
3. On the **Visual types** pane, choose the scatter plot icon.
4. From the **Fields list** pane, drag the fields that you want to use to the appropriate field wells. Typically, you want to use dimension or measure fields as indicated by the target field well. If you choose to use a dimension field as a measure, the **Count** aggregate function is automatically applied to it to create a numeric value.

To create a scatter plot, drag a measure to the **X axis** field well, a measure to the **Y axis** field well, and a dimension to the **Color** or **Label** field well. To represent another measure with bubble size, drag that measure to the **Size** field well.

5. (Optional) Add drill-down layers by dragging one or more additional fields to the **Color** field well. For more information about adding drill-downs, see [Adding drill-downs to visual data in Quick Sight](#).

Scatter plot use cases

You can choose to plot unaggregated values even if you are using a field on Color by using the aggregate option **none** on the field menu, which also contains aggregation options like **sum**, **min**, and **max**. If one value is set to be aggregated, the other value will be automatically set as aggregated. The same applies to unaggregated scenarios. Mixed aggregation scenarios are not supported, meaning that one value cannot be set as aggregated while the other is unaggregated. Note that the unaggregated scenario, which is the **none** option, is supported only for numerical values, while categorical values, such as dates or dimensions, will display only aggregate values, such as **count** and **count distinct**.

Using the **none** option, you can choose to set both X and Y values to either aggregated or unaggregated from the **X axis** and **Y axis** field menus. This will define whether or not values will be aggregated by dimensions in the **Color** and **Label** field wells. To get started, add the required fields and choose the appropriate aggregation based on your use case, as shown in the following sections.

Unaggregated use cases

- Unaggregated X and Y values with Color

- Unaggregated X and Y values with Label

• Unaggregated X and Y values with Color and Label

Aggregated use cases

- Aggregated X and Y values with Color

- Aggregated X and Y values with Label

• Aggregated X and Y values with Color and Label

Using tables as visuals

Use a table visual to see a customized table view of your data. To create a table visual, choose at least one field of any data type. You can add as many columns as you need, up to 200. You can also add calculated columns.

Table visuals don't display a legend. You can hide or display the title on a table. You can also hide or display totals, and choose to show totals at the top or the bottom of the table. For more information, see [Analytics formatting per type in Quick](#).

To create a table visual

1. Open Amazon Quick and choose **Analyses** on the navigation pane at left.
2. Choose one of the following:
 - To create a new analysis, choose **New analysis** at upper right. For more information, see [Starting an analysis in Quick Sight](#).
 - To use an existing analysis, choose the analysis that you want to edit.
3. Choose **Insert** from the file menu and then **Add Visual**.
4. At lower left, choose the table icon from **Visual types**.
5. On the **Fields** list pane, choose the fields that you want to use. If you want to add a calculated field, choose **Insert** on the file menu and then **Add Calculated Field**.

To create a nonaggregated view of the data, add fields only to the **Value** field well. Doing this shows data without any aggregations.

To create an aggregated view of the data, choose the fields that you want to aggregate by, and then add them to the **Group by** field well.

To show or hide columns on a table

1. On your visual, choose the field that you want to hide, then choose **Hide column**.
2. To display hidden columns, choose any column, then choose **Show all hidden columns**.

To transpose columns to rows and rows to columns

- Choose the transpose icon (

)

near the top right of the visual. It has two arrows at a 90 degree angle.

To vertically align columns

- On your visual, choose the **Format visual** icon (

)

near the top right of the visual.

- In the **Properties** pane, choose **Table options**, and choose your table's vertical alignment.

To wrap the text for headers

- On your visual, choose the **Format visual** icon (

)

near the top right of the visual.

- In the **Properties** pane, choose **Table options**, and select **Wrap header text**.

To rearrange columns in a table chart

- Open the analysis with the visual that you want to sort. Visuals pane will be open by default.
- Do one of the following:
 - Drag and drop one or more fields in **Field wells** to rearrange their order.
 - Select a field directly in the table and choose the left or right arrow on **Move column**.

Using field styling

You can render URLs in a table as links by using the **Field styling** pane of the format visual menu. You can add up to 500 rows of links for each page in a table. Only https and mailto hyperlinks are supported.

To add links to your tables

1. From the Quick homepage, choose **Analyses**, and then choose the analysis that you want to customize.
2. Choose the table that you want to change.
3. On the menu at the upper right of the table, choose **Format visual**.
4. For **Format visual**, choose **Field styling**.
5. On the **Field styling** pane, choose the field that you want to style from the menu.
6. In the **Url options** section of the **Field styling** menu, choose **Make URLs hyperlinks**.

After you add links to your table, you can choose where you want the links to open when they're selected in the **Open in** section of the **Field style** pane. You can choose to have links open in a new tab, a new window, or in the same tab.

You can also choose how you want to style the link in the **Style as** section of **Field style** pane. Your links can appear as hyperlinks, icons, or plain text, or you can set a custom link.

To adjust the font size of a link icon or URL, change the **Font size** in the **Cells** section of the **Table options** pane of the **Format visual** menu.

You can set any URLs in your table that point to images to render in the table as images. Doing this can be useful when you want to include an image of a product as a part of a table.

To show URLs as images

1. From the Quick home page, choose **Analyses**, and then choose the analysis that you want to customize.
2. Choose the table that you want to change.
3. On the menu at the upper-right of the table, choose **Format visual**.
4. In the **Format visual** menu, choose **Field styling**.
5. In the **Field styling** pane, choose the field that you want to style from the menu.
6. In the **Url options** section of the **Field styling** menu, choose **Show URLs as images**.

After rendering images in a table, you can choose how to size the images in the **Image sizing** section of the **Field style** pane. You can fit images to their cell's height or width, or you can choose not to scale the image. Images fit to a cell's height by default.

Freeze columns to table visuals

You can freeze columns to your table visuals to lock specific columns in place on screen. This allows essential information to remain visible while readers scroll across the table. You can freeze columns one at a time, or you can freeze groups of columns in one action. All pinned columns are fixed to the far left side of the table and stay visible on screen at all times. This allows Quick readers to have a constant reference point for key data or information as they interact with other parts of the table.

To freeze columns to a table

1. On the table that you want to freeze a column to, choose the column that you want to pin.
2. Choose one of the following options.
 - To freeze a single column, choose **Freeze column**.
 - To freeze all columns up to the column that you choose, choose **Freeze up to this column**.

If your table has multiple pinned columns, you can reorder the columns in the order that you want. To adjust the order of the pinned columns on a table, choose the header of the column that you want to move, and then choose **Move** in the direction that you want.

To unfreeze columns from a table

1. On the table that you want to change, choose the pinned column that you want to unpin.
2. Choose one of the following options.
 - To unfreeze a single column, choose **Unfreeze column**.
 - To unfreeze all frozen columns, choose **Unfreeze all columns**.

Custom total values

Quick authors can define the total and subtotal aggregations for their table or pivot table visuals from the field wells. For tables, the custom total menu is only available if totals are toggled on for the visual.

To change the aggregation of a total or subtotal

1. Navigate to the analysis that you want to change, and choose the table or pivot table visual whose total you want to define.

2. Choose the field that you want to change from the field wells.
3. Choose **Total**, and then choose the aggregation that you want. The following options are available.
 - **Default** – The total calculation uses the same aggregation as the metric field.
 - **Sum** – Calculates the sum of the data in the visual.
 - **Average** – Calculates the average of the data in the visual.
 - **Min** – Calculates the minimum value of the data in the visual.
 - **Max** – Calculates the maximum value of the data in the visual.
 - **None (HIDE)** – Totals are not calculated. When you choose this option, the total and subtotal cells in the visual are left blank. If the outer dimension is sorted with the metric field that calculates the total or subtotal, the dimension is sorted alphabetically. When you change the value from **None (HIDE)** to another value, the outer dimension is sorted by the subtotals that are calculated with the specified aggregation type.

The following limitations apply to custom totals.

- Conditional formatting is not supported for custom totals.
- Total aggregations aren't supported for string columns. Total aggregations include **Min**, **Max**, **Sum**, and **Average**.
- Date columns are incompatible with **Average** and **Sum** total aggregation functions.

Sorting tables

In Amazon Quick, you can sort values in a table by fields in the columns headers of the table or with the **Sort visual** tool. You can sort up to 10 columns in a single table. Quick can also use an off-visual sort. You can sort columns in an **Ascending** or a **Descending** order. The following image shows the **Sort visual** icon and pop over.

Single column sort options

Quick Authors can access single column sort options from the field wells, the column headers, or from the **Sort visual** menu. Use the procedure below to use set up a single column sort on a table in Quick.

1. Open the [Quick console](#).
2. Open the analysis that you want to work in and navigate to the table that you want to sort.
3. Choose the header of the column that you want to sort.
4. For **Sort by**, choose the arrow icon, and then choose the field that you want to sort by.

You can also set up a single column sort in the **Sort visual** menu. To access the sort visual menu, choose the **Sort visual** icon in the on-visual menu. In the **Sort visual** menu, choose the field that you want to sort by, and then choose if you want the sort in an ascending or descending order. By default, new sorts are sorted in an ascending order. When you are finished, choose **APPLY**.

Tables that use single column sorting are sorted one column at a time. When a user chooses a new column to sort by, the previous sort order is overridden.

To make changes to a single column sort, open the **Sort visual** menu annd use the dropdown menus to choose a new field or sort order. When you are finished with your changes, choose **APPLY**.

To reset a table to its original state, open the **Sort visual** menu and choose **RESET**.

Multi column sort options

Quick authors can access multi column sort options from the **Sort visual** menu. Use the procedure below to set up a multi column sort for a table.

1. Open the [Quick console](#).

2. Open the analysis that you want to work in and navigate to the table that you want to sort.
3. Choose the **Sort visual** icon to open the **Sort visual** menu.
 - a. Alternatively, choose a header that you want to sort.
 - b. For **Sort by**, choose the arrow icon, and then choose **Multiple fields**.
4. In the **Sort visual** menu that opens, choose a field from the **Sort by** dropdown, and then choose whether you want the field sorted in an ascending or descending order.
5. To add another sort, choose **ADD SORT**, and repeat the workflow from Step 4. You can add up to 10 sorts to each table.
6. When you are finished, choose **APPLY**.

Columns are sorted in the order that they are added to the **Sort visual** menu. To change the order that columns are sorted by, open the **Sort visual** menu and use the **Sort by** dropdowns to reorder the sorts. When you are finished, choose **APPLY** to apply the new sort order to the table.

To reset a table to its original state, open the **Sort visual** menu and choose **RESET**.

Off visual sort options

Quick authors can configure an off-visual sort to sort the values in a table by a field and aggregation that is a part of the dataset that the table uses but not in one of the table's field wells. One off-field sort can be configured to a single table at a time.

Use the procedure below to configure an off-visual sort.

To add an off-visual sort to a table

1. Open the [Quick console](#).
2. Open the analysis that you want to work in and navigate to the table that you want to sort.
3. Choose the header of any column in the table.
4. For **Sort by**, choose the arrow icon, and then choose **Off-visual field**.
5. In the **Off-visual field** pane that appears, open the **Sort by** dropdown menu and choose the field that you want to sort.
6. For **Aggregation** open the dropdown menu and choose the aggregation that you want to use.
7. For **Sort order**, choose if you want the sort to be in an ascending or descending order.
8. When you are finished, choose **Apply**.

After a off-visual sort is applied to a table, the sort is shown in the **Sort visual** menu. The sort order of a table that contains an off-visual sort depends on the sort configuration of the table when the off-visual sort is added. If an off-visual sort is added to a table that already has a single or multi column sort configured, the off-visual sort overrides all other sorts. If the off-visual sort is applied before single or multi column sorts, you can add and reorder more sorts to the table.

Using text boxes

Add text to add context to sheets in an analysis by using a text box. Text can hold directions, descriptions, or even hyperlinks to external websites. The toolbar on the text box offers font settings so you can customize the font type, style, color, size, spacing, size in pixels, text highlights, and alignment. The text box itself has no format settings.

To add text to a new text box, simply select it and begin typing.

Using tree maps

To visualize one or two measures for a dimension, use tree maps.

Each rectangle on the tree map represents one item in the dimension. Rectangle size represents the proportion of the value for the selected measure that the item represents compared to the whole for the dimension. You can optionally use rectangle color to represent another measure for the item. Rectangle color represents where the value for the item falls in the range for the measure, with darker colors indicating higher values and lighter colors indicating lower ones.

Tree maps show up to 100 data points for the **Group by** field. For more information about how Amazon Quick handles data that falls outside display limits, see [Display limits](#).

Tree map features

To understand the features supported by tree maps, use the following table.

Feature	Supported?	Comments	For more information
Changing the legend display	Yes		Legends on visual types in Quick
Changing the title display	Yes		Titles and subtitles on visual types in Quick

Feature	Supported?	Comments	For more information
Changing the axis range	Not applicable		Range and scale on visual types in Quick
Changing the visual colors	No		Colors in visual types in Quick
Focusing on or excluding elements	Yes, with exceptions	You can focus on or exclude a rectangle from a tree map, except when you are using a date field as the dimension. In that case, you can only focus on a rectangle, not exclude it.	Focusing on visual elements Excluding visual elements
Sorting	No	Default sorting is in descending order by the measure in the Size column.	Sorting visual data in Amazon Quick
Performing field aggregation	Yes	You must apply aggregation to the fields you choose for size and color, and can't apply aggregation to the field that you choose to group by.	Changing field aggregation
Adding drill-downs	Yes	You can add drill-down levels to the Group by field well.	Adding drill-downs to visual data in Quick Sight

Creating a tree map

Use the following procedure to create a tree map.

To create a tree map

1. On the analysis page, choose **Visualize** on the tool bar.

2. Choose **Add** on the application bar, and then choose **Add visual**.
3. On the **Visual types** pane, choose the tree map icon.
4. From the **Fields list** pane, drag the fields that you want to use to the appropriate field wells. Typically, you want to use dimension or measure fields as indicated by the target field well. If you choose to use a dimension field as a measure, the **Count** aggregate function is automatically applied to it to create a numeric value.

To create a tree map, drag a measure to the **Size** field well and a dimension to the **Group by** field well. Optionally, drag another measure to the **Color** field well.

5. (Optional) Add drill-down layers by dragging one or more additional fields to the **Group by** field well. For more information about adding drill-downs, see [Adding drill-downs to visual data in Quick Sight](#).

Using waterfall charts

Use a waterfall chart to visualize a sequential summation as values are added or subtracted. In a waterfall chart, the initial value goes through a (positive or negative) change, with each change represented as a bar. The final total is represented by the last bar. Waterfall charts are also known as *bridges* because the connectors between the bars bridge the bars together, showing that they visually belong to the same story.

Waterfall charts are most commonly used to present financial data, because you can show change within one time period or from one time period to another. This way, you can visualize the different factors that have an impact your project cost. For example, you can use a waterfall chart to show gross sales to net income within the same month, or the difference in net income from last year to this year, and the factors that were responsible for this change.

You can also use waterfall charts to present statistical data, for example how many new employees you hired and how many employees left your company within a year.

The following screenshot shows a waterfall chart.

To create a basic waterfall chart visual

1. Open Amazon Quick and choose **Analyses** on the navigation pane at left.
2. Choose one of the following:
 - To create a new analysis, choose **New analysis** at upper right. For more information, see [Starting an analysis in Quick Sight](#).
 - To use an existing analysis, choose the analysis that you want to edit.
3. Choose **Add (+), Add Visual**.
4. At lower left, choose the waterfall chart icon from **Visual types**.
5. On the **Fields list** pane, choose the fields that you want to use for the appropriate field wells. Waterfall charts require one category or measure in **Value**.
6. (Optional) Add drill-down layers by dragging one or more additional fields to the **Group/Color** field well. For more information about adding drill-downs, see [Adding drill-downs to visual data in Quick Sight](#).

To understand the features supported by waterfall charts, see [Analytics formatting per type in Quick](#). For customization options, see [Formatting in Amazon Quick](#).

Using word clouds

As an engaging way to display how often a word is used in relation to other words in a dataset, use word clouds. The best use for this type of visual is to show word or phrase frequency. It can also make a fun addition to show trending items or actions. You can use a fixed dataset for

Each word in a word cloud represents one or more values in a dimension. The size of the word represents the frequency of a value's occurrence in a selected dimension, in proportion to the occurrences of other values in the same dimension. Word clouds are best when precision isn't important and there aren't a large number of distinct values.

Other

Word clouds usually look better with 20–100 words or phrases, but the format settings offer a wide range of flexibility. If you choose too many words, they can become too small to be legible, depending on the size of your display. By default, word clouds display 100 distinct words. To show more, change the format setting for **Number of words**.

Creating a word cloud

Use the following procedure to create a word cloud.

To create a word cloud

1. On the analysis page, choose **Visualize** on the tool bar.
2. Choose **Add** on the application bar, and then choose **Add visual**.
3. On the **Visual types** pane, choose the word cloud icon.
4. From the **Fields list** pane, drag the fields that you want to use to the appropriate field wells. Typically, you want to use dimension or measure fields as indicated by the target field well. If you choose to use a dimension field as a measure, the **Count** aggregate function is applied by default.

To create a word cloud, add a dimension to the **Group by** field well. Optionally, add a measure to the **Size** field well.

5. (Optional) Add drill-down layers by dragging one or more additional fields to the **Group by** field well. For more information about adding drill-downs, see [Adding drill-downs to visual data in Quick Sight](#).

Formatting in Amazon Quick

You choose from a variety of options to format and style your data visualizations. To format a visual, select the visual that you want to format and choose the **Format visual** icon on the upper-right corner of the visual. Once you have the format visual pane open, you can click on different

visuals and controls to view formatting data for the specific visual or control. For more information about formatting a visual control, see [Using a control with a parameter in Amazon Quick](#).

Use the following sections to format and style your content:

 Note

Any format changes applied from the field wells are applied only to the selected visual.

Analytics formatting per type in Quick

Use the following list to see what type of formatting works in a visualization during analysis:

- Bar charts (both horizontal and vertical) support the following formatting:
 - Customize, display, or hide title, field labels, and data labels
 - Customize, display, or hide legend (exception: simple charts without clustering or multiple measures don't show a legend)
 - Specify axis range and steps on the x-axis for horizontal bar charts, and on the y-axis for vertical bar charts
 - Choose how many data points to display on the x-axis for vertical bar charts, and on the y-axis for horizontal bar charts
 - Show or hide axis lines, axis labels, axis sort icons, and chart grid lines
 - Customize, display, or remove reference lines
 - Show or hide the "other" category

Horizontal bar charts support sorting on the y-axis and **Value**. Vertical bar charts support sorting on the x-axis and **Value**.

Stacked bar charts support showing totals.

- Box plots support the following formatting:
 - Customize, display, or hide title
 - Customize, display, or hide legend
 - Specify axis range and label tick on the x-axis and axis range and step on the y-axis
 - Show or hide axis lines, axis labels, axis sort icons, and chart grid lines
 - Choose how many data points to display on the y-axis.
 - Show or hide the "other" category
 - Add reference lines

Box plots support sorting on **Group by**.

- Combo charts support the following formatting:
 - Customize, display, or hide title, field labels, and data labels
 - Customize, display, or hide legend (exception: simple charts without clustering, stacking, or multiple measures don't show a legend)

- Specify axis range on bars and lines
- Synchronize the Y axes for both bars and lines into a single axis.
- Choose how many data points to display on the x-axis
- Show or hide axis lines, axis labels, axis sort icons, and chart grid lines
- Customize, display, or remove reference lines
- Show or hide the "other" category

Combo charts support sorting on the x-axis, **Bars**, and **Lines**.

- Donut charts support the following formatting:
 - Customize, display, or hide title, data labels, and legend
 - Customize, display, or hide the labels for group or color and value fields
 - Choose how many slices to display from **Group/Color**
 - Show or hide the "other" category

Donut charts support sorting on **Group/Color** and **Value**.

- Filled maps support the following formatting:
 - Customize, display, or hide title.
 - Customize, display, or hide the legend

Filled maps support sorting on **Location** and **Color**.

- Funnel charts support the following formatting:
 - Customize, display, or hide title, and data labels
 - Customize, display, or hide the labels for group or color and value fields
 - Choose how many stages to display in the **Group by** field
 - Show or hide the "other" category

Funnel charts support sorting on **Group by** and **Value**.

- Gauge charts support the following formatting:
 - Customize, display, or hide title. Display or hide axis labels.
 - Customize how to display the value or values: hidden, actual value, comparison
 - Choose the comparison method (available when you use two measures)
 - Choose the axis range and padding to display in the gauge chart

- Choose the arc style (degrees from 180 to 360) and arc thickness

Gauge charts don't support sorting.

- Geospatial charts (maps) support the following formatting:
 - Customize, display, or hide title and legend
 - Choose the base map image.
 - Choose to display map points with or without clustering.

Geospatial charts don't support sorting.

- Heat maps support the following formatting:
 - Customize, display, or hide title, legend, and labels
 - Choose how many rows and columns to display
 - Choose colors or gradients.
 - Show or hide the "other" category

Heat maps support sorting on **Values** and **Columns**.

- Histogram charts support the following formatting:
 - Customize, display, or hide title, field labels, and data labels
 - Specify axis range, scale, and steps on the y-axis
 - Choose how many data points to display on the x-axis
 - Show or hide axis lines, axis labels, axis sort icons, and chart grid lines

Histogram charts don't support sorting.

- Key performance indicators (KPIs) support the following formatting:
 - Customize, display, or hide title
 - Display or hide trend arrows and progress bar
 - Customize comparison method as auto, difference, percent (%), or difference as percent (%)
 - Customize primary value displayed to be comparison or actual
 - Conditional formatting

KPIs don't support sorting.

- Line charts support the following formatting:
 - Customize, display, or hide title, field labels, and data labels

• Customize, display, or hide legend (exception: simple charts don't show a legend)

- Specify axis range and steps (on y-axis)
- Choose how many data points to display on the x-axis
- Show or hide axis lines, axis labels, axis sort icons, and chart grid lines
- Customize, display, or remove reference lines
- Customize the styling of lines and the markers for data points on a line
- Show or hide the "other" category, except when the x-axis is a date

Line charts support sorting on the x-axis and **Value** for numeric purposes only.

- Pie charts support the following formatting:
 - Customize, display, or hide title, data labels, and legend
 - Customize, display, or hide the labels for group or color and value fields
 - Show metrics as values, percentages, or both
 - Choose how many slices to display from the **Group/Color** field
 - Show or hide the "other" category

Pie charts support sorting on **Value** and **Group/Color**.

- Pivot tables support the following formatting:
 - Customize, display, or hide title
 - Customize, display, or hide the labels for column, row, and value fields
 - Customize the font sizes for table headers and cells/body
 - Display or hide totals and subtotals on rows or columns
 - Custom labels for totals or subtotals
 - Choose additional styling options: fit table to view, hide +/- buttons, hide column field names, hide duplicate label when using single metric
 - Conditional formatting

Pivot tables support sorting on **Column** and **Row**. For more information on sorting pivot table data, see [Sorting pivot tables in Quick](#).

- Scatter plots support the following formatting:
 - Customize, display, or hide title, legend, field labels, and data labels
 - Customize, display, or remove reference lines

- Show or hide axis lines, axis labels, axis sort icons, and chart grid lines

Scatter plots don't support sorting.

- Tables support the following formatting:
 - Customize, display, or hide title, legend, and columns
 - Customize, display, or hide the column names for group-by and value fields
 - Customize the font sizes for table headers and cells/body
 - Display or hide totals at the top or bottom of the table
 - Provide a custom label for totals
 - Add conditional formatting

Tables support sorting on **Group by** and **Value**.

- Tree maps support the following formatting:
 - Customize, display, or hide title and legend
 - Customize, display, or hide the labels for group-by, size, and color fields
 - Choose colors or gradients.
 - Choose how many squares to display from the **Group by** field
 - Show or hide the "other" category

Line charts support sorting on **Size**, **Group by** and **Color**.

- Waterfall charts support the following formatting:
 - Customize, display, or hide title or subtitle
 - Customize the total label
 - Specify x-axis label size and orientation and y-axis label range and orientation.
 - Show or hide axis lines, axis labels, axis sort icons, and chart grid lines
 - Show or hide the "other" category
 - Customize the legend size and position.
 - Customize and display or hide data labels.

Waterfall charts support sorting on **Category** and **Value**.

- Word clouds support the following formatting:
 - Customize, display, or hide title
 - Customize the word color, and the number of words to display from the **Group by** field

- Show or hide the "other" category
- Choose additional styling options: allow vertical words, emphasize scale, or work with fluid layout, lowercase, padding level, or maximum string length

Word clouds support sorting on **Group by**.

Table and pivot table formatting options in Quick

You can customize tables and pivot tables in Quick to meet your business needs. You can customize table headers, cells, and totals by specifying the color, size, wrap, and alignment of text in each. You can also specify the height of rows in a table, add borders and grid lines, and add custom background colors. In addition, you can customize how to display totals and subtotals.

If you have applied conditional formatting to a table or pivot table, it takes precedence over any other styling you configure.

When you export table or pivot table visuals to Microsoft Excel, the formatting customizations that you applied to the visual aren't reflected in the downloaded Excel file.

To format a table or pivot table

- In your analysis, choose the table or pivot table that you want to customize, and then choose the **Format visual** icon.

The **Properties** pane opens at left.

Following, you can find descriptions for options for customizing each area of your table or pivot table in the **Properties** pane.

Topics

- [Headers](#)
- [Cell formatting](#)
- [Totals and subtotals](#)
- [Row and column size in tables and pivot tables in Quick](#)
- [Customize pivot table data](#)

Headers

Expand all headers

You can choose to expand all headers in a pivot table to show all child and grandchild rows of a header.

To expand all headers of a pivot table

1. On the visual that you want to change, select any header to open the **On-visual** menu.
2. Choose **Expand all below**.

Header height

You can customize table header height.

To customize the height of headers in a table

1. In the **Properties** pane, choose **Headers**.
2. For **Row height**, enter a number in pixels. You can enter a whole number from 8 through 500.

To customize the height of headers in a pivot table

1. In the **Properties** pane, choose **Headers**.
2. In the **Columns** section, for **Row height**, enter a number in pixels. You can enter a whole number from 8 through 500.

Header text

You can customize table header text.

To customize header text in a table

1. In the **Properties** pane, choose **Headers**.
2. Navigate to the **TEXT** section and do one or more of the following:
 - To change the color of the header text, choose the color swatch underneath **Text styling**, and then choose the color that you want the table text to be.

- To change the font or font size of the header text, open the **Font** or **Font size** dropdown and choose the font or font size that you want.
- To bold, italicize, or underline the header text, choose the appropriate icon from the style bar.
- To wrap text in headers that are too long to fit, select **Wrap text**. Wrapping text in a header doesn't automatically increase the height of the header. Follow the previous procedure for increasing header height.
- To change the horizontal alignment of text in the header, choose a horizontal alignment icon. You can choose left alignment, center alignment, right alignment, or automatic alignment.
- To change the vertical alignment of text in the header, choose a vertical alignment icon. You can choose top alignment, middle alignment, or bottom alignment.

To customize header text in a pivot table

1. In the **Properties** pane, choose **Headers**.

The Headers section expands to show options for customizing column and row headers.

2. In the **Headers** section, do one or more of the following:
 - To apply row styling to field names of the rows or columns, choose **Style rows label** or **Style columns label** depending on the label that you want to customize.
 - To customize the header font, navigate to the **TEXT** subsection of the **Rows** or **Columns** section and do one or more of the following:
 - To change the color of the header text, choose the color swatch underneath **Text styling**, and then choose the color that you want the table text to be.
 - To change the font or font size of the header text, open the **Font** or **Font size** dropdown and choose the font or font size that you want.
 - To bold, italicize, or underline the header text, choose the appropriate icon from the style bar.
 - To change the horizontal alignment of text in the header, choose an alignment icon. You can choose left alignment, center alignment, right alignment, or automatic alignment. You can choose a horizontal alignment for column headers in the **Columns** section, and for row headers in the **Rows** section.

- To change the vertical alignment of text in the header, choose an alignment icon. You can choose top alignment, middle alignment, or bottom alignment. You can choose a vertical alignment for column headers in the **Columns** section, and row headers in the **Rows** section.
- To hide the rows label or column field names, choose the eye icon next to **Rows label** or **Column field names**.

Header background color

You can customize table headers' background color.

To customize the background color of table headers

1. In the **Properties** pane, choose **Headers**.
2. For **Background**, choose the background color icon, and then choose a color. You can choose one of the provided colors, reset the header text color to the default color, or create a custom color.

To customize the background color of pivot table headers

1. In the **Properties** pane, choose **Headers**.

The **Headers** section expands to show options for customizing column and row headers.

2. In the **Columns** section, choose the background color icon, and then choose a color.
3. In the **Rows** section, choose the background color icon, and then choose a color.

Header borders

You can customize header borders' color.

To customize header borders in a table

1. In the **Properties** pane, choose **Headers**.
2. For **Borders**, do one or more of the following:
 - To customize the type of border that you want, choose a border type icon. You can choose no borders, horizontal borders only, vertical borders only, or all borders.
 - To customize the border thickness, choose a border thickness.

- To customize the border color, choose the border color icon, and then choose a color. You can choose one of the provided colors, reset the border color to the default color, or create a custom color.

To customize header borders in a pivot table

1. In the **Properties** pane, choose **Headers**.

The **Headers** section expands to show options for customizing column and row headers.

2. In the **Columns** and **Rows** sections, for **Borders**, do one or more of the following:
 - To customize the type of border that you want, choose a border type icon. You can choose no borders, horizontal borders only, vertical borders only, or all borders.
 - To customize the border thickness, choose a border thickness.
 - To customize the border color, choose the border color icon, and then choose a color. You can choose one of the provided colors, reset the border color to the default color, or create a custom color.

Header styling options for hierarchy pivot tables

You can hide or rename the **Rows** label of a hierarchy pivot table.

To make changes to the Rows label of a hierarchy pivot table

1. Select the hierarchy pivot table that you want to change and open the **Format visual** menu.
2. In the **Headers** section, you can perform the following tasks
 - Choose **Hide rows label** to hide the **Rows** label from your pivot table.
 - For **Rows label**, enter the label that you want displayed on the pivot table.

Cell formatting

Row height

You can customize table row height.

To customize the height of rows in a table or pivot table

1. In the **Properties** pane, choose **Cells**.

The **Cells** section expands to show options for customizing cells.

2. For **Row height**, enter a number in pixels. You can enter a whole number from 8 through 500.

Cell text

You can customize the formatting for cell text within a table.

To format the cell text in a table or pivot table

1. In the **Properties** pane, choose **Cells**.

The **Cells** section expands to show options for customizing cells.

2. For **Text**, do one or more of the following:
 - To change the color of the cell text, choose the color swatch underneath **Text styling**, and then choose the color that you want the table text to be.
 - To change the font or font size of the cell text, open the **Font** or **Font size** dropdown and choose the font or font size that you want.
 - To bold, italicize, or underline the cell text, choose the appropriate icon from the style bar.
 - To wrap text in headers that are too long to fit, select **Wrap text**. Wrapping text in cells doesn't automatically increase the row height. Follow the previous procedure for increasing row height.
 - To change the horizontal alignment of text in cells, choose a horizontal alignment icon. You can choose left alignment, center alignment, right alignment, or automatic alignment. Horizontal alignment can only be configured for the **Rows** fields of a hierarchy pivot table.
 - To change the vertical alignment of text in cells, choose a vertical alignment icon. You can choose top alignment, middle alignment, bottom alignment, or automatic. For tabular pivot tables, the value for **Automatic** is vertical. For hierarchy pivot tables, the value for **Automatic** is middle.

TEXT

☒ Wrap text

Cell background color

You can customize table cells' background color.

To customize the background color of cells in a table or pivot table

1. In the **Properties** pane, choose **Cells**.

The **Cells** section expands to show options for customizing cells.

2. For **Background**, do one or more of the following:
 - To alternate background colors between rows, select **Alternate row colors**. Clearing this option means that all cells have the same background color.
 - If you choose to alternate background colors between rows, choose a color for **Odd rows** and a color for **Even rows** by choosing the background color icon for each and selecting a color. You can choose one of the provided colors, reset the background color to the default color, or create a custom color.
 - If you choose not to alternate background colors between rows, choose the background color icon and select a color for all cells. You can choose one of the provided colors, reset the background color to the default color, or create a custom color.

Cell borders

You can customize table cells' borders.

To customize the borders for cells in a table or pivot table

1. In the **Properties** pane, choose **Cells**.

The **Cells** section expands to show options for customizing cells.

2. For **Borders**, do one or more of the following:

- To customize the type of border that you want, choose a border type icon. You can choose no borders, horizontal borders only, vertical borders only, or all borders.
- To customize the border thickness, choose a border thickness.
- To customize the border color, choose the border color icon, and then choose a color. You can choose one of the provided colors, reset the border color to the default color, or create a custom color.

Totals and subtotals

On tables and pivot tables, you can configure the display of totals or subtotals. Tables can display totals at the top or the bottom of the visual. Pivot tables can display totals and subtotals on rows and columns.

Add totals and subtotals to tables and pivot tables in Quick

You can add total columns to your table and pivot table visuals. You can also add subtotal columns to your pivot table visuals.

To display or hide totals and subtotals for a pivot table

1. To display totals, open the **Properties** pane and choose **Total**.
 - To show totals for rows, toggle the **ROWS** switch on. Totals are displayed on the bottom row of the visual. Choose **Pin totals** to keep the totals visible as you scroll through the table.
 - To show totals for columns, toggle the **COLUMNS** switch on. Totals are displayed on the last column of the visual.
2. To display totals, open the **Properties** pane and choose **Subtotal**.
 - To show subtotals for rows, toggle the **ROWS** switch on. Totals are displayed on the bottom row of the visual.
 - To show subtotals for columns, toggle the **COLUMNS** switch on.
 - For **Level**, choose one of the following:
 - Choose **Last** to only show the subtotal of the last field in the chart's hierarchy. This is the default option.

- Choose **All** to show subtotals for every field.
- Choose **Custom** to customize which fields show subtotals.

After you add row totals to your table or pivot table visual, you can also choose to position the totals at the top or bottom of the visual. You can also change the position of column totals in pivot tables.

To position row or column totals in a table or pivot table

1. In the **Properties** pane, choose **Total**.
2. (Optional) For **Rows**, choose **Show totals**.
3. (Optional) For **Columns**, choose **Show totals**.
4. (Optional) In the **Rows** menu, open the **Position** dropdown and choose the position that you want the totals to be displayed. Choose **Top** to position totals at the top of the table, or **Bottom** to position totals at the bottom of the table.
5. (Optional) In the **Columns** menu, open the **Position** dropdown and choose the position that you want the totals to be displayed. Choose **Left** to position totals at the left of the table, or **Right** to position totals at the right of the table.

You can't change the position of the subtotals of a pivot table visual. If your pivot table uses a hierarchy layout, the subtotal rows are positioned at the top of the table. Tabular pivot table subtotals are displayed at the bottom of the table.

Customize labels for totals and subtotals

You can rename the totals in table and pivot table visuals to provide better context for account readers. By default, the totals and subtotals appear without a label.

To rename totals in a table or pivot table visual

1. In the **Properties** pane, choose **Total** or **Subtotal**.
2. For **Label**, enter a word or short phrase that you want displayed for the total.

In pivot tables, you can also add labels to column totals and subtotals. To do so, enter a word or short phrase for **Label** in the **Columns** section.

3. (Optional) For tabular pivot tables, you can also add group names to subtotals. To add a group name to row subtotals, choose the **Plus (+)** icon next to the **Label** field to add the group name parameter that you want. You can also enter a word or short phrase to this field.

You can also make changes to the text size and font color of the total and subtotal labels of your table and pivot table visuals.

To format totals and subtotals text

1. In the **Properties** pane, choose **Total** or **Subtotal**.
2. For **Text**, do one or more of the following.
 - To change the color of the total or subtotal text, choose the color swatch underneath **Text styling**, and then choose the color that you want the table text to be.
 - To change the font or font size of the total or subtotal text, open the **Font** or **Font size** dropdown and choose the font or font size that you want.
 - To bold, italicize, or underline the total or subtotal text, choose the appropriate icon from the style bar.

In pivot tables, you can also add format text for column totals and subtotals. To do so, repeat the above steps in the **Columns** section.

Totals and subtotals background color

To customize the background color for totals and subtotals

1. In the **Properties** pane, choose **Total** or **Subtotal**.
2. For **Background**, choose the background color icon, and then choose a color. You can choose one of the provided colors, reset the background color to the default color, or create a custom color.

In pivot tables, you can also add background colors for column totals and subtotals. To do so, choose a the background color icon for **Background** in the **Columns** section.

Totals and subtotals borders

To customize the borders for totals and subtotals

1. In the **Properties** pane, choose **Total** or **Subtotal**.
2. For **Borders**, do one or more of the following:
 - To customize the type of border that you want, choose a border type icon. You can choose no borders, horizontal borders only, vertical borders only, or all borders.
 - To customize the border thickness, choose a border thickness.
 - To customize the border color, choose the border color icon, and then choose a color. You can choose one of the provided colors, reset the border color to the default color, or create a custom color.

In pivot tables, you can also add borders for column totals and subtotals. To do so, repeat the above steps in the **Columns** section.

Applying totals and subtotals styling to cells

In pivot tables, you can apply any text, background color, and border styling you apply to totals to cells in that same column or row. Row subtotals appear differently depending on the layout that your pivot table uses. For tabular pivot tables, explicit subtotal headers appear on the visual. For hierarchy pivot tables, explicit subtotal headers do not appear. Instead, authors apply subtotal styling to individual fields from the **Format visual** menu. Collapsed headers cannot be styled as subtotals.

To apply totals and subtotals styling to cells

1. In the **Properties** pane, choose **Total** or **Subtotal**.
2. For **Apply styling to**, choose the visual that you want to apply subtotal styling to. You can choose from the following options.
 - **None**– Removes styling options from all cells.
 - **Headers only**– Applies styling options to all headers in the pivot table.
 - **Cells only**– Applies styling options to all cells that aren't headers in the pivot table.
 - **Headers and cells**– Applies styling options to all cells in the pivot table.

Row and column size in tables and pivot tables in Quick

Authors and readers can resize rows and columns in a table or pivot table visual. They can adjust both row height and column width. Authors can also set the default column width for columns in a pivot table visual.

To resize a row in a table or pivot table

- In the table or pivot table visual, hover your cursor over the line that you want to resize until you see the horizontal cursor appear. When it appears, select the line and drag it to a new height.

You can adjust the row height by selecting the horizontal lines on cells and row headers.

To set the default column width for columns in a pivot table

1. Select the pivot table that you want to change and open the **Format visual** menu.
2. In the **Pivot options** section, navigate to the **Value column width (pixels)** field and enter the default value that you want in pixels.

Customize pivot table data

You can customize how Quick readers view pivot tables so that they are easier to read and understand at a glance. You can choose to hide a pivot table's plus and minus icons, hide columns that only have a single-metric value, and hide collapsed columns from view. These options can help Quick authors remove clutter from their pivot tables and provide an easier reader experience for Quick users. This is not the same as choosing a pivot table layout. For more information on pivot table layout options, see [Choosing a layout](#).

These options can also be accessed from the **Combined row fields menu** of a pivot table. The layout that you choose for your pivot table determines how this menu is accessed. For more information on accessing the **Combined row fields** menu, see .

To make changes to a pivot table's layout

1. In the **Format visual** pane, choose **Pivot options**.
2. In the **Pivot options** menu, select the following options to customize the view:
 - **Hide +/- buttons** – Hide the plus and minus icons from your pivot table by default. Readers can still choose to show the plus and minus icons and expand or collapse columns and rows.
 - **Hide single metric** – Hide columns that only have a single metric value.
 - **Hide collapsed columns** – Automatically hide all collapsed columns in a pivot table. This option is only available for tabular pivot tables.

Adding data bars to tables in Quick

You can use data bars to add visual context to your table visuals in Amazon Quick. By injecting color into your tables, data bars can make it easier to visualize and compare data in a range of fields. *Data bars* are bars of different colors or shades that you add to the cells of a table. The bars are measured relative to the range of all cells in a single column, which is similar to a bar chart. You can use data bars to highlight a fluctuating trend, such as profit per quarter during the year.

You can only apply data bars to fields that are added to the **Values** field well of the visual. You can't apply data bars to items that are added to group bys.

You can create up to 200 different data bar configurations for a single table.

Sum of Sales (Sum) and Sum of Profit (Sum) by Industry

industry	sales (SUM)	profit (SUM)

To add data bars to a table

1. On the analysis page, choose the visual that you want to format.

2. On the menu in the upper-right corner of the visual, select the **Format visual** icon. The **Format visual** pane opens.
3. In the **Properties** pane, open the **Visuals** dropdown list and choose **ADD DATA BARS**.
4. In the **Data bars** popup that appears, choose the value field that you want represented by the data bars. You can only choose from fields that are added to the **Values** field well of the visual.
5. (Optional) Choose the icon labeled **Positive color** to select the color that you want to represent positive value data bars. The default color is green.
6. (Optional) Choose the icon labeled **Negative color** to select the color that you want to represent negative value data bars. The default color is red.

When you create data bars, they are named for the field values that they are representing. For example, if you add data bars to represent the profit of a product over time, the data bar configuration is labeled "Profit". In the **Visuals** pane of the **Properties** menu, data bars are listed in the order that they are created.

To remove data bars from a visual

1. On the menu in the upper-right corner of the visual, select the **Format visual** icon. The **Properties** pane opens.
2. In the **Properties** pane, open the **Visuals** dropdown list and choose the data bar that you want to remove.
3. Choose **REMOVE DATA BARS**.

Adding sparklines to tables in Quick

Sparklines are small inline charts that display trends directly within table cells, helping readers quickly identify patterns and seasonality without leaving the table view. Use sparklines when you need compact trend visualization alongside your tabular data.

To apply sparklines to a table

1. On the analysis page, choose the table visual that you want to format.
2. On the menu in the upper-right corner of the visual, select the **Format visual** icon. The **Format visual** pane opens.
3. In the **Properties** pane, open the **Visuals** dropdown list and choose **APPLY SPARKLINES**.
4. In the sparklines editing pane, configure the data settings:

- For **Value column**, choose the measure field that you want the sparkline to represent. Fields already used by another sparkline or data bar are not available.
 - For **X-axis field**, choose the dimension field to plot along the horizontal axis. The X-axis field must not be the same as a field in the **Group by** field well. You can also configure the sort direction and time granularity (for date/time fields) of the X-axis field.
5. (Optional) Expand the **Presentation** section to customize the sparkline appearance. See [Sparkline options](#) for details.
6. (Optional) Configure marker visibility. All markers are hidden by default. You can choose to show:
- **All points** – Show a marker on every data point.
 - **Max value** – Show a marker on the highest value.
 - **Min value** – Show a marker on the lowest value.
7. Choose **Apply**.

The sparkline is named after the value field it represents (for example, "Profit"). Sparklines appear in the **Visuals** pane in the order they are created.

Sparkline options

The following table describes the sparkline presentation options.

Setting	Options	Default	Description
Y-axis behavior	Shared, Independent	Shared	Shared uses the same Y-axis scale across all rows for easy comparison. Independent scales each row separately to highlight individual trend shapes.
Visual type	Line, Area line	Line	Area line adds a shaded area beneath the line.
Line color	Color picker	Theme color	Custom color for the sparkline line.

Setting	Options	Default	Description
Line interpolation	Linear, Smooth, Stepped	Linear	Controls how points are connected.

Editing and removing sparklines

To edit a sparkline, open the **Visuals** dropdown in the **Format visual** pane and choose the edit icon next to the sparkline you want to modify. Update the settings and choose **Apply**.

To remove a sparkline, open the edit pane for the sparkline and choose **Delete**.

Automatic removal

Quick automatically removes sparklines when field changes make them invalid:

- All **Group by** fields are removed – all sparklines are removed.
- A sparkline's value column is removed from the **Values** field well – that sparkline is removed.
- A sparkline's X-axis field is added to the **Group by** field well – that sparkline is removed.

A notification appears when a sparkline is automatically removed.

Sparkline limitations

Consider the following when working with sparklines:

- **Maximum sparklines per table** – Up to 3 sparkline columns per table visual
- **Maximum data points** – Up to 52 data points per sparkline. If your data exceeds this limit, Quick displays the last 52 data points according to your X-axis sort order.
- **Field requirements** – At least one field in the **Group by** field well and one field in the **Values** field well
- **X-axis constraint** – The X-axis field cannot be the same as any **Group by** field
- **Exclusive value column usage** – A value column cannot be used by both a sparkline and a data bar
- **Export support** – Sparklines are included in PDF exports but not in CSV or Excel exports
- **Filter behavior** – Filters applied to the table also filter sparkline data

Map and geospatial chart formatting options in Quick

In Amazon Quick, you can choose from multiple formatting options for your maps and geospatial charts. You can view formatting options by opening the **Properties** pane from the on-visual menu located at the top right of the currently selected geospatial map.

Quick authors and readers can also toggle the different formatting options of a geospatial map visual from the on visual menu.

Topics

- [Base maps on geospatial maps in Quick](#)
- [Geospatial heatmaps in Amazon Quick](#)
- [Marker clustering on geospatial point maps in Quick](#)

Base maps on geospatial maps in Quick

When you create a map visual in Quick, you can change the base of the map. A *base map* is the style of map that appears beneath your data on a map. An example is a satellite view versus a street view.

In Quick, there are four options for base maps: light gray canvas, dark gray canvas, streets, and imagery. The following list contains an example of each base map option:

⚠ Important

Only the light gray canvas is supported in the Asia Pacific (Mumbai) AWS Region (ap-south-1).

- Light gray canvas

- Dark gray canvas

- Streets

- Imagery

Changing base maps

Use the following procedure to change a base map.

To change a base map

1. Create a point or filled map in an analysis. For more information, see [Creating maps and geospatial charts](#).
2. On the map visual, choose the **Format visual** icon.
3. In the **Properties** pane that opens, choose the **Base map** section and then choose the base map that you want.

Geospatial heatmaps in Amazon Quick

Use geospatial heatmaps to reveal patterns of marker concentration in your geospatial visuals. Heat maps display concentrations of data points using a colored overlay that highlights the intensity or concentration of the visual's markers.

Field wells

Sheet 1 ▾ +

To turn a geospatial map into a heat map

1. Open your analysis and choose the geospatial map that you want to format. When you select a visual, it displays with a highlight around it.
2. To open the formatting pane, select the **Format visual** icon from the on-visual menu.
3. On the formatting pane at left, choose **Points**.
4. Choose **Heatmap**.
5. (Optional) For **Heatmap gradient**, choose a color that you want for the **High density** and **Low density** values.

Marker clustering on geospatial point maps in Quick

Use marker clustering to improve readability of collocated points on a map. Geospatial locations on point maps are represented using markers. Usually, there is one marker per data point. However, if there are too many markers close together, the map becomes difficult to read. To make it easier to interpret the map, you can enable marker clustering to represent groupings of locations on the

map. As the reader zooms in on the map, the clustered markers leave the area marker to display separately.

To add cluster points to a map

1. Open your analysis, and choose the geospatial map that you want to format. When you select a visual, it displays with a highlight around it.
2. To open the formatting pane, select the **Format visual** icon from the on-visual menu.
3. On the formatting pane at left, choose **Points**.
4. Choose one of the following options:
 - **Basic** – use the default display setting for map points.
 - **Cluster points** – cluster map points together when there are many in one area.

Axes and grid lines on visual types in Quick

When you create a chart in Quick, axis lines, axis labels, axis sort icons, and grid lines are added to the chart automatically. You can format your visuals to show or hide these if you want, and also customize the axis label size and orientation.

You can format axis lines, grid lines, and axis labels and axis sort icons for the following chart types:

- Bar charts

- Box plot charts
- Combo charts
- Histograms
- Line charts
- Scatter plots
- Waterfall charts

To format axis lines, axis labels, and grid lines in a chart

1. On the analysis page, choose the visual that you want to format.
2. On the menu in the upper-right corner of the visual, select the format visual icon.

The **Properties** pane opens at left.

To show or hide axis lines

1. In the **Properties** pane, choose the axis that you want to format.
2. Choose **Show axis line**. Clear the check box to hide the axis line for the chosen axis. Select the check box to show it.

To customize axis titles

1. In the **Properties** pane, choose the axis that you want to format.
2. Choose **Show title**. Clear the check box to hide the axis title and drop-down caret icon for the chosen axis. Select the check box to show them.
3. To change the title from the default field name, enter a title in the text box.

Note

In addition to the chart types listed previously in this topic, you can also customize the axis titles in pie charts, donut charts, funnel charts, heat maps, and tree maps.

To modify axis font settings

1. In the **Properties** pane, choose the axis that you want to format.
2. Adjust the following properties:
 - **Font family**
 - **Text size**
 - **Style** (Bold, Italic, Underline)
 - **Color**

Note

- **Underline** is supported for axis titles, but not for axis labels
- Different chart types use different terminology:
 - **Bar/Line charts** - **X-axis** and **Y-axis**
 - **Pie charts** - **Values**
 - **Heat maps** - **Rows** and **Columns**

To show or hide the sort icon

1. In the **Properties** pane, choose the axis that you want to format.
2. Choose **Show sort**. Clear the check box to hide the sort icon for the chosen axis. Select the check box to show it.

When you choose to remove the sort icon, the sort icon is removed from the axis. Any sorts that were applied to the visual before removing the icon are not removed from the visual.

Note

In addition to the chart types listed previously in this topic, you can also show or hide the sort icon in pie charts, donut charts, funnel charts, heat maps, and tree maps.

To show or hide the data zoom

1. In the **Properties** pane, choose **X-axis**.
2. Choose **Show data zoom**. Clear the check box to hide the data zoom. Select the check box to show it.

The data zoom bar appears automatically on charts with an X-axis that contain more than one data point. Adjust the bar from the left and right to zoom to specific data points in the chart.

Note

If you zoom in or out using the data zoom bar, and then choose to hide the data zoom bar, the zoom position isn't maintained. The visual zooms completely out to include all data points. Showing the data zoom again returns the visual to its previous state.

To show or hide axis labels

1. In the **Properties** pane, choose the axis that you want to format.
2. Choose **Show labels**. Clear the check box to hide the axis labels for the chosen axis. Select the check box to show it.

To change the label size

1. In the **Properties** pane, choose the axis that you want to format.
2. For **Label size**, choose a size.

To change the label orientation

1. In the **Properties** pane, choose the axis that you want to format.
2. For **Label orientation**, choose an orientation.

To show or hide grid lines

1. In the **Properties** pane, choose the axis that you want to format.
2. Choose **Show grid lines**. Clear the check box to hide grid lines for the chosen axis. Select the check box to show it.

Colors in visual types in Quick

You can change the color of one, some, or all elements on the following types of charts:

- Bar charts
- Donut charts
- Gauge charts
- Heat maps
- Line charts
- Scatter plots
- Tree maps

To change colors on bar charts, donut charts, gauge charts, line charts, and scatter plots, see [Changing colors on charts](#).

To change colors on heat maps and tree maps, see [Changing colors on heat maps and tree maps](#).

Changing colors on charts

You can change the chart color used by all elements on the chart, and also change the color of individual elements. When you set the color for an individual element, it overrides the chart color.

For example, suppose that you set the chart color to green.

All of the bars turn green. Even though you choose the first bar, the chart color applies to all the bars. Then you set the color for the **SMB** bar to blue.

Looking at the result, you decide that you need more contrast between the green and blue bars, so you change the chart color to orange. If you are changing the chart color, it doesn't matter which bar you choose to open the context menu from.

The **SMB** bar remains blue. This is because it was directly configured. The remaining bars turn orange.

When you change the color of an element that is grouped, the color for that element is changed in all of the groups. An example is a bar in a clustered bar chart. In the following example, Customer Segment is moved out of the **Y-axis** and into the **Group/Color** field well. Customer Region is added as the **Y-axis**. The chart color stays orange, and SMB stays blue for all Customer Regions.

If your visual has a legend that shows categories (dimensions), you can click on the values in the legend to see a menu of available actions. For example, suppose that your bar chart has a field in the **Color** or **Group/Color** field well. The bar chart menu displays the actions that you can choose by clicking or right-clicking on a bar, such as the following:

- Focusing on, or excluding, visual elements
- Changing colors of visual elements
- Drilling down into a hierarchy
- Custom actions activated from the menu, including filtering or URL actions

Following is an example of using the legend to change the color for a dimension.

Setting new colors for a visual

Use the following procedure to change the colors for a visual.

To change the colors for a visual

1. On the analysis page, choose the visual that you want to modify.
2. To change the chart color, choose any element on the visual, and then choose **Chart Color**.

To select elements, do the following:

- On a bar chart, choose any bar.
 - On a line chart, choose the end of a line.
 - On a scatter plot, choose an element. The field must be in the **Group/Color** section of **Field wells**.
3. Choose the color that you want to use. You can choose a color from the existing palette, or you can choose a custom color. To use a custom color, enter the hexadecimal code for that color.

All elements on the visual are changed to use this color, except for any that have previously had their color individually set. In that case, the element color overrides the chart color.

4. To change the color for a single element on the visual, choose that element, choose **Color <field name>**, and then choose the color that you want to use. You can choose a color from the existing palette, or you can choose a custom color. To use a custom color, enter the hexadecimal code for that color.

Repeat this step until you have set the color on all elements that you want to modify. To change the color back to the color it was originally, choose **Reset to default**.

Setting visual colors back to defaults

Use the following procedure to return to using the default colors on a visual.

To return to default colors on a visual

1. On the analysis page, choose the visual that you want to modify.
2. Choose **Chart Color**, choose any element on the visual, and then choose **Reset to Default**. Doing this changes the chart color back to the default color for that visual type.

All elements on the visual are changed to the default color for the visual type, except for any that have previously had their color individually set. In that case, the element color setting overrides the chart color setting.

3. To change the color for a single element back to the default, choose that element, choose **Color <field name>**, and then choose **Reset to Default**.

The default color for individual elements is the chart color if you have specified one, or the default color for the visual type otherwise.

Changing colors on heat maps and tree maps

To change the colors that display on a heat map or a tree map

1. Choose the heat map or tree map that you want to edit.
2. Choose **Expand** for the settings menu, and choose the cog icon to open the **Properties** panel.
3. For **Color**, choose the settings that you want to use:
4. For **Gradient color** or **Discrete color**, choose the color square next to the color bar, and then choose the color that you want to use. Repeat for each color square. The bar holds two colors by default.
5. Select the **Enable 3 colors** check box if you want to add a third color. A new square appears in the middle of the color bar.

You can enter a number that defines the midpoint between the two main gradient colors. If you add a value, the middle color represents the number you entered. If you leave this blank, the middle color acts like the other colors in the gradient.

6. Select the **Enable steps** check box if you want to limit the chart to the colors that you chose. Doing this changes the label on the color bar from **Gradient color** to **Discrete color**.
7. For **Color for Null Value**, choose a color to depict NULL values. This option is only available on heat maps.

Working with field level coloring in Amazon Quick

With field level coloring, you can assign specific colors to specific field values across all visuals in a Quick analysis or dashboard. Colors are assigned on a per-field basis to simplify the process of setting colors and ensure consistency across all visuals that use the same field. For example, let's say you're a shipping company that wants to create a set of visuals that track shipping rates in different regions. With field level coloring, you can assign each region a different color to represent the field across all visuals in an analysis or dashboard. This way, account readers quickly learn what field colors they're looking for and have an easier time finding the information that they need.

Quick authors can configure up to 50 field based colors per field. Colors that are defined at the visual level take precedence over field based colors. This means that if the author sets a color for a value on the visual, that color will override the field based colors configuration for that individual visual.

To apply field level coloring to a legacy account

1. In the **Fields** pane of the analysis, choose the ellipsis (three dots) next to the field that you want to assign a color to, and then choose **Edit field colors**.
2. In the **Edit field colors** pane that appears, choose the value that you want to assign a color to and choose the color that you want. You can apply colors to every value that appears in the **Field values** pane.
3. When you are finished assigning colors to the fields that you want, choose **Apply**.

If you want to reset the color value of a field, open the **Edit field colors** pane and choose the refresh icon next to the field that you want to reset. You can reset all color values in an analysis by choosing **RESET COLORS**.

You can view a list of unused colors that can be configured to new fields by choosing **Show unused colors** in the **Edit field colors** pane. When you reset a field's color, the discarded color is added to the **Unused colors** list and can be assigned to a new field.

Conditional formatting on visual types in Quick

In some visual types, you can add conditional formatting to highlight some of your data. The conditional formatting options currently supported include changing text or background color and using symbolic icons. You can use icons from the provided set, or you can use Unicode icons instead.

Conditional formatting is available on the following visuals:

- Gauge charts
- Key performance indicators (KPIs)
- Pivot tables
- Tables

For tables and pivot tables, you can set multiple conditions for fields or supported aggregations, along with format options to apply to a target cell. For KPIs and gauge charts, you can format the primary value based on conditions that are applied to any dimension in the dataset. For gauge charts, you can also format the foreground color of the arc based on conditions.

To use conditional formatting on a visual

1. On the analysis page, choose the visual that you want to format.
2. On the visual, open the context menu on the down icon at the upper-right. Then choose **Conditional formatting**.

Options for formatting display on the left. Choose one of the following:

- **For pivot tables** – Begin by choosing a measure that you want to use. You can set conditional formatting on one or more fields. The selection is limited to the measures that are in the **Values** field well.
 - **For tables** – Begin by choosing a field that you want to use. You can set conditional formatting on one or more fields. You can also choose to apply formatting to the entire row. Formatting the entire row adds an option to **Apply on top**, which applies the row formatting in addition to formatting added by other conditions.
 - **For KPIs** – Apply formatting to the primary value or the progress bar or both.
3. For the remaining steps in this procedure, choose the features that you want to use. Not all options are available for all visuals.
 4. (Optional) Choose **Add background color** to set a background color. If a background color is already added, choose **Background**.
 - **Fill type** – The background color can be **Solid** or **Gradient**. If you choose to use a gradient, additional color options display, enabling you to choose a minimum and maximum value for the gradient scale. The minimum value defaults to the lowest value, and the maximum value defaults to the highest value.

- **Format field based on** – The field to use when applying the format.
 - **Aggregation** – The aggregation to use (displays only the available aggregations).
 - **Condition** – The comparison operator to use, for example "greater than".
 - **Value** – The value to use.
 - **Color** – The color to use.
 - **Additional options:** In pivot tables, you can set what you want to format by choosing options from the context menu (...): **Values**, **Subtotals**, and **Totals**.
5. (Optional) Choose **Add text color** to set a text color. If a text color is already added, choose **Text**.
- **Format field based on** – The field or item to use when applying the format.
 - **Aggregation** – The aggregation to use (displays only the available aggregations). This option applies to tables and pivot tables.
 - **Condition** – The comparison operator to use, for example "greater than".
 - **Value** – The value to use.
 - **Color** – The color to use.
 - **Additional options:** In tables and pivot tables, you can set what you want to format by choosing options from the context menu (...): **Values**, **Subtotals**, and **Totals**.
6. (Optional) Choose **Add icons** to set an icon or icon set. If an icon is already added, choose **Icon**.
- **Format field based on** – The field or item to use when applying the format.
 - **Aggregation** – The aggregation to use (displays only the available aggregations). This option applies to tables and pivot tables.
 - **Icon set** – The icon set to apply to field in **Format field based on**. This option applies to tables and pivot tables.
 - **Reverse colors** – Reverses the colors of the icons for tables and pivot tables.
 - **Custom conditions** – Provides more icon options for tables and pivot tables.
 - **Condition** – The comparison operator to use.
 - **Value** – The value to use.
 - **Icon** – The icon to use. To choose an icon set, use the **Icon** symbol to choose the icons to use. Choose from the provided icon sets. In some cases, you can add your own. To use your own icon, choose **Use custom Unicode icon**. Paste in the Unicode glyph that you want to use as an icon. Choose **Apply** to save or choose **Cancel** to exit icon setup.

- **Color** – The color to use.
 - **Show icon only** – Replaces the value with the icon for tables and pivot tables.
 - **Additional options:**
 - In tables and pivot tables, you can set what you want to format by choosing options from the context menu (...): **Values**, **Subtotals**, and **Totals**.
 - In pivot tables, enabling **Custom conditions** activates preset conditional formatting that you can keep, add to, or overwrite with your own settings.
7. (Optional) Choose **Add foreground color** to set the foreground color of a KPI progress bar. If a foreground color is already added, choose **Foreground**.
- **Format field based on** – The field to use when applying the format.
 - **Condition** – The comparison operator to use.
 - **Value** – The value to use.
 - **Color** – The color to use.
8. When you are finished configuring conditional formatting, choose one or more of the following:
- To save your work, choose **Apply**.
 - To cancel selections and return to the previous panel, choose **Cancel**.
 - To close the settings panel, choose **Close**.
 - To reset all settings on this panel, choose **Clear**.

KPI options

You can customize KPIs in Amazon Quick to meet your business needs. You can add contextual sparklines or progress bars, assign primary and secondary values, and add conditional formatting to your KPIs.

To format a KPI in Quick, navigate to the KPI that you want to change and choose the **Format visual** icon to open the **Format visual**.

Use the following procedures to perform formatting tasks for KPIs.

Add a visual to a KPI

You can choose to add an area sparkline, a sparkline, or a progress bar to any KPI in Quick. Adding visuals to KPIs provides visual context to readers who are viewing KPI data. Use the following procedure to add a visual to a KPI.

To add a visual to a KPI

1. Navigate to the KPI that you want to change and open the format visual menu.
2. In the **Properties** menu, choose the **Visual** box to display a visual on your KPI chart.
3. (Optional) Open the **Visual** dropdown and choose the type of visual that you want to display on your KPI. You can choose to display an area sparkline, a sparkline, or a progress bar. To display a sparkline, make sure that your KPI has a value in the **Trend** field well. **Area sparkline** is the default value.
4. (Optional) To change the color of the sparkline, choose the color icon to the left of the **Visual** dropdown and choose the color that you want. Color formatting isn't supported for the progress bar.
5. (Optional) Choose **Add tooltip** to add a tooltip to the KPI visual.

Customizing primary and secondary values

Use the **Format visual** menu to customize the font, color, and to choose which primary value is displayed. You can also choose to display a secondary value.

To customize the primary and secondary values of a KPI

1. Navigate to the KPI that you want to change, open the **Format visual** menu, and navigate to the **KPI** section.
2. For **Primary value**, use the **Font** dropdown to choose the font size that you want. The default value is **Auto**.
3. (Optional) To change the color of the primary value's font, choose the color icon next to the **Font** dropdown, and then choose the color that you want.
4. For **Primary value displayed**, you can choose to display the actual value or the comparison value of the primary value.
5. To add a secondary value, choose **Secondary value**.

- a. (Optional) Use the **Font** dropdown to choose the font size that you want. The default value is **Extra large**.
- b. (Optional) To change the color of the secondary value's font, choose the color icon next to the **Font** dropdown, and then choose the color that you want.

Conditional formatting options for KPIs

Conditional formatting for KPIs is automatically set for comparison values. By default, positive values are represented in green and negative values are represented in red. You can customize the color values of these color values from the **Properties** pane.

To change the color of positive and negative values

1. In the **Properties** pane, open the **Conditional formatting** section and choose the comparison value that you want to change.
2. To change the color of the positive value, navigate to **Condition #1**, choose the **Color** icon, and then choose the color tht you want.
3. To change the color of the negative value, navigate to **Condition #2**, choose the **Color** icon, and then choose the color tht you want.
4. When you are finished making the changes that you want, choose **Apply**.

You can also add text colors and icons for the **Actual value** in thee **Conditional formatting** menu. To add a text color or icon to the actual value, choose **Add text color** or **Add icon** to set the new values.

Labels on visual types in Quick

Use the following procedure to customize, display, or hide the labels for a visual.

To customize, display, or hide the labels for a visual

1. On the analysis page, choose the visual that you want to format. You can change the labels by choosing the label directly on the visual, and choosing **Rename**. To revert to the default name, delete your entry.
2. To see more options, choose the on-visual menu from the down icon at the upper-right corner of the visual, and then choose the **Format visual** icon.

For pivot tables, you can relabel row names, column names, and value names. Additionally, under **Styling**, you can choose to hide columns labels or metric labels (for single metrics only).

You can add the same value to the same visual multiple times. You can do so to show the same value with different aggregations or table calculations applied. By default, the fields all display the same label. You can edit the names by using the **Properties** panel, which you open by choosing the **V**-shaped icon at top right.

3. On the **Properties** pane, enable or disable **Show title**. This option removes the axis title.
4. Close the **Properties** pane by choosing the **X** icon in the upper-right corner of the pane.

Data labels on visual types in Quick

To customize data labels on a visual, you can use the **Properties** pane to show data labels, and then use the settings to configure them. Data label customization is supported on bar, line, combo, area, scatterplot, donut, boxplot, waterfall, heatmap, treemap, histogram, funnel, sankey, gauge, radar, and pie charts.

You can customize the following options:

- Position, which determines where the label appears in relation to the data point (for bar, combo, and line charts):
 - For vertical bar charts, you can customize to set position:
 - Above bars
 - Inside of bars
 - Bottom of bars
 - Top of bars
 - For horizontal bar charts, you can customize to set position:
 - Right of bars
 - Inside of bars
 - For line charts, you can customize to set position:
 - Above lines
 - Left or right of points on lines
 - Below lines
 - For scatter charts, you can customize to set position:

- Above points
- Left or right of points
- Below points
- Font size and color (for bar, combo, line, scatter, and pie charts)
- Label pattern, which determines how data is labeled (for bar, combo, line, and scatter charts):
 - For bar, combo, and scatter charts, you can label:
 - All
 - By group or color
 - For line charts, the following label options are available:
 - All
 - By group or color
 - Line ends
 - Minimum or maximum value only
 - Minimum and maximum values
 - For pie charts, the following label options are available:
 - Show category
 - Show metric
 - Choose to show the metric label as value, percent, or both
- Group selection (for bars and lines, when the label pattern is "by group/color")
- Allow labels to overlap (for bars and lines), for use with fewer data points
- For vertical bar, combo, and line charts, labels that are too long are angled by default. You can configure the degree of angle under the **X-axis** settings.

Note

If you add more than one measure to an axis, the data label displays the formatting for the first measure only.

To configure data labels

1. On the analysis page, choose the visual that you want to format.

2. Choose the on-visual menu from the down icon at the upper-right corner of the visual, and then choose the **Format visual** icon.
3. On the **Properties** pane, choose **Data Labels**.
4. Enable **Show data labels** to show and customize labels. Disable this option to hide data labels.
5. Choose the settings that you want to use. The settings offered are slightly different for each chart type. To see all available options, see the list before this procedure.

You can immediately view the effect of each change on the visual.

6. To modify the data label font settings, adjust the following properties:
 - **Font family**
 - **Text size**
 - **Style** (Bold, Italic)
 - **Color**
7. Close the **Properties** pane by choosing the X icon in the upper-right corner of the pane.

Formatting visual numeric data based on language settings in Quick

In Amazon Quick, you can choose how your numeric data values appear in visuals so that they align with the regional language that you have chosen.

As a Quick author, you can choose the language formatting that best fits your audience. Amazon Quick configures numeric data languages at the analysis level based on the language that you have chosen to view Quick in. You can change the format of numbers, currencies, and dates. You can change your Quick language settings in the **Language** dropdown list of the Quick **User** menu in the top-right corner. You can change the language formatting for a field across every visual in a sheet, or you can change the language formatting at the individual visual level.

To change the numeric language formatting of all visuals in an analysis

1. On the **Visuals** pane of the analysis that you want to change, choose the more actions (three dots) icon next to the field that you want to change. From the menu that appears, open the **Format** dropdown list, and then choose **More formatting options**.
2. In the **Format data** pane that appears on the left, choose **Apply language format**.

You can reset the default language format of the field by reopening the **Format data** menu and choosing **Reset to defaults**. The default language format is American English.

To change the numeric language formatting of a single visual in an analysis

1. On the analysis page, choose the visual that you want to modify.
2. Navigate to the **Format data** pane using one of the following options:
 - On the visual that contains the data that you want to change, select the field that you want to change, open the **Format** dropdown list, and then choose **More formatting options**.

- In the **Field wells** section of the analysis, open the dropdown next to the field that you want to change. Open the **Format** menu, and choose **More formatting options**.

3. In the **Format data** pane that appears, choose **Apply language format**.

You can reset the default language format of the visual by reopening the **Format data** menu and choosing **Reset to defaults**. The default language format is American English.

Legends on visual types in Quick

The *visual legend* helps you identify what a visual element represents by mapping its value to a color. By default, the visual legend displays to the right of the visual. You can choose to hide or display the visual legend, and format the legend title and position. You can also customize the font settings for the legend title and items.

To display or hide a visual legend

1. Sign in to Quick at <https://quicksight.aws.amazon.com/>.
2. On the analysis page, choose the visual that you want to format.
3. Choose the visual that you want to format, and then choose the **Properties** icon to open the Properties pane.
4. Toggle the **Legend** on to display the visual's legend. When shown, the legend displays the values in alphabetical order. To hide the legend, toggle the **Legend** switch off.

To customize a visual legend

1. Open the Properties pane and expand the **Legend** section.
2. Use the **Position** dropdown to customize the position of the legend in the visual.
3. For **Legend title**, enter a custom name for the legend and perform all or some of the following actions:
 - a. (Optional) To change the color of the legend title, choose the color swatch underneath the legend title, and then choose the color that you want the legend title to be.
 - b. (Optional) To change the font or font size of the legend title, open the **Font** or **Font size** dropdown and choose the font or font size that you want.
 - c. (Optional) To bold, italicize, or underline the legend title, choose the appropriate icon from the style bar.
4. For **Legend item**, perform all or some of the following actions:
 - a. (Optional) To change the color of the legend item font, choose the color swatch, and then choose the color that you want the legend title to be.
 - b. (Optional) To change the font or font size of the legend item, open the **Font** or **Font size** dropdown and choose the font or font size that you want.

- c. (Optional) To bold, italicize, or underline the legend item font, choose the appropriate icon from the style bar.
5. Choose the **X** icon at upper right to close the **Properties** pane.

Line and marker styling on line charts in Quick

In Quick line charts, you have multiple options to emphasize what you want readers to focus on: color, line style, and markers. You can use these options together or separately to help readers understand your line charts more quickly under different circumstances. For example, if some of your readers won't see color differences—perhaps because of color blindness or because of monochrome printing—you can use line patterns to distinguish one or more lines in a chart.

In other cases, you could use step lines to call attention to abrupt changes or intervals between changes in data. For example, let's say you build a chart showing the changing price of postage stamps in the US, and you want to emphasize the amount of increase in price over time. You can use a step line, which remains flat between data points until the next price change occurs. The data story about abrupt increases in price is more clear to the reader with a step line. If you wanted to show a story of gradual change over time, you'd be more likely to style the line with a smooth slope instead.

To customize the styling for a visualization

1. Open your analysis, and choose the chart that you want to format.
2. On the top right of the visual you want to format, select **Format visual**, which is represented by a pencil icon.
3. At left, choose **Data series**.
4. Choose one of the following options:
 - **Base style** – to edit the styling of all lines and markers on the chart
 - **Select series to style** – to edit the styling of the field that you choose from the list

Different options display depending on how many compatible fields are in the visual.

5. Toggle **Line** to turn line styling on or off.

You can customize the following line options:

- The weight or thickness of the line.

- The style of the line: solid, dashed, or dotted.
 - The color of the line.
 - The type of line that it is: Linear, Smooth, or Stepped.
6. Toggle **Marker** to turn marker styling on or off.

You can customize the following marker options:

- The weight or thickness of the marker.
 - The style of the marker: circle, triangle, square, diamond, and so on.
 - The color of the marker.
7. For **Axis**, choose whether to display the axis on the left or the right.
 8. Your changes are saved automatically.
 9. (Optional) To undo customizations, choose one or more of the following options:
 - To undo one change, click the undo arrow at top left. Repeat as needed. There is also a redo arrow.
 - To reset the base style for a data series, select **Base style** and then click **Reset to default**.
 - To remove all styling from a data series, listed in **Styled series**, select a field and then click **Remove styling**.

Missing data on visual types in Quick

You can customize how missing data points are visualized in your line charts and area charts. You can choose to have your missing data points appear in the following formats:

- *Broken line*: A disjointed line that breaks when a data point is missing. This is the default missing data format.
- *Continuous line*: Displays a continuous line by skipping over the missing data point and connecting the line to the next available data point in the series. To show a continuous line, the **Show date gaps** box on the **X axis** pane should be unchecked.
- *Show as zero*: Sets the value of the missing data point to zero.

To customize a visual's missing data settings

1. On the analysis page, choose the visual that you want to format.

2. Choose the **Format visual** icon in the upper right corner of the visual to access the **Format visual** menu.
3. Open the **Y axis** pane of the format visual menu and navigate to the **Missing data** section.
4. Select the missing data format that you want.

Reference lines on visuals types in Quick

Reference lines are visual markings in a visual, similar to ruler lines. You typically use a reference line for a value that needs to be displayed with the data. You use the reference line to communicate thresholds or limits in values. The reference line isn't part of the data that's used to build a chart. Instead, it's based on a value that you enter or a field that you identify in the dataset used by a chart.

Quick supports reference lines in the following:

- Bar charts
- Line charts
- Combo charts

You can create, change, and delete reference lines while designing an analysis. You can customize the line pattern, the label font, and the colors for each of those separately. You can show numeric values as numbers, currency, or percent. You can also customize a value's numerical format in the same way that you can customize a field in the field well.

There are two types of reference lines:

- A *constant line* displays at a position that's based on a value that you specify in the format settings. This value doesn't need to relate to any field. You can customize the formatting of the line.
- A *calculated line* displays at a position that's based on a value that is the result of a function. During configuration, you specify which measure (metric) you want to use and which aggregation to apply. These are the same aggregations you can apply to in the field wells. Then, you need to provide an aggregation to apply to the field calculation for the reference line, for example average, minimum, maximum, or percentile. The field needs to be in the dataset used by the chart, although it doesn't need to be displayed in the chart's field wells.

Calculated reference lines aren't supported in 100% stacked charts.

To add or edit a reference line (console)

1. Open the [Quick console](#).
2. Open the analysis that you want to change.
3. Choose the visual that you want to change and open the **Properties** menu.
4. In the **Properties** pane that opens, open the **Reference lines** dropdown, and then choose **ADD NEW LINE**.
5. The **New reference line** menu opens. Use this menu to configure your new reference line. The list below describes all reference line properties that can be configured.
 - **Data**
 - **Type** – The type of reference line that you want to use. Choose one of the following options:
 - To create a constant line based on a single value that you enter, choose **Constant line**.
 - To create a calculated line based on a field, choose **Calculated line**.

- **Value** – (For constant lines only) The value that you want to use. This becomes the location of the line on the visual. It appears immediately, so you can experiment with the setting.
- **Column** – (For calculated lines only) The column that you want to use for the reference line.
- **Aggregated as (column)** – (For calculated lines only) The aggregation that you want to apply to the selected column.
- **Calculate** – (For calculated lines only) The calculation that you want to apply to the aggregation.
- **Percentile value** – (Only if you set **Calculate** to **Percentile**) Enter a number from 1 through 100.
- **Chart type** – (For combo charts) Choose **Bars** or **Lines**.
- **Line style**
 - **Pattern** – The pattern used for the line. Valid options include **Dashed**, **Dotted**, and **Solid**.
 - **Color** – The color used for the line.
- **Label**
 - **Type** – The type of label to display. Valid options include **Value only**, **Custom text**, **Custom text and value**, **No label**. If you choose an option that includes custom text, enter the label text that you want to appear on the line.
 - **Enter custom text (text box)** – (Only if you set **Type** to **Custom text and value**) Choose where to show the value in relation to the label. Valid options are **Left** or **Right**.
 - **Position** – The position of the label in relation to the line. Valid options include a combination of the following: left, middle, right, above, and below.
 - **Value format** – The format to use for the value. Choose one of the following:
 - **Same as value** – Uses the formatting that's already selected for this field in the visualization.
 - **Show as** – Choose from the available options, for example number, currency, or percent.
 - **Format** – Choose from the available formatting options.
 - **Font size** – The font size to use for the label text.
 - **Color** – The color to use for the label text.

6. Choose **Done** to save your selections.

To list existing reference lines

1. Choose the visual that you want to change and open the **Properties** pane.
2. In the **Properties** pane, open the **Reference lines** dropdown, and then choose the ellipsis (three dots) next to the line that you want to change.
3. Choose **Edit**.
4. The **New reference line** menu opens. Use this menu to make changes to your reference line. When you are finished, choose **Done**.

To disable a reference line

1. Choose the visual that you want to change and open the **Properties** pane.
2. In the **Properties** pane, open the **Reference lines** dropdown, and then choose the ellipsis (three dots) next to the line that you want to change.
3. Choose **Disable**.

To delete a reference line

1. Choose the visual that you want to change and open the **Properties** pane.
2. In the **Properties** pane, open the **Reference lines** dropdown, and then choose the ellipsis (three dots) next to the line that you want to change.
3. Choose **Delete**.

Formatting radar charts in Quick

You can customize radar charts in Amazon Quick to arrange your data the way that you want. You can customize the series style, start angle, fill area, and grid shape of a radar chart.

To set the series style of a radar chart

1. Choose the radar chart visual that you want to change, and choose the **Format visual** icon on the top right corner of the visual.
2. In the **Properties** pane on the left, open the **Radar chart** dropdown list.
3. Under **Series style**, choose the style that you want. You can choose between the following styles:

- **LINE.** When selected, the polygons that are created by the data are outlined.
- **AREA.** When selected, the polygons that are created by the data are filled in.

The default selected value is **LINE**.

To choose the start angle of a radar chart

1. Choose the radar chart visual that you want to change, and choose the **Format visual** icon on the top right corner of the visual.
2. In the **Properties** pane on the left, open the **Radar chart** dropdown list.
3. Under **Start angle**, enter the start angle value that you want. The default value is 90 degrees.

To set the fill area of a radar chart

1. Choose the radar chart visual that you want to change, and choose the **Format visual** icon on the top right corner of the visual.
2. In the **Properties** pane on the left, open the **Axis** dropdown list.
3. Select the **Fill grid lines** check box.
4. (Optional) Select colors for the even and odd numbered grid lines.
 - Choose the **Even color** icon that appears, and then choose the color that you want the even numbered grid lines to be. The default color for this value is white.
 - Choose the **Odd color** icon that appears, and then choose the color that you want the odd numbered grid lines to be. The default color for this value is white.

To choose the grid shape of a radar chart

1. Choose the radar chart visual that you want to change, and choose the **Format visual** icon on the top right corner of the visual.
2. In the **Properties** pane on the left, open the **Radar chart** dropdown list.
3. Under **Grid shape**, choose the shape that you want the radar chart grid to be. You can choose between a **POLYGON** and a **CIRCLE**.

Range and scale on visual types in Quick

To change the scale of the values shown on the visual, you can use the **Properties** pane to set the range for one or both axes of the visual. This option is available for the value axes on bar charts, combo charts, line charts, and scatter plots.

By default, the axis range starts at 0 and ends with the highest value for the measure being displayed. For the group-by axis, you can use the data zoom tool on the visual to dynamically adjust the scale.

To set the axis range for a visual

1. On the analysis page, choose the visual that you want to format.
2. Choose the control menu at the upper-right corner of the visual, and then choose the cog icon.
3. On the **Properties** pane, choose **X-Axis** or **Y-Axis**, depending on what type of visual you are customizing. This is the **X-Axis** section for horizontal bar charts, the **Y-Axis** section for vertical bar charts and line charts, and both axes are available for scatter plots. On combo charts, use **Bars** and **Lines** instead.
4. Enter a new name in the box to rename the axis. To revert to the default name, delete your entry.
5. Set the range for the axis by choosing one of the following options:
 - Choose **Auto (starting at 0)** to have the range start at 0 and end around the highest value for the measure being displayed.
 - Choose **Auto (based on data range)** to have the range start at the lowest value for the measure being displayed and end around the highest value for the measure being displayed.
 - Choose **Custom** to have the range start and end at values that you specify.

If you choose **Custom**, enter the start and end values in the fields in that section. Typically, you use integers for the range values. For stacked 100 percent bar charts, use a decimal value to indicate the percentage that you want. For example, if you want the range to be 0–30 percent instead of 0–100 percent, enter 0 for the start value and .3 for the end value.

6. For **Scale**, the default is linear scale. To show logarithmic scale, also called log scale, enable the logarithmic option. Quick chooses the axis labels to display based on the range of values in that axis.

- On a linear scale, the axis labels are evenly spaced to show the arithmetical difference between them. The labels display the numbers in sets like {1000, 2000, 3000...} or {0, 50 million, 100 million...}, but not {10 thousand, 1 million, 1 billion...}.

Use a *linear scale* for the following cases:

- All the numbers that display on the chart are in the same order of magnitude.
- You want the axis labels to be evenly spaced.
- The axis values have a similar number of digits, for example 100, 200, 300, and so on.
- The rate of change between numbers is relatively slow and steady—in other words, your trend line never approaches becoming vertical.

Examples:

- Profits in different regions of the same country
- Costs incurred for manufacture of an item
- On a *logarithmic scale*, the axis values are spaced to show the orders of magnitude as a way of comparing them. The log scale is often used to display very large ranges of values or percentages, or to show exponential growth.

Use logarithmic scale for the following cases:

- The numbers that display on the chart aren't in the same order of magnitude.
- You want the axis labels to be flexibly spaced to reflect the wide range of values in that axis. This might mean that the axis values have a different number of digits, for example 10, 100, 1000, and so on. It might also mean that the axis labels are unevenly spaced.
- The rate of change between numbers is growing exponentially or is too large to display in a meaningful way.
- The customer of your chart understands how to interpret data on a log scale.
- The chart displays values that growing faster and faster. Moving given distance on the scale means the number has been multiplied by another number.

Examples:

- High yield stock prices over a long range of time
- Growth of pandemic infection rates

7. To customize the number of values to show on the axis labels, enter in an integer between 1 and 50.

8. For combo charts, choose **Single Y Axis** to synchronize the Y-axes for both bars and lines into a single axis.
9. Close the **Properties** pane by choosing the **X** icon in the upper-right corner of the pane.

Small multiples axis options

You can configure the x and y axes for each individual panel of a small multiples visual. You can group your data along an independent x-axis or an independent y-axis. You can also position the x and y axes inside or outside the chart to improve the readability of your data.

For small multiples visuals that use an independent x-axis, only the values that are relevant to each panel are shown on the axis. For example, say you have a small multiples visual that uses one panel to represent each region of the United States. With an independent x-axis, each panel only shows states in the region that the panel represents and hides states that are outside of the panel's region.

For small multiples visuals that use an independent y-axis, each panel uses its own y-axis scale that is determined by the range of the data it contains. By default, data labels appear on the inside of the panel.

To configure independent axes for small multiples visuals

1. Select the small multiples visual that you want to change and open the **Format visual** menu.
2. In the **Properties** pane that appears, open the **Multiples options** menu.
3. For **X-axis**, choose **Independent** from the dropdown.

Or, for **Y-axis**, choose **Independent** from the dropdown.

You can revert your changes by choosing **Shared** from the **X-axis** or **Y-axis** dropdown menus.

You can also configure the label positions of the x and y axes of all panels in a small multiples visual. You can choose to display axis labels inside or outside the panel.

To configure the axis label position for small multiples visuals

1. Select the small multiples visual that you want to change and open the **Format visual** menu.
2. In the **Properties** pane that appears, open the **Multiples options** menu.
3. For **X-axis labels**, choose **Inside** or **Outside** from the dropdown.

Or, for **Y-axis labels**, choose **Inside** or **Outside** from the dropdown.

Titles and subtitles on visual types in Quick

In Quick, you can format visual titles and subtitles to meet your business needs. Quick offers rich text formatting for titles and subtitles, and the ability to add hyperlinks and parameters in titles. You can edit titles in the Properties pane, or by double-clicking on a title or subtitle in the visual.

Use the following procedure to customize the way the title and subtitle of a visual is displayed. The visual title is shown by default. After subtitles are created, they're also shown by default.

1. Sign in to Quick at <https://quicksight.aws.amazon.com/>.
2. Open the analysis that you want to update.
3. On the analysis page, choose the visual that you want to format.
4. At the visual's right, choose the **Properties** icon.
5. In the **Properties** pane that opens, choose the **Display settings** tab.
6. To edit the title or subtitle of a visual, choose the paintbrush icon next to **Edit title** or **Edit subtitle**. Alternatively, you can choose the eyeball icon next to **Edit title** or **Edit subtitle** to hide the title or subtitle, shown in the following image.
7. In the **Edit title** or **Edit subtitle** popup that opens, you can use the following options to make the updates that you want:
 - To enter a custom title or subtitle, enter your title or subtitle text in the editor. Titles can be up to 120 characters long, including spaces. Subtitles can be up to 500 characters long.
 - To change the font type, choose a font type from the list at left.
 - To change the font size, choose a size from the list at right.
 - To change the font weight and emphasis, or to underline or strikethrough text, choose the bold, emphasis, underline, or strikethrough icons.
 - To change the font color, choose the color (Abc) icon, and then pick a color. You can also enter a hexadecimal number or RGB values.
 - To add an unordered list, choose the unordered list icon.
 - To change the text alignment, choose the left, center, or right alignment icons.

- To add a parameter to a title or subtitle, choose an existing parameter from the list under **Parameters** at right. For more information about how to create parameters, see [Setting up parameters in Amazon Quick](#).
- To add a hyperlink, highlight the text that you want to link, choose the hyperlink icon, and then choose from the following options:
 - For **Enter link**, enter the URL that you want to link to.

Choose the + icon at right to add an existing parameter, function, or computation to the URL.

- To edit the display text, enter text for **Display text**.
- To open the hyperlink in the same browser tab as Quick, select **Same tab**.
- To open the hyperlink in a new browser tab, select **New tab**.
- To delete the hyperlink, choose the delete icon at bottom left.

When finished configuring the hyperlink, choose **Save**.

8. When you are finished, choose **Save**.
9. For **Alt text**, enter the alt text that you want for the visual.
10. When you are finished, close the properties pane.

Tooltips on visual types in Quick

When you hover your cursor over any graphical element in an Quick visual, a tooltip appears with information about that specific element. For example, when you hover your cursor over dates in a line chart, a tooltip appears with information about those dates. By default, the fields in the Fields well determine what information displays in tooltips. Tooltips can display up to 10 fields.

You can provide your viewers with additional information about data in your visual, customizing what viewers can see. You can even prevent tooltips from appearing when viewers hover a cursor over an element. To do this, you can customize the tooltips for that visual.

Customizing tooltips in a visual

Use the following procedure to customize tooltips in a visual.

To customize tooltips in a visual

1. On the analysis page, choose the visual that you want to format.

2. On the menu in the upper-right corner of the visual, choose the **Format visual** icon.
3. In the **Properties** pane that opens, choose **Tooltip**.
4. For **Type**, choose **Detailed tooltip**. A new set of options appear.

To show or hide titles in a tooltip

- Choose **Use primary value as title**.

Clearing the option hides titles in the tooltip. Selecting the option shows the primary field value as the title in the tooltip.

To show or hide aggregations for fields in the tooltip

- Choose **Show aggregations**.

Clearing the option hides the aggregation for fields in the tooltip. Selecting the option shows the aggregation for fields in the tooltip.

To add a field to the tooltip

1. Choose **Add field**.
2. In the **Add field to tooltip** page that opens, choose **Select field** and then select a field from the list.

You can add up to 10 fields to tooltips.

3. (Optional) For **Label**, enter a label for the field. This option creates a custom label for the field in the tooltip.
4. (Optional) Depending on whether you add a dimension or a measure, choose how you want the aggregation to display in the tooltip. If you don't select an option, Quick uses the default aggregation.

If you add a measure to the tooltip, you can select how you want the field to be aggregated. To do so, choose **Select aggregation**, and then select an aggregation from the list. For more information about the types of aggregations in Quick, see [Changing field aggregation](#).

5. Choose **Save**.

A new field is added to the list of fields in your tooltip.

To remove a field from the tooltip

- Under the **Fields** list, select the field menu for the field that you want to remove (the three dots) and choose **Hide**.

To rearrange the order of the fields in the tooltip

- Under the **Fields** list, select the field menu for a field (the three dots) and choose either **Move up** or **Move down**.

To customize the label for a field in the tooltip

- Select the field menu for the field that you want to customize (the three dots) and choose **Edit**.
- In the **Edit tooltip field** page that opens, for **Label**, enter the label that you want to appear in the tooltip.
- Choose **Save**.

Using sheet tooltips in Quick

Sheet tooltips transform how viewers explore data by providing rich context without disrupting their analysis flow. Instead of navigating away from a visual or opening separate sheets, viewers get instant access to detailed breakdowns, trends, and supporting information, making dashboards more intuitive and reducing the need for multiple sheets.

Sheet tooltips are available on interactive sheets only. They are not supported on paginated reports. You can duplicate a tooltip sheet to another tooltip sheet, or duplicate a tooltip sheet to a regular interactive sheet. Additionally, you can duplicate a visual to a tooltip sheet.

How sheet tooltips work

When an author creates a sheet tooltip, a tooltip sheet is created and associated with a visual. This tooltip sheet works like a regular sheet. You can add visuals, text boxes, and images to it using a free-form layout. When a viewer hovers over a data point, the tooltip sheet inherits all filters from the source visual and adds an additional filter for the specific data point. For example, if your source visual is filtered to "2025 data" and a viewer hovers over "Electronics," the tooltip shows Electronics data for 2025 only.

Consider a bar chart showing sales by product category. You could create a sheet tooltip that shows a trend line of monthly sales, a KPI of year-over-year growth, and a text box with the category name, all filtered to whichever category the viewer hovers over.

Sheet tooltip limits

The following limits apply to sheet tooltips:

- Up to 50 tooltip sheets per analysis
- Up to 5 visuals per tooltip sheet
- Up to 5 text boxes per tooltip sheet
- Up to 5 images per tooltip sheet
- Tooltip sheets use free-form layout only
- Layer map visuals are not allowed on tooltip sheets
- Maximum size of a tooltip sheet is 640px wide by 720px tall

Creating a sheet tooltip

Use the following procedure to create a sheet tooltip for a visual.

To create a tooltip sheet

1. On the analysis page, choose the visual that you want to add a sheet tooltip to.

2. On the menu in the upper-right corner of the visual, choose the **Format visual** icon.
3. In the **Properties** pane that opens, choose **Interactions > Tooltip**.
4. For **Type**, choose **Sheet tooltip**.

5. Choose **Create tooltip sheet**. You will automatically navigate to a tooltip sheet editing experience. A tooltip name is auto-generated and you can edit it by choosing the tab title.
6. Add visuals, text boxes, or images to the tooltip sheet. Arrange them using the free-form layout.
7. When you are finished, return to the source sheet by choosing the **Back** button located to the left of the sheet tooltip title. To preview the tooltip, hover over any data points in the visual.

Assigning a tooltip sheet to a visual

When you select **Sheet tooltip** as the tooltip type in the **Properties** pane, a control appears that lets you select all tooltip sheets available in the analysis. You can assign one tooltip sheet to multiple visuals or create separate tooltip sheets for each visual.

If you would like to apply the same tooltip sheet to another visual, you can do this by assigning one tooltip sheet to multiple visuals in the **Interactions > Tooltip** accordion in the **Properties** pane.

Editing a tooltip sheet

Use the following procedure to edit an existing sheet tooltip.

To edit a tooltip sheet

1. Choose any visual where a sheet tooltip is enabled.
2. Open the **Properties** pane and navigate to **Interactions > Tooltip**.
3. In the **Tooltip** accordion, select the tooltip that you would like to edit and choose the edit icon next to the tooltip sheet name to navigate to it.
4. Make your changes to the visuals, text boxes, or images on the tooltip sheet.

Switching between tooltip types

You can switch a visual's tooltip between basic, detailed, and sheet tooltip types at any time.

To change the tooltip type

1. Choose the visual that you want to update.
2. Open the **Properties** pane, choose **Interactions**, and then choose **Tooltip**.
3. For **Type**, select the tooltip type that you want: **Basic tooltip**, **Detailed tooltip**, or **Sheet tooltip**.

Note

Switching away from a sheet tooltip preserves your work. You can always switch back without losing your tooltip sheet design.

Sheet tooltip considerations

Keep the following in mind when working with sheet tooltips:

- Tables and pivot tables support sheet tooltips but not basic or detailed tooltips.
- Visuals in a tooltip sheet do not support context menus, on-visual menus, or custom actions.
- [Using custom actions for filtering and navigating](#) on visuals in a tooltip sheet are not supported when the sheet is rendered as a tooltip.
- Sheet tooltips support filters, cross-sheet filtering, and parameters. Filter controls are not supported.
- Sheet descriptions are not displayed on tooltip sheets.
- Cross-sheet filters cannot be scoped to tooltip sheets.
- An analysis must contain at least one regular interactive sheet. An analysis cannot consist of only tooltip sheets.
- Layer map visuals cannot be placed inside a tooltip sheet.
- Tooltips on tooltip sheets are not supported.
- Sheet tooltips are not supported on the following chart types: Sankey, Waterfall, KPI, Radar, Wordcloud, Custom content, and Highcharts.

These limits ensure tooltip sheets load quickly and maintain a focused, scannable experience for viewers. For more complex analysis, consider using drill-down actions or separate detail sheets.

Hiding tooltips in a visual

If you don't want tooltips to appear when you hover your cursor over data in a visual, you can hide them.

To hide tooltips in a visual

1. On the analysis page, choose the visual that you want to format.

2. On the menu in the upper-right corner of the visual, choose the **Format visual** icon.
3. In the **Properties** pane that opens, choose **Tooltip**.
4. Choose **Show tooltip**.

Clearing the option hides tooltips for the visual. Selecting the option shows them.

Customizing data presentation

To gain further insight into your data when creating visuals (charts) in an Quick analysis, you can sort and filter data in a visual. You can also change the granularity of date fields, data type, role, and format of fields in a visual.

Topics

- [Changing fields used by a visual in Amazon Quick](#)
- [Sorting visual data in Amazon Quick](#)

Changing fields used by a visual in Amazon Quick

You can add or modify fields for a visual by using the **Fields list** pane, the field wells, or the on-visual editors or drop targets on the visual.

The field wells, on-visual editors, and drop targets available for a specific visual depends on the visual type selected. For details, see the appropriate visual type topic in the [Visual types in Amazon Quick Sight](#) section.

Important

You can also change the data type and format of numeric fields by using field wells and on-visual editors. If you change a field in this way, it changes for the selected visual only. For more information about changing numeric field data types and formats, see [Changing fields used by a visual in Amazon Quick](#).

Use the following topics to learn more about adding, removing, and modifying fields on a visual.

Topics

- [Using visual field controls](#)

- [Adding or removing a field](#)
- [Changing the field associated with a visual element](#)
- [Changing field aggregation](#)
- [Changing date field granularity](#)
- [Customizing a field format](#)

Using visual field controls

You can edit the fields used by a visual with user interface (UI) controls.

You can use these controls as follows:

- Create a visual and assign fields to different elements on it by selecting fields in the **Fields list** pane, or dragging fields to field wells or drop targets.
- Change the field associated with a visual element by dragging a field to a drop target or field well, or selecting a different field in a field well or on-visual editor.
- Change field aggregation or date granularity by using the field wells or the on-visual editors.

The field wells, on-visual editors, and drop targets available on a specific visual depends on the visual type selected.

Dragging fields to drop targets or field wells

When you drag a field to either a drop target or field well, Amazon Quick provides you with information about whether the target element expects a measure or a dimension. Amazon Quick also provides you with information about whether that element is available for field assignment.

For example, when you drag a measure to the value drop target on a new single-measure line chart, you see the drop target color-coded green. That green color coding indicates that the drop target expects a measure. The drag label indicates that the target is available to add a field.

When you drag a dimension to the x-axis or color drop target on a new line chart, you see a label color-coded blue. That blue color coding indicates that the drop target expects a dimension. The drag label indicates that the target is available to add a field.

You can also drag a measure or dimension to a drop target on a line chart where the element is already associated with a field. In this case, the drag label indicates that you are replacing the field currently associated with the drop target.

Adding or removing a field

You can add a field to a visual by choosing it on the **Fields list** pane. You can also drag it to a drop target on the visual or to a field well. There is a 1:1 correspondence of drop targets to field wells for each visual type, so you can use either method.

On some charts, the **Axis title** field is hidden when there are two or more fields in the **Value** field on any side of the chart. This effect can happen with the following charts:

- Bar charts
- Line charts
- Box plots
- Combo charts
- Waterfall charts

To remove a field from a visual, clear selection from it in the **Fields list** pane. Or choose an on-visual editor or field well that uses that field, and then choose **Remove** from the context (right-click) menu.

Adding a field by selecting it in the fields list pane

You can also let Amazon Quick map the field to the most appropriate visual element. To do so, choose the field in the **Fields list** pane. Amazon Quick adds the field to the visual by populating the first empty field well that corresponds with that field type (either measure or dimension). If all of the visual elements are already populated, Amazon Quick determines the most appropriate field well and replaces the field in it with the field you selected.

Adding a field by using a drop target

To add a field to a visual by using a drop target, first choose a field in the **Fields list** pane. Then drag the field to your chosen drop target on the visual, making sure the drop indicator shows that the field is being added.

Adding a field by using a field well

To add a field to a visual by using a field well, choose a field in the **Fields list** pane. Then drag the field to the target field well, making sure that the drop indicator shows that the field is being added.

1. Drag a field item into a **Field well**.

2. Drag the field that you want to add from the **Fields list** pane to the appropriate field well.

Note

You can add the same value to the same visual multiple times. You can do so to show the same value with different aggregations or table calculations applied. By default, the fields all display the same label. You can edit the names by using the **Properties** panel, which you open by choosing the **V**-shaped icon at top right.

Changing the field associated with a visual element

You can change the field assigned to an element in a visual by using the field wells, drop targets, or the on-visual editors on the visual. For pivot tables, use field wells or drop targets because this visual type doesn't provide on-visual editors.

Change a field mapping by using an on-visual editor

Use the following procedure to modify the mapping of a field to a visual element.

To modify the mapping of a field by using an on-visual editor

1. On the visual, choose the on-visual editor for the visual element for which you want to change the field.
2. On the on-visual editor menu, choose the field that you want to associate with that visual element.

Changing a field mapping by using a drop target

To modify the mapping of a field to a visual element by using a drop target, choose a field in the **Fields list** pane. Then drag the field to a drop target on the visual, making sure that the drop indicator shows that the field is being replaced.

Changing a field mapping by using a field well

Use the following procedure to modify the mapping of a field to a visual element.

To modify the mapping of a field by using a field well

1. Drag a field item into a **Field well**.

2. Choose the field well that represents the element that you want to remap, and then choose a new field from the menu that appears.

Changing field aggregation

You can apply functions to fields to display aggregate information, like the sum of the sales for a given product. You can apply an aggregate function by using the options in either an on-visual editor or a field well. The following aggregate functions are available in Amazon Quick:

- Average – Calculates the average value for the selected field.
- Count – Provides a count of the number of records containing the selected measure for a given dimension. An example is a count of Order ID by State.
- Distinct Count – Provides a count of how many different values are in the selected measure, for the selected dimension or dimensions. An example is a count of Product by Region. A simple count can show how many products are sold for each region. A distinct count can show how many different products are sold for each region. You might have sold 2,000 items, but only two different types of items.
- Max – Calculates the maximum value for the selected field.
- Min – Calculates the minimum value for the selected field.
- Median – Calculates the median value of the specified measure, grouped by the chosen dimension or dimensions.
- Sum – Totals all of the values for the selected field.
- Standard Deviation – Calculates the standard deviation of the set of numbers in the specified measure, grouped by the chosen dimension or dimensions, based on a sample or on a biased population.
- Variance – Calculates the variance of the set of numbers in the specified measure, grouped by the chosen dimension or dimensions, based on a sample or on a biased population.
- Percentile – Computes the *n*th percentile of the specified measure, grouped by the chosen dimension or dimensions.

All aggregate functions can be applied to numeric fields. *Count* is automatically applied to a dimension if you choose to use it in a field well that expects a measure. If you have used a dimension in that way, you can also change the aggregate function applied to it. You can't apply aggregate functions to fields in dimension field wells.

The visual elements that support aggregated fields varies by visual type.

Changing or adding aggregation on a field by using an on-visual editor

Use the following procedure to change or add aggregation on a field.

To change or add aggregation on a field

1. On the visual, choose the on-visual editor for the field that you want to apply aggregation to.
2. On the on-visual editor menu, choose **Aggregate**, then choose the aggregate function that you want to apply.

Changing or adding aggregation to a field by using a field well

Use the following procedure to add aggregation to a field for a pivot table visual.

To add aggregation to a field for a pivot table visual

1. Drag a field item into a **Field well**.
2. Choose the field well containing the field that you want to apply an aggregate function to.
3. On the field well menu, choose **Aggregate**, then choose the aggregate function that you want to apply.

Changing date field granularity

You can change the granularity for a date field on a visual to determine the intervals for which item values are shown. You can set the date field granularity to one of the following values:

- Year
- Quarter
- Month
- Week
- Day (this is the default)
- Hour
- Minute
- Second

Hour and minute are available only if the field contains time data.

Changing date field granularity by using an on-visual editor

Use the following procedure to change date field granularity by using an on-visual editor.

To change date field granularity with an on-visual editor

1. On the visual, choose the field well for the date field whose granularity you want to change.
2. On the field well menu, choose **Aggregate**, then choose the time interval that you want to apply, as shown following:

Changing date field granularity by using a field well

Use the following procedure to change date field granularity by using a field well.

To change date field granularity with a field well

1. Drag a field item into a **Field well**.
2. Choose the field well containing the date field, and then choose **Aggregate**. Choose the date granularity that you want to use.

Customizing a field format

Use the following procedure to customize the appearance of fields in an analysis.

To customize the appearance of fields in an analysis

1. In an analysis, choose a field to format, either by choosing it in the field well or in the **Fields list** of the **Visualize** pane.
2. Choose **Show as** to change how the field shows in the analysis, and choose from the options on the context menu. The list of available options varies based on the field's data type. If you choose a non-numeric field from the fields list, you can change the *count format*, which is the formatting used when the field is counted.
3. Choose **Format** to change the format of the field, and choose from the options on the context menu. If you don't see an option that you want to use, choose **More formatting options** from the context menu.

The **Format Data** pane opens, presenting options for the type of numeric or date field you chose.

The options for **Show as** from the context menu now appear in the drop-down list at the top of the **Format Data** pane. The rest of the options are specific to the data type and how you choose to show the field.

For date and time data, the default format pattern is YYYY-MM-DDTHH:mm:ssZZ, for example 2016-09-22T17:00:00-07:00.

For numbers, you can choose from the following units to display after the number:

- No unit suffix. This is the default.
- Thousands (K)
- Millions (M)
- Billions (B)
- Trillions (T)
- A custom unit prefix or suffix

For currency, you can choose from the following symbols:

- Dollars (\$)
- Euros (€)
- Pounds (£)
- Yen (¥)

Changing a field format

You can change the format of a field within the context of an analysis. The formatting options available for fields vary based on the field's data type.

Use menu options in the **Field list** pane or the visual field wells to make simple format changes, or use the **Format data** pane to make more extensive formatting changes.

Topics

- [Format a currency field](#)
- [Format a date field](#)
- [Format a number field](#)
- [Format a percent field](#)
- [Format a text field](#)
- [Return a field's format to default settings](#)

Format a currency field

When you format a currency field, you can either choose the currency symbol from a list of common options, or open the **Format data** pane and manually format the field. Manually formatting the field allows you to choose which symbol to use, which separators to use, the number of decimal places to show, which units to use, and how to display negative numbers.

Changing a field format changes it for all visuals in the analysis, but does not change it in the underlying dataset.

If you want to choose the symbol for a currency field from a list of common options, you can access such a list in several ways. You can access it from the **Field list** pane, an on-visual editor, or a visual field well.

To select a currency field's symbol by choosing a list option

1. Choose one of the following options:
 - In the **Field list** pane, choose the selector icon to the right of the number field that you want to format.
 - On any visual that contains an on-visual editor associated with the currency field that you want to format, choose that on-visual editor. Expand the **Field wells** pane, and then choose the field well associated with the number field that you want to change.
2. Choose **Format**, and then choose the currency field that you want:
 - Display in dollars (\$).
 - Display in pounds (£).
 - Display in euros (€).
 - Display in yen or yuan (¥).

To manually change a currency field's format

1. Choose one of the following options:
 - In the **Field list** pane, choose the selector icon to the right of the number field that you want to format.
 - On any visual that contains an on-visual editor associated with the number field that you want to format, choose that on-visual editor. Expand the **Field wells** pane, and then choose the field well associated with the number field that you want to change.
2. Choose **Format**, and then choose **More Formatting Options**.

The **Format data** pane opens.

3. Expand the **Symbol** section and choose from the following options:
 - Display in dollars (\$). This is the default.
 - Display in pounds (£).
 - Display in euros (€).
 - Display in yen or yuan (¥).
4. Expand the **Separators** section and choose from the following options:
 - Under **Decimal**, choose a dot or a comma for the decimal separator. A dot is the default. If you choose a comma instead, use a dot or a space as the thousands separator.
 - Under **Thousands**, select or clear **Enabled** to indicate whether you want to use a thousands separator. **Enabled** is selected by default.
 - If you are using a thousands separator, choose whether to use a comma, dot, or space for the separator. A comma is the default. If you choose a dot instead, use a comma as the decimal separator.
5. Expand the **Decimal Places** section and choose the number of decimal places to use. The default is 2. Field values are rounded to the decimal places specified. For example, if you specify two decimal places, the value 6.728 is rounded to 6.73.
6. Expand the **Units** section and choose from the following options:
 - Choose the unit to use. Choosing a unit adds the appropriate suffix to the number value. For example, if you choose **Thousands**, a field value of 1234 displays as 1.234K.

The unit options are as follows:

- No unit suffix. This is the default.
 - Thousands (K)
 - Millions (M)
 - Billions (B)
 - Trillions (T)
 - If you want to use a custom prefix or suffix, specify it in the **Prefix** or **Suffix** box. Using a custom suffix is a good way to specify a currency suffix outside of those already offered by Amazon Quick. You can specify both. You can also specify a custom prefix in addition to the suffix added by selecting a unit.
7. Expand the **Negatives** section and choose whether to display a negative value by using a minus sign or by enclosing it in parentheses. Using a minus sign is the default.
 8. Expand the **Null values** section and choose whether to display null values as `null` or as a custom value. Using `null` is the default.

 Note

When using a table or pivot table, null values only display for fields that are placed in the **Rows**, **Columns**, or **Group by** field wells. Null values for fields in the **Values** field well appear empty in the table or pivot table.

Format a date field

When you format a date field, you can choose a list of common formatting options. Or you can open the **Format data** pane to choose from a list of common formats, or specify custom formatting for the date and time values.

Changing a field format changes it for all visuals in the analysis that use that dataset, but does not change it in the dataset itself.

If you want to format a date field by choosing from a list of common options, you can access such a list in several ways. You can access it from the **Field list** pane, a visual on-visual editor, or a visual field well.

To change a date field's format by choosing a list option

1. Choose one of the following options:

- In the **Field list** pane, choose the selector icon to the right of the number field that you want to format.
 - On any visual that contains an on-visual editor associated with the number field that you want to format, choose that on-visual editor. Expand the **Field wells** pane, and then choose the field well associated with the number field that you want to change.
2. Choose **Format**, and then choose the format that you want. The following quick formatting options are offered for date fields:
 - Show the month, day, year, and time.
 - Show the month, day, and year.
 - Show the month and year.
 - Show the year.

To manually change a date field's format

1. Choose one of the following options:
 - In the **Field list** pane, choose the selector icon to the right of the number field that you want to format.
 - On any visual that contains an on-visual editor associated with the number field that you want to format, choose that on-visual editor. Expand the **Field wells** pane, and then choose the field well associated with the number field that you want to change.

2. Choose **Format**, and then choose **More Formatting Options**.

The **Format data** pane opens.

3. Expand the **Date** section. Choose an existing date format, or choose **Custom** and specify a format pattern in the **Custom** section lower down in the **Format data** pane. If you choose **Custom** for the **Date** section, you must also choose **Custom** for the following **Time** section. The pattern that you specify in the **Custom** section must include any date and time formatting that you want.

The default selection is **Custom**, with a default format pattern of MMM D, YYYY h:mm, for example Sep 20, 2022 5:30pm.

4. Expand the **Time** section. Choose an existing time format, or choose **Custom** and specify a format pattern in the **Custom** section lower down in the **Format data** pane. If you choose

Custom for the **Time** section, you must also choose **Custom** for the preceding **Date** section. The pattern that you specify in the **Custom** section must include any date and time formatting that you want.

The default selection is **Custom**, with a default format pattern of MMM D, YYYY h:mma, for example Sep 20, 2022 5:30pm.

5. If you chose **Custom** in the **Date** and **Time** sections, expand the **Custom** section and specify the format pattern that you want, using the format pattern syntax specified in [Moment.js Display Format](#) in the Moment.js JavaScript documentation.

 Note

The time zone related display token Z from the Moment.js library is supported in Quick, but the z token is not.

If you chose something other than **Custom** in the **Date** and **Time** sections, **Custom** is populated with the format pattern that reflects your selections. For example, if you chose Jun 21, 2016 in the **Date** section and 17:00:00pm in the **Time** section, the **Custom** section shows the format pattern MMM D, YYYY H:mm:ssa.

6. (Optional) Expand the **Custom** section and use **Preview** to verify your specified format.
7. Expand the **Null values** section and choose whether to display null values as `null` or as a custom value. Using `null` is the default.

Customizing date formats in Quick

In Quick, you can customize how dates are formatted in your filter and parameter controls. For example, you can specify to format the date in a control as 20-09-2021, or, if you'd rather, as 09-20-2021. You can also specify to shorten the month in your dates (such as September) to three letters (Sep), among other customizations.

Following is a list of tokens you can use to create custom date formats. You can use them in combination with one another to control how dates appear in your controls.

List of supported tokens for formatting dates

Use the following tokens to customize the format of dates in Quick.

Example	Description	Token
0–6	Numeric representation of a particular day of the week. 0 is Sunday and 6 is Saturday.	d
Mo–Su	A 2-character textual representation of a particular day of the week.	dd
Mon–Sun	A 3-character textual representation of a particular day of the week.	ddd
Monday–Sunday	A textual representation of a particular day of the week.	dddd
99 or 21	A 2-digit representation of a year.	YY
1999 or 2021	A full, 4-digit numeric representation of a year.	YYYY
1–12	Number of a month, without leading zeros.	M
1st, 2nd, to 12th	Number of a month without leading zeros and with an ordinal suffix.	Mo
01–12	Number of a month with leading zeros.	MM

Example	Description	Token
Jan–Dec	A 3-digit textual representation of a month.	MMM
January–December	A full textual representation of a month.	MMMM
1–4	A numeric representation of a quarter.	Q
1st–4th	A numeric representation of a quarter with an ordinal suffix.	Qo
1–31	Day of the month without leading zeros.	D
1st, 2nd, to 31st	Day of the month without leading zeros and an ordinal suffix.	Do
01–31	A 2-digit day of the month with leading zeros.	DD
1–365	Day of the year without leading zeros.	DDD
001–365	Day of the year with leading zeros.	DDDD
1–53	Week of the year without leading zeros.	w

Example	Description	Token
1st–53rd	The week of the year without leading zeros and with an ordinal suffix.	wo
01–53rd	Week of the year with leading zeros.	ww
1–23	Hours, in 24-hour format, without leading zeros.	H
01–23	Hours, in 24-hour format, with leading zeros.	HH
1–12	Hours, in 12-hour format, without leading zeros.	h
01–12	Hours, in 12-hour format, with leading zeros.	hh
0–59	Minutes without leading zeros.	m
00–59	Minutes with leading zeros.	mm
0–59	Seconds without leading zeros.	s
00–59	Seconds with leading zeros.	ss
am or pm	am/pm	a

Example	Description	Token
AM or PM	AM/PM	A
1632184215	Unix timestamp.	X
1632184215000	Millisecond Unix timestamp.	x
Z	Zero UTC offset.	Z

The following date types are not supported.

- Time zones offset with a colon. For example, +07:00.
- Time zones offset without a colon. For example, +0730.

Preset date formats

To quickly customize dates and times to appear as one of the following example formats, you can use the following Quick preset tokens.

Example	Token
8:30 PM	LT
8:30:25 PM	LTS
August 2 1985	LL
Aug 2 1985	11
August 2 1985 08:30 PM	LLL

Example	Token
Aug 2 1985 08:30 PM	l11
Thursday, August 2 1985 08:30 PM	LLLL
Thu, Aug 2 1985 08:30 PM	l111

Common date formats

Following are three common date examples and their associated token formats for your quick reference.

Example	Token Format
Sep 20, 2021	MMM DD, YYYY
20-09-21 5pm	DD-MM-YY ha
Monday, September 20, 2021 17:30:15	dddd, MMMM DD, YYYY HH:mm:ss

Adding words to dates

To include words in your date formats, such as the word "of" in *20th of Sep, 2021*, enter backslashes (\) before each character in the word. For example, for the 20th of Sep, 2021 date example, use the following token format: Do \o\f MMM, YYYY.

Example: Customizing the date format in a filter control

Use the following procedure to learn how to use date token formats to customize dates for a filter control.

To learn to customize dates for a filter control with data tokens

1. In a Quick analysis, choose the filter control that you want to customize.
2. On the filter control, choose the **Edit control** icon.

3. On the **Edit control** page that opens, for **Date format**, enter the custom date format that you want. Use the tokens listed previously in this topic.

For example, let's say that you want to customize your dates using the following format: *Sep 3rd, 2020 at 5pm*. To do so, you can enter the following token format:

MMM Do, YYYY \a\t ha

A preview of the date format appears below the input field as you enter each token.

4. Choose **Apply**.

The dates in the control update to the format you specified.

Format a number field

When you format a number field, you can choose the decimal place and thousand separator format from a list of common options. Or you can open the **Format Data** pane and manually format the field. Manually formatting the field enables you to choose which separators to use and the number of decimal places to show. It also enables you to choose which units to use, and how to display negative numbers.

Changing a field format changes it for all visuals in the analysis, but does not change it in the underlying dataset.

If you want to format a number field by choosing from a list of common options, you can access such a list from the **Field list** pane, an on-visual editor, or a visual field well.

To change a number field's format by choosing a list option:

- Choose one of the following options:
 - In the **Field list** pane, choose the selector icon to the right of the number field that you want to format.
 - On any visual that contains an on-visual editor associated with the number field that you want to format, choose that on-visual editor. Expand the **Field wells** pane, and then choose the field well associated with the number field that you want to change.
- Choose **Format**, and then choose the format that you want. The following quick formatting options are offered for number fields:
 - Use commas to separate groups of thousands and use a decimal point to show the fractional part of the number, for example 1,234.56.

- Use a decimal point to show the fractional part of the number, for example 1234.56.
- Show the number as an integer and use commas to separate groups of thousands, for example 1,234.
- Show the number as an integer, for example 1234.

To manually change a number field's format:

1. Choose one of the following options:

- In the **Field list** pane, choose the selector icon to the right of the number field that you want to format.
- On any visual that contains an on-visual editor associated with the number field that you want to format, choose that on-visual editor. Expand the **Field wells** pane, and then choose the field well associated with the number field that you want to change.

2. Choose **Format**, and then choose **More Formatting Options**.

The **Format data** pane opens.

3. Expand the **Separators** section and choose from the following options:

- Under **Decimal**, choose a dot or a comma for the decimal separator. A dot is the default. If you choose a comma instead, use a dot or a space as the thousands separator.
- Under **Thousands**, select or clear **Enabled** to indicate whether you want to use a thousands separator. **Enabled** is selected by default.
- If you are using a thousands separator, choose whether to use a comma, dot, or space for the separator. A comma is the default. If you choose a dot instead, use a comma as the decimal separator.

4. Expand the **Decimal Places** section and choose from the following options:

- Choose **Auto** to have Amazon Quick automatically determine the appropriate number of decimal places, or choose **Custom** to specify a number of decimal places. **Auto** is the default.
- If you chose **Custom**, enter the number of decimal places to use. Field values are rounded to the decimal places specified. For example, if you specify two decimal places, the value 6.728 is rounded to 6.73.

5. Expand the **Units** section and choose from the following options:

- Choose the unit to use. Choosing a unit adds the appropriate suffix to the number value. For example, if you choose **Thousands**, a field value of 1234 displays as 1.234K.

The unit options are as follows:

- No unit suffix. This is the default.
 - Thousands (K)
 - Millions (M)
 - Billions (B)
 - Trillions (T)
- If you want to use a custom prefix or suffix, specify it in the **Prefix** or **Suffix** box. You can specify both. You can also specify a custom prefix in addition to the suffix added by selecting a unit.
6. Expand the **Negatives** section and choose whether to display a negative value by using a minus sign or by enclosing it in parentheses. Using a minus sign is the default.
7. Expand the **Null values** section and choose whether to display null values as `null` or as a custom value. Using `null` is the default.

 Note

When using a table or pivot table, null values only display for fields that are placed in the **Rows**, **Columns**, or **Group by** field wells. Null values for fields in the **Values** field well appear empty in the table or pivot table.

Format a percent field

When you format a percent field, you can choose the number of decimal places from a list of common options. Or you can open the **Format data** pane and manually format the field. Manually formatting the field enables you to choose which separators to use. It also enables you to choose the number of decimal places to show and how to display negative numbers.

Changing a field format changes it for all visuals in the analysis, but does not change it in the underlying dataset.

If you want to choose the number of decimal places for a percent field from a list of common options, you can access such a list in several ways. You can access it from the **Field list** pane, an on-visual editor, or a visual field well.

To change a percent field's number of decimal places by choosing a list option

1. Choose one of the following options:
 - In the **Field list** pane, choose the selector icon to the right of the number field that you want to format.
 - On any visual that contains an on-visual editor associated with the percent field that you want to format, choose that on-visual editor. Expand the **Field wells** pane, and then choose the field well associated with the number field that you want to change.
2. Choose **Format**, and then choose the number of decimal places that you want. The following quick formats are offered for percent fields:
 - Display the value with two decimal places.
 - Display the value with one decimal place.
 - Display the value with no decimal places.

To manually change a percent field's format

1. Choose one of the following options:
 - In the **Field list** pane, choose the selector icon to the right of the number field that you want to format.
 - On any visual that contains an on-visual editor associated with the number field that you want to format, choose that on-visual editor. Expand the **Field wells** pane, and then choose the field well associated with the number field that you want to change.

2. Choose **Format**, and then choose **More Formatting Options**.

The **Format data** pane opens.

3. Expand the **Separators** section and choose from the following options:
 - Under **Decimal**, choose a dot or a comma for the decimal separator. A dot is the default. If you choose a comma instead, use a dot or a space as the thousands separator.
 - Under **Thousands**, select or clear **Enabled** to indicate whether you want to use a thousands separator. **Enabled** is selected by default.
 - If you are using a thousands separator, choose whether to use a comma, dot, or space for the separator. A comma is the default. If you choose a dot instead, use a comma as the decimal separator.

4. Expand the **Decimal Places** section and choose from the following options:
 - Choose **Auto** to have Amazon Quick automatically determine the appropriate number of decimal places, or choose **Custom** to specify a number of decimal places. **Auto** is the default.
 - If you chose **Custom**, enter the number of decimal places to use. Field values are rounded to the decimal places specified. For example, if you specify two decimal places, the value 6.728 is rounded to 6.73.
5. Expand the **Negatives** section and choose whether to display a negative value by using a minus sign or by enclosing it in parentheses. Using a minus sign is the default.
6. Expand the **Null values** section and choose whether to display null values as null or as a custom value. Using null is the default.

 Note

When using a table or pivot table, null values only display for fields that are placed in the **Rows**, **Columns**, or **Group by** field wells. Null values for fields in the **Values** field well appear empty in the table or pivot table.

Format a text field

When you format a text field, you can choose how to display null values using the **Field list** pane, an on-visual editor, or a visual field well.

To choose how to display a text field's null values

1. Choose one of the following options:
 - In the **Field list** pane, choose the selector icon to the right of the number field that you want to format.
 - On any visual that contains an on-visual editor associated with the percent field that you want to format, choose that on-visual editor. Expand the **Field wells** pane, and then choose the field well associated with the number field that you want to change.
2. Choose **Format**, and then choose **More Formatting Options**.

The **Format data** pane opens.

3. Expand the **Null values** section and choose whether to display null values as null or as a custom value. Using null is the default.

Return a field's format to default settings

Use the following procedure to return a field's format to the default settings.

To return a field's format to the default settings

1. In the **Field list** pane, choose the selector icon to the right of the field that you want to reset.
2. Choose **Format**, and then choose **More Formatting options**.

The **Format data** pane opens.

3. Choose **Reset to defaults**.

Sorting visual data in Amazon Quick

You can sort data using multiple methods for most visual types. You can choose the sort order of on-visual data by using the quick sort option or field wells. You can also use field wells to sort data by an off-visual metric. The visual element you can sort by depends on the visual type and whether sorting is supported for that visual. For more information on which visual types support sorting, see [Analytics formatting per type in Quick](#).

Pivot tables behave differently than tables when sorting values. For more information about sorting pivot tables, see [Sorting pivot tables in Quick](#).

For SPICE datasets, you can sort text strings of sizes up to the following limitations:

- Up to two million (2,000,000) unique values
- Up to 16 columns

When you exceed the limitations, the visual displays a notification at the upper right.

You can sort any visual type that supports sorting. If a visual type supports sorting, you can sort by using either the quick sort option or a field well.

To quickly sort dimensions and measures

- Do one of the following:
 - Choose the sort icon that appears near the field name on either axis. In direct queries, this icon appears for any data type. For SPICE, this icon is available only for datetime, numeric, and decimal data types.

- Choose the field name and then choose the sort option from the menu. If the label doesn't display on the axis, check the visual format to see if the axis is set to display labels. The display labels are automatically hidden on smaller visuals. You might need to make the visual large enough to display labels.

To sort by using an off-visual metric

1. Open the analysis with the visual that you want to sort. Visuals pane will be open by default.
2. Choose a field well that supports sorting, then choose **Sort by, Sort options**.
3. On the **Sort options** pane, sort by specific fields, choose an aggregation, or sort ascending or descending, or do a combination of these.
4. Choose **Apply** to save your changes. Or choose **Clear** to start over or **Cancel** to go back.

To sort by using a field well

1. Open the analysis with the visual that you want to sort. Visuals pane will be open by default.
2. Choose a field well that supports sorting.
3. On the field well menu, choose **Sort**, and then choose the ascending or descending sort order icon.

Using themes in Amazon Quick Sight

In Amazon Quick Sight, a *theme* is a collection of settings that you can apply to multiple analyses and dashboards. Amazon Quick Sight includes some themes, and you can add your own by using the theme editor. You can share themes with permissions levels set to user or owner. Anyone who has access to the theme can apply it to analyses and dashboards, or use **Save as** to make their own copy of it. Theme owners can also edit the theme and share it with others.

An analysis can have only one theme applied. If you apply a theme to an analysis (by using the **Apply** button), it instantly changes it for everyone—both analysis and dashboard viewers. To explore and save color options without applying them, avoid editing and saving the applied theme.

All colors come in pairs of background and foreground colors. The foreground colors are meant to specifically appear above their matching background color, so choose something that contrasts well.

The following table defines the different settings.

Group	Setting	What the setting changes
Main	Primary background	The background color used for visuals and other high emphasis UI.
Main	Primary foreground	The color of text and other foreground elements that appear over the primary background regions such as grid lines, borders, table banding, icons, and so on.
Main	Secondary background	The background color used for the sheet background and sheet controls.
Main	Secondary foreground	The foreground color used for any sheet title, sheet control text, or UI that appears over the secondary background.
Main	Accent	This setting is used as an interactive hint for the following: - Buttons - Borders around the selected visual - Loading indicators - Narration customizations

Group	Setting	What the setting changes
		• Links • Filter panes for embedded dashboards
Main	Accent foreground	The foreground color applies to any text or other elements that appear over the accent color.
Main	Font	The font to use for all of the text. You can choose from a variety of fonts supported by Amazon Quick Sight.
Data	Data colors	These are the data colors that charts rotate through when assigning colors to groups. You can add or remove colors to this list, or choose a color to change it.
Data	Min max gradient	The default minimum and maximum gradient colors to use when a gradient is used as a scale, for example in heat maps.

Group	Setting	What the setting changes
Data	Empty fill color	This is the color used with your data colors to indicate a lack of data. For example, this color appears in the empty portion of the progress bars that are shown in key performance indication (KPI) and gauge charts, or for empty heat map cells.
Layout	Border	This setting toggles the border around the visuals that aren't currently selected. The selected visual's border still displays the accent color.
Layout	Margin	This setting toggles the space between the sheet boundaries and the visuals.
Layout	Gutter	This setting shows or hides the space between visuals in the grid.
Other	Success Success foreground	These colors are used for success messages, for example the check mark for a successful download.
Other	Warning Warning foreground	These colors are used for warning and informational messages.
Other	Danger Danger foreground	These colors are used for error messages.

Group	Setting	What the setting changes
Other	Dimension Dimension foreground	These colors are used for the names of fields that are identified as dimensions. This option also sets the color for dimensions in the filter panel of embedded dashboards.
Other	Measure Measure foreground	These colors are used for the names of fields that are identified as measures. These colors also apply to measures in the filter panel of embedded dashboards.

To take a short tour of the theme viewer and editor

1. Open the [Quick console](#).
2. Open an analysis, or create a new one. You must have an analysis open to work with themes. However, the view you see with the theme applied is only a preview.

Themes are separate from analyses. No changes are made to your analysis, even when you save a theme.

3. Choose **Edit** from the application bar, and then choose **Themes**. The themes panel opens.
4. The list of themes shows the following:
 - **Applied theme** shows the theme that is currently applied to this analysis and its dashboards.
 - **My themes** shows themes that you created and themes that are shared with you.
 - **Starter themes** shows themes created by Amazon Quick Sight.
5. Each theme has context menu that you can access from the ... icon.

The actions that are available to you on each theme depend on your level of access.

- **Theme owners** – If you created the theme, or someone shared it with you and made you an owner, you can do the following:

- **Edit** – Change the settings for the theme, and save them.
 - **Save** – Save changes you made to the theme. If you edit the applied theme save your changes, the new theme settings apply to all the analyses and dashboards that use it. An informational message displays before you overwrite an applied theme.
 - **Share** – Share the theme and assign user or owner permissions to other people.
 - **Delete** – Delete a theme. You can't undo this action. An informational message displays before you confirm deletion.
 - **Theme users** – If someone shared the theme with you, or if it's an Amazon Quick Sight theme, you can do the following:
 - **Apply** – Apply the theme to the current analysis. This option also applies the theme to dashboards created from the analysis. An informational message displays before you overwrite an applied theme.
 - **Save as** – Save the current theme to another name, so you can edit it.
 - **Analysis authors** – If you have access to the analysis, but not the theme, you can do the following:
 - You can see the analysis with the theme applied.
 - You can see the theme in the **Theme** panel.
 - You can use **Save as** to create your own copy of the theme.
 - **Dashboard viewers** – If you have access to the dashboard, but not the theme, you can do the following:
 - You can see the dashboard with the theme applied.
 - You can't see the theme or its settings. Dashboard users can't see the **Theme** panel.
6. To explore a theme's settings, choose the icons on the left to see settings for colors.

The following procedure walks you through creating a theme. You can start on the analysis, or a copy of the analysis, that you want to use to preview the colors. Or you can start a new analysis. After you save the theme, you can apply it to the current analysis or to other analyses. If you share it, other people can use it too.

To use the theme editor

1. Open the [Quick console](#).
2. Open an analysis, or create a new one. Choose **Edit** from the application bar, and then choose **Themes**. The **Themes** panel opens.

You must have an analysis open to work with themes. However, the view you see with the theme applied is only a preview. Themes are separate from analyses. No changes are made to your analysis, even when you save a theme.

3. Choose **Main**. The color picker used in each of these settings is the standard one used throughout Amazon Quick Sight.

Set colors for **Primary background** and **Primary foreground** to use in visuals and other high impact UI.

Set colors for **Secondary background** and **Secondary foreground** to use in sheets and sheet controls.

Set colors for **Accent** and **Accent foreground** to use in interactive hints including buttons, borders around selected visuals, loading indicators, narration customizations, links, and the filter pane in embedded dashboards.

4. Choose **Data**.

Set the **Colors** to use as data colors. Charts rotate through these when assigning colors. You can add or delete colors, or change the order they're in by dragging and dropping. To change an existing color, select it to open the color editor.

Set colors for **Min max gradient** to use when a gradient is used as a scale, for example in heat maps.

Set the color for **Empty fill** to use when showing a lack of data, for example the unfilled part of a progress bar.

5. Choose **Layout**.

Enable or disable the **Border** check box to show or hide the border around the visuals that aren't currently selected.

Enable or disable the **Margin** check box to show or hide the space between the sheet boundaries and the visuals.

Enable or disable the **Gutter** check box to show or hide the space between visuals in the grid.

6. Choose **Other**.

Set the color for **Success** to use in success messages, for example when you successfully download a .csv file. The success foreground color isn't currently used.

Set the color for **Warning** to use in warning and informational messages. The warning foreground color isn't currently used.

Set the color for **Danger** to use in error messages. The danger foreground color isn't currently used.

Set the color for **Dimension** to use for the names of fields that are identified as dimensions. This option also sets the color for dimensions in the filter panel of embedded dashboards.

Set the color for **Measure** to use for the names of fields that are identified as measures. This option also sets the color for measures in the filter panel of embedded dashboards.

7. To save the theme, choose **Main** and give the new theme a name, and then choose **Save** at the upper-right of the browser.

Saving a theme doesn't apply it to the analysis, even though you can see a preview of the colors that uses the current analysis.

8. To share the theme, save or close the theme you are viewing. Find the theme in your theme collection. Choose **Share** from the context menu (...).
9. To apply the theme, save or close the theme you are viewing. Find the theme in your theme collection. Choose **Apply** from the context menu (...).

Accessing Amazon Quick Sight using keyboard shortcuts

You can use the following keyboard shortcuts to navigate a Amazon Quick Sight dashboard or analysis:

- Use the TAB key to navigate among menu options or visuals.
- Use the Shift+TAB keys to move backward to the previous selection.
- Use the Enter key to select a visual or menu option.
- Use the ESC key to clear the selection from a visual or menu item.

Using shortcuts within a visual

You can use the TAB, Shift+TAB, and Enter keys to navigate and select different fields within a selected visual. For example, say that you want to use a link that's a part of your visuals title. To do this, select the visual that you want, then use the TAB key until just the link is selected. Then, use the Enter key to click on the link.

You can also use these keyboard shortcuts to navigate and enter the on-visual menu on the upper-right corner of a visual. To do this, select the visual that you want and use the TAB key to get to the field that you want to select. If you miss the field that you want, use the Shift+TAB keys to go back a field.

Sharing and subscribing to data in Amazon Quick Sight with dashboards and reports

A *dashboard* is a read-only snapshot of an analysis that you can share with other Amazon Quick Sight users for reporting purposes. A dashboard preserves the configuration of the analysis at the time you publish it, including such things as filtering, parameters, controls, and sort order. The data used for the analysis isn't captured as part of the dashboard. When you view the dashboard, it reflects the current data in the data sets used by the analysis.

When you share a dashboard, you specify which users have access to it. Users who are dashboard viewers can view and filter the dashboard data. Any selections to filters, controls, or sorting that users apply while viewing the dashboard exist only while the user is viewing the dashboard, and aren't saved after it's closed. Users who are dashboard owners can edit and share the dashboard, and optionally can edit and share the analysis. If you want them to also edit and share the data set, you can set that up in the analysis.

A shared dashboard can also be embedded in a website or app, if you are using Enterprise edition. For more information about embedded dashboards, see [Embedded analytics for Amazon Quick Sight](#).

Use the following sections to learn how to publish and share dashboards, subscribe to threshold alerts, and send and subscribe to dashboard email reports.

Topics

- [Publishing dashboards](#)
- [Sharing Amazon Quick Sight dashboards](#)
- [Using Quick connectors in dashboard visuals](#)
- [Sharing your view of a Amazon Quick Sight dashboard](#)
- [Scheduling and sending Quick Sight reports by email](#)
- [Subscribing to email reports in Amazon Quick Sight](#)
- [Working with threshold alerts in Amazon Quick Sight](#)
- [Printing a dashboard or analysis](#)
- [Exporting Amazon Quick Sight analyses or dashboards as PDFs](#)
- [Error codes for failed PDF export jobs](#)
- [Organizing assets into folders for Amazon Quick](#)

Publishing dashboards

When you publish an analysis, that analysis becomes a dashboard that can be shared and interacted with by users of your Amazon Quick account or, in some cases, with anonymous users that aren't on your account. You can choose to publish one sheet of an analysis, all sheets in the analysis, or any other combination of sheets that you want. When you publish an interactive sheet, that sheet becomes an interactive dashboard that users can interact with. When you publish a pixel perfect report sheet, the sheet becomes a pixel perfect report that generates and saves a snapshot of the report's data when you schedule a report in Amazon Quick Sight. You can publish a dashboard that contains any combination of interactive sheets and pixel perfect reports from the same analysis.

For more information about scheduling a report, see [Scheduling and sending Quick Sight reports by email](#).

For more information about viewing a report's snapshots, see [Consuming pixel perfect reports in Amazon Quick Sight](#).

Use the following procedure to publish and optionally share a dashboard. You can also use this procedure to rename a published dashboard. A renamed dashboard retains its security and emailed report settings.

1. Open the analysis that you want to use. Choose **Publish**.
2. Do one of the following:
 - To create a new dashboard, choose **New dashboard**, and then type a dashboard name.
 - To replace an existing dashboard, do one of the following. Replacing a dashboard updates it without altering security or emailed report settings.
 - To update it with your changes, choose **Replace an existing dashboard** and then choose a dashboard from the list.
 - To rename it, choose **Replace an existing dashboard**, choose a dashboard from the list, and then select the pencil icon. Enter a new name to rename the existing dashboard and click the checkmark or press enter to confirm. When you publish a dashboard after renaming, it also saves any changes you made to the analysis. Changes to the analysis or dashboard are not persisted until you **Publish**. An initial version of a dashboard must be published in order to rename it.
3. (Optional) Choose the sheets that you want to publish in the **SHEETS** dropdown. When you select sheets to add to the new dashboard, the dropdown shows how many sheets are selected for publishing. The default option is **ALL SHEETS SELECTED**.

If you are replacing an existing dashboard, the sheets that are already published to the existing dashboard are pre-selected in the dropdown, unless you are publishing from an analysis you have not previously published from. You can make changes to this by selecting or de-selecting sheets from the dropdown list.

4. (Optional) Add comments on the changes you have made in the notes section, which is available to view under [Version History](#).
5. (Optional) To allow dashboard readers to share data stories, choose **Allow sharing data stories**. For more information about data stories, see [Working with data stories in Amazon Quick Sight](#).
6. (Optional) Open **More Settings**. These options are only available if at least one sheet in the new dashboard is an interactive sheet.

 Note

This is a scrollable window. Scroll down in the **Publish a dashboard** window to view all available options.

There are some options that you can turn off to simplify the experience for this dashboard, as follows:

- For **Dashboard options**:
 - Leave **Expand on-sheet controls by default** cleared to show a simplified view. This is disabled by default. To show the controls by default, turn on this option.
 - Clear **Enable advanced filtering on the left pane** to remove the ability for dashboard viewers to filter the data themselves. If they create their own filters, the filters exist only while the user is viewing the dashboard. Filters can't be saved or reused.
 - Clear **Enable on-hover tooltip** to turn off tooltips.
- For **Visual options**:
 - Clear **Enable visual menu**, to turn off the on-visual menu entirely.
 - Clear **Enable download options** if your dashboard viewers don't need to be able to download data from the visuals in the dashboard. The CSV file includes only what is currently visible in the visual at the time they download it. The viewer downloads data by using the on-visual menu on each individual visual.
 - Clear **Enable maximize visual option** to turn off the ability to enlarge visuals to fill the screen.
- For **Data point options**:
 - Clear **Enable drill up/down** if your dashboard doesn't offer drillable field hierarchies.
 - Clear **Enable on-click tooltip** to turn off tooltips that appear when the reader chooses (clicks on) a data point.
 - Clear **Enable sort options** to turn off sorting controls.

7. Choose **Publish dashboard**.

If you renamed the existing dashboard, the top of the screen refreshes to show the new name.

8. (Optional) Do one of the following:

- To publish a dashboard without sharing, choose **x** at the upper right of the **Share dashboard with users** screen when it appears. You can always share the dashboard later by choosing **File>Share** from the application bar.
- To share the dashboard, follow the procedure in [Sharing Amazon Quick Sight dashboards](#).

After you complete these steps, you complete creating and sharing the dashboard. Subscribers of the dashboard receive email that contains a link to the dashboard. Groups don't receive invitation emails.

Copying an Amazon Quick Sight dashboard

If you have co-owner access or **Save as** privileges on an existing dashboard, you can copy it. To do this, create a new analysis from the dashboard and then create a new dashboard from the analysis that you copied.

After you save the original dashboard as a new analysis, you can collaborate on it by sharing the new analysis with other users. For example, you can use this workflow to preserve a production version of the dashboard, while also developing or testing a new version of it.

To copy a dashboard

1. Sign in to Quick and choose **Dashboards** from the homepage.
2. Open the dashboard that you want to duplicate.
3. At upper right, choose **Save As**, and then enter a name for the new analysis. When you save an existing dashboard using **Save As**, it creates an analysis based on the dashboard.

Note

If you can't see **Save as**, check with your administrator that you have the right permissions.

4. (Optional) Make changes to the new analysis.
5. (Optional) Share the analysis with other users so you can collaborate on changes. All users who have access can make changes to the new analysis.

To share the analysis with other users, choose **Share** from the top right corner of the page, and then choose **Share analysis**.

6. (Optional) Create a new dashboard with your changes to the new analysis by choosing **Share**, and then choosing **Publish Dashboard**.

For more information, see the following:

- [Sharing Amazon Quick Sight dashboards](#)
- [Sharing Quick Sight analyses](#)

Deleting an Amazon Quick Sight dashboard

When you delete an Amazon Quick Sight dashboard, the dashboard is permanently removed from your account and all folders that the dashboard was a part of. You will no longer be able to access the deleted dashboard. You can only delete dashboards that you own or co-own. Use the following procedure to delete a dashboard.

To delete a dashboard

1. On the **Dashboards** tab of the Amazon Quick homepage, choose the details icon (vertical dots :) on the dashboard that you want to delete.
2. Choose **Delete**. Then choose **Delete** again to confirm that you want to delete the dashboard. Deleting a dashboard permanently deletes the dashboard from your account, and the dashboard will disappear from all folders that it belonged to. You can still access and create other dashboards from the analysis that the deleted dashboard was published from.

Publishing a previous version of an Amazon Quick Sight dashboard

Each time you make updates to an analysis and publish it, a new version of the Amazon Quick Sight dashboard is created. To revert back to a previous version of a dashboard, you can search for it under the dashboard's **Version History** and publish the former version you are interested in. Each dashboard can store up to 1000 versions that are never deleted. Use the following procedure to publish a previous version of a dashboard.

To publish a previous version of a dashboard

1. On the **Dashboards** tab of the Amazon Quick homepage, choose the dashboard that you want to manage.

2. Choose **Version History** on the toolbar on the right. The version of the dashboard that is currently published, as well as previous available versions, will appear in a list. Any comments that were added in the notes section will appear with the respective version.
3. Select the version of the dashboard you are interested in. You can see when this version was published and which user published it.
4. To revert to this version, select **Publish**. Click **Confirm** to publish the version.

Sharing Amazon Quick Sight dashboards

By default, dashboards in Amazon Quick Sight aren't shared with anyone and are only accessible to the owner. However, after you publish a dashboard, you can share it with other users or groups in your Amazon Quick account. You can also choose to share the dashboard with everyone in your Quick account and make the dashboard visible on the Quick homepage for all users in your account. Additionally, you can copy a link to the dashboard to share with others who have access to it.

Important

Users who have access to the dashboard can also see the data used in the associated analysis.

After you share a dashboard, you can review the other users or groups that have access to it and control the type of access they have. You can revoke access to the dashboard for any user. You can also remove yourself from it.

You can also embed interactive dashboards and visuals in websites and apps by copying the dashboard or visual embed code and pasting it in your application. For more information, see [Embedding Amazon Quick Sight visuals and dashboards for registered users with a 1-click embed code](#).

Granting access to a dashboard

You can share dashboards and visuals with specific users or groups in your account or with everyone in your Amazon Quick account. Or you share them with anyone on the internet. You can share dashboards and visuals by using the Quick console or the Quick Sight API. Access to a shared visual depends on the sharing settings that are configured for the dashboard that the visual

belongs to. To share and embed visuals to your website or application, adjust the sharing settings of the dashboard that it belongs to. For more information, see the following:

- [Granting individual Amazon Quick Sight users and groups access to a dashboard in Amazon Quick Sight](#)
- [Granting everyone in your Amazon Quick Sight account access to a dashboard](#)
- [Granting anyone on the internet access to an Amazon Quick Sight dashboard](#)
- [Granting everyone in your Amazon Quick account access to a dashboard with the Quick Sight API](#)
- [Granting anyone on the internet access to an Amazon Quick Sight dashboard using the Quick Sight API](#)

Granting individual Amazon Quick Sight users and groups access to a dashboard in Amazon Quick Sight

Use the following procedure to grant access to a dashboard.

To grant users or groups access to a dashboard

1. Open the published dashboard and choose **Share** at upper right. Then choose **Share dashboard**.
2. In the **Share dashboard** page that opens, do the following:
 - a. For **Invite users and groups to dashboard** at left, enter a user email or group name in the search box.

Any users or groups that match your query appear in a list below the search box. Only active users and groups appear in the list.

- b. For the user or group that you want to grant access to the dashboard, choose **Add**. Then choose the level of permissions that you want them to have.

You can select **Viewer** or **Co-owner**, depending on the user's Quick role. The available permissions for each role are as follows:

- **Readers** – Quick readers can only be granted **Viewer** access to dashboards. They can view, export, and print the dashboard, but they can't save the dashboard as an analysis. They can view, filter, and sort the dashboard data. They can also use any controls or custom actions that are on the dashboard. Any changes that they make to the

dashboard exist only while they are viewing it, and aren't saved after they close the dashboard.

- **Authors** – Quick authors can be granted **Viewer** or **Co-owner** access to dashboards.
 - Authors with Viewer access can view, export, and print the dashboard. They can view, filter, and sort the dashboard data. They can also use any controls or custom actions that are on the dashboard. Any changes that they make to the dashboard exist only while they are viewing it, and aren't saved after they close the dashboard.

However, they can save the dashboard as an analysis, unless the dashboard owner specifies otherwise. This privilege grants them read-only access to the datasets so that they can create new analyses from them. The owner has the option to provide them with the same permissions to the analysis. If the owner wants them also to edit and share the datasets, the owner can set that up inside the analysis.

- Authors with Co-owner access can view, export, and print the dashboard. They can also edit, share, and delete it. They can also save the dashboard as an analysis, unless the dashboard owner specifies otherwise. This privilege grants them read-only access to the datasets so that they can create new analyses from them. The owner has the option to provide them with the same permissions to the analysis. If the owner wants them to also edit and share the datasets, the owner can set that up inside the analysis.
- **Groups** – Quick groups can only be granted **Viewer** access to dashboards. They can view, export, and print the dashboard, but they can't save the dashboard as an analysis.

After you add a user or group to the dashboard, you can see information about them in the **Manage permissions** section, under **Users & Groups**. You can see their user name, email, permission level, and "save as" privileges.

To allow a user or group to save the dashboard as an analysis, turn on **Allow "save as"** in the **Save as Analysis** column.

- c. To add more users to the dashboard, enter another user email or group name in the search box and repeat steps A and B.

Granting everyone in your Amazon Quick Sight account access to a dashboard

Alternatively, you can share your Amazon Quick Sight dashboard with everyone in your account. When you do this, everyone in your account can access the dashboard, even if they weren't granted

access individually and assigned permissions. They can access the dashboard if they have a link to it (shared by you) or if it's embedded.

Sharing the dashboard with everyone in your account doesn't affect email reports. For example, suppose that you choose to share the dashboard with everyone in your account. Suppose also that you choose **Send email report to all users with access to dashboard** when setting up an email report for the same dashboard. In this case, the email report is sent only to people who have access to the dashboard. They receive access either through someone explicitly sharing it with them, through groups, or through shared folders.

To grant everyone in your account access to a dashboard

1. Open the published dashboard and choose **Share** at upper right. Then choose **Share dashboard**.
2. In the **Share dashboard** page that opens, for **Enable access for** at bottom left, toggle on **Everyone in this account**. Accounts that sign in with an Active Directory can't access the **Everyone in this account** switch. Accounts that use Active Directory can enable this setting with an `UpdateDashboardPermissions` API call. For more information on `UpdateDashboardPermissions`, see [UpdateDashboardPermissions](#) in the *Amazon Quick Sight API Reference*.
3. (Optional) Toggle on **Discoverable in Quick Sight**.

When you share a dashboard with everyone in the account, owners can also choose to make the dashboard discoverable in Quick Sight. A dashboard that's discoverable appears in everyone's list of dashboards on the **Dashboards** page. When this option is turned on, everyone in the account can see and search for the dashboard. When this option is turned off, they can only access the dashboard if they have a link or if it's embedded. The dashboard doesn't appear on the **Dashboards** page, and users can't search for it.

Granting anyone on the internet access to an Amazon Quick Sight dashboard

Applies to: Enterprise Edition

You can also share your Amazon Quick Sight dashboard with anyone on the internet from the **Share** menu in the Amazon Quick console. When you do this, anyone on the internet will be able to

access the dashboard, even if they aren't a registered user on your Quick account, when you share the dashboard link or embed the dashboard.

Use the following sections to grant anyone on the internet access to dashboard when you share it.

Topics

- [Before you start](#)
- [Granting anyone on the internet access to a dashboard](#)
- [Updating a publicly shared dashboard](#)
- [Turning off public sharing settings](#)

Before you start

Before you can share a dashboard with anyone on the internet, make sure to do the following:

1. Turn on session capacity pricing on your account. If you have not turned on session capacity pricing on your account, you won't be able to update your account's public sharing settings.
2. Assign public sharing permissions to an administrative user in the IAM console. You can add these permissions with a new policy or you can add the new permissions to an existing user.

The following sample policy provides permissions for use with `UpdatePublicSharingSettings`.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": "quicksight:UpdatePublicSharingSettings",
      "Resource": "*",
      "Effect": "Allow"
    }
  ]
}
```

Accounts that don't want users with administrator access to use this feature can add an IAM policy that denies public sharing permissions. The following sample policy denies permissions for use with `UpdatePublicSharingSettings`.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": "quicksight:UpdatePublicSharingSettings",
      "Resource": "*",
      "Effect": "Deny"
    }
  ]
}
```

For more information on using IAM with Quick Sight, see [Using Quick with IAM](#).

You can also use the "Deny" policy as a Service Control Policy (SCP) if you don't want any of the accounts in your organization to have the public sharing feature. For more information, see [Service control policies \(SCPs\)](#) in the *AWS Organizations User Guide*.

3. Turn on public sharing on your Amazon Quick account.
 1. From the Amazon Quick start page, choose your user icon at the upper right of your browser window, and then choose **Manage Quick**.
 2. In the page that opens, scroll down to the **Permissions** section.
 3. Choose **Public access to dashboards** at left.
 4. On the page that opens, choose **Anyone on the internet**.

When you turn on this setting, a pop up will appear asking you to confirm your choice. Once you've confirmed your choice, you can grant the public access to specific dashboards and share those dashboards with them with a link or by embedding the dashboard in a public application, wiki, or portal.

Granting anyone on the internet access to a dashboard

To grant anyone on the internet access to a dashboard

1. In Quick, open the published dashboard that you want to share. You must be the owner or a co-owner of the dashboard.

2. In the published dashboard, choose the **Share** icon at upper-right, and then choose **Share dashboard**.
3. In the **Share dashboard** page that opens, choose **Anyone on the internet (public)** in the **Enable access for** section at bottom-left.

This setting allows you to share the dashboard with anyone on the internet with the share link or when embedded. Turning on this switch also automatically turns on the **Everyone in this account** option, which means that the dashboard will be shared with anyone in your Quick account. If you do not want this, turn off this option.

4. In the **Allow public access** pop-up that appears, enter `confirm` in the box to confirm your choice, and then choose **Confirm**.

After you confirm your dashboard's access settings, an orange **PUBLIC** tag appears at upper right of your dashboard in the Amazon Quick console. Additionally, an eye icon appears on the dashboard on the Quick Sight Dashboards page, both in tile and list view.

Note that when public access is turned on, the dashboard can only be accessed using the link or when embedded using the embed code. For more information about sharing a link to the dashboard, see [Sharing a link a shared dashboard](#). For more information about embedding dashboards for anyone on the internet, see [Embedding Amazon Quick Sight visuals and dashboards for anonymous users with a 1-click embed code](#).

Updating a publicly shared dashboard

Use the following procedure to update a shared dashboard that can be accessed by anyone on the internet.

To update a public dashboard:

1. From the Amazon Quick start page, choose the analysis that is tied to the dashboard that you want to update and make your desired changes. You must be the owner or a co-owner of the analysis.
2. In the analysis, choose **Publish**.
3. In the pop-up that appears, choose **Replace an existing dashboard** and select the public dashboard that you want to update.
4. To confirm your choice, enter `confirm` and then choose **Publish dashboard**.

Once you choose **Publish dashboard**, your public dashboard is updated to reflect the new changes.

Turning off public sharing settings

You can turn off public sharing settings for dashboards at anytime. You can turn off public sharing for an individual dashboard, or for all dashboards in your account. Visual sharing settings are determined at the dashboard level. If you turn off public sharing settings to a dashboard that holds a visual that you are embedding, users won't be able to access the visual.

The following table describes the different scenarios for when a dashboard is publicly available.

Account-level public setting	Dashboard-level public setting	Public access	Visual indicators
Off	Off	Off	None
On	Off	Off	None
On	On	Yes	An orange badge appears on the dashboard and an eye icon appears on the dashboard in the Dashboards page.
Off	On	No	A grey badge appears on the dashboard and an eye icon with a slash appears on the dashboard in the Dashboards page. It can take up to two minutes for

Account-level public setting	Dashboard-level public setting	Public access	Visual indicators
			a dashboard's public access to be revoked.

To turn off public sharing for a single dashboard

1. In Amazon Quick, open the published dashboard that you no longer want to share. You must be the owner or a co-owner of the dashboard.
2. In the published dashboard, choose the **Share** icon at upper-right, and then choose **Share dashboard**.
3. In the **Share dashboard** page that opens, toggle off the **Anyone on the internet (public)** switch in the **Enable access for** section at bottom-left.

This action will remove public access to the dashboard. It will now only be accessible to users that it has been shared with.

To turn off public sharing settings for all dashboards in a Quick user account

1. From the Amazon Quick start page, choose your user icon at upper right of your browser window, and then choose **Manage Quick**.
2. In the page that opens, scroll down to the **Permissions** section.
3. Choose **Public access to dashboards** at left.
4. On the page that opens, toggle off the **Anyone on the internet** switch.

When you disable public sharing settings from the **Public sharing** menu, a pop-up will appear asking you to confirm your choice. Select **I have read and acknowledge this change** and then choose **Confirm** to confirm your choice.

This action will remove public access to every dashboard on your account. Dashboards that were visible to anyone on the internet will now only be accessible to users that each dashboard has been shared with. Individual dashboards that have their public settings turned on will have a gray badge and the eye icon that appears on the **Dashboards** page will have a strike through

it to indicate that the account level public settings are disabled and that the dashboard can't be viewed. It can take up to two minutes for a dashboard's public access to be revoked.

If your session capacity pricing subscription has expired, public sharing settings will be automatically removed across your account. Renew your subscription to restore access to public sharing settings.

Granting everyone in your Amazon Quick account access to a dashboard with the Quick Sight API

Intended audience: Amazon Quick developers

Alternatively, you can grant everyone in your account access to the dashboard with the Quick Sight API using the `UpdateDashboardPermissions` operation.

The following example API request illustrates how to do so using an AWS CLI command. It grants link permissions on the dashboard in your account, and allows the following operations: `DescribeDashboard`, `QueryDashboard` and `ListDashboard`.

```
aws quicksight update-dashboard-permissions \  
--aws-account-id account-id \  
--region aws-directory-region \  
--dashboard-id dashboard-id \  
--grant-link-permissions  
Principal="arn:aws:quicksight:aws-directory-region:account-id:namespace/default",  
Actions="quicksight:DescribeDashboard, quicksight:QueryDashboard,  
quicksight:ListDashboardVersions"
```

The response for the preceding request looks similar to the following.

```
{  
  "Status": 200,  
  "DashboardArn": "arn:aws:quicksight:AWSDIRECTORYREGION:ACCOUNTID:dashboard/  
DASHBOARDID",  
  "DashboardId": "DASHBOARDID",  
  "LinkSharingConfiguration": {  
    "Permissions": [  
      {  
        "Actions": [  

```

```

    "quicksight:DescribeDashboard",
    "quicksight:ListDashboardVersions",
    "quicksight:QueryDashboard"
  ],
  "Principal": "arn:aws:quicksight:AWSDIRECTORYREGION:ACCOUNTID:namespace/default"
}
],
"Permissions": [
  // other dashboard permissions here
],
"RequestId": "REQUESTID"
}

```

You can also prevent all users in your account from accessing the dashboard using the same API operation. The following example request illustrates how by using a CLI command.

```

aws quicksight update-dashboard-permissions \
--aws-account-id account-id \
--region aws-directory-region \
--dashboard-id dashboard-id \
--revoke-link-permissions
Principal="arn:aws:quicksight:aws-directory-region:account-id:namespace/default",
Actions="quicksight:DescribeDashboard, quicksight:QueryDashboard,
quicksight:ListDashboardVersions"

```

For more information, see [UpdateDashboardPermissions](#) in the *Amazon Quick API Reference*.

When all users in a Quick user account are granted access to the dashboard, the following snippet is added to AWS CloudTrail log as part of the eventName `UpdateDashboardAccess`, and the eventCategory `Management`.

```

"linkPermissionPolicies":
[
{
  "principal": "arn:aws:quicksight:AWSDIRECTORYREGION:ACCOUNTID:
    namespace/default",
  "actions":
  [
    "quicksight:DescribeDashboard",
    "quicksight:ListDashboardVersions",
    "quicksight:QueryDashboard"
  ]
}
]

```

```
]
}
]
```

Granting anyone on the internet access to an Amazon Quick Sight dashboard using the Quick Sight API

Alternatively, you can grant anyone on the internet access to the dashboard with the Amazon Quick Sight API using the `UpdateDashboardPermissions` operation.

Before you begin, make sure to grant everyone in your account access to the dashboard. For more information, see [Granting everyone in your Amazon Quick account access to a dashboard with the Quick Sight API](#).

The following example API request illustrates how to grant anyone on the internet access to a dashboard using an AWS CLI command. It grants link permissions on the dashboard in your account, and allows the following operations: `DescribeDashboard`, `QueryDashboard` and `ListDashboardVersions`.

```
aws quicksight update-dashboard-permissions
--aws-account-id account-id
--region aws-directory-region
--dashboard-id dashboard-id
--grant-link-permissions
Principal="arn:aws:quicksight::publicAnonymousUser/*",
Actions="quicksight:DescribeDashboard, quicksight:QueryDashboard,
quicksight:ListDashboardVersions"
```

The response for the preceding request looks similar to the following.

```
{
  "Status": 200,
  "DashboardArn": "arn:aws:quicksight:AWSDIRECTORYREGION:ACCOUNTID:dashboard/DASHBOARDID",
  "DashboardId": "DASHBOARDID",
  "LinkSharingConfiguration": {
    "Permissions": [
      {
        "Actions": [
          "quicksight:DescribeDashboard",
          "quicksight:ListDashboardVersions",
          "quicksight:QueryDashboard"
        ]
      }
    ]
  }
}
```

```

        ],
        "Principal":
"arn:aws:quicksight:AWSDIRECTORYREGION:ACCOUNTID:namespace/default"
    },
    "Principal": "arn:aws:quicksight:::publicAnonymousUser/*",
    "Actions": [
        "quicksight:DescribeDashboard",
        "quicksight:ListDashboardVersions",
        "quicksight:QueryDashboard"
    ]
    }
    ]
},
"Permissions": [
    // other dashboard permissions here
],
"RequestId": "REQUESTID"
}

```

You can also prevent anyone on the internet from accessing the dashboard using the same API operation. The following example request illustrates how by using a CLI command.

```

aws quicksight update-dashboard-permissions \
--aws-account-id account-id \
--region aws-directory-region \
--dashboard-id dashboard-id \
--revoke-link-permissions
Principal="arn:aws:quicksight:::publicAnonymousUser/*",
Actions="quicksight:DescribeDashboard, quicksight:QueryDashboard,
quicksight:ListDashboardVersions"

```

For more information, see [UpdateDashboardPermissions](#) in the *Amazon Quick API Reference*.

When anyone on the internet is granted access to the dashboard, the following snippet is added to AWS CloudTrail log as part of the eventName `UpdateDashboardAccess`, and the eventCategory `Management`.

```

"linkPermissionPolicies":
[
{
    "principal": "arn:aws:quicksight:::publicAnonymousUser/*",
    "actions":

```

```
[
  "quicksight:DescribeDashboard",
  "quicksight:ListDashboardVersions",
  "quicksight:QueryDashboard"
]
}
```

Sharing a link a shared dashboard

After you grant users access to a dashboard, you can copy a link to it and send it to them. Anyone with access to the dashboard can access the link and see the dashboard.

To send users a link to the dashboard

1. Open the published dashboard and choose **Share** at upper right. Then choose **Share dashboard**.
2. In the **Share dashboard** page that opens, choose **Copy link** at upper left.

The link to the dashboard is copied to your clipboard. It's similar to the following,

```
https://quicksight.aws.amazon.com/sn/accounts/accountid/
dashboards/dashboardid?directory_alias=account_directory_alias
```

Users and groups (or all users on your Quick account) who have access to this dashboard can access it by using the link. If they are accessing Quick for the first time, they will be asked to sign in with their email address or Quick user name and password for the account. After they sign in, they will have access to the dashboard.

View who has access to a shared dashboard

Use the following procedure to see which users or groups have access to the dashboard.

1. Open the published dashboard and choose **Share** at upper right. Then choose **Share dashboard**.
2. In the **Share dashboard** page that opens, under **Manage permissions**, review the users and groups, and their roles and settings.

You can search to locate a specific user or group by entering their name or any part of their name in the search box at upper right. Searching is case-sensitive, and wildcards aren't supported. Delete the search term to return the view to all users.

Revoke access to a shared dashboard

Use the following procedure to revoke user access to a dashboard.

To revoke user access to a dashboard

1. Open the dashboard and choose **Share** at top right. Then choose **Share dashboard**.
2. In the **Share dashboard** page that opens, under **Manage permissions**, locate the user that you want to remove and choose the delete icon at far right.

Using Quick connectors in dashboard visuals

Prerequisites

Before you begin, make sure to [create at least one connector](#).

The connector must meet these requirements:

- Uses the **User Auth** authentication method
- Uses one of the following integrations:
 - Atlassian Jira Cloud
 - Microsoft Outlook
 - Microsoft Teams
 - Salesforce
 - ServiceNow
 - Slack

Enable Quick actions on a dashboard to use connectors

To enable Quick actions on a dashboard to use connectors

1. If a dashboard exists, go to the source analysis of the dashboard. Otherwise, [create a new analysis](#).
2. Choose **Publish**.
3. Choose between **New Dashboard** or **Replace existing dashboard**.
4. Choose the **Enable Quick actions** checkbox under **Dashboard options**.
5. Choose **Publish dashboard**.

Use connectors on a visual

To use connectors on a visual

1. Open a dashboard with the **Enable Quick actions** publishing option turned on.
2. Hover over a visual.
3. Choose the lightening bolt icon.
4. A menu appears with a list of all supported connectors and actions.
5. Choose the desired action from the list.
6. If you have not used the connector before, or if your previous login credentials have expired, an authentication modal will appear. Log in with appropriate credentials for your organization.
7. An **Action** form appears in the right pane.
8. Enter all the information you need to include with the action.
9. Some fields allow the inclusion of autofill values. Choose **Autofill** to open the menu. Choose the values you need and they will be added to your entered text.
 - **Today's date**: Injects today's date
 - **Visual name**: Injects visual name
 - **All**: Injects both of the above
10. Some actions support the ability to include an attachment. You can optionally attach an image of the visual with these actions by selecting the **Visual image** checkbox.
11. Select the action button at the bottom of the form to invoke the action.

Security and customizations

Custom Permissions/Capability Customization

- **Actions** capability: You cannot see or use actions if your user or role is restricted the permission to use the Actions capability

To learn more about custom permissions, see [Custom permissions in Amazon Quick](#).

Row Level Security (RLS) / Column Level Security (CLS)

- You cannot see or use actions on visuals that are based on datasets that use RLS or CLS.

To learn more about RLS, see [Using row-level security in Amazon Quick](#).

To learn more about CLS, see [Using column-level security to restrict access to a dataset](#).

Dashboard publishing options

- Enable Quick actions
 - You cannot see or use actions on any visuals of a dashboard that was published with the **Enable Quick actions** publishing option disabled.

To learn more about dashboard publishing options, see [Publishing dashboards](#).

Limitations

Visual Image attachment support

The following visual types do not support image attachments:

- High charts (when HTML is used)
- ML Insights (when HTML is used)
- Textbox and insights (when HTML is used)
- Custom content

 Note

For these visuals, the **Visual image** checkbox will not appear on the UI.

Sharing your view of a Amazon Quick Sight dashboard

While interacting with a published dashboard, you can choose to share a unique link to the dashboard with only your changes. For example, if you filter the data in the dashboard, you can share what you see with others who have permissions to see the dashboard. That way, they can see what you see, without your having to create a new dashboard.

When others access your view of the dashboard by using the link that you sent them, they see the dashboard exactly as it was when the link was created. They see any parameters, filters, or controls that you changed.

To share your view of a dashboard

1. Open the published dashboard, and make any changes that you want.
2. Choose **Share** at upper right, and then choose **Share this view**.
3. On the **Share using a link** page that opens, choose **Copy link**.
4. Paste the link in an email or IM message to share it with others.

Only people with permissions to see the dashboard in Quick Sight can access the link.

Scheduling and sending Quick Sight reports by email

 Important

Amazon Quick Sight in the Europe (Spain) (eu-south-2) region uses an internal email service (Amazon SES) in the Europe (Ireland) (eu-west-1) to send emails to Quick Sight users. Customer data that's included in scheduled reports, alerts, and other features are passed by email from Europe (Spain) to Europe (Ireland) before it reaches Quick Sight users. As a privacy protection measure, the following features that send customer data in emails have been limited or disabled by default.

- File attachments and sheet previews in Scheduled Report emails. The [download link option](#) is the default.

- Emails that use threshold alerts.
- Anomaly detection alerts.

For more information about AWS privacy features, see [Privacy Features of AWS Services](#).

In Enterprise edition, you can send a dashboard in report form either once or on a schedule (daily, weekly, monthly, or yearly). You can email the reports to users or groups who share your Amazon Quick subscription. To receive email reports, the users or group members must meet the following conditions:

- They are part of your Quick subscription.
- You already shared the dashboard with them.
- Amazon Quick Sight can't send scheduled emails to more than 5,000 members.

Amazon Quick Sight generates a custom email snapshot for each user or group based on their data permissions, which are defined in the dashboard. Row Level Security (RLS), Column Level Security (CLS) and Dynamic Default Parameters for email reports works for both scheduled and ad hoc (one-time) emails.

Quick authors can run scheduled reports with the **Report now** button in the Quick console or with the [StartDashboardSnapshotJobSchedule](#) API.

Subscribers who are readers see an option for **Reports** on the dashboard when an email report is available for that dashboard. They can use the **Schedules** menu to subscribe to or unsubscribe from the emails. For more information, see [Subscribing to email reports in Amazon Quick Sight](#).

You can create up to five schedules for each dashboard.

Quick Sight dashboard viewers can also schedule their own reports for themselves from a Quick Sight dashboard. For more information about reader generated reports, see [Creating a reader generated report in Amazon Quick Sight](#).

Use the following topics to learn more about email report settings and report billing.

Topics

- [Configuring email report settings for a Quick Sight dashboard](#)
- [How billing works for email reports](#)

Configuring email report settings for a Quick Sight dashboard

Applies to: Enterprise Edition

In Amazon Quick Enterprise edition, you can email a report from any sheet in a dashboard. You can send reports from interactive dashboards and pixel perfect report sheets. Schedules include settings for when to send them, the contents to include, and who receives the email. You can view a sample report and a list of the datasets used in the report. To set up or change the schedule sent from a dashboard, make sure that you're an owner or co-owner of the dashboard.

If you have access to the dashboard, you can change your subscription options by opening your view of the dashboard. For more information on how this works, see [Subscribing to email reports in Amazon Quick Sight](#).

Scheduling options that are available for an email report include the following:

- **Once (Does not repeat)** – Sends the report only once at the date and time that you choose.
- **Daily** – Repeats daily at the time that you choose.
- **Weekly** – Repeats each week on the same day or days at the time that you choose. You can also use this option to send reports in weekly intervals, such as every other week or every three weeks.
- **Monthly** – Repeats each month on the same day of the month at the time that you choose. You can also use this option to send reports on specific days of the month, such as the second Wednesday or the last Friday of each month.
- **Yearly** – Repeats each year on the same day of the month or months selected at the time that you choose. You can also use this option to send reports on specific days or sets of days in selected months. For example, you can configure a report to be sent on the first Monday of January, March, and September, or on July 14th, or on the second day of February, April, and June each year.
- **Custom** – Configure your own scheduled report that best fits your business needs.

You can customize the title of the report, the optional email subject, and the body text.

Although you can configure the report so that everyone who has access receives a copy, this is not usually the best plan. We recommend limiting automated emails, especially those sent to groups.

You can start with a small number of subscribers by choosing specific people from the access list. Verify your company's policy before subscribing anyone to a subscription.

You can directly add people to a report subscription in these ways:

- (Recommended) Choose recipients from the provided access list to specify and maintain a list of people who you want to email reports to. You can use the search box to find people by email or group name.
- To send reports to all of the dashboard's subscribers, choose **Send email report to all users with access to dashboard** when prompted.

Anyone else who wants to get the emails can open the dashboard and set their own subscription options to either opt in or opt out.

Important

When you share the dashboard with new Quick user names or groups, they automatically start receiving the email reports. If you don't want this to happen, you need to edit the report settings each time you add people to the dashboard.

For existing email schedules, you can pause the schedule in Amazon Quick Sight while you make changes. In the **Schedules** pane, you can pause or resume a scheduled report with the toggle that appears under each report. Pausing a report does not delete the report's schedule from Quick Sight.

If your report includes custom visuals, be aware that you can't include images from a private network in an email report, even if you can access the images. If you want to include an image, use a publicly available one.

Before you begin, make sure that you are using Amazon Quick Enterprise edition and that you have shared the dashboard with intended recipients.

To create or change an email report

1. Open Quick and choose **Dashboards** on the navigation pane at left.
2. Open a dashboard to configure its email report.
3. At top right, choose **Schedules**, and then choose **Schedules**.

4. Choose **ADD SCHEDULE**.
5. In the **New schedule** pane that appears, enter the schedule name. Optionally, add a description for the new schedule.
6. In the **Content** tab, toggle the **PDF**, **CSV**, or **Excel** switches to choose the report format. CSV and Excel format are currently supported for pixel perfect reports.
7. In the **Sheet** dropdown on the **Content** tab, choose the sheet that you want to schedule a report for.

If you choose **CSV** or **Excel**, choose the table or pivot table visuals from any sheet of the dashboard that you want to include in the report. You can select up to 5 visuals for each schedule.

If you choose **Excel**, one Excel workbook is generated as a final output.

8. In the **Dates** tab, choose the frequency for the report in the **Repeat** dropdown. If you're not sure, choose **Send once (Does not repeat)**.
9. For **Start date**, choose the start date and runtime that you want to send the first report on.
10. For **Timezone**, choose the time zone from the dropdown.
11. In the **Email** tab, for **E-mail subject line**, enter a custom subject line, or leave it blank to use the report title.
12. Enter the email addresses of the Quick group name of the users or groups that you want to receive the report. You can also select the **Send to all users with access** box to send the report to everyone that has access to the dashboard in your account.
13. For **Email header**, enter the header that you want the email report to show.
14. (Optional) For **E-mail body text**, leave it blank or enter a custom message to display at the beginning of the email.
15. (Optional) For PDF attachments, you can choose **Include sheet in email body** to show the first page of the PDF snapshot in the email's body.
16. Choose the method of attachment that you want the report to use. The following options are available.
 - **File attachment**– uploads an attachment of the snapshot to the email. The email size can't exceed 10 MB. This limit includes all attachments.
 - **Download link**– adds a link to the email body that users can access to download the snapshot report. When a user chooses the download link, they are prompted to sign in before the report starts to download. The link expires one year after the report is sent.

17. (Optional, recommended) To send a sample of the report before you save changes, choose **Send test report**. This option displays beside the user name of the owner of the dashboard.
18. Do one of the following:
 - (Recommended) Choose **Save** to confirm your entries.
 - To immediately send a report, choose **Save and run now**. The report is sent immediately, even if your schedule's start date is in the future.

How billing works for email reports

Authors and admins can receive any number of email reports at no extra charge.

For readers (users in the reader role), it costs one session per report, up to the monthly maximum. After receiving an email report, the reader gets a session credit to access the dashboard at no additional cost during the same month. Reader session credits don't carry over to the next billing month.

For a reader, charges for email reports and interactive sessions both accrue up to the monthly maximum charge. For readers who hit the monthly max charge, there are no further charges, and they can receive as many additional email reports as they need.

Subscribing to email reports in Amazon Quick Sight

In Enterprise edition, Amazon Quick authors can set up subscriptions to a dashboard in report form. For more information, see [Scheduling and sending Quick Sight reports by email](#). Quick readers and authors can then subscribe to a dashboard and adjust their report settings. For more information about subscribing to dashboards as a reader, see [Subscribing to Amazon Quick Sight dashboard emails and alerts](#).

Use the following procedure to change your subscription and report settings for a specific dashboard.

1. First, open a dashboard that is shared with you, or a dashboard that you own or co-own.
2. Choose the **Reports** icon at top right.
3. The **Change report preferences** screen appears. This screen shows the current report schedule, in addition to the subscription and optimization options.

For **Subscription**, choose **Subscribe** to start receiving reports, or **Unsubscribe** to stop receiving reports.

Under **Optimize**, choose the device you prefer to view the report on.

- If you usually use a mobile device or you prefer to view reports in a portrait format, choose **Viewing on a mobile device**. When you receive the report, the visuals display in a single vertical column.
- If you usually use a desktop or you prefer to view reports in a landscape format, choose **Viewing on a desktop**. When you receive the report, the visuals display in the same layout shown in your dashboard on your desktop.

4. Choose **Update** to confirm your choices, or choose **Cancel** to discard your changes.

Working with threshold alerts in Amazon Quick Sight

Applies to: Enterprise Edition

To stay informed about important changes in your data, you can create threshold alerts using KPI, Gauge, Table, and Pivot table visuals in an Amazon Quick Sight dashboard. With these alerts, you can set thresholds for your data and be notified by email when your data crosses them. You can also view and manage your alerts at anytime in a Quick Sight supported web browser.

For example, let's say that you're a customer success manager for a large organization and you want to know when the number of tickets in a support queue exceeds a certain number. Let's say too that you have a dashboard with a KPI, Gauge, Table or Pivot table visual that tracks the number of tickets in this queue. In this case, you can create an alert and be notified by email when the number exceeds the threshold you specified. That way, you can take action as soon as you're notified.

You can create multiple alerts for a single visual. If the visual is updated or deleted by the author after you create an alert, your alert settings don't change. When you create an alert, the alert takes on any filters applied to the visual at that time. If you or the author changes the filter, your existing alert doesn't change. However, if you create a new alert, your new alert takes on the new filter settings.

For example, let's say you have a dashboard with a filter control that you can use to switch the data for each visual in the dashboard from one US city to another. You have a KPI visual on the dashboard that shows average flight delays, and you're interested in delays for flights leaving from Seattle, Washington, in the US. You change the filter control to Seattle and set an alert on

the visual. This alert tracks flight delays from Seattle. Tomorrow, let's say that you want to also track flight delays from Portland, Oregon, so you change the filter control to Portland and create another alert. This new alert tracks flight delays from Portland. You now have two alerts, one on Seattle and one on Portland, working independently.

Threshold alerts are not available in the eu-central-2 Europe (Zurich) region.

For more information on KPI, Gauge, Table, or Pivot table visuals, see [Visual types in Amazon Quick Sight](#).

Note

You can't create alerts for visuals in an embedded dashboard or from the Quick mobile app. For table visuals, threshold alerts can't be created for values that are located in the Group by field well. Alerts can only be created for values that are located in the Value field well. KPI visuals that don't use a date-time field as a trend don't support alerts. An example is a KPI that shows the difference in flights between carriers X and Y instead of a KPI that shows the difference in flights between dates A and B.

Use the sections below to create and configure threshold alerts for KPI, Gauge, Table, and Pivot table visuals in Quick Sight.

Topics

- [Alert Permissions](#)
- [Creating Alerts](#)
- [Managing Threshold Alerts](#)
- [Investigating Alert Failures](#)
- [Alert Scheduling](#)
- [Using Quick connectors in threshold alerts](#)

Alert Permissions

If you're an administrator, you can control who in your organization can set threshold alerts in Quick Sight by creating a custom permissions policy. To set custom permissions in Quick, choose your user name at the upper-right corner of any Quick page, choose **Manage Quick**, and then choose **Custom permissions**.

Creating Alerts

Use the following procedure to create threshold alerts for KPI or Gauge visuals in a dashboard.

To create an alert

1. Open Quick and navigate to the dashboard that you want.

For more information about viewing dashboards as a dashboard subscriber in Quick, see [Interacting with Amazon Quick Sight dashboards](#).

2. In the dashboard, select the visual that you want to create an alert for, open the menu at the upper-right, and choose **Create alert**.
3. On the menu at upper-right on the visual, choose the **Create alert** icon.

Alternatively, you can choose the alert icon in the blue toolbar at upper right. Then, in the **Create alert** page that opens, select the KPI, Gauge, Table or Pivot table visual that you want to create an alert for, and then choose **Next**.

You can also create alerts on table or pivot table visuals by selecting a cell and choosing **Create alert**. You can only create alerts for single cells. Alerts can't be created for entire columns or for values that use a custom aggregation. For more information about custom aggregations, see [Aggregate functions](#).

4. On the **Create alert** page that opens at right, do the following:

- a. For **Name**, enter a name for the alert.

By default, the visual name is used for the alert name. You can change it if you want.

- b. For **Value to track**, choose a value that you want to set the threshold for. The information presented will vary based on the visual type you're creating an alert for.

The values that are available for this option are based on the values the dashboard author sets in the visual. For example, let's say you have a KPI visual that shows a percent difference between two dates. Given that, you see two alert value options: percent difference and actual.

If there is only one value in the visual, you can't change this option. It is the current value and it is displayed here so that you can use it as a reference while you choose a threshold. For example, if you're setting an alert on average cost, this value will show you what the

current average cost is (say, \$5). With this reference value you can make more informed decisions while setting your threshold.

- c. For **Condition**, choose a condition for the threshold.

You can choose the following conditions.

- **Is above** – Sets a rule that the alert triggers if the alert value goes above the threshold you set.
- **Is below** – Sets a rule that the alert triggers if the alert value goes below the threshold that you set.
- **Is equal to** – Sets a rule that the alert triggers if the alert value is equal to the threshold you set.

- d. For **Threshold**, enter a value to prompt the alert.

- e. For **Notification preference**, choose how often you want to be notified about a breach to the threshold you set.

You can choose from the following options.

- **As frequently as possible** - This option alerts you whenever the threshold is breached. If you choose this option, you might get alerts multiple times a day.
 - **Daily at most** - This option alerts you once per day when the threshold is breached.
 - **Weekly at most** - This option alerts you once per week when the threshold is breached.
- f. (Optional) Choose **Email me when there is no data** - When you select this option, you're notified when there's no data to check your alert rule against.
- g. Choose **Save**.

A message at upper-right appears indicating that the alert has been saved. If your data crosses the threshold you set, you get a notification by email at the address that's associated with your Quick account.

Managing Threshold Alerts

You can edit your existing alerts, turn them on or off, or view the history of times when the alert was triggered. Use the following procedures to do so.

To edit an existing alert

1. Open Quick, choose **Dashboards**, and then navigate to the dashboard that you want to edit an alert for.
2. On the Dashboards page, choose **Alerts** at upper-right.
3. On the **Manage alerts** page that opens, find the alert that you want to edit, and then choose **Edit** beneath the alert name.

You can edit the alert name, condition, and threshold.

4. Choose **Save**.

To view the history of when an alert was triggered

1. Open Quick, choose **Dashboards**, and then navigate to the dashboard that you want to view alert history for.
2. On the Dashboards page, choose **Alerts** at upper-right.
3. On the **Manage alerts** page that opens, find the alert that you want to view the history for, and then choose **History** beneath the alert name.

To turn on or turn off an existing alert

1. Open Quick, choose **Dashboards**, and navigate to the dashboard that you want to turn on or turn off an alert for.
2. On the Dashboards page, choose **Alerts** at upper-right.
3. On the **Manage alerts** page that opens, find the alert that you want to turn on or off, and then select or clear the toggle by the alert name.

The alert is turned on when the toggle is blue, and turned off when the toggle is gray.

To delete an existing alert

1. Open Quick, choose **Dashboards**, and navigate to the dashboard that you want to delete an alert from.
2. On the Dashboards page, choose **Alerts** at upper-right.
3. On the **Manage alerts** page that opens, find the alert that you want to turn on or off, choose the three-dot menu next to the alert, and then choose **Delete** from the dropdown.

Investigating Alert Failures

When an alert fails, Quick sends you an email notification about the failure. Alerts can fail for many reasons, including the following:

- The dataset the alert is using was deleted.
- The owner of the alert lost permissions to the dataset or to certain rows or columns in the dataset.
- The owner of the alert lost access to the dashboard.
- There is no data for the data tracked by the alert.

When a failure occurs, Quick sends you a notification and disables the alert if the reason for the failure isn't likely to be fixed. For example, if the alert fails due to the loss of access to a dashboard, or if the dashboard was deleted. Otherwise, Quick attempts to check your data for threshold breaches again. After four failures, Quick turns off the alert and notifies you that the alert is turned off. If the alert can be checked again, Quick sends you a notification.

To investigate why an alert failed, check that you still have access to the dashboard. Also check that you have permissions to the correct dataset and to the correct rows and columns in the dataset. If you have lost access or permissions, contact the dashboard owner. If you have the necessary access and permissions, you might need to edit your alert to avoid future alert failures.

Alert Scheduling

When you create an alert, Quick checks your data for any breaches against the thresholds you set based on when your dataset is scheduled to refresh. The information presented in the alert varies based on the visual type that you're creating an alert for. For SPICE datasets, alert rules are checked after a successful refresh of your SPICE dataset. For direct query datasets, alert rules are checked at a random time between 6:00 PM and 8:00 AM in the AWS Region that holds the dataset by default.

If you're a dataset owner, you can set an alert evaluation schedule in the dataset settings. See the following procedure to learn how.

To set an alert evaluation schedule for a dataset

1. In Quick, choose **Data** in the navigation bar at left.
2. Choose the dataset that you want to schedule alert evaluations for.

3. Choose **Set alert schedule**.
4. In the **Set alert schedule** page that opens, do the following.
 - For **Time zone**, choose a time zone.
 - For **Repeats**, choose how often you want the data to be evaluated.
 - For **Starts**, enter the time that you want the alert evaluation to start.

Using Quick connectors in threshold alerts

Prerequisites

Before you begin, make sure to [create at least one connector](#).

The connector must meet these requirements:

- Uses the **Service Auth** authentication method
- Uses one of the following integrations:
 - Atlassian Jira Cloud
 - Microsoft Outlook
 - Salesforce
 - ServiceNow

Enable Quick actions on a dashboard to use connectors

To enable Quick actions on a dashboard to use connectors

1. If a dashboard exists, go to the source analysis of the dashboard. Otherwise, [create a new analysis](#).
2. Choose **Publish**.
3. Choose between **New Dashboard** or **Replace existing dashboard**.
4. Choose the **Enable Quick actions** checkbox under **Dashboard options**.
5. Choose **Publish dashboard**.

Use connectors in a threshold alert

To use connectors in a threshold alert

1. Open a dashboard with the **Enable Quick actions** publishing option turned on.
2. Hover over a visual that supports threshold alerts. The types of visuals that support alerts can be found [here](#).
3. Choose the bell icon.
4. The **Create alert** pane opens at right.
5. Choose **Add Action**.
6. A menu appears with a list of all supported connectors and actions.
7. Choose the desired action from the list.
8. An **Action** form appears in the right pane.
9. Enter all the information you need to include with the action.
10. Some fields allow the inclusion of autofill values. Choose **Autofill** to open the menu. Choose the values you need and they will be added to your entered text.
 - **Value:** Injects the current value that was used by the alert to evaluate the alert condition
 - **Alert name:** Injects the alert name
 - **Condition:** Injects the alert condition
 - **Threshold:** Injects the threshold value
 - **All:** Injects all of the above
11. Some actions support the ability to include an attachment. You can optionally attach a PDF of the current dashboard sheet with these actions by selecting the **Include this sheet as PDF** checkbox.
12. Choose **Add action** to add the action to the alert.
13. Back at the **Create alert** pane, the configured action is added to the alert at the bottom.
14. Configure all the other desired fields of the alert and choose **Save**.
15. When your configured threshold is breached, this action should get invoked. To learn more about when a threshold alert is evaluated, see [Alert Scheduling](#).

Security and customizations

Custom Permissions/Capability Customization

- **Actions** capability: You cannot see or use actions if your user or role is restricted the permission to use the Actions capability
- **Export To PDF** capability:
 - New actions on alerts: You will not see the option to attach a PDF of the sheet while adding a new action to an alert if your user or role is restricted the permission to use the **Export To PDF** capability.
 - Existing actions on alerts: If you have existing alerts with actions containing PDF attachments then those actions will be sent out without the PDF attachments when your user or role gets restricted from using the **Export To PDF** capability.

To learn more about custom permissions, see [Custom permissions in Amazon Quick](#).

Row Level Security (RLS) / Column Level Security (CLS)

- New actions on alerts: If your dashboard contains a dataset with RLS or CLS, then
 - You cannot add actions to new alerts that track the dataset with RLS or CLS
 - You can add actions to new alerts that track a different dataset without RLS or CLS, but you cannot include PDF attachments in these actions
- Existing actions on alerts: If you add RLS or CLS to a dataset after creating alerts with actions, then
 - Existing actions on alerts tracking that dataset will stop working completely
 - Existing actions on alerts tracking a different dataset on the same dashboard will be sent out without any PDF attachments

To learn more about RLS, see [Using row-level security in Amazon Quick](#).

To learn more about CLS, see [Using column-level security to restrict access to a dataset](#).

Dashboard publishing options

- Enable PDF generation for interactive sheets
 - New actions on alerts: You will not see the option to attach a PDF of the sheet while adding a new action on alert if your dashboard has the **Enable PDF generation for interactive sheets** publishing option disabled.

- Existing actions on alerts: If you have existing alerts with actions containing PDF attachments, then those actions will be sent out without the PDF attachments when the **Enable PDF generation for interactive sheets** publishing option gets disabled on your dashboard.
- Enable Quick actions
 - New actions on alerts: You will not see the option to add an action to the alert if your dashboard has the **Enable Quick actions** publishing option turned off.
 - Existing actions on alerts: Your existing actions on alerts will stop working completely when the **Enable Quick actions** publishing option gets disabled on your dashboard.

To learn more about dashboard publishing options, see [Publishing dashboards](#).

Printing a dashboard or analysis

You can print a dashboard or an analysis in Amazon Quick Sight.

Use the following procedure to print.

1. Open the dashboard or the analysis that you want to print.
2. Choose the **Print** icon at top right.
3. On the **Prepare for printing** screen, choose the paper size and orientation that you want to use.
4. Choose **Go to Preview**.
5. Do one of the following:
 - To proceed to printing, choose **Print** to open your operating system's print dialog.
 - To make changes to the paper size or orientation, choose **Configure**.
6. To exit the preview screen, choose **Exit preview**.

Exporting Amazon Quick Sight analyses or dashboards as PDFs

You can export content from a dashboard into a Portable Document Format file (PDF). Similar to a print-out, this format provides a snapshot of the current sheet as it appears on-screen at the time of download.

To export a dashboard sheet as a PDF

1. Open Quick and choose **Dashboards** on the navigation pane at left.
2. Open the dashboard that you want to export.
3. At upper right, choose **Export, Download as PDF**. The download is prepared in the background.

When the file is ready to download, a message appears saying **Your PDF is ready..**

4. Choose **Download now** to download the file. Choose **Close** to close without downloading.

If you close this dialog box without downloading the file and want to recreate the file, repeat the previous step. Also, the downloadable file is available only temporarily for five minutes. If you wait too long to download it, the file expires. If this happens, Quick Sight instead displays an error message saying that the request has expired.

5. Repeat the previous steps for each sheet that you want to export.

You can also attach PDFs to dashboard email reports. For more information, see [Scheduling and sending Quick Sight reports by email](#).

Error codes for failed PDF export jobs

When you generate PDF reports in Amazon Quick Sight, you may encounter instances where your request to generate a PDF report fails. There are many reasons why a failure might occur. Quick Sight provides error codes that can help you understand why the error occurred and provide guidance to troubleshoot the issue. The following table lists the error codes that Quick Sight returns when a PDF export job fails.

Error code	Guidance
INVALID_DATAPREP_SYNTAX	Check the syntax for your calculated fields, and try again.
POST_AGGREGATED_METRIC_AS_DIMENSION	Aggregated metrics/operands can't be used as visual's grouping dimensions. Choose a valid visual's grouping dimensions, and try again.

Error code	Guidance
SPICE_TABLE_NOT_FOUND	The dataset has been deleted or is unavailable. Import a valid dataset, and try again.
FIELD_NOT_FOUND	A field is no longer available. Update or replace the missing fields in this dataset, and try again.
FIELD_ACCESS_DENIED	You don't have access to some fields in this dataset. Request access, and try again.
PERMISSIONS_DATASET_INVALID_COLUMN_VALUE	An invalid row level permission column value was found. Check your parent dataset rules, and try again.
COLUMN_NOT_FOUND	Replace the missing columns in your filters or parameters, and try again.
INVALID_COLUMN_TYPE	Some fields' data types have been changed and can not be automatically updated. Adjust these fields in your dataset, and try again.
PERMISSIONS_DATASET_USER_DENIED	You don't have access to this dataset. Request access to this dataset, and try again.
DATA_SOURCE_TIMEOUT	Your query has timed out. Reduce the amount of data, or import the data into SPICE, and try again.
MAX_PAGE_EXCEEDED_ERROR	Your file is ready but content is not complete. PDFs have a 1,000 page limit. Choose a shorter PDF, and try again.
INSUFFICIENT_BODY_HEIGHT_ERROR	Adjust the header and footer to be less than the page height, and try again.
FIRST_PAGE_HEIGHT_TOO_SMALL_ERROR	Adjust sections to make room for your tables, and try again.

Error code	Guidance
INTERNAL_ERROR	We can't create your PDF right now. Wait a few minutes, and try again.

Organizing assets into folders for Amazon Quick

Applies to: Enterprise Edition

In Quick Enterprise edition, your team members can create personal and shared folders to add hierarchical structure to Quick asset management. Using folders, people can more easily organize, navigate through, and discover dashboards, analyses, datasets, data sources, and topics. Within a folder, you can still use your usual tools to search for assets or to add assets to your favorites list.

You can use the following types of folders with Quick:

- Personal folders to organize work for yourself.

Personal folders are visible only to the person who owns them. You can't transfer ownership of personal folders to anyone else.

- Shared folders:
 - **Shared folders** organize work and simplify sharing among multiple people. To create and manage shared folders, you need to be a Quick administrator.
 - **Shared restricted folders** are a type of shared folder in Quick that ensure that assets remain in the shared folder. Assets that are created from assets that exist within a shared restricted folder must also stay in the restricted folder. Assets that are located in restricted folders can't be moved or shared outside of the restricted folder. For example, if you create a dataset that uses a data source that's located in a shared restricted folder, the new dataset can't be moved outside of that shared restricted folder.

Assets that are located in a restricted folder can be moved within the restricted folder tree into one or more subfolders. Subfolders of restricted folders behave like restricted folders, but dependent assets can exist in different subfolders under the same root restricted folder. The root restricted folder acts as a boundary that all assets in all subfolders can exist in as long as they remain within the root folder tree. For example, a dataset that is located in one subfolder

can use a data source that is located either another subfolder in the same folder tree or in the root folder. Any supported asset type can be created in a root folder or in any of its subfolders. Users can have different roles in different subfolders. Subfolder permissions are inherited from the parent folders of that subfolder.

Restricted folder boundary enforcement scope

Restricted folders enforce the security boundary only between these assets: analyses, dashboards, datasets, data sources, and topics. Other asset types and features in Quick can access data in a restricted folder.

For example, an analysis in a restricted folder can be built only on a dataset within the same restricted folder tree, so it respects the boundary. However, a chat agent not in a restricted folder can still retrieve details from a dataset in a restricted folder.

Restricted folders can only be created with the Quick [CreateFolder](#) API operation.

- Users that are viewers on a folder and have the Author or Admin role in Quick can view all asset types that are in the folder. Users that are viewers on a folder and have the Reader role in Quick can only see dashboards and stories that are in the folder.

All shared folders are visible to people who have access to them.

Use the following topics to learn more about creating and configuring a folder or subfolder in Quick.

Topics

- [Considerations for Quick folders](#)
- [Overview of Quick folders](#)
- [Permissions for Quick shared folders](#)
- [Create and manage membership permissions for Quick shared folders](#)
- [Creating Quick scaled folders with the Quick APIs](#)

Considerations for Quick folders

Before you get started creating and modifying folders in Amazon Quick, review the following limitations that apply to Quick folders.

- You can't share folders in your AWS account with people in other AWS accounts.
- For people who have Quick reader permissions, the following limitations apply:
 - Readers can't own a personal or shared folder.
 - Readers can't create or manage folders or folder content.
 - Readers can't have the *contributor* access level.
 - In shared folders, readers can only see dashboard assets.

In addition, these limitations apply specifically to shared folders:

- The name of a shared folder (at the top level of the tree) must be unique in your AWS account.
- In a single folder, multiple assets can't have the same name. For example, in your top-level folder, you can't create two subfolders with the same name. In the same folder, you can't add two assets with the same name, even if they have different asset IDs. The path to each asset behaves like an Amazon S3 key name. It must be unique in your AWS account.
- Restricted shared folders can only be created with the Quick CLI.

See [Overview of Quick folders](#) to learn more about the different types of folder available in Amazon Quick.

Overview of Quick folders

In Quick, you can create personal and shared folders. You can also favorite your personal or shared folders for quick access by choosing the favorite (

)

icon next to it.

You can do the following with personal folders:

- Create subfolders.
- Add assets to your folder, including analyses, dashboards, datasets, and data sources. To add assets to a personal folder, you must already have access to the assets. Multiple assets can have the same name.

Shared folders (unrestricted)

Quick administrators can perform the following tasks with shared folders.

- Create or delete a shared folder and subfolders inside of it. You can move either of these around within the top-level folder.
- Add or remove owners, contributors, and viewers. When you make a person an *owner* of the folder, you give them ownership of every asset in the folder. For more information, see [Permissions for Quick shared folders](#).

The following table summarizes the actions that a Quick user can take when working with unrestricted shared folders based on their role.

Action	Owner	Contributor	Viewer
Share an asset in a folder with users that don't have access to the folder	✔ Yes	✘ No	✘ No
Modify folder permissions	✔ Yes	✘ No	✘ No
Create assets in the folder	✔ Yes	✔ Yes	✘ No
Modify assets in the folder	✔ Yes	✔ Yes	✘ No
Delete assets in the folder	✔ Yes	✔ Yes	✘ No
Add an existing asset to a folder	✔ Yes	✔ Yes	✘ No
Remove an asset from a shared folder	✔ Yes	✘ No	✘ No
View assets in the folder	✔ Yes	✔ Yes	✔ Yes

Action	Owner	Contributor	Viewer
Create downstream assets outside of the shared folder that use assets that are located in the shared folder	✔ Yes	✔ Yes	✔ Yes*
Create downstream assets in the folder that use assets that are located outside of the folder	✔ Yes	✔ Yes	✘ No
Create subfolders	✔ Yes	✔ Yes	✘ No
Delete subfolders	✔ Yes	✘ No	✘ No
Manage subfolder permissions	✔ Yes	✘ No	✘ No
Add existing assets to subfolders	✔ Yes	✘ No	✘ No
Create new assets in subfolders	✔ Yes	✔ Yes	✘ No

Action	Owner	Contributor	Viewer
Delete assets in subfolders	✔ Yes	✔ Yes	✘ No

*The user must be assigned an admin or author role to create assets.

Restricted shared folders

Restricted shared folders provide an additional security boundary that restricts the sharing of data outside of the folder. Administrators with the appropriate IAM permissions can perform the following tasks with restricted shared folders.

- Restricted folders can be created using the `CreateFolder` API operation. For more information about the `CreateFolder` API operation, see [CreateFolder](#).
- The contributor role is assigned to users that can create and edit assets within the restricted folders. Contributors can't manage the permissions of the folder or of the assets that are in the restricted folder.
- Administrators can assign folder contributor and viewer permissions to users with the `UpdateFolderPermissions` API operation. For more information about the `UpdateFolderPermissions` API operation, see [UpdateFolderPermissions](#).

The following table summarizes the actions that a Quick user can take when working with restricted shared folders based on their role.

Action	Contributor	Viewer
Share an asset in a folder with users that don't have access to the folder	✘ No	✘ No
Modify folder permissions	✘ No	✘ No
Create assets in the folder	✔ Yes	✘ No

Action	Contributor	Viewer
Modify assets in the folder	✔ Yes	✘ No
Delete assets from the folder	✔ Yes	✘ No
Add an existing asset to a folder	✘ No	✘ No
Remove an asset from a shared folder	✘ No	✘ No
View assets in the folder	✔ Yes	✔ Yes
Create downstream assets outside of the shared folder that use assets that are located in the shared folder	✘ No	✘ No
Create downstream assets in the folder that use assets that are located outside of the folder	✘ No	✘ No
Create subfolders	✔ Yes	✘ No
Delete subfolders	✘ No	✘ No
Manage subfolder permissions	✘ No	✘ No
Add existing assets to subfolders	✘ No	✘ No

Action	Contributor	Viewer
Create new assets in subfolders	✔ Yes	✘ No
Delete assets from subfolders	✔ Yes	✘ No

The owner role is not supported for restricted shared folders.

After you choose which folder type best fits your use case, see [Permissions for Quick shared folders](#) and [Create and manage membership permissions for Quick shared folders](#) to create folders and set up folder permissions.

Permissions for Quick shared folders

Shared folders have three permission levels. To set folder-level permissions for a user or group, see [Create and manage membership permissions for Quick shared folders](#).

- **Owners** - The folder *owner* owns everything (folders, analyses, dashboards, datasets, data sources, topics) inside of the folder. They can create, edit, and delete the assets in the folder, modify permissions on the folder and its assets, and delete the folder entirely. The owner role is not supported for restricted shared folders.
- **Contributors** - A *contributor* can create, edit, and delete assets in a folder just like an owner. They can't delete the folder or modify permissions on the folder or on assets where they have contributor access that they inherited from the folder.
- **Viewers** - A *viewer* can only view the assets (folders, dashboards, datasets, data sources, topics) in the folder. A viewer can't edit or share those assets.

The following rules also apply to security for shared folders:

- Quick readers' sharing status for a folder gets shared with the folder. However, a reader gets only read access to folders, and only dashboard access to visuals.
- AWS security is enforced on every object within a folder. The folder applies the same type of security to the assets of whoever the folder is shared with according to their access level (admin, author, or reader).

- The *top-level folder* is the root folder of any subfolders. When a subfolder is shared at any level, the person whom the folder was shared with sees the root folder in the top-level folders view.
- The folder permission is the permission on the current folder, combined with permissions of all the folders leading to the root folder.
- A *shared asset* inherits its permission from the folder. A shared asset is created when an asset that belongs to the folder owner is added to a shared folder.
- If you own an unrestricted shared folder, you can transfer ownership of the folder to another Quick admin.
- The owner role is not supported for restricted folders. The contributor role is assigned to authors that create and edit assets within the restricted folders. Folder contributors can't manage the permissions of the restricted folder or its assets.
- The correct IAM permissions are required to update the permissions of a restricted shared folder with the `UpdateFolderPermissions` API.

To create and manage permissions of a shared folder, see [Create and manage membership permissions for Quick shared folders](#).

Create and manage membership permissions for Quick shared folders

Shared folders (unrestricted)

To create a shared folder and to share the folder with one or more groups in the Quick console, you must be an Amazon QuickSight administrator. You can also create a shared folder with the `CreateFolder` API operation. Use the following procedure to share or modify the membership permissions of a shared folder.

1. From the left navigation, choose **Folders** then **Shared Folders**. Find the folder that you want to share or manage permissions for.
2. To open the actions menu for that folder's row, choose the ellipsis (three dots).
3. Choose **Share**.
4. In the **Share folder** modal, add the groups and users with whom you want to share the contents of the folder.
5. For each user and group that you add, choose a permission level from the **Permissions** menu in that row.
6. To update the permission type for an existing user, choose **Manage folder access**.

7. When you're done setting user and group permissions for the folder, choose **Share**. Users are not notified that they now have access to the folder.

Restricted shared folders

Restricted shared folders can only be created with the CreateFolder API operation. The following example creates a restricted shared folder.

```
aws quicksight create-folder \  
--aws-account-id AWSACCOUNTID \  
--region us-east-1 \  
--folder-id example-folder-name \  
--folder-type RESTRICTED \  
--name "Example Folder" \
```

After you create a restricted shared folder, assign folder contributor and viewer permissions with a UpdateFolderPermissions API call. The following example updates the permissions of a restricted shared folder to grant contributor permissions to a user.

```
aws quicksight update-folder-permissions \  
--aws-account-id AWSACCOUNTID \  
--region us-east-1 \  
--folder-id example-folder-name \  
--grant-permissions Principal=arn:aws:quicksight::us-east-1::AWSACCOUNTID:user/default/:username,Actions=quicksight:CreateFolder  
,quicksight:DescribeFolder, \  
quicksight:CreateFolderMembership,quicksight>DeleteFolderMembership,qu  
icksight:DescribeFolderPermissions \
```

The permissions that you pass to the user depend on the type of folder role that you want to grant them. Use the following lists to determine which permissions are needed for the user that you want to grant folder access to.

Folder owner

- quicksight:CreateFolder
- quicksight:DescribeFolder
- quicksight:UpdateFolder
- quicksight>DeleteFolder

- quicksight:CreateFolderMembership
- quicksight>DeleteFolderMembership
- quicksight:DescribeFolderPermissions
- quicksight:UpdateFolderPermissions

Folder contributor

- quicksight:CreateFolder
- quicksight:DescribeFolder
- quicksight:CreateFolderMembership
- quicksight>DeleteFolderMembership
- quicksight:DescribeFolderPermissions

Folder viewer

- quicksight:DescribeFolder

After you create a shared folder, you can begin using the folder in Quick.

You can also use the Quick APIs to create special scaled folders that can be shared with up to 3000 namespaces. To learn more about creating a scaled folder, see [Creating Quick scaled folders with the Quick APIs](#).

Creating Quick scaled folders with the Quick APIs

You can use the Amazon Quick APIs to create special scaled folders that can be shared with up to 3000 namespaces. Each namespace that is added to a folder can contain up to 100 principals. A *principal* is a user or a group of users. After you create a scaled folder and add the principals that you want, any QuickSight asset can be added to the folder. It can then be shared to every principal in the namespaces that the folder principals are assigned to. This streamlines the process to share Quick assets with thousands of users.

Scaled folders can only be created with the Quick APIs. When you create a scaled folder, you can share the folder with up to 100 principals that are in the same namespace. You can add principals that belong to a different namespace with an UpdateFolderPermissions API call. After the

folder is created, you can add and remove assets from the folder with the Quick APIs or the Quick console.

Each Amazon Quick account holds up to 100 scaled folders. You can add up to 100 assets to a scaled folder. If you want to share a scaled folder with more than 3000 namespaces, contact [AWS support](#).

Examples

The following examples show how to create a scaled folder with the Quick APIs.

Prerequisites

Before you begin, verify that you have an AWS Identity and Access Management role that grants the API user access to call the Quick API operations. The following example shows an IAM policy that you can add to an existing IAM role to create, delete, or modify a scaled folder. With the sample policy, users can add dashboards, analyses, and datasets to a scaled folder.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "quicksight:CreateFolder",
        "quicksight:CreateFolderMembership",
        "quicksight>DeleteFolderMembership",
        "quicksight>DeleteFolder",
        "quicksight:DescribeFolderPermissions",
        "quicksight:DescribeFolderResolvedPermissions",
        "quicksight:UpdateFolderPermissions",
        "quicksight:UpdateDashboardPermissions",
        "quicksight:UpdateAnalysisPermissions",
        "quicksight:UpdateDataSetPermissions"
      ],
      "Resource": "*"
    }
  ]
}
```

The following example creates a scaled folder.

```
aws quicksight create-folder \  
--aws-account-id "AWSACCOUNTID" \  
--region "us-east-1" \  
--name "eastcoast-users" \  
--sharing-model "NAMESPACE" \  
--folder-id "eastcoast-users"
```

After you create a scaled folder, share the folder with a principal in your account. You can only grant or revoke permissions to users and groups that are within the same namespace in each API call. The following example shares a scaled folder with a user in the same account that the folder exists in.

```
aws quicksight update-folder-permissions \  
--aws-account-id "AWSACCOUNTID" \  
--region "us-east-1" \  
--folder-id "eastcoast-users" \  
--grant-permissions \  
  '[  
    {"Actions":  
      ["quicksight:DescribeFolder",  
       "quicksight:UpdateFolder",  
       "quicksight>DeleteFolder",  
       "quicksight:DescribeFolderPermissions",  
       "quicksight:UpdateFolderPermissions",  
       "quicksight:CreateFolderMembership",  
       "quicksight>DeleteFolderMembership",  
       "quicksight:CreateFolder"  
      ],  
      "Principal": "arn:aws:quicksight:us-east-1:AWSACCOUNTID:user/default/my-user"  
    }  
  ]'
```

After you share the folder with a new principal, validate the new folder permissions with a `describe-folder-permissions` API call.

```
aws quicksight describe-folder-permissions \  
--aws-account-id "AWSACCOUNTID" \  
--region "us-east-1" \  
--folder-id "eastcoast-users" \  

```

```
--namespace "default"
```

After you validate the new folder permissions, create a subfolder within the scaled folder. The subfolder inherits the permissions of the scaled folder that it's created in.

```
aws quicksight create-folder \  
--aws-account-id "AWSACCOUNTID" \  
--region "us-east-1" \  
--name "new-york-users" \  
--sharing-model "NAMESPACE" \  
--folder-id "new-york-users" \  
--parent-folder-arn "arn:aws:quicksight:us-east-1:AWSACCOUNTID:folder/eastcoast-users"
```

The following example validates the inherited permissions of the new subfolder.

```
aws quicksight describe-folder-resolved-permissions \  
--aws-account-id "AWSACCOUNTID" \  
--region "us-east-1" \  
--folder-id "new-york-users" \  
--namespace "default"
```

After you validate the permissions of the subfolder, add the Quick asset that you want to share to the folder. After you add the asset to the subfolder, the asset is shared with every principal that the subfolder is shared with. The following example adds a dashboard to a subfolder.

```
aws quicksight create-folder-membership \  
--aws-account-id "AWSACCOUNTID" \  
--folder-id "new-york-users" \  
--member-id "my-dashboard" \  
--member-type "DASHBOARD" \  
--region "us-east-1"
```

Exploring interactive dashboards in Amazon Quick Sight

Intended audience: Amazon Quick Dashboard subscribers or viewership

In Amazon Quick Sight, a *data dashboard* is a collection of charts, graphs, and insights. It's like a newspaper that's all about the data that you're interested in, except it has digital pages. Instead of reading it, you interact with it.

Dashboards come in a wide variety of designs, depending on what you do and the analytics that you need to do it well. Using Quick Sight, you can interact with your data on a webpage or your mobile device. If you also subscribe by mail, you can see a static preview of it.

The story told by your data reflects the expertise of the analysts and data scientists who built the dashboards. They refine the data, add calculations, find angles on the story, and decide how to present it. The publisher designs the dashboard and fills it with interactive data visualizations and controls that adjust your view. Publishers can customize the level of interactivity that you have, including filter and search options. You can interact with the active items on the screen to filter, sort, drill down, or jump to another tool.

When you view a dashboard, you're seeing the most recently received data. As you interact with the items on the screen, any changes you make change your view of the dashboard, and no one else's. Thus, your device's privacy is assured, although the publisher can tell what you looked at. After you close the dashboard, your explorations aren't preserved and neither is the data. As always, while you're an Quick reader, your monthly subscription is provided by the publishers of the dashboards at no additional cost to you.

If you're also a dashboard publisher—we call them authors, because they write reports—you can also save a copy of the dashboard for further analysis. If you find a new feature of the data that you want to publish, work with the original authors to update it. That way, everyone can see the same version of the story. However, you can also use your copy to learn how their design works or to inspire your work on something entirely new. Then, when you're finished, you can publish your analysis as a new dashboard.

To learn to set up dashboards, see [Sharing and subscribing to data in Amazon Quick Sight with dashboards and reports](#).

Topics

Interacting with Amazon Quick Sight dashboards

To access a dashboard that you've been invited to share, follow the instructions in the invitation email. You can also access a dashboard if it's embedded into an application or website that you already have access to.

To fit the dashboard to your screen, open the **View** menu at upper right and select **Fit to window**.

Depending on how the dashboard is configured, you can find all or some of the following elements:

- The menu bar – This displays the name of the dashboard. Also, the menu bar shows what you can do with the dashboard, including **Undo**, **Redo**, and **Reset**, on the left. As you interact with the dashboard, you can use these as tools to help you explore, knowing that you can change your view without losing anything. On the right, you can find options to **Print** the dashboard, work with **Data**, choose a different AWS **Region**, and open your **User Profile**. The user profile menu has options so you can choose the language that Amazon Quick Sight displays. It also has links to the Quick **Community** and the online documentation (**Help**).
- The dashboard sheets – If your dashboard has multiple sheets, these display as tabs across the top of the dashboard.
- The **Filter** menu – This option displays to the left of the dashboard, if the dashboard publisher allows filtering.
- The **Controls** palette – If your dashboard includes controls, you can use them to choose the options (parameters) that you want to apply to your dashboard. Sometimes a control value is selected for you, and sometimes it's set to **ALL**.
- The dashboard title – If your dashboard has a title, it is usually a larger heading. It might have some status information or instructions below it.
- The dashboard widgets – The items on the screen can include charts, graphs, insights, narratives, or images. To see them all, you might need to scroll vertically or horizontally.

Using filters on Amazon Quick Sight dashboard data

You can use filters to refine the data displayed in a visual. Filters are applied to the data before any aggregate functions. If you have multiple filters, all top-level filters apply together using AND. If the filters are grouped inside a top-level filter, the filters in the group apply using OR.

Amazon Quick Sight applies all of the enabled filters to the field. For example, suppose that there is one filter of `state = WA` and another filter of `sales >= 500`. In this case, the dataset contains only records that meet both of those criteria. If you disable one of these, only one filter applies. Take care that multiple filters applied to the same field aren't mutually exclusive.

Viewing filters

To see the existing filters, choose **Filter** on the element settings menu, then choose to view filters. The filters display in the **Applied filters** panel in order of creation, with the oldest filter on top.

Understanding filter icons in an Amazon Quick Sight dashboard

Filters in the **Applied filters** panel display icons to indicate how they are scoped and whether they are enabled.

A filter that isn't enabled is grayed out, and you can't select its check box.

One of several scope icons displays to the right of the filter name to indicate the scope set on that filter. The scope icon resembled four boxes in a square. If all boxes are filled, the filter applies to all visuals on the analysis sheet. If only one box is filled, the filter applies to the selected visual only. If some boxes are filled, the filter applies to some of the visuals on the sheet, including the one currently selected.

The scope icons match the ones that display on the filter menu when you are choosing the scope for the filter.

Viewing filter details in an Amazon Quick Sight dashboard

To see filter details, choose **Filter** at left. The filter view retains your last selection. So when you open **Filter**, you see either the **Applied filters** or the **Edit filter** view.

In the **Applied filters** view, you can choose any filter to view its details. The filters in this list can change depending on the scope of the filter, and which visual you currently have selected.

You can close the **Edit filter** view by choosing the selector on the right. Doing this resets the **Filter** view.

Filtering data during your session in Amazon Quick Sight

While your dashboard session is active, you can filter data in three ways:

1. If your dashboard has controls at the top of the screen, you can use them to filter data by choosing from a preset list of values.
2. You can use the filter icon on each widget's settings menu.
3. You can create your own filters by using the filter panel on the left side of the page. The filter icon looks like the following.

To create a filter, choose the **Filter** icon at left.

The first step is to choose which dashboard element you want to filter.

Click on the item you choose, so that a highlight appears around the selected item. Also, if any filters are already there, they display in a list. If there aren't any filters, you can add one by using the plus sign (+) near **Filters**.

Filtering options vary depending on the data type of the field you want to filter, and on the options you choose inside the filter. The following screenshot shows some of the options available for a time-range date filter.

For each filter, you can choose whether to apply it to one, some, or all dashboard elements. You can also enable or disable filters by using the check box next to the name of the filter. To delete a filter, edit it and scroll to the bottom to see the options. Remember that your filters aren't saved from one session to the next.

For more detailed information on creating filters, see [Filtering data in Amazon Quick Sight](#).

Using the elements on the Amazon Quick Sight dashboard

Each widget has a settings menu that appears when you select that widget. This menu provides options to zoom in or out, filter the data, export the data, and more. The options vary depending on what type of widget the element is.

When you choose a data point, several actions are available. You can click or tap on a data point, for example on a bar in a bar chart, on a point where the line bends on a line chart, and so on. The available options vary based on what type of item it is.

These actions are as follows:

- Focus on or exclude.

You can focus on or exclude specific data in a field, for example regions, metrics, or dates.

- Drill up or drill down.

If your dashboard contains data on which you can drill down or up, you can drill up to a higher level or drill down to explore deeper details.

- Custom URL actions.

If your dashboard contains custom actions, you can activate them by choosing a data point or by right-clicking it. For example, you might be able to email someone directly from the dashboard. Or you might open another sheet, website, or application, and send it the value you chose from this one.

- Change chart colors or specific field colors.

You can change all the chart colors to a specific color. Or you can choose a specific field value to change its color of the element it's part of.

Sorting dashboard data in Amazon Quick Sight

You can sort data in three ways:

1. You can hover over the label for the field you want to sort by, and choose the sort icon.
2. You can choose the filter icon at the upper right of one of the dashboard elements.
3. You can click or tap on the field and choose **Sort** from the context menu.

Sorting for pivot tables is different; you specify the sort order by using the column sort icon on the pivot table.

Exporting and printing interactive Amazon Quick Sight dashboard reports

You can export or print a PDF version of an interactive dashboard. You can also export some visuals in a dashboard to a CSV. Exporting an entire dashboard to a CSV is not currently supported for interactive dashboards.

Exporting data from a dashboard to a PDF

To export an interactive dashboard report as a PDF

1. From the dashboard report that you want to export, choose the **Export** icon at the top right.

2. Choose **Generate PDF**.
3. When you choose **Generate PDF**, Quick Sight will begin preparing the dashboard report for download. Choose **View downloads** in the blue pop-up to open the **Downloads** pane on the right.
4. There are two ways to download your report:
 - Choose **DOWNLOAD NOW** in the green pop-up.
 - Choose the **Export** icon at the top right, and then choose **View downloads** to view and download every report that is ready to download.

To print an interactive dashboard report

1. From the report that you want to print, choose the **Export** icon at the top right, and then choose **Print**.
2. In the **Prepare for printing** pop-up that appears, choose the paper size and orientation that you want. You can optionally choose to include the background color by selecting **Print background color**.
3. Choose **GO TO PREVIEW**.
4. In the preview window that appears, choose **PRINT**.

Exporting data from a dashboard to a CSV

Note

Export files can directly return information from the dataset import. This makes the files vulnerable to CSV injection if the imported data contains formulas or commands. For this reason, export files can prompt security warnings. To avoid malicious activity, turn off links and macros when reading exported files.

To export data from an analysis or dashboard to a comma-separated value (CSV) file, use the settings menu at the upper right of a widget. Exports only include data that currently displays in the item that you choose.

In tables and pivot tables, you can export data to a comma-separated value (CSV) file or Microsoft Excel file. You can choose to export only visible fields or all fields.

To export only visible fields to a CSV or Excel file, choose the menu at upper-right of the visual. Choose either **Export to CSV** or **Export to Excel**, and then choose **Export visible fields to CSV** or **Export visible fields to Excel**.

To export all fields to a CSV or Excel file, choose the menu at upper-right of the visual. Choose either **Export to CSV** or **Export to Excel**, and then choose **Export all fields to CSV** or **Export all fields to Excel**.

Generate an executive summary of an Amazon Quick Sight dashboard

Dashboard readers can generate executive summaries that provide a summary of all insights that Quick Sight has generated for the dashboard. Executive summaries make it easier for readers to find key insights and information about a dashboard at a glance.

When readers are viewing a dashboard that uses executive summaries, the **Executive summary** option is available in the **Build** dropdown list that is located in the top right of the Dashboard's page. Use the procedure below to generate an executive summary. If a dashboard doesn't use executive summaries, the **Executive summary** option does not appear in the **Build** dropdown list.

To generate an executive summary

1. In the dashboard that you want to work in, choose **Build**, and then choose **Executive summary**.
2. Choose **Summarize**. The executive summary is generated and the appears on the left.

Executive summaries use the data of the current dashboard sheet and visual settings. If the dashboard or visual settings are updated, a warning appears at the top of an executive summary. To refresh the executive summary of an updated dashboard, generate a new executive summary.

After an executive summary is generated, Amazon Quick readers can copy the summary to their clipboard in order to share with others, or include in a Quick Sight story. For more information about Quick Sight stories, see [Working with data stories in Amazon Quick Sight](#).

Customizing tables and pivot tables in Amazon Quick Sight

Reader customization for tables and pivot tables is enabled by default. You can change the visual to fit your analysis needs without requesting updates from the dashboard author. Your customizations are private – other readers of the same dashboard don't see your changes unless you share them.

For dashboard authors

To disable reader customization, choose **Format Visual**, choose **Interactions**, and then turn off **Reader Customization**. Republish the dashboard for the change to take effect.

You can customize tables and pivot tables in the following ways:

- **Sort columns** – Organize data in ascending or descending order.
- **Reorder columns** – Rearrange columns to reflect the order that matters most to you.
- **Hide and show columns** – Focus on relevant data by hiding columns you don't need, and show them again when you do.
- **Freeze columns** – Keep important columns visible while scrolling horizontally through large datasets.
- **Add and remove fields** – Include additional fields from the dataset or remove fields you don't need.
- **Change aggregations** – Modify how a measure is aggregated (for example, change from *Sum* to *Average*).
- **Modify formatting** – Adjust field formatting directly in the dashboard view.

Note

Reader customization is supported for tables and pivot tables only. Other visual types don't support reader-level customization at this time.

Sorting columns

To sort data in a table or pivot table, choose the column header that you want to sort by. Choose it again to toggle between ascending and descending order.

Reordering columns

To rearrange columns, choose the column header menu and then choose **Move left** or **Move right**.

Hiding and showing columns

To hide a column, choose the column header menu and then choose **Hide**.

To show hidden columns, choose any column header menu and then choose **Show all hidden fields**.

Freezing columns

To freeze a column so that it stays in place while you scroll horizontally, choose the column header menu and then choose **Freeze column**.

This is useful for keeping key identifiers, such as region names or account numbers, visible while you review a wide table.

Adding and removing fields

If the author has made additional fields available for customization, you can add or remove them from the visual.

To add or remove fields

1. On the table or pivot table, choose **Customize**.
2. In the field list, select the fields you want to add (for example, *City*, *Profit*, or *Quantity*).
3. To remove a field, clear its selection in the field list.

The available fields are determined by the author. By default, you can add back, remove, hide, show, reorder, and change aggregations for the fields that are already in the visual. Authors can extend this list to include additional fields from the underlying dataset.

Changing aggregations

After you add or select a measure field, you can change its aggregation type. For example, you can change *Order Date* to aggregate by **Quarter**, or change *Quantity* from **Sum** to **Average**.

To change an aggregation, choose the field in the customization panel and then select a different aggregation type.

Resetting to the default view

To discard all of your customizations and return to the author's original configuration, choose any column header menu and then choose **Reset visual**.

Saving your customizations

Your customizations are saved automatically. When you return to the dashboard, your personalized view is preserved – you don't need to reapply settings each time you open the dashboard.

Sharing customized views

You can share your customized view with other readers in the following ways:

- **Share this view** – Generate a link that preserves your current filters, column selections, and ordering. Other users who open the link see the same view. This is useful for ad-hoc collaboration.
- **Bookmarks** – Save your customizations as a bookmark for recurring use. Bookmarks capture visual customizations and applied filters, so you can return to your preferred view at any time. Bookmarks can be private or shared across teams.

Exporting customized views

You can schedule and export your customized table or pivot table in the following formats:

- PDF
- CSV
- Excel

This is useful for sharing data with stakeholders who don't have Amazon Quick Sight access or for offline analysis.

Embedding behavior

When tables and pivot tables are embedded in an application, customization availability and persistence depend on the embedding method.

- **Visual embedding (registered or anonymous users)** – You can customize the visual. Customizations are not persisted – the original dashboard is displayed when the page reloads.
- **Dashboard embedding for registered users** – You can customize the visual. If state persistence is enabled through embedding options, your customized view is preserved on reload. If state persistence is not enabled, the original dashboard is displayed.
- **Dashboard embedding for anonymous users** – You can customize the visual. Customizations are not persisted – the original dashboard is displayed when the page reloads.

The `createSharedView` SDK function supports generating a shared view from a customized embedded dashboard.

Limitations

- Reader customization is supported for tables and pivot tables only. Other visual types, such as bar charts, line charts, and KPIs, don't support reader-level customization.
- The fields available for readers to add or remove are controlled by the dashboard author. If you need access to a field that isn't available, contact the dashboard author.

Interacting with pixel perfect reports in Amazon Quick Sight

To access a pixel perfect report that you've been invited to share, follow the instructions in the invitation email. You can also access a pixel perfect report if it's embedded into an application or website that you already have access to.

To fit the pixel perfect report to your screen, open the **View** menu at upper right and select **Fit to window**. You can also zoom in and out using the plus (+) and minus (-) icons on the top left corner of the report.

Exporting and printing Amazon Quick Sight reports

Pixel perfect reports are designed to be viewed from a specific point of time. These reports, or snapshots, can be printed or downloaded as a PDF or CSV.

To export a pixel perfect report report as a PDF

1. From the pixel perfect report that you want to export, choose the **Export** icon at the top right.
2. Choose **Generate PDF**.
3. When you choose **Generate PDF**, Quick Sight will begin preparing the pixel perfect report for download. When the report is ready, a green pop up will appear that says **Your PDF is ready**.
4. There are two ways to download your report:
 - Choose **DOWNLOAD NOW** in the green pop-up.
 - Choose the **Export** icon at the top right, and then choose **View downloads** to view and download every report that is ready to download.

To export a pixel perfect report as a CSV

1. From the report that you want to export, choose the **Scheduling** icon at the top right, and then choose **Recent snapshots**.
2. In the **Recent snapshots** menu that appears on the right, snapshots are sorted from most recently generated to the oldest. Snapshots are stored for up to 1 year. Find the report that you want to download and choose the download icon to the right of the report.
3. In the report pop-up that appears, choose the download icon next to the version of the report that you want to download. You can choose to download the report as a CSV, or you can download the report as a PDF.

To print a pixel perfect report

1. From the report that you want to print, choose the **Export** icon at the top right, and then choose **Print**.
2. When you choose **Print**, your browser's printer pop-up appears. From here, you can print the PDF the same way you would print anything else on your browser.

Subscribing to Amazon Quick Sight dashboard emails and alerts

Using Amazon Quick Sight, you can subscribe to updates for certain events, such as dashboard updates and anomaly alerts.

Topics

- [Sign up for dashboard emails](#)
- [Sign up for anomaly alerts](#)

Sign up for dashboard emails

You can sign up to get a dashboard in report form, and receive it in an email. You can also configure your report settings.

To change subscription and report settings for a dashboard

1. Open a dashboard that is shared with you.
2. Choose the **Schedules** icon at upper right, and then choose **Schedules** in the dropdown.

3. The **Schedules** pane appears on the right. This pane shows all of the different scheduled reports that you are or can be subscribed to. Navigate to the report that you want and toggle the switch to subscribe or unsubscribe from the report.

Sign up for anomaly alerts

On a dashboard that has a narrative insight that's configured for anomaly detection, you can sign up to get alerts for anomalies and contribution analysis. You receive anomaly alerts when anomalies are updated. The alerts email displays the total number of anomalies, and provides detail on the top five, according to your personal alert configuration. You receive key driver contribution analysis when it's updated, provided that contribution analysis is configured to run with anomaly detection.

To set up anomaly alerts

1. Open a dashboard that is shared with you.
2. You can configure alerts from one of two screens. Choose one of the following, then go to the next step:
 - In the dashboard, locate the anomaly widget that you're interested in. Select it so that it has a highlighted box around it.
 - If you're in the dashboard and have the **Explore Anomalies** page open, you can configure the alert without returning to the dashboard view.
3. At upper right, choose **Configure alert**. The **Alert** configuration screen appears.
4. For **Severity**, choose the lowest level of significance that you want to see.

For **Direction**, choose to get alerts about anomalies that are **Higher than expected** or **Lower than expected**. You can also choose **[ALL]** to receive alerts about all anomalies.

5. Choose **OK** to confirm your choices.
6. To stop receiving to an anomaly alert, locate the anomaly widget in the dashboard and use the bell icon to unsubscribe. You can also use the **To manage this alert** link at the bottom of an alert email.

Creating a reader generated report in Amazon Quick Sight

If a Amazon Quick author has set up a prompted report for a Quick Sight pixel perfect report, Quick Sight dashboard viewers can use the prompt to schedule their own reports for themselves. For more information about prompts for pixel perfect reports, see [Setting up prompts for paginated reports](#).

Use the following sections to learn how to create and modify a reader generated report.

Topics

- [Creating a reader generated report](#)
- [Loading a saved view of a Quick Sight reader generated report](#)
- [Updating the view of a scheduled reader generated report](#)
- [Updating a reader generated report schedule](#)

Creating a reader generated report

Use the following procedure to create a reader generated report.

To create a reader generated report

1. Open the [Quick console](#).
2. Open the dashboard that you want to create a report for.
3. Choose the **Scheduling** at the top of the dashboard page.
4. The scheduling pane opens. To add a new report schedule, choose **Add**. If you do not see the **Add** button, the dashboard does not contain a pixel perfect sheet, or your Quick account does not have the Pixel perfect reports add on. For more information about the paginated reports add on, see [Getting started](#).
5. For **Schedule name**, enter a name for the new schedule. The schedule name can be up to 100 characters long.
6. For **Description**, choose the view option that you want the report to use. You can choose from the following views:
 - **Custom view** – The current view of the dashboard.
 - **Original view** – The author published view of the dashboard.
7. For **Content**, choose the pixel perfect report sheet that you want to generate a PDF report for.

8. For **Dates**, choose the frequency at which you want to receive the report. Scheduling options that are available for an email report include the following:
 - **Once (Does not repeat)** – Sends the report only once at the date and time that you choose.
 - **Daily** – Repeats daily at the time that you choose.
 - **Weekly** – Repeats each week on the same day or days at the time that you choose. You can also use this option to send reports in weekly intervals, such as every other week or every three weeks.
 - **Monthly** – Repeats each month on the same day of the month at the time that you choose. You can also use this option to send reports on specific days of the month, such as the second Wednesday or the last Friday of each month.
 - **Yearly** – Repeats each year on the same day of the month or months selected at the time that you choose. You can also use this option to send reports on specific days or sets of days in selected months. For example, you can configure a report to be sent on the first Monday of January, March, and September, or on July 14th, or on the second day of February, April, and June each year.
 - **Custom** – Configure your own scheduled report that best fits your business needs.

The scheduled report is sent within 1 hour from the specified time. Delays may occur during peak hours.

9. In the **Email** tab, for **E-mail subject line**, enter a custom subject line, or leave it blank to use the report title.
10. Enter the email addresses of the Quick group name of the users or groups that you want to receive the report.
11. For **Email header**, enter the header that you want the email report to show.
12. (Optional) For **E-mail body text**, leave it blank or enter a custom message to display at the beginning of the email.
13. (Optional, recommended) To send a sample of the report before you save changes, choose **Send test report**.
14. Do one of the following:
 - (Recommended) Choose **Save** to confirm your entries.
 - To immediately send a report, choose **Save and run now**. The report is sent immediately, even if your schedule's start date is in the future.

After you save a report schedule, the schedule appears in the **Schedules** pane. Reader generated reports are only available to the user that created them and can't be shared.

Loading a saved view of a Quick Sight reader generated report

Amazon Quick readers can use the **Schedules** pane to load a saved view of any scheduled pixel perfect report they have created or received. Use the following procedure to load a saved review of a scheduled report.

To load a saved view of a scheduled report

1. Open the [Quick console](#).
2. Open the dashboard that contains the report that you want to change.
3. Choose the **Scheduling** at the top of the dashboard page.
4. The scheduling pane opens. Locate the schedule that you want to change and choose the ellipsis (three dots) icon next to the report to open the schedule menu, and then choose **Details**.
5. Choose **Load saved view**. The saved view of the dashboard that was used for the selected schedule is rendered. All filter values that were active when the dashboard snapshot was taken are applied to the dashboard. When a saved view of a dashboard is loaded, the reader's current view of the dashboard is lost.

Updating the view of a scheduled reader generated report

After a Amazon Quick reader has created a report in Quick Sight, they can use the **Schedules** pane to update the dashboard view that is used in the scheduled report. Use the following procedure to update the dashboard view of a scheduled report.

To change the dashboard view of a scheduled report

1. Open the [Quick console](#).
2. Open the dashboard that contains the report that you want to change.
3. Choose the **Scheduling** at the top of the dashboard page.
4. The scheduling pane opens. Locate the schedule that you want to change and choose the ellipsis (three dots) icon next to the report to open the schedule menu, and then choose **Details**.

5. Choose **Load saved view**. The saved view of the dashboard that was used for the selected schedule is rendered. All filter values that were active when the dashboard snapshot was taken are applied to the dashboard. When a saved view of a dashboard is loaded, the reader's current view of the dashboard is lost.
6. Update the dashboard filters that you want to change.
7. Choose the **Scheduling** at the top of the dashboard page.
8. The scheduling pane opens. Locate the schedule that you want to change and choose the ellipsis (three dots) icon next to the report to open the schedule menu, and then choose **Edit**.
9. Navigate to the **Dashboard view** section, and then choose **Custom view**. The new filter values that you updated are applied to the dashboard report.
10. Choose **Save** to update the schedule.

Updating a reader generated report schedule

After they create a reader generated report, Amazon Quick readers can use the **Schedules** pane to make a report schedule active or inactive. Use the following procedure to update active status of a reader generated report schedule.

1. Open the [Quick console](#).
2. Open the dashboard that contains the report that you want to change.
3. Choose the **Scheduling** at the top of the dashboard page to open the **Schedules** pane.
4. Choose **Schedules**.
5. Navigate to the **My schedules** section and find the schedule that you want to update.
6. Use the toggle to set the report schedule to **Active** or **Inactive**.
7. When you are finished making changes to the report schedule, close the **Schedules** pane.

Bookmarking views of a Amazon Quick Sight dashboard

When you load a dashboard as an Amazon Quick reader or author, you can create bookmarks to capture specific views of your interests. For example, you can create a bookmark for a dashboard with a specific filter setting that differs from the original published dashboard. By doing this, you can quickly return to the data that's relevant to you.

After you create a bookmark, you can set it as the default view of the dashboard that you see when you open the dashboard in a new session. This doesn't affect anyone else's view of the dashboard.

You can create up to 200 bookmarks for a dashboard and share them by a URL link with other subscribers of that dashboard.

Dashboard bookmarks are available on the Quick console.

Dashboard bookmarks for pixel perfect reports are currently not supported. For more information on pixel perfect reports, see [Working with pixel perfect reports in Amazon Quick Sight](#).

Use the following topics to learn how to use bookmarks.

Topics

- [Creating bookmarks in Amazon Quick Sight](#)
- [Updating bookmarks in Amazon Quick Sight](#)
- [Renaming bookmarks in Amazon Quick Sight](#)
- [Making a bookmark the default view in Amazon Quick Sight](#)
- [Sharing bookmarks in Amazon Quick Sight](#)
- [Deleting bookmarks in Amazon Quick Sight](#)

Creating bookmarks in Amazon Quick Sight

Use the following procedure to create a bookmark for a dashboard.

To create a bookmark for a dashboard

1. Open the published dashboard that you want to view and make changes to the filters or parameters, or select the sheet that you want. For example, you can filter to the Region that interests you, or you can select a specific date range using a sheet control on the dashboard.
2. Choose the bookmark icon at upper right, and then choose **Add bookmark**.
3. In the **Add a bookmark** pane that opens, enter a name for the bookmark, and then choose **Save**.

The bookmark is saved, and the dashboard name updates with the bookmark name (at top left).

You can return to the original dashboard view that the author published at any time by selecting **Original dashboard** in the **Bookmarks** pane at right.

Updating bookmarks in Amazon Quick Sight

At any time, you can change a bookmark dashboard view and update the bookmark to always reflect those changes.

To update a bookmark

1. Open the published dashboard and make needed changes to the filters or parameters, or select a sheet.
2. Choose the bookmark icon at upper right.
3. In the **Bookmarks** pane that opens, choose the context menu (the three vertical dots) for the bookmark that you want to update, and then choose **Update**.

A message appears, confirming the update.

Renaming bookmarks in Amazon Quick Sight

Use the following procedure to rename a bookmark.

To rename a bookmark

1. In a published dashboard, choose the bookmark icon at upper right to open the **Bookmarks** pane.
2. In the **Bookmarks** pane, choose the context menu (the three vertical dots) for the bookmark that you want to rename, and then choose **rename**.
3. In the **Rename bookmark** pane, enter a name for the bookmark, and then choose **Save**.

Making a bookmark the default view in Amazon Quick Sight

By default, when you update a dashboard, Quick Sight remembers those changes and keeps them after you close the dashboard. This way, you can pick up where you left off when you open the dashboard again. You can set a bookmark as the default view of a dashboard instead. If you do, anytime that you open the dashboard, the bookmark view is presented to you, regardless of the changes you made during your last session.

To set a bookmark as your default view of the dashboard

1. In a published dashboard, choose the bookmark icon at upper right to open the **Bookmarks** pane.
2. In the **Bookmarks** pane, choose the context menu (the three dots) for the bookmark that you want to set as your default view, and then choose **Set as default**.

Sharing bookmarks in Amazon Quick Sight

After you create a bookmark, you can share a URL link for the view with others who have permission to view the dashboard. They can then save that view as their own bookmark.

To share a bookmark with another dashboard subscriber

1. In a published dashboard, choose the bookmark icon at upper right to open the **Bookmarks** pane.
2. In the **Bookmarks** pane, choose the bookmark that you want to share so that the dashboard updates to that view.
3. Choose the share icon at upper right, and then choose **Share this view**.

You can copy the URL link that Quick Sight provides and paste it in an email or IM message to share it with others. The recipient of the URL link can then save the view as their own bookmark. For more information about sharing views of a dashboard, see [Sharing your view of a Amazon Quick Sight dashboard](#).

Deleting bookmarks in Amazon Quick Sight

Use the following procedure to delete a bookmark.

To delete a bookmark

1. In a published dashboard, choose the bookmark icon at upper right to open the **Bookmarks** pane.
2. In the **Bookmarks** pane, choose the context menu (the three vertical dots) for the bookmark that you want to delete, and then choose **Delete**.
3. In the **Delete Bookmark** pane that opens, choose **Yes, Delete Bookmark**.

Gaining insights with machine learning (ML) in Amazon Quick Sight

Amazon Quick Sight uses machine learning to help you uncover hidden insights and trends in your data, identify key drivers, and forecast business metrics. You can also consume these insights in natural language narratives embedded in dashboards.

Using machine learning (ML) and natural language capabilities, Amazon Quick Sight Enterprise Edition takes you beyond descriptive and diagnostic analysis, and launches you into forecasting and decision-making. You can understand your data at a glance, share your findings, and discover the best decisions to achieve your goals. You can do this without developing teams and technology to create the necessary machine learning models and algorithms.

You likely have already built visualizations that answer questions about what happened, when, where, and provide drill down for investigation and identification of patterns. With ML insights, you can avoid spending hours manually analyzing and investigating. You can select from a list of customized context-sensitive narratives, called *autonarratives*, and add them to your analysis. In addition to choosing autonarratives, you can choose to view forecasts, anomalies, and factors contributing to these. You can also add autonarratives that explain the key takeaways in plain language, providing a single data-driven truth for your company.

As time passes and data flows through the system, Amazon Quick Sight continually learns so it can deliver ever more pertinent insights. Instead of deciding what the data means, you can decide what to do with the information it provides.

With a shared foundation based on machine learning, all of your analysts and stakeholders can see trends, anomalies, forecasts, and custom narratives built on millions of metrics. They can see root causes, consider forecasts, evaluate risks, and make well-informed, justifiable decisions.

You can create a dashboard like this with no manual analysis, no custom development skills, and no understanding of machine learning modeling or algorithms. All this capability is built into Amazon Quick Sight Enterprise Edition.

Note

Machine learning capabilities are used as needed throughout the product. Features that actively use machine learning are labeled as such.

With ML Insights, Amazon Quick Sight provides three major features:

- **ML-powered anomaly detection** – Amazon Quick Sight uses Amazon's proven machine learning technology to continuously analyze all your data to detect anomalies (outliers). You can identify the top drivers that contribute to any significant change in your business metrics, such as higher-than-expected sales or a dip in your website traffic. Amazon Quick Sight uses the Random Cut Forest algorithm on millions of metrics and billions of data points. Doing this enables you to get deep insights that are often buried in the aggregates, inaccessible through manual analysis.
- **ML-powered forecasting** – Amazon Quick Sight enables nontechnical users to confidently forecast their key business metrics. The built-in ML Random Cut Forest algorithm automatically handles complex real-world scenarios such as detecting seasonality and trends, excluding outliers, and imputing missing values. You can interact with the data with point-and-click simplicity.
- **Autonarratives** – By using automatic narratives in Amazon Quick Sight, you can build rich dashboards with embedded narratives to tell the story of your data in plain language. Doing this can save hours of sifting through charts and tables to extract the key insights for reporting. It also creates a shared understanding of the data within your organization so you make decisions faster. You can use the suggested autonarrative, or you can customize the computations and language to meet your unique requirements. Amazon Quick Sight is like providing a personal data analyst to all of your users.

Understanding the ML algorithm used by Amazon Quick Sight

You don't need any technical experience in machine learning to use the ML-powered features in Amazon Quick Sight. This section dives into the

technical aspects of the algorithm, for those who want the details about how it works. This information isn't required reading to use the features.

Amazon Quick Sight uses a built-in version of the Random Cut Forest (RCF) algorithm. The following sections explain what that means and how it is used in Amazon Quick Sight.

First, let's look at some of the terminology involved:

- **Anomaly** – Something that is characterized by its difference from the majority of the other things in the same sample. Also known as an outlier, an exception, a deviation, and so on.
- **Data point** – A discrete unit—or simply put, a row—in a dataset. However, a row can have multiple data points if you use a measure over different dimensions.
- **Decision Tree** – A way of visualizing the decision process of the algorithm that evaluates patterns in the data.
- **Forecast** – A prediction of future behavior based on current and past behavior.
- **Model** – A mathematical representation of the algorithm or what the algorithm learns.
- **Seasonality** – The repeating patterns of behavior that occur cyclically in time series data.
- **Time series** – An ordered set of date or time data in one field or column.

- [How RCF is applied to generate forecasts](#)
- [References for machine learning and RCF](#)

What's the difference between anomaly detection and forecasting?

Anomaly detection identifies outliers and their contributing drivers to answer the question "What happened that doesn't usually happen?" Forecasting answers the question "If everything continues to happen as expected, what happens in the future?" The math that allows forecasting also enables us to ask "If a few things change, what happens then?"

Both anomaly detection and forecasting begin by examining the current known data points. Amazon Quick Sight anomaly detection begins with what is known so it can establish what is outside the known set, and identify those data points as anomalous (outliers). Amazon Quick Sight forecasting excludes the anomalous data points, and sticks with the known pattern. Forecasting focuses on the established pattern of data distribution. In contrast, anomaly detection focuses on the data points that deviate from what is expected. Each method approaches decision-making from a different direction.

What is RCF?

A *random cut forest* (RCF) is a special type of *random forest* (RF) algorithm, a widely used and successful technique in machine learning. It takes a set of random data points, cuts them down to the same number of points, and then builds a collection of models. In contrast, a model corresponds to a decision tree—thus the name forest. Because RFs can't be easily updated in an incremental manner, RCFs were invented with variables in tree construction that were designed to allow incremental updates.

As an unsupervised algorithm, RCF uses cluster analysis to detect spikes in time series data, breaks in periodicity or seasonality, and data point exceptions. Random cut forests can work as a synopsis or sketch of a dynamic data stream (or a time-indexed sequence of numbers). The answers to our questions about the stream come out of that synopsis. The following characteristics address the stream and how we make connections to anomaly detection and forecasting:

- A *streaming algorithm* is an online algorithm with a small memory footprint. An online algorithm makes its decision about the input point indexed by time t before it sees the $(t+1)$ -st point. The small memory allows nimble algorithms that can produce answers with low latency and allow a user to interact with the data.
- Respecting the ordering imposed by time, as in an *online* algorithm, is necessary in anomaly detection and forecasting. If we already know what will happen the day after tomorrow, then predicting what happens tomorrow isn't a forecast—it's just interpolating an unknown missing value. Similarly, a new product introduced today can be an anomaly, but it doesn't necessarily remain an anomaly at the end of the next quarter.

How RCF is applied to detect anomalies

A human can easily distinguish a data point that stands out from the rest of the data. RCF does the same thing by building a "forest" of decision trees, and then monitoring how new data points change the forest.

An *anomaly* is a data point that draws your attention away from normal points—think of an image of a red flower in a field of yellow flowers. This "displacement of attention" is encoded in the (expected) position of a tree (that is, a model in RCF) that would be occupied by the input point. The idea is to create a forest where each decision tree grows out of a partition of the data sampled for training the algorithm. In more technical terms, each tree builds a specific type of binary space partitioning tree on the samples. As Amazon Quick Sight samples the data, RCF assigns each data point an anomaly score. It gives higher scores to data points that look anomalous. The score is, in approximation, inversely proportional to the resulting depth of the point in the tree. The random cut forest assigns an anomaly score by computing the average score from each constituent tree and scaling the result with respect to the sample size.

The votes or scores of the different models are aggregated because each of the models by itself is a weak predictor. Amazon Quick Sight identifies a data point as anomalous when its score is significantly different from the recent points. What qualifies as an anomaly depends on the application.

The paper [Random Cut Forest Based Anomaly Detection On Streams](#) provides multiple examples of this state-of-the-art online anomaly detection (time-series anomaly detection). RCFs are used on contiguous segments or "shingles" of data, where the data in the immediate segment acts as a context for the most recent one. Previous versions of RCF-based anomaly-detection algorithms score an entire shingle. The algorithm in Amazon Quick Sight also provides an approximate location of the anomaly in the current extended context. This approximate location can be useful in the scenario where there is delay in detecting the anomaly. Delays occur because any algorithm needs to characterize "previously seen deviations" to "anomalous deviations," which can unfold over some time.

How RCF is applied to generate forecasts

To forecast the next value in a stationary time sequence, the RCF algorithm answers the question "What would be the most likely completion, after we have a candidate value?" It uses a single tree in RCF to perform a search for the best candidate. The candidates across different trees are aggregated, because each tree by itself a weak predictor. The aggregation also allows the generation of quantile errors. This process is repeated t times to predict the t -th value in the future.

The algorithm in Amazon Quick Sight is called *BIFOCAL*. It uses two RCFs to create a CALibrated BI-FOrest architecture. The first RCF is used to filter out anomalies and provide a weak forecast, which is corrected by the second. Overall, this approach provides significantly more robust forecasts in comparison to other widely available algorithms such as ETS.

The number of parameters in the Amazon Quick Sight forecasting algorithm is significantly fewer than for other widely available algorithms. This allows it to be useful out of the box, without human adjustment for a larger number of time series data points. As more data accumulates in a particular time series, the forecasts in Amazon Quick Sight can adjust to data drifts and changes of pattern. For time series that show trends, trend detection is performed first to make the series stationary. The forecast of that stationary sequence is projected back with the trend.

Because the algorithm relies on an efficient online algorithm (RCF), it can support interactive "what-if" queries. In these, some of the forecasts can be altered and treated as hypotheticals to provide conditional forecasts. This is the origin of the ability to explore "what-if" scenarios during analysis.

References for machine learning and RCF

To learn more about machine learning and this algorithm, we suggest the following resources:

- The article [Robust Random Cut Forest \(RRCF\): A No Math Explanation](#) provides a lucid explanation without the mathematical equations.
- The book [The Elements of Statistical Learning: Data Mining, Inference, and Prediction, Second Edition \(Springer Series in Statistics\)](#) provides a thorough foundation on machine learning.
- [Random Cut Forest Based Anomaly Detection On Streams](#), a scholarly paper that dives deep into the technicalities of both anomaly detection and forecasting, with examples.

A different approach to RCF appears in other AWS services. If you want to explore how RCF is used in other services, see the following:

- *Amazon Managed Service for Apache Flink SQL Reference*: [RANDOM_CUT_FOREST](#) and [RANDOM_CUT_FOREST_WITH_EXPLANATION](#)
- *Amazon SageMaker Developer Guide*: [Random Cut Forest \(RCF\) Algorithm](#). This approach is also explained in [The Random Cut Forest Algorithm](#), a chapter in [Machine Learning for Business](#) (October 2018).

Dataset requirements for using ML insights with Amazon Quick Sight

To begin using the machine learning capabilities of Amazon Quick Sight, you need to connect to or import your data. You can use an existing Amazon Quick Sight dataset or create a new one. You can directly query your SQL-compatible source, or ingest the data into SPICE.

The data must have the following properties:

- At least one metric (for example, sales, orders, shipped units, sign ups, and so on).
- At least one category dimension (for example, product category, channel, segment, industry, and so on). Categories with NULL values are ignored.
- Anomaly detection requires a minimum of 15 data points for training. For example, if the grain of your data is daily, you need at least 15 days of data. If the grain is monthly, you need at least 15 months of data.
- Forecasting work best with more data. Make sure that your dataset has enough historical data for optimal results. For example, if the grain of your data is daily, you need at least 38 days of data. If the grain is monthly, you need at least 43 months of data. Following are the requirements for each time grain:
 - Years: 32 data points
 - Quarters: 35 data points
 - Months: 43 data points
 - Weeks: 35 data points
 - Days: 38 data points
 - Hours: 39 data points
 - Minutes: 46 data points
 - Seconds: 46 data points
- If you want to analyze anomalies or forecasts, you also need at least one date dimension.

If you don't have a dataset to get started, you can download this sample dataset: [ML Insights Sample Dataset VI](#). After you have a dataset ready, create a new analysis from the dataset.

Working with insights in Amazon Quick Sight

In Amazon Quick Sight, you can add ready-to-use analytical computations to your analysis as widgets. You can work with insights in two ways:

- **Suggested insights**

Amazon Quick Sight creates a list of suggested insights based on its interpretation of the data you put into your visuals. The list changes based on context. In other words, you can see different suggestions depending on what fields you add to your visual and what type of visual you choose.

For example, if you have a time-series visualization, your insights might include period-over-period changes, anomalies, and forecasts. As you add more visualizations to your analysis, you generate more suggested insights.

- **Custom insights**

Custom insights enable you to create your own computation, using your own words to give context to the fields that appear in the widget. When you create a custom insight, you add it to the analysis, and then choose what type of calculation that you want to use. Then, you can add text and formatting to make it look how you want. You can also add more fields, calculations, and parameters.

You can add any combination of suggested and custom insights to your analysis, to create the decision-making environment that best serves your purposes.

Topics

- [Adding suggested insights](#)
- [Adding custom insights to your analysis](#)

Adding suggested insights

Use the following procedure to add suggested insights to your analysis.

Before you begin, make sure that your dataset meets the criteria outlined in [Dataset requirements for using ML insights with Amazon Quick Sight](#).

1. Begin with an analysis that has a few fields added to a visual.
2. On the left, choose **Insights**. The **Insights** panel opens and displays a list of ready-to-use suggested insights.

Each visual also displays a small box on its top border to display how many insights are available for that visual. You can choose this box to open the **Insights** panel, and it opens to whatever view you most recently had open.

Scroll down to preview more insights.

The insights that appear are controlled by the data type of the fields you choose to include in your visual. This list is generated each time you change your visual. If you make changes,

check **Insights** to see what is new. To get a specific insight, see [Adding custom insights to your analysis](#).

3. (Optional) Open the context menu with more options for one of the insights. To do this, choose the ellipses on the top right of the insight (...).

The options are different for each type of insight. The options that you can interact with include the following:

- **Change the time series aggregation** – To year, quarter, month, week, day, hour, or minute.
 - **Analyze contributions to metrics** – Choose contributors and a time frame to analyze.
 - **Show all anomalies** – Browse anomalies in this time frame.
 - **Edit forecast** – Choose forecast length, prediction interval, and seasonality.
 - **Focus on** or **Exclude** – Zoom in or zoom out on your dimensional data.
 - **Show details** – View more information about a recent anomaly (outlier).
 - Provide feedback on the usefulness of the insight in your analysis.
4. Add a suggested insight to your analysis by choosing the plus sign (+) near the insight title.
 5. (Optional) After you add an insight to your analysis, customize the narrative that you want it to display. To do this, choose the v-shaped on-visual menu, then choose **Customize narrative**. For more information, see [Creating autonarratives with Amazon Quick Sight](#).

If your insight is for anomalies (outliers), you can also change the settings for the anomaly detection job. To do this, choose **Configure anomaly**. For more information, see [Setting up ML-powered anomaly detection for outlier analysis](#).

6. (Optional) To remove the insight from your analysis, choose the v-shaped on-visual menu at the top right of the visual. Then choose **Delete**.

Adding custom insights to your analysis

If you don't want to use any of the suggested insights, you can create your own custom insight. Use the following procedure to create a custom computational insight.

1. Start with an existing analysis. On the top menu bar, choose **Add+**. Then choose **Add Insight**.

A container for the new insight is added to the analysis.

2. Do one of the following:

- Choose the computation that you want to use from the list. As you choose each item, an example of that insight's output displays. When you find the one that you want to use, choose **Select**.
- Exit this screen and customize the insight manually. An unconfigured insight has a **Customize insight** button. Choose the button to open the **Configure narrative** screen. For more information on using the expression editor, see [Creating autonarratives with Amazon Quick Sight](#).

Because you are initiating the creation of the insight, it's not based on an existing visual. When the insight is added to the analysis, it displays a note showing what kind of data it needs to complete your request. For example, it might ask for **1 dimension in Time**. In this case, you add a dimension to the **Time** field well.

3. After you have the correct data, follow any remaining screen prompts to finish creating the custom insight.
4. (Optional) To remove the insight from your analysis, choose the v-shaped on-visual menu at the top right of the visual. Then choose **Delete**.

Creating autonarratives with Amazon Quick Sight

An *autonarrative* is a natural-language summary widget that displays descriptive text instead of charts. You can embed these widgets throughout your analysis to highlight key insights and callouts. You don't have to sift through the visual, drilling down, comparing values, and rechecking ideas to extract a conclusion. You also don't have to try to understand what the data means, or discuss different interpretations with your colleagues. Instead, you can extrapolate the conclusion from the data, and display it in the analysis, stated plainly. A single interpretation can be shared by everyone.

Amazon Quick Sight automatically interprets the charts and tables in your dashboard and provides a number of suggested insights in natural language. The suggested insights that you can choose from are ready-made and come with words, calculations, and functions. But you can change them if you want to. You can also design your own. As the author of the dashboard, you have complete flexibility to customize the computations and language for your needs. You can use narratives to effectively tell the story of your data in plain language.

Note

Narratives are separate from machine learning. They only use ML if you add forecast or anomaly (outlier) computations to them.

Topics

- [Insights that include autonarratives](#)

- [The expression editor workspace](#)
- [Adding URLs](#)
- [Working with autonarrative computations](#)

Insights that include autonarratives

When you are adding an insight, also known as an autonarrative, to your analysis, you can choose from the following templates. In the following list, they are defined by example. Each definition includes a list of the minimum required fields for the autonarrative to work. If you are using only the suggested insights on the **Insights** tab, choose the appropriate fields to get an insight to show up in the suggested insights list.

For more information on customizing autonarratives, see [Working with autonarrative computations](#).

- **Bottom ranked** – For example, the bottom three states by sales revenue. Requires that you have at least one dimension in the **Categories** field well.
- **Bottom movers** – For example, the bottom three products sold, by sales revenue. Requires that you have at least one dimension in the **Time** field well and at least one dimension in the **Categories** field well.
- **Forecast (ML-powered insight)** – For example, "Total sales are forecasted to be \$58,613 for Jan 2016." Requires that you have at least one dimension in the **Time** field well.
- **Growth rate** – For example, "The 3-month compounded growth rate for sales is 22.23%." Requires that you have at least one dimension in the **Time** field well.
- **Maximum** – For example, "Highest month is Nov 2014 with sales of \$112,326." Requires that you have at least one dimension in the **Time** field well.

- **Metric comparison** – For example, "Total sales for Dec 2014 is \$90,474, 10% higher than target of \$81,426." Requires that you have at least one dimension in the **Time** field well and at least two measures in the **Values** field well.
- **Minimum** – For example, "Lowest month is Feb 2011 with sales of \$4,810." Requires that you have at least one dimension in the **Time** field well.
- **Anomaly detection (ML-powered insight)** – For example, top three outliers and their contributing drivers for total sales on January 3, 2019. Requires that you have at least one dimension in the **Time** field well, at least one measure in the **Values** field well, and at least one dimension in the **Categories** field well.
- **Period over period** – For example, "Total sales for Nov 2014 increased by 44.39% (\$34,532) from \$77,793 to \$112,326." Requires that you have at least one dimension in the **Time** field well.
- **Period to date** – For example, "Year-to-date sales for Nov 30, 2014 increased by 25.87% (\$132,236) from \$511,236 to \$643,472." Requires that you have at least one dimension in the **Time** field well.
- **Top ranked** – For example, top three states by sales revenue. Requires that you have at least one dimension in the **Categories** field well.
- **Top movers** – For example, top products by sales revenue for November 2014. Requires that you have at least one dimension in the **Time** field well and at least one dimension in the **Categories** field well.
- **Total aggregation** – For example, "Total revenue is \$2,297,200." Requires that you have at least one dimension in the **Time** field well and at least one measure in the **Values** field well.
- **Unique values** – For example, "There are 793 unique values in Customer_IDs." Requires that you have at least one dimension in the **Categories** field well.

Use the narrative expression editor

The following walkthrough shows an example of how to customize a narrative. For this example, we use a period over period computation type.

1. Begin with an existing analysis. Add a **period over period** insight to it. The easiest way to do this is to choose the + icon, then **Add insight**, then choose a type of insight from the list. To learn what type of computational insights you can add as autonarratives, see [Insights that include autonarratives](#).

After you choose a type of insight, choose **Select** to create the widget. To create an empty narrative, close this screen without choosing a template. To follow this example, choose **Period over period**.

If you had a visual selected when you added the insight, the field wells have preconfigured fields for the date, metric, and category. These come from the visualization that you chose when you created the insight. You can customize the fields as needed.

You can only customize a narrative for a new or existing insight (text-based) widget. You can't add one to an existing visual (chart based), because it's a different type of widget.

2. Edit the narrative in the expressions editor by choosing the on-visual menu, then choosing **Customize narrative**.

In this context, **Computations** are predefined calculations (period-over-period, period-to-date, growth rate, max, min, top movers, and so on) that you can reference in your template to describe your data. Currently, Amazon Quick Sight supports 13 different types of computations that you can add to your insight. In this example, **PeriodOverPeriod** is added by default because we chose the **Period Over Period** template from the suggested insights panel.

3. Choose **Add computation** at bottom right to add a new computation, and then choose one from the list. For this walkthrough, choose **Growth rate**, and then choose **Next**.
4. Configure the computation by choosing the number of periods that you want to compute over. The default is four, and that works for our example. Optionally, you can change the name of the computation at the top of the screen. However, for our purposes, leave the name unchanged.

Note

The computation names that you create are unique within the insight. You can reference multiple computations of the same type in your narrative template. For example, suppose that you have two metrics, sales revenue and units sold. You can create growth rate computations for each metric if they have different names. However, anomaly computations aren't compatible with any other computation type in the same widget. Anomaly detection must exist in an insight by itself. To use other computations in the same analysis, put them into insights separate from anomalies.

To proceed, choose **Add**.

- Expand **Computations** on the right. The computations that are part of the narrative display in the list. In this case, it's **PeriodOverPeriod** and **GrowthRate**.
- In the workspace, add the following text after the final period: **Compounded growth rate for the last**, then add a space.
- Next, to add the computation leave your cursor after the space after the word **last**. On the right, under **GrowthRate**, choose the expression named **timePeriods** (click only once to add it).

Doing this inserts the expression **GrowthRate.timePeriods**, which is the number of periods you set in the configuration for **GrowthRate**.

- Complete the sentence with **days is** (a space before and afterwards), and add the expression **GrowthRate.compoundedGrowthRate.formattedValue**, followed by a period (.). Choose the expression from the list, rather than typing it in. However, you can edit the contents of the expression after you add it.

Note

The **formattedValue** expression returns a string that is formatted based on the formatting applied for the metric on the field. To perform metric math, use **value** instead, which returns the raw value as an integer or decimal.

- Add a conditional statement and formatting. Place your cursor at the end of the template, after the **formattedValue** expression. Add a space if necessary. On the **Edit narrative** menu bar, choose **Insert code**, and then choose **Inline IF** from the list. An expression block opens.

10. With the expression block open, choose **GrowthRate**, **compoundedGrowthRate**, **value** from the expression list. Enter **>0** at the end of the expression. Choose **Save**. Don't move your cursor yet.

A prompt appears for the conditional content; enter **better than expected!** Then select the text you just entered, and use the formatting toolbar at the top to turn it green and bold.
11. Add another expression block for the case when the growth rate wasn't that great by repeating the previous step. But this time, make it **<0** and enter the text **worse than expected**. Make it red instead of green.
12. Choose **Save**. The customized narrative that we just created should look similar to the following.

The expression editor provides you with a sophisticated tool to customize your narratives. You can also reference the parameters you create for your analysis or dashboard, and use a set of built-in functions for further customization.

Tip

To create an empty narrative, add an insight using the **+** icon and then **Add insights**. But instead of choosing a template, simply close the screen.
The best way to get started with customizing narratives is to use the existing templates to learn the syntax.

The expression editor workspace

Use the expression editor to customize a narrative to best fit your business needs. The information below provides an overview of the expression editor workspace and lists all menu options that can be configured for your narrative. For a walkthrough that shows you how to create a custom narrative, see [Use the narrative expression editor](#).

On the right side of the screen, there's a list of items that you can add to the narrative:

- **Computations** – Use this to choose from the computations that are available in this insight. You can expand this list.
- **Parameters** – Use this to choose from the parameters that exist in your analysis. You can expand this list.
- **Functions** – Use this to choose from functions that you can add to a narrative. You can expand this list.
- **Add computation** – Use this button to create another computation. New computations appear in the **Computations** list, ready to add to the insight.

At the bottom of the narrative expression editor, there's a preview of the narrative that updates as you work. This area also shows an alert if you introduce an error into the narrative or if the narrative is empty. To see a preview of ML-powered insights like anomaly detection or forecasting, run your insight calculation at least once before customizing the narrative.

Editing tools are located across the top of the screen. They offer the following options:

- **Insert code** – You can insert the following code blocks from this menu:
 - **Expressions** – Add a free-form expression.
 - **Inline IF** – Add an IF statement that displays inline with the existing block of text.
 - **Inline FOR** – Add a FOR statement that displays inline with the existing block of text.
 - **Block IF** – Add an IF statement that displays in a separate block of text.
 - **Block FOR** – Add a FOR statement that displays in a separate block of text.

The IF and FOR statements enable you to create content that is conditionally formatted. For example, you might add a **block IF** statement, then configure it to compare an integer to a value from a calculation. To do this, you use the following steps, also demonstrated in [Use the narrative expression editor](#):

1. Open the calculations menu at right, and choose one of the blue highlighted items from one of the calculations. Doing this adds the item to the narrative.
2. Click once on the item to open it.
3. Enter the comparison that you want to make. The expression looks something like this:
`PeriodOverPeriod.currentMetricValue.value>0.`
4. Save this expression in the pop-up editor, which prompts you for **Conditional content**.
5. Enter what you want to display in the insight, and format it as you want it to appear. Or if you prefer, you can add an image or a URL—or add a URL to an image.

- **Paragraph** – This menu offers options for changes to the font size:
 - **H1 Large header**
 - H2 Header
 - H3 Small header
 - ¶1 Large paragraph
 - ¶2 Paragraph
 - ¶3 Small paragraph
- **Font** – Use this menu tray to choose options for text formatting. These include bold, italic, underline, strikethrough, foreground color of the text (the letters themselves), and background color of the text. Choose the icon to turn on an option; choose it again to toggle the option off.
- **Formatting** – Use this menu tray to choose options for paragraph formatting, including bulleted list, left justify, center, and right justify. Choose the icon to turn on an option, choose it again to toggle the option off.
- **Image** – Use this icon add an image URL. The image displays in your insight, provided the link is accessible. You can resize images. To display an image based on a condition, put the image inside an IF block.
- **URL** – Use this icon to add a static or dynamic URL. You can also add URLs to images. For example, you can add traffic light indicator images to an insight for an executive dashboard, with links to a new sheet for red, amber, and green conditions.

Adding URLs

Using the **URL** button on the editing menu of the narrative expression editor, you can add static and dynamic URLs (hyperlinks) into a narrative. You can also use the following keyboard shortcuts: ⌘+⬆+L or Ctrl+⬆+L.

A static URL is a link that doesn't change; it always opens the same URL. A dynamic URL is a link that changes based on the expressions or parameters that you provide when you set it up. It's built with dynamically evaluated expressions or parameters.

Following are of examples of when you might add a static link in your narrative:

- **In an IF statement, you might use the URL in the conditional content.** If you do and a metric fails to meet an expected value, your link might send the user to a wiki with a list of best practices to improve the metric.

- **You might use a static URL to create a link to another sheet in the same dashboard, by using the following steps:**

1. Go to the sheet that you want to make the link to.
2. Copy that sheet's URL.
3. Return to the narrative editor and create a link using the URL that you just copied.

Following are examples of when you might add a dynamic link in your narrative:

- **To search a website with a query, by using the following steps.**

1. Create a URL with the following link.

```
https://google.com?q=<<formatDate(now(), 'yyyy-MM-dd')>>
```

This link sends a query to Google with search text that is the evaluated value of the following.

```
formatDate(now(), 'yyyy-MM-dd')
```

If the value of `now()` is 02/02/2020, then the link on your narrative contains `https://google.com?q=2020-02-02`.

- **To create a link that updates a parameter.** To do this, create or edit a link and set the URL to the current dashboard or analysis URL. Then add the expression that sets the parameter value to at the end, for example `#p.myParameter=12345`.

Suppose that the following is the dashboard link that you start with.

```
https://us-east-1.quicksight.aws.amazon.com/sn/analyses/00000000-1111-2222-3333-44444444
```

If you add a parameter value assignment to it, it looks like the following.

```
https://us-east-1.quicksight.aws.amazon.com/sn/analyses/00000000-1111-2222-3333-44444444#p.myParameter=12345
```

For more information on parameters in URLs, see [Using parameters in a URL](#).

Working with autonarrative computations

Use this section to help you understand what functions are available to you when you are customizing an autonarrative. You only need to customize a narrative if you want to change or build on the default computation.

After you create an autonarrative, the expression editor opens. You can also activate the expression editor by choosing the on-visual menu, and then **Customize Narrative**. To add a computation while using the expression editor, choose **+ Add computation**.

You can use the following code expression to build your autonarrative. These are available from the list that's labeled **Insert code**. Code statements can display inline (in a sentence) or as a block (in a list).

- Expression – Create your own code expression.
- IF – An IF statement that includes an expression after evaluating a condition.
- FOR – A FOR statement that loops through values.

You can use the following computations to build your autonarrative. You can use the expression editor without editing any syntax, but you can also customize it if you want to. To interact with the syntax, open the computational widget in the autonarrative expression editor.

ML-powered anomaly detection for outliers

The ML-powered anomaly detection computation searches your data for outliers. For example, you can detect the top three outliers for total sales on January 3, 2019. If you enable contribution analysis, you can also detect the key drivers for each outlier.

To use this function, you need at least one dimension in the **Time** field well, at least one measure in the **Values** field well, and at least one dimension in the **Categories** field well. The configuration screen provides an option to analyze the contribution of other fields as key drivers, even if those fields aren't in the field wells.

For more information, see [Detecting outliers with ML-powered anomaly detection](#).

Note

You can't add ML-powered anomaly detection to another computation, and you can't add another computation to an anomaly detection.

Computation outputs

Each function generates a set of output parameters. You can add these outputs to the autonarrative to customize what it displays. You can also add your own custom text.

To locate the output parameters, open the **Computations** tab on the right, and locate the computation that you want to use. The names of the computations come from the name that you provide when you create the insight. Choose the output parameter by clicking on it only once. If you click twice, you add the same output twice. You can use items displayed in **bold monospace font** following in the narrative.

- `timeField` – From the **Time** field well.
 - `name` – The formatted display name of the field.
 - `timeGranularity` – The time field granularity (**DAY**, **YEAR**, and so on).
- `categoryFields` – From the **Categories** field well.
 - `name` – The formatted display name of the field.

- **metricField** – From the **Values** field well.
 - **name** – The formatted display name of the field.
 - **aggregationFunction** – The aggregation used for the metric (**SUM**, **AVG**, and so on).
- **itemsCount** – The number of items included in this computation.
- **items** – Anomalous items.
 - **timeValue** – The values in the date dimension.
 - **value** – The date/time field at the point of the anomaly (outlier).
 - **formattedValue** – The formatted value in the date/time field at the point of the anomaly.
 - **categoryName** – The actual name of the category (cat1, cat2, and so on).
 - **direction** – The direction on the x-axis or y-axis that's identified as anomalous: HIGH or LOW. HIGH means "higher than expected." LOW means "lower than expected."

When iterating on items, `AnomalyDetection.items[index].direction` can contain either HIGH or LOW. For example, `AnomalyDetection.items[index].direction='HIGH'` or `AnomalyDetection.items[index].direction=LOW`.

`AnomalyDetection.direction` can have an empty string for ALL. An example is `AnomalyDetection.direction=' '`.

- **actualValue** – The metric's actual value at the point of the anomaly or outlier.
 - **value** – The raw value.
 - **formattedValue** – The value formatted by the metric field.
 - **formattedAbsoluteValue** – The absolute value formatted by the metric field.
- **expectedValue** – The metric's expected value at the point of the anomaly (outlier).
 - **value** – The raw value.
 - **formattedValue** – The value formatted by the metric field.
 - **formattedAbsoluteValue** – The absolute value formatted by the metric field.

Bottom movers computation

The bottom movers computation counts the requested number of categories by date that rank in the bottom of the autonarrative's dataset. For example, you can create a computation to find the bottom three products sold, by sales revenue.

To use this function, at least one dimension in the **Time** field well and at least one dimension in the **Categories** field well.

Parameters

name

A unique descriptive name that you assign or change. A name is assigned if you don't create your own. You can edit this later.

Date

The date dimension that you want to rank.

Category

The category dimension that you want to rank.

Value

The aggregated measure that the computation is based on.

Number of movers

The number of ranked results that you want to display.

Order by

The order that you want to use, percent difference or absolute difference.

Computation outputs

Each function generates a set of output parameters. You can add these outputs to the autonarrative to customize what it displays. You can also add your own custom text.

To locate the output parameters, open the **Computations** tab on the right, and locate the computation that you want to use. The names of the computations come from the name you provide when you create the insight. Choose the output parameter by clicking on it only once. If you click twice, you add the same output twice. Items displayed in **bold** can be used in the narrative.

Note

These are the same output parameters as the ones that are returned by the top movers computation.

- **timeField** – From the **Time** field well.
 - **name** – The formatted display name of the field.
 - **timeGranularity** – The time field granularity (**DAY**, **YEAR**, and so on).
- **categoryField** – From the **Categories** field well.
 - **name** – The formatted display name of the field.
- **metricField** – From the **Values** field well.
 - **name** – The formatted display name of the field.
 - **aggregationFunction** – The aggregation used for the metric (**SUM**, **AVG**, and so on).
- **startTimeValue** – The value in the date dimension.
 - **value** – The raw value.
 - **formattedValue** – The value formatted by the datetime field.
- **endTimeValue** – The value in the date dimension.
 - **value** – The raw value.
 - **formattedValue** – The absolute value formatted by the datetime field.
- **itemsCount** – The number of items included in this computation.
- **items**: Bottom moving items.
 - **categoryField** – The category field.
 - **value** – The value (contents) of the category field.
 - **formattedValue** – The formatted value (contents) of the category field. If the field is null, this displays 'NULL'. If the field is empty, it displays '(empty)'.
 - **currentMetricValue** – The current value for the metric field.
 - **value** – The raw value.
 - **formattedValue** – The value formatted by the metric field
 - **formattedAbsoluteValue** – The absolute value formatted by the metric field.
 - **previousMetricValue** – The previous value for the metric field.
 - **value** – The raw value.
 - **formattedValue** – The value formatted by the metric field
 - **formattedAbsoluteValue** – The absolute value formatted by the metric field.
 - **percentDifference** – The percent difference between the current and previous values of the metric field.
 - **value** – The raw value of the calculation of the percent difference.

- **formattedValue** – The formatted value of the percent difference (for example, -42%).
- **formattedAbsoluteValue** – The formatted absolute value of the percent difference (for example, 42%).
- **absoluteDifference** – The absolute difference between the current and previous values of the metric field.
 - **value** – The raw value of the calculation of the absolute difference.
 - **formattedValue** – The absolute difference formatted by the settings in the metric field's format preferences.
 - **formattedAbsoluteValue** – The absolute value of the difference formatted by the metric field.

Bottom ranked computation

The bottom ranked computation calculates the requested number of categories by value that rank in the bottom of the autonarrative's dataset. For example, you can create a computation to find the bottom three states by sales revenue.

To use this function, you need at least one dimension in the **Categories** field well.

Parameters

name

A unique descriptive name that you assign or change. A name is assigned if you don't create your own. You can edit this later.

Category

The category dimension that you want to rank.

Value

The aggregated measure that the computation is based on.

Number of results

The number of ranked results that you want to display.

Computation outputs

Each function generates a set of output parameters. You can add these outputs to the autonarrative to customize what it displays. You can also add your own custom text.

To locate the output parameters, open the **Computations** tab on the right, and locate the computation that you want to use. The names of the computations come from the name you provide when you create the insight. Choose the output parameter by clicking on it only once. If you click twice, you add the same output twice. Items displayed in **bold** can be used in the narrative.

Note

These are the same output parameters as the ones that are returned by the top ranked computation.

- **categoryField** – From the **Categories** field well.
 - **name** – The formatted display name of the field.
- **metricField** – From the **Values** field well.
 - **name** – The formatted display name of the field.
 - **aggregationFunction** – The aggregation used for the metric (**SUM**, **AVG**, and so on).
- **itemsCount** – The number of items included in this computation.
- **items**: Bottom ranked items.
 - **categoryField** – The category field.
 - **value** – The value (contents) of the category field.
 - **formattedValue** – The formatted value (contents) of the category field. If the field is null, this displays 'NULL'. If the field is empty, it displays '(empty)'.
 - **metricValue** – The metric field.
 - **value** – The raw value.
 - **formattedValue** – The value formatted by the metric field.
 - **formattedAbsoluteValue** – The absolute value formatted by the metric field.

Example

The following screenshot shows the default configuration for the bottom-ranked computation.

ML-powered forecasting

The ML-powered forecast computation forecasts future metrics based on patterns of previous metrics by seasonality. For example, you can create a computation to forecast total revenue for the next six months.

To use this function, you need at least one dimension in the **Time** field well.

For more information about working with forecasts, see [Forecasting and creating what-if scenarios with Amazon Quick Sight](#).

Parameters

name

A unique descriptive name that you assign or change. A name is assigned if you don't create your own. You can edit this later.

Date

The date dimension that you want to rank.

Value

The aggregated measure that the computation is based on.

Periods forward

The number of time periods in the future that you want to forecast. Ranges from 1 to 1,000.

Periods backward

The number of time periods in the past that you want to base your forecast on. Ranges from 0 to 1,000.

Seasonality

The number of seasons included in the calendar year. The default setting, **automatic** detects this for you. Ranges from 1 to 180.

Computation outputs

Each function generates a set of output parameters. You can add these outputs to the autonarrative to customize what it displays. You can also add your own custom text.

To locate the output parameters, open the **Computations** tab on the right, and locate the computation that you want to use. The names of the computations come from the name you provide when you create the insight. Choose the output parameter by clicking on it only once. If you click twice, you add the same output twice. Items displayed in **bold** can be used in the narrative.

- `timeField` – From the **Time** field well.
 - **name** – The formatted display name of the field.
 - **timeGranularity** – The time field granularity (**DAY**, **YEAR**, and so on).
- `metricField` – From the **Values** field well.
 - **name** – The formatted display name of the field.
 - **aggregationFunction** – The aggregation used for the metric (**SUM**, **AVG**, and so on).
- `metricValue` – The value in the metric dimension.
 - **value** – The raw value.
 - **formattedValue** – The value formatted by the metric field.
 - **formattedAbsoluteValue** – The absolute value formatted by the metric field.
- `timeValue` – The value in the date dimension.
 - **value** – The raw value.
 - **formattedValue** – The value formatted by the date field.
- **relativePeriodsToForecast** – The relative number of periods between latest datetime record and last forecast record.

Growth rate computation

The growth rate computation compares values over time periods. For example, you can create a computation to find the three-month compounded growth rate for sales, expressed as a percentage.

To use this function, you need at least one dimension in the **Time** field well.

Parameters

name

A unique descriptive name that you assign or change. A name is assigned if you don't create your own. You can edit this later.

Date

The date dimension that you want to rank.

Value

The aggregated measure that the computation is based on.

Number of periods

The number of time periods in the future that you want to use to compute the growth rate.

Computation outputs

Each function generates a set of output parameters. You can add these outputs to the autonarrative to customize what it displays. You can also add your own custom text.

To locate the output parameters, open the **Computations** tab on the right, and locate the computation that you want to use. The names of the computations come from the name you provide when you create the insight. Choose the output parameter by clicking on it only once. If you click twice, you add the same output twice. Items displayed in **bold** can be used in the narrative.

- `timeField` – From the **Time** field well.
 - **name** – The formatted display name of the field.
 - **timeGranularity** – The time field granularity (**DAY**, **YEAR**, and so on).
- `metricField` – From the **Values** field well.
 - **name** – The formatted display name of the field.

- **aggregationFunction** – The aggregation used for the metric (**SUM**, **AVG**, and so on).
- **previousMetricValue** – The previous value in the metric dimension.
 - **value** – The raw value.
 - **formattedValue** – The value formatted by the metric field.
 - **formattedAbsoluteValue** – The absolute value formatted by the metric field.
- **previousTimeValue** – The previous value in the datetime dimension.
 - **value** – The raw value.
 - **formattedValue** – The value formatted by the datetime field.
- **compoundedGrowthRate** – The percent difference between the current and previous values of the metric field.
 - **value** – The raw value of the calculation of the percent difference.
 - **formattedValue** – The formatted value of the percent difference (for example, -42%).
 - **formattedAbsoluteValue** – The formatted absolute value of the percent difference (for example, 42%).
- **absoluteDifference** – The absolute difference between the current and previous values of the metric field.
 - **value** – The raw value of the calculation of the absolute difference.
 - **formattedValue** – The absolute difference formatted by the settings in the metric field's format preferences.
 - **formattedAbsoluteValue** – The absolute value of the difference formatted by the metric field.

Maximum computation

The maximum computation finds the maximum dimension by value. For example, you can create a computation to find the month with the highest revenue.

To use this function, you need at least one dimension in the **Time** field well.

Parameters

name

A unique descriptive name that you assign or change. A name is assigned if you don't create your own. You can edit this later.

Date

The date dimension that you want to rank.

Value

The aggregated measure that the computation is based on.

Computation outputs

Each function generates a set of output parameters. You can add these outputs to the autonarrative to customize what it displays. You can also add your own custom text.

To locate the output parameters, open the **Computations** tab on the right, and locate the computation that you want to use. The names of the computations come from the name you provide when you create the insight. Choose the output parameter by clicking on it only once. If you click twice, you add the same output twice. Items displayed in **bold** can be used in the narrative.

Note

These are the same output parameters as the ones that are returned by the minimum computation.

- `timeField` – From the **Time** field well.
 - **name** – The formatted display name of the field.
 - **timeGranularity** – The time field granularity (**DAY**, **YEAR**, and so on).
- `metricField` – From the **Values** field well.
 - **name** – The formatted display name of the field.
 - **aggregationFunction** – The aggregation used for the metric (**SUM**, **AVG**, and so on).
- `metricValue` – The value in the metric dimension.
 - **value** – The raw value.
 - **formattedValue** – The value formatted by the metric field.
 - **formattedAbsoluteValue** – The absolute value formatted by the metric field.
- `timeValue` – The value in the datetime dimension.
 - **value** – The raw value.

- **formattedValue** – The value formatted by the datetime field.

Metric comparison computation

The metric comparison computation compares values in different measures. For example, you can create a computation to compare two values, such as actual sales compared to sales goals.

To use this function, you need at least one dimension in the **Time** field well and at least two measures in the **Values** field well.

Parameters

name

A unique descriptive name that you assign or change. A name is assigned if you don't create your own. You can edit this later.

Date

The date dimension that you want to rank.

Value

The aggregated measure that the computation is based on.

Target value

The field that you want to compare to the value.

Computation outputs

Each function generates a set of output parameters. You can add these outputs to the autonarrative to customize what it displays. You can also add your own custom text.

To locate the output parameters, open the **Computations** tab on the right, and locate the computation that you want to use. The names of the computations come from the name you provide when you create the insight. Choose the output parameter by clicking on it only once. If you click twice, you add the same output twice. Items displayed in **bold** can be used in the narrative.

- **timeField** – From the **Time** field well.
- **name** – The formatted display name of the field.

- **timeGranularity** – The time field granularity (**DAY**, **YEAR**, and so on).
- **fromMetricField** – From the **Values** field well.
 - **name** – The formatted display name of the field.
 - **aggregationFunction** – The aggregation used for the metric (**SUM**, **AVG**, and so on).
- **fromMetricValue** – The value in the metric dimension.
 - **value** – The raw value.
 - **formattedValue** – The value formatted by the metric field.
 - **formattedAbsoluteValue** – The absolute value formatted by the metric field.
- **toMetricField** – From the **Values** field well.
 - **name** – The formatted display name of the field.
 - **aggregationFunction** – The aggregation used for the metric (**SUM**, **AVG**, and so on).
- **toMetricValue** – The current value in the metric dimension.
 - **value** – The raw value.
 - **formattedValue** – The value formatted by the metric field.
 - **formattedAbsoluteValue** – The absolute value formatted by the metric field.
- **timeValue** – The value in the datetime dimension.
 - **value** – The raw value.
 - **formattedValue** – The value formatted by the datetime field.
- **percentDifference** – The percent difference between the current and previous values of the metric field.
 - **value** – The raw value of the calculation of the percent difference.
 - **formattedValue** – The formatted value of the percent difference (for example, -42%).
 - **formattedAbsoluteValue** – The formatted absolute value of the percent difference (for example, 42%).
- **absoluteDifference** – The absolute difference between the current and previous values of the metric field.
 - **value** – The raw value of the calculation of the absolute difference.
 - **formattedValue** – The absolute difference formatted by the settings in the metric field's format preferences.
 - **formattedAbsoluteValue** – The absolute value of the difference formatted by the metric field.

Minimum computation

The minimum computation finds the minimum dimension by value. For example, you can create a computation to find the month with the lowest revenue.

To use this function, you need at least one dimension in the **Time** field well.

Parameters

name

A unique descriptive name that you assign or change. A name is assigned if you don't create your own. You can edit this later.

Date

The date dimension that you want to rank.

Value

The aggregated measure that the computation is based on.

Computation outputs

Each function generates a set of output parameters. You can add these outputs to the autonarrative to customize what it displays. You can also add your own custom text.

To locate the output parameters, open the **Computations** tab on the right, and locate the computation that you want to use. The names of the computations come from the name you provide when you create the insight. Choose the output parameter by clicking on it only once. If you click twice, you add the same output twice. Items displayed in **bold** can be used in the narrative.

Note

These are the same output parameters as the ones that are returned by the maximum computation.

- `timeField` – From the **Time** field well.
- **name** – The formatted display name of the field.
- **timeGranularity** – The time field granularity (**DAY**, **YEAR**, and so on).

- **metricField** – From the **Values** field well.
 - **name** – The formatted display name of the field.
 - **aggregationFunction** – The aggregation used for the metric (**SUM**, **AVG**, and so on).
- **metricValue** – The value in the metric dimension.
 - **value** – The raw value.
 - **formattedValue** – The value formatted by the metric field.
 - **formattedAbsoluteValue** – The absolute value formatted by the metric field.
- **timeValue** – The value in the datetime dimension.
 - **value** – The raw value.
 - **formattedValue** – The value formatted by the datetime field.

Period over period computation

The period over period computation compares values from two different time periods. For example, you can create a computation to find out how much sales increased or decreased since the previous time period.

To use this function, you need at least one dimension in the **Time** field well.

Parameters

name

A unique descriptive name that you assign or change. A name is assigned if you don't create your own. You can edit this later.

Date

The date dimension that you want to rank.

Value

The aggregated measure that the computation is based on.

Computation outputs

Each function generates a set of output parameters. You can add these outputs to the autonarrative to customize what it displays. You can also add your own custom text.

To locate the output parameters, open the **Computations** tab on the right, and locate the computation that you want to use. The names of the computations come from the name you provide when you create the insight. Choose the output parameter by clicking on it only once. If you click twice, you add the same output twice. Items displayed in **bold** can be used in the narrative.

- `timeField` – From the **Time** field well.
 - **name** – The formatted display name of the field.
 - **timeGranularity** – The time field granularity (**DAY**, **YEAR**, and so on).
- `metricField` – From the **Values** field well.
 - **name** – The formatted display name of the field.
 - **aggregationFunction** – The aggregation used for the metric (**SUM**, **AVG**, and so on).
- `previousMetricValue` – The previous value in the metric dimension.
 - **value** – The raw value.
 - **formattedValue** – The value formatted by the metric field.
 - **formattedAbsoluteValue** – The absolute value formatted by the metric field.
- `previousTimeValue` – The previous value in the datetime dimension.
 - **value** – The raw value.
 - **formattedValue** – The value formatted by the datetime field.
- `currentMetricValue` – The current value in the metric dimension.
 - **value** – The raw value.
 - **formattedValue** – The value formatted by the metric field.
 - **formattedAbsoluteValue** – The absolute value formatted by the metric field.
- `currentTimeValue` – The current value in the datetime dimension.
 - **value** – The raw value.
 - **formattedValue** – The value formatted by the datetime field.
- `percentDifference` – The percent difference between the current and previous values of the metric field.
 - **value** – The raw value of the calculation of the percent difference.
 - **formattedValue** – The formatted value of the percent difference (for example, -42%).
 - **formattedAbsoluteValue** – The formatted absolute value of the percent difference (for example, 42%).

- **absoluteDifference** – The absolute difference between the current and previous values of the metric field.
- **value** – The raw value of the calculation of the absolute difference.
- **formattedValue** – The absolute difference formatted by the settings in the metric field's format preferences.
- **formattedAbsoluteValue** – The absolute value of the difference formatted by the metric field.

Example

To create a Period over period computation

1. In the analysis that you want to change, choose **Add insight**.
2. For **Computation type**, choose **Period over period**, and then choose **Select**.
3. In the new insight that you created, add the time dimension and value dimension fields that you want to compare. In the screenshot below, **Order Date** and **Sales (Sum)** are added to the insight. With these two fields selected, Quick Sight shows the year to date sales of the latest month and the percentage difference compared with the previous month.

4. (Optional) To further customize the insight, open the on-visual menu and choose **Customize narrative**. In the **Edit narrative** window that appears, drag and drop the fields that you need from the **Computations** list, and then choose **Save**.

Period to date computation

The period to date computation evaluates values for a specified period to date. For example, you can create a computation to find out how much you've earned in year-to-date sales.

To use this function, you need at least one dimension in the **Time** field well.

Parameters

name

A unique descriptive name that you assign or change. A name is assigned if you don't create your own. You can edit this later.

Date

The date dimension that you want to rank.

Value

The aggregated measure that the computation is based on.

Time granularity

The date granularity that you want to use for the computation, for example year to date.

Computation outputs

Each function generates a set of output parameters. You can add these outputs to the autonarrative to customize what it displays. You can also add your own custom text.

To locate the output parameters, open the **Computations** tab on the right, and locate the computation that you want to use. The names of the computations come from the name you provide when you create the insight. Choose the output parameter by clicking on it only once. If you click twice, you add the same output twice. Items displayed in **bold** can be used in the narrative.

- `timeField` – From the **Time** field well.
 - **name** – The formatted display name of the field.
 - **timeGranularity** – The time field granularity (**DAY**, **YEAR**, and so on).
- `metricField` – From the **Values** field well.
 - **name** – The formatted display name of the field.
 - **aggregationFunction** – The aggregation used for the metric (**SUM**, **AVG**, and so on).
- `previousMetricValue` – The previous value in the metric dimension.
 - **value** – The raw value.
 - **formattedValue** – The value formatted by the metric field.

- **formattedAbsoluteValue** – The absolute value formatted by the metric field.
- **previousTimeValue** – The previous value in the datetime dimension.
 - **value** – The raw value.
 - **formattedValue** – The value formatted by the datetime field.
- **currentMetricValue** – The current value in the metric dimension.
 - **value** – The raw value.
 - **formattedValue** – The value formatted by the metric field.
 - **formattedAbsoluteValue** – The absolute value formatted by the metric field.
- **currentTimeValue** – The current value in the datetime dimension.
 - **value** – The raw value.
 - **formattedValue** – The value formatted by the datetime field.
- **periodGranularity** – The period granularity for this computation (**MONTH**, **YEAR**, and so on).
- **percentDifference** – The percent difference between the current and previous values of the metric field.
 - **value** – The raw value of the calculation of the percent difference.
 - **formattedValue** – The formatted value of the percent difference (for example, -42%).
 - **formattedAbsoluteValue** – The formatted absolute value of the percent difference (for example, 42%).
- **absoluteDifference** – The absolute difference between the current and previous values of the metric field.
 - **value** – The raw value of the calculation of the absolute difference.
 - **formattedValue** – The absolute difference formatted by the settings in the metric field's format preferences.
 - **formattedAbsoluteValue** – The absolute value of the difference formatted by the metric field.

Example

To create a Period to date computation

1. In the analysis that you want to change, choose **Add insight**.
2. For **Computation type**, choose **Period to date**, and then choose **Select**.

3. In the new insight that you created, add the time dimension and value dimension fields that you want to compare. In the screenshot below, **Order Date** and **Sales (Sum)** are added to the insight. With these two fields selected, Quick Sight shows the year to date sales of the latest month and the percentage difference compared with the previous month.

4. (Optional) To further customize the insight, open the on-visual menu and choose **Customize narrative**. In the **Edit narrative** window that appears, drag and drop the fields that you need from the **Computations** list, and then choose **Save**.

Top movers computation

The top movers computation counts the requested number of categories by date that rank in the top of the autonarrative's dataset. For example, you can create a computation to find the top products by sales revenue for a time period.

To use this function, you need at least one dimension in the **Time** field well and at least one dimension in the **Categories** field well.

Parameters

name

A unique descriptive name that you assign or change. A name is assigned if you don't create your own. You can edit this later.

Category

The category dimension you want to rank.

Value

The aggregated measure that the computation is based on.

Number of results

The number of top ranking items you want to find.

Computation outputs

Each function generates a set of output parameters. You can add these outputs to the autonarrative to customize what it displays. You can also add your own custom text.

To locate the output parameters, open the **Computations** tab on the right, and locate the computation that you want to use. The names of the computations come from the name you provide when you create the insight. Choose the output parameter by clicking on it only once. If you click twice, you add the same output twice. Items displayed in **bold** can be used in the narrative.

Note

These are the same output parameters as the ones that are returned by the bottom movers computation.

- `timeField` – From the **Time** field well.
 - **name** – The formatted display name of the field.
 - **timeGranularity** – The time field granularity (**DAY**, **YEAR**, and so on).
- `categoryField` – From the **Categories** field well.
 - **name** – The formatted display name of the field.
- `metricField` – From the **Values** field well.
 - **name** – The formatted display name of the field.
 - **aggregationFunction** – The aggregation used for the metric (**SUM**, **AVG**, and so on).
- `startTimeValue` – The value in the date dimension.
 - **value** – The raw value.
 - **formattedValue** – The value formatted by the datetime field.
- `endTimeValue` – The value in the date dimension.
 - **value** – The raw value.
 - **formattedValue** – The absolute value formatted by the datetime field.
- **itemsCount** – The number of items included in this computation.
- **items**: Top moving items.
 - `categoryField` – The category field.

- **value** – The value (contents) of the category field.
- **formattedValue** – The formatted value (contents) of the category field. If the field is null, this displays 'NULL'. If the field is empty, it displays '(empty)'.
- **currentMetricValue** – The current value for the metric field.
 - **value** – The raw value.
 - **formattedValue** – The value formatted by the metric field.
 - **formattedAbsoluteValue** – The absolute value formatted by the metric field.
- **previousMetricValue** – The previous value for the metric field.
 - **value** – The raw value.
 - **formattedValue** – The value formatted by the metric field.
 - **formattedAbsoluteValue** – The absolute value formatted by the metric field.
- **percentDifference** – The percent difference between the current and previous values of the metric field.
 - **value** – The raw value of the calculation of the percent difference.
 - **formattedValue** – The formatted value of the percent difference (for example, -42%).
 - **formattedAbsoluteValue** – The formatted absolute value of the percent difference (for example, 42%).
- **absoluteDifference** – The absolute difference between the current and previous values of the metric field.
 - **value** – The raw value of the calculation of the absolute difference.
 - **formattedValue** – The absolute difference formatted by the settings in the metric field's format preferences.
 - **formattedAbsoluteValue** – The absolute value of the difference formatted by the metric field.

Top ranked computation

The top ranked computation finds the top ranking dimensions by value. For example, you can create a computation to find the top three states by sales revenue.

To use this function, you need at least one dimension in the **Categories** field well.

Parameters

name

A unique descriptive name that you assign or change. A name is assigned if you don't create your own. You can edit this later.

Category

The category dimension that you want to rank.

Value

The aggregated measure that the computation is based on.

Number of results

The number of top ranking items that you want to find.

Computation outputs

Each function generates a set of output parameters. You can add these outputs to the autonarrative to customize what it displays. You can also add your own custom text.

To locate the output parameters, open the **Computations** tab on the right, and locate the computation that you want to use. The names of the computations come from the name you provide when you create the insight. Choose the output parameter by clicking on it only once. If you click twice, you add the same output twice. Items displayed in **bold** can be used in the narrative.

Note

These are the same output parameters as the ones that are returned by the bottom ranked computation.

- `categoryField` – From the **Categories** field well.
 - **name** – The formatted display name of the field.
- `metricField` – From the **Values** field well.
 - **name** – The formatted display name of the field.
 - **aggregationFunction** – The aggregation used for the metric (**SUM**, **AVG**, and so on).

- **itemsCount** – The number of items included in this computation.
- **items**: Top ranked items.
 - **categoryField** – The category field.
 - **value** – The value (contents) of the category field.
 - **formattedValue** – The formatted value (contents) of the category field. If the field is null, this displays 'NULL'. If the field is empty, it displays '(empty)'.
 - **metricValue** – The metric field.
 - **value** – The raw value.
 - **formattedValue** – The value formatted by the metric field.
 - **formattedAbsoluteValue** – The absolute value formatted by the metric field.

Total aggregation computation

The total aggregation computation creates a grand total of the value. For example, you can create a computation to find the total revenue.

To use this function, you need at least one dimension in the **Time** field well and at least one measure in the **Values** field well.

Parameters

name

A unique descriptive name that you assign or change. A name is assigned if you don't create your own. You can edit this later.

Value

The aggregated measure that the computation is based on.

Computation outputs

Each function generates a set of output parameters. You can add these outputs to the autonarrative to customize what it displays. You can also add your own custom text.

To locate the output parameters, open the **Computations** tab on the right, and locate the computation that you want to use. The names of the computations come from the name you provide when you create the insight. Choose the output parameter by clicking on it only once.

If you click twice, you add the same output twice. Items displayed in **bold** can be used in the narrative.

- **categoryField** – The category field.
 - **name** – The display name of the category field.
- **metricField** – From the **Values** field well.
 - **name** – The formatted display name of the field.
 - **aggregationFunction** – The aggregation used for the metric (**SUM**, **AVG**, and so on).
- **totalAggregate** – The total value of the metric aggregation.
 - **value** – The raw value.
 - **formattedValue** – The value formatted by the metric field.
 - **formattedAbsoluteValue** – The absolute value formatted by the metric field.

Unique values computation

The unique values computation counts the unique values in a category field. For example, you can create a computation to count the number of unique values in a dimension, such as how many customers you have

To use this function, you need at least one dimension in the **Categories** field well.

Parameters

name

A unique descriptive name that you assign or change. A name is assigned if you don't create your own. You can edit this later.

Category

The category dimension that you want to rank.

Computation outputs

Each function generates a set of output parameters. You can add these outputs to the autonarrative to customize what it displays. You can also add your own custom text.

To locate the output parameters, open the **Computations** tab on the right, and locate the computation that you want to use. The names of the computations come from the name you

provide when you create the insight. Choose the output parameter by clicking on it only once. If you click twice, you add the same output twice. Items displayed in **bold** can be used in the narrative.

- `categoryField` – The category field.
 - **name** – The display name of the category field.
- **uniqueGroupValuesCount** – The number of unique values included in this computation.

Detecting outliers with ML-powered anomaly detection

Amazon Quick Sight uses proven Amazon technology to continuously run ML-powered anomaly detection across millions of metrics to discover hidden trends and outliers in your data. This tool allows you to get deep insights that are often buried in the aggregates and not scalable with manual analysis. With ML-powered anomaly detection, you can find outliers in your data without the need for manual analysis, custom development, or ML domain expertise.

Amazon Quick Sight notifies you in your visuals if it detects that you can analyze an anomaly or do some forecasting on your data.

Anomaly detection is not available in the eu-central-2 Europe (Zurich) region.

Important

ML-powered anomaly detection is a compute-intensive task. Before you start using it, you can get an idea of costs by analyzing the amount of data that you want to use. We offer a tiered pricing model that is based on the number of metrics you process per month.

Topics

- [Concepts for anomaly or outlier detection](#)
- [Setting up ML-powered anomaly detection for outlier analysis](#)
- [Exploring outliers and key drivers with ML-powered anomaly detection and contribution analysis](#)

Concepts for anomaly or outlier detection

Amazon Quick Sight uses the word *anomaly* to describe data points that fall outside an overall pattern of distribution. There are many other words for anomalies, which is a scientific term,

including outliers, deviations, oddities, exceptions, irregularities, quirks, and many more. The term that you use might be based on the type of analysis you do, or the type of data you use, or even just the preference of your group. These outlying data points represent an entity—a person, place, thing, or time—which is exceptional in some way.

Humans easily recognize patterns and spot things that aren't like the others. Our senses provide this information for us. If the pattern is simple, and there is only a little data, you can easily make a graph to highlight the outliers in your data. Some simple examples include the following:

- A red balloon in a group of blue ones
- A racehorse that is far ahead of the others
- A kid who isn't paying attention during class
- A day when online orders are up, but shipping is down
- A person who got well, where others didn't

Some data points represent a significant event, and others represent a random occurrence. Analysis uncovers which data is worth investigating, based on what driving factors (key drivers) contributed to the event. Questions are essential to data analysis. Why did it happen? What's it related to? Did it happen only once or many times? What can you do to encourage or discourage more like it?

Understanding how and why a variation exists, and whether there is a pattern in the variations, requires more thought. Without the assistance of machine learning, each person might come to a different conclusion, because they have different experience and information. Therefore, each person might make a slightly different business decision. If there is a lot of data or variables to consider, it can require an overwhelming amount of analysis.

ML-powered anomaly detection identifies the causations and correlations to enable you to make data-driven decisions. You still have control over defining how you want the job to work on your data. You can specify your own parameters, and choose additional options, such as identifying key drivers in a contribution analysis. Or you can use the default settings. The following section walks you through the setup process, and provides explanations for the options available.

Setting up ML-powered anomaly detection for outlier analysis

Use procedures in the following sections to start detecting outliers, detecting anomalies, and identifying the key drivers that contribute to them.

Topics

- [Viewing anomaly and forecast notifications](#)
- [Adding an ML insight to detect outliers and key drivers](#)
- [Using contribution analysis for key drivers](#)

Viewing anomaly and forecast notifications

Amazon Quick Sight notifies you on a visual where it detects an anomaly, key drivers, or a forecasting opportunity. You can follow the prompts to set up anomaly detection or forecasting based on the data in that visual.

1. In an existing line chart, look for an insight notification in the menu on the visual widget.
2. Choose the lightbulb icon to display the notification.
3. If you want more information about the ML insight, you can follow the screen prompts to add an ML insight.

Adding an ML insight to detect outliers and key drivers

You can add an ML insight that detects *anomalies*, which are outliers that seem significant. To get started, you create for your insight a widget, also known as an *autonarrative*. As you configure your options, you can view a limited screenshot of your insight in the **Preview** pane at screen right.

In your insight widget, you can add up to five dimension fields that are not calculated fields. In the field wells, values for **Categories** represent the dimensional values that Amazon Quick Sight uses to split the metric. For example, let's say that you are analyzing revenue across all product categories and product SKUs. There are 10 product categories, each with 10 product SKUs. Amazon Quick Sight splits the metric by the 100 unique combinations and runs anomaly detection on each combination for the split.

The following procedure shows how to do this, and also how to add contribution analysis to detect the key drivers that are causing each anomaly. You can add contribution analysis later, as described in [Using contribution analysis for key drivers](#).

To set up outlier analysis, including key drivers

1. Open your analysis and in the toolbar, choose **Insights**, then **Add**. From the list, choose **Anomaly detection** and **Select**.
2. Follow the screen prompt on the new widget, which tells you to choose fields for the insight. Add at least one date, one measure, and one dimension.

3. Choose **Get started** on the widget. The configuration screen appears.
4. Under **Compute options**, choose values for the following options:
 - a. For **Combinations to be analysed**, choose one of the following options:

- i. **Hierarchical**

Choose this option if you want to analyze the fields hierarchically. For example, if you chose a date (T), a measure (N), and three dimension categories (C1, C2, and C3), Quick Sight analyses the fields hierarchically, as shown following.

T-N, T-C1-N, T-C1-C2-N, T-C1-C2-C3-N

- ii. **Exact**

Choose this option if you want to analyze only the exact combination of fields in the Category field well, as they are listed. For example, if you chose a date (T), a measure (N), and three dimension categories (C1, C2, and C3), Quick Sight analyses only the exact combination of category fields in the order they are listed, as shown following.

T-C1-C2-C3-N

- iii. **All**

Choose this option if you want to analyze all field combinations in the Category field well. For example, if you chose a date (T), a measure (N), and three dimension categories (C1, C2, and C3), Quick Sight analyses all combinations of fields, as shown following.

T-N, T-C1-N, T-C1-C2-N, T-C1-C2-C3-N, T-C1-C3-N, T-C2-N, T-C2-C3-N, T-C3-N

If you chose a date and a measure only, Quick Sight analyses the fields by date and then by measure.

In the **Fields to be analyzed** section, you can see a list of fields from the field wells for reference.

- b. For **Name**, enter a descriptive alphanumeric name with no spaces, or choose the default value. This provides a name for the computation.

If you plan on editing the narrative that automatically displays on the widget, you can use the name to identify this widget's calculation. Customize the name if you plan to edit the autonarrative and if you have other similar calculations in your analysis.

5. In the **Display options** section, choose the following options to customize what is displayed in your insight widget. You can still explore all your results, no matter what you display.
 - a. **Maximum number of anomalies to show** – The number of outliers you want to display in the narrative widget.
 - b. **Severity** – The minimum level of severity for anomalies that you want to display in the insight widget.

A level of severity is a range of anomaly scores that is characterized by the lowest actual anomaly score included in the range. All anomalies that score higher are included in the range. If you set severity to **Low**, the insight displays all of the anomalies that rank between low and very high. If you set the severity to **Very high**, the insight displays only the anomalies that have the highest anomaly scores.

You can use the following options:

- **Very high**
 - **High and above**
 - **Medium and above**
 - **Low and above**
- c. **Direction** – The direction on the x-axis or y-axis that you want to identify as anomalous. You can choose from the following:
 - **Higher than expected** to identify higher values as anomalies.
 - **Lower than expected** to identify lower values as anomalies.
 - **[ALL]** to identify all anomalous values, high and low (default setting).
 - d. **Delta** – Enter a custom value to use to identify anomalies. Any amount higher than the threshold value counts as an anomaly. The values here change how the insight works in your analysis. In this section, you can set the following:
 - **Absolute value** – The actual value to use. For example, suppose this is 48. Amazon Quick Sight then identifies values as anomalous when the difference between a value and the expected value is greater than 48.

- **Percentage** – The percentage threshold to use. For example, suppose this is 12.5%. Amazon Quick Sight then identifies values as anomalous when the difference between a value and the expected value is greater than 12.5%.
- e. **Sort by** – Choose a sort method for your results. Some methods are based on the anomaly score that Amazon Quick Sight generates. Amazon Quick Sight gives higher scores to data points that look anomalous. You can use any of the following options:
- **Weighted anomaly score** – The anomaly score multiplied by the log of the absolute value of the difference between the actual value and the expected value. This score is always a positive number.
 - **Anomaly score** – The actual anomaly score assigned to this data point.
 - **Weighted difference from expected value** – The anomaly score multiplied by the difference between the actual value and the expected value (default).
 - **Difference from expected value** – The actual difference between the actual value and the expected value (that is, actual–expected).
 - **Actual value** – The actual value with no formula applied.
6. In the **Schedule options** section, set the schedule for automatically running the insight recalculation. The schedule runs only for published dashboards. In the analysis, you can run it manually as needed. Scheduling includes the following settings:
- **Occurrence** – How often that you want the recalculation to run: every hour, every day, every week, or every month.
 - **Start schedule on** – The date and time to start running this schedule.
 - **Timezone** – The time zone that the schedule runs in. To view a list, delete the current entry.
7. In the **Top contributors** section, set Amazon Quick Sight to analyze the key drivers when an outlier (anomaly) is detected.

For example, Amazon Quick Sight can show the top customers that contributed to a spike in sales in the US for home improvement products. You can add up to four dimensions from your dataset. These include dimensions that you didn't add to the field wells of this insight widget.

For a list of dimensions available for contribution analysis, choose **Select fields**.

8. Choose **Save** to confirm your choices. Choose **Cancel** to exit without saving.
9. From the insight widget, choose **Run now** to run the anomaly detection and view your insight.

The amount of time that anomaly detection takes to complete varies depending on how many unique data points you are analyzing. The process can take a few minutes for a minimum number of points, or it can take many hours.

While it's running in the background, you can do other work in your analysis. Make sure to wait for it to complete before you change the configuration, edit the narrative, or open the **Explore anomalies** page for this insight.

The insight widget needs to run at least once before you can see results. If you think the status might be out of date, you can refresh the page. The insight can have the following states.

Appears on the Page	Status
Run now button	The job has not yet started.
Message about Analyzing for anomalies	The job is currently running.
Narrative about the detected anomalies (outliers)	The job has run successfully. The message says when this widget's calculation was last updated.
Alert icon with an exclamation point (!)	This icon indicates there was an error during the last run. If the narrative also displays, you can still use Explore anomalies to use data from the previous successful run.

Using contribution analysis for key drivers

Amazon Quick Sight can identify the dimensions (categories) that contribute to outliers in measures (metrics) between two points in time. The key driver that contributes to an outlier helps you to answer the question: What happened to cause this anomaly?

If you are already using anomaly detection without contribution analysis, you can enable the existing ML insight to find key drivers. Use the following procedure to add contribution analysis and identify the key drivers behind outliers. Your insight for anomaly detection needs to include a time field and at least one aggregated metric (SUM, AVERAGE, or COUNT). You can include multiple categories (dimension fields) if you wish, but you can also run contribution analysis without specifying any category or dimension field.

You can also use this procedure to change or remove fields as key drivers in your anomaly detection.

To add contribution analysis to identify key drivers

1. Open your analysis and locate an existing ML insight for anomaly detection. Select the insight widget to highlight it.
2. Choose **Menu Options (...)** from the menu on the visual.
3. Choose **Configure anomaly** to edit the settings.
4. The **Contribution analysis (optional)** setting allows Amazon Quick Sight to analyze the key drivers when an outlier (anomaly) is detected. For example, Amazon Quick Sight can show you the top customers that contributed to a spike in sales in the US for home improvement products. You can add up to four dimensions from your dataset, including dimensions that you didn't add to the field wells of this insight widget.

To view a list of dimensions available for contribution analysis, choose **Select fields**.

If you want to change the fields you're using as key drivers, change the fields that are enabled in this list. If you disable all of them, Quick Sight won't perform any contribution analysis in this insight.

5. To save your changes, scroll to the bottom of the configuration options, and choose **Save**. To exit without saving, choose **Cancel**. To completely remove these settings, choose **Delete**.

Exploring outliers and key drivers with ML-powered anomaly detection and contribution analysis

You can interactively explore the anomalies (also known as outliers) in your analysis, along with the contributors (key drivers). The analysis is available for you to explore after the ML-powered anomaly detection runs. The changes you make in this screen aren't saved when you go back to the analysis.

To begin, choose **Explore anomalies** in the insight. The following screenshot shows the anomalies screen as it appears when you first open it. In this example, contributors analysis is set up and shows two key drivers.

The sections of the screen include the following, from top left to bottom right:

- **Contributors** displays key drivers. To see this section, you need to have contributors set up in your anomaly configuration.
- **Controls** contains settings for anomaly exploration.
- **Number of anomalies** displays outliers detected over time. You can hide or show this chart section.
- **Your field names** for category or dimension fields act as titles for charts that show anomalies for each category or dimension.

The following sections provide detailed information for each aspect of exploring anomalies.

Topics

- [Exploring contributors \(key drivers\)](#)
- [Setting controls for anomaly detection](#)
- [Showing and hiding anomalies by date](#)

- [Exploring anomalies per category or dimension](#)

Exploring contributors (key drivers)

If your anomaly insight is set up to detect key drivers, Quick Sight runs the contribution analysis to determine which categories (dimensions) are influencing the outliers. The **Contributors** section appears on the left.

Contributors contains the following sections:

- **Narrative** – At top left, a summary describes any changes in the metrics.
- **Top contributors configuration** – Choose **Configure** to change the contributors and the date range to use in this section.
- **Sort by** – Sets the sort applied to the results that appear below. You can choose from the following:
 - **Absolute difference**
 - **Contribution percentage** (default)
 - **Deviation from expected**
 - **Percentage difference**
- **Top contributor results** – Displays the results of the top contributor analysis for the point in time selected on the timeline at right.

Contribution analysis identifies up to four of the top contributing factors or key drivers of an anomaly. For example, Amazon Quick Sight can show you the top customers that contributed to a spike in sales in the US for health products. This panel appears only if you choose to include fields in contribution analysis when you configure the anomaly.

If you don't see this panel and you want to display it, you can turn it on. To do so, go to the analysis, choose anomaly configuration from the insight's menu, and choose up to four fields to analyze for contributions. If you make changes in the sheet controls that exclude the contributing drivers, the **Contributions** panel closes.

Setting controls for anomaly detection

You can find the settings for anomaly detection in the **Controls** section of the screen. You can open and close this section by clicking the word **Controls**.

The settings include the following:

- **Controls** – The current settings appear at the top of the workspace. You can expand this section by choosing the double arrow icon on the right side. The following settings are available for exploring outliers generated by ML-powered anomaly detection:
 - **Severity** – Sets how sensitive your detector is to detected anomalies (outliers). You should expect to see more anomalies with the threshold set to **Low and above**, and fewer anomalies when the threshold is set to **High and above**. This sensitivity is determined based on standard deviations of the anomaly score generated by the RCF algorithm. The default is **Medium and above**.
 - **Direction** – The direction on the x-axis or y-axis that you want to identify as anomalous. The default is [ALL]. You can choose the following:
 - Set to **Higher than expected** to identify higher values as anomalies.
 - Set to **Lower than expected** to identify lower values as anomalies.
 - Set to **[ALL]** to identify all anomalous values, both high and low.
 - **Minimum Delta - absolute value** – Enter a custom value to use to as the absolute threshold to identify anomalies. Any amount higher than this value counts as an anomaly.
 - **Minimum Delta - percentage** – Enter a custom value to use to as the percentage threshold to identify anomalies. Any amount higher than this value counts as an anomaly.
 - **Sort by** – Choose the method that you want to apply to sorting anomalies. These are listed in preferred order on the screen. View the following list for a description of each method.
 - **Weighted anomaly score** – The anomaly score multiplied by the log of the absolute value of the difference between the actual value and the expected value. This score is always a positive number.
 - **Anomaly score** – The actual anomaly score assigned to this data point.
 - **Weighted difference from expected value** – (Default) The anomaly score multiplied by the difference between the actual value and the expected value.
 - **Difference from expected value** – The actual difference between the actual value and the expected value (actual–expected).
 - **Actual value** – The actual value with no formula applied.
 - **Categories** – One or more settings can appear at the end of the other settings. There is one for each category field that you added to the category field well. You can use category settings to limit the data that displays in the screen.

Showing and hiding anomalies by date

The **Number of anomalies** chart shows outliers detected over time. If you don't see this chart, you can display it by choosing **SHOW ANOMALIES BY DATE**.

This chart shows anomalies (outliers) for the most recent data point in the time series. When expanded, it displays the following components:

- **Anomalies** – The middle of the screen displays the anomalies for the most recent data point in the time series. One or more graphs appear with a chart showing variations in a metric over time. To use this graph, select a point along the timeline. The currently selected point in time is highlighted in the graph, and includes a menu offering you the option to analyze contributions to the current metric. You can also drag the cursor over the timeline without choosing a specific point to display the metric value for that point in time.
- **Anomalies by date** – If you choose **SHOW ANOMALIES BY DATE**, another graph appears that shows how many significant anomalies there were for each time point. You can see details in this chart on each bar's context menu.
- **Timeline adjustment** – Each graph has a timeline adjustor tool below the dates, which you can use to compress, expand, or choose a period of time to view.

Exploring anomalies per category or dimension

The main section of the **Explore anomalies** screen is locked to the lower right of the screen. It remains here no matter how many other sections of the screen are open. If multiple anomalies exist, you can scroll out to highlight them. The chart displays anomalies in color ranges and shows where they occur over a period of time.

Each category or dimension has a separate chart that uses the field name as the chart title. Each chart contains the following components:

- **Configure alerts** – If you are exploring anomalies from a dashboard, select this button to subscribe to alerts and contribution analysis (if configured). You can set up the alerts for the level

of severity (medium, high, and so on). You can get the top five alerts for **Higher than expected**, **Lower than expected**, or **ALL**. Dashboard readers can configure alerts for themselves. If you open the **Explore Anomalies** page doesn't display this button if you opened the page from an analysis.

 Note

The ability to configure alerts is available only in published dashboards.

- **Status** – Under the **Anomalies** header, the status label displays information on the last run. For example, you might see "Anomalies for Revenue on November 17, 2018." This label tells you how many metrics were processed and how long ago. You can choose the link to learn more about the details, such as how many metrics were ignored.

Forecasting and creating what-if scenarios with Amazon Quick Sight

Using ML-powered forecasting, you can forecast your key business metrics with point-and-click simplicity. No machine learning expertise is required. The built-in ML algorithm in Amazon Quick Sight is designed to handle complex real-world scenarios. Amazon Quick Sight uses machine learning to help provide more reliable forecasts than available by traditional means.

For example, suppose that you are a business manager. Suppose that you want to forecast sales to see if you are going to meet your goal by the end of the year. Or, suppose that you expect a large deal to come through in two weeks and you want to know how it's going to affect your overall forecast.

You can forecast your business revenue with multiple levels of seasonality (for example, sales with both weekly and quarterly trends). Amazon Quick Sight automatically excludes anomalies in the data (for example, a spike in sales due to price drop or promotion) from influencing the forecast. You also don't have to clean and reprep the data with missing values because Amazon Quick Sight automatically handles that. In addition, with ML-powered forecasting, you can perform interactive what-if analyses to determine the growth trajectory you need to meet business goals.

Using forecasts and what-if scenarios

You can add a forecasting widget to your existing analysis, and publish it as a dashboard. To analyze what-if scenarios, use an analysis, not a dashboard. With ML-powered forecasting, Amazon

Quick Sight enables you to forecast complex, real-world scenarios such as data with multiple seasonality. It automatically excludes outliers that it identifies and imputes missing values.

Use the following procedure to add a graphical forecast to your analysis, and explore what-if scenarios.

Although the following procedure is for graphical forecasting, you can also add a forecast as a narrative in an insight widget. To learn more, see [Creating autonarratives with Amazon Quick Sight](#).

ML-powered forecasting is not compatible with [small multiples](#). To ensure accurate display of data and forecasts, avoid using small multiples in your visualizations.

To add a graphical forecast to your analysis

1. Create a visual that uses a single date field and up to three metrics (measures).
2. On the menu in the upper-right corner of the visual, choose the **Menu options** icon (the three dots), and then choose **Add forecast**.

Quick Sight automatically analyzes the historical data using ML, and displays a graphical forecast for the next 14 periods. Forecast properties apply to all metrics in your visual. If you want individual forecasts for each metric, consider creating a separate visual for each metric and adding a forecast to each.

3. On the **Forecast properties** panel at left, customize one or more of the following settings:
 - **Forecast length** – Set **Periods forward** to forecast, or set **Periods backward** to look for patterns to base the forecast on.

- **Prediction interval** – Set the estimated range for the forecast. Doing this changes how wide the band of possibility is around the predicted line.
- **Seasonality** – Set the number of time periods involved in the predictable seasonal pattern of data. The range is 1–180, and the default setting is **Automatic**.
- **Forecast boundaries** – Set a minimum and/or maximum forecast value to prevent forecast values from going above or below a specified value. For example, if your forecasting predicts the number of new hires the company will make in the next month to be in the negative numbers, you can set a forecast boundary minimum to zero. This stops the forecasted values from ever going below zero.

To save your changes, choose **Apply**.

If your forecast contains multiple metrics, you can isolate one of the forecasts by selecting anywhere inside the orange band. When you do this, the other forecasts disappear. Select the isolated forecast band again to have them reappear.

4. Analyze what-if scenarios by choosing a forecasted data point (in the orange band) on the chart, and then choosing **What-if analysis** from the context menu.

The **What-if analysis** panel opens at left. Set the following options:

- **Scenario** – Set a target for a date, or set a target for a time range.
- **Dates** – If you are setting a target for a specific date, enter that date here. If you are using a time range, set the start and end dates.
- **Target** – Set a target value for the metric.

Amazon Quick Sight adjusts the forecast to meet the target.

 Note

The **What-if analysis** option isn't available for multiple-metric forecasts. If you want to perform a what-if scenario on your forecast, your visual should contain only one metric.

5. Keep your changes by choosing **Apply**. To discard them, close the **What-if analysis** panel.

If you keep your changes, you see the new forecast adjusted for the target, alongside the original forecast without the what-if.

The what-if analysis is represented on the visual as a dot on the metric line. You can hover over the data points on the forecasting line to see the details.

Here are other things you can do:

- To interact with or remove a what-if analysis, choose the dot on the metric line.
- To create additional what-if scenarios, close the what-if analysis before choosing a new point on the line.

Note

What-if analyses can exist inside an analysis only, not inside a dashboard.

Generative BI with Quick Sight

Note

Powered by Amazon Bedrock: Amazon Q in Quick is built on Amazon Bedrock and includes [automated abuse detection](#) implemented in Amazon Bedrock to enforce safety, security, and the responsible use of AI.

Important

For the latest Amazon Quick chat experience — including cross-dataset Q&A with multi-dataset Topics, agentic workflows, and LLM-powered natural language querying — see [Ask questions, explore data, and get insights with chat in Amazon Quick](#). To learn about the new multi-dataset Topics that serve as the semantic layer for both chat and analysis, see [Working with Amazon Quick Sight Topics](#).

The Generative BI features described on this page represent the earlier experience. They continue to work as before.

With Amazon Quick chat, you can utilize the Generative BI authoring experience, create executive summaries of your data, ask and answer questions of data, and generate data stories.

To access all Quick Sight Generative BI features that are relevant to your task, choose the sparkle icon at the top right of any Quick page. In the pane that opens, the chat displays all content that is available based on the context of the task that you are performing. For example, if you're working in an Analysis, you can build a calculation, edit visuals, set up Q&A, or ask questions about your data. If you're working in a Dashboard, you can build a data story, generate an executive summary, or ask questions about the dashboard.

 Note

Generative BI features are not available in all AWS regions. To see a list of regions that Generative BI features are available in, see [Supported AWS Regions for Amazon Q in Quick](#)

Use the following topics to learn more about Generative BI.

Topics

- [Get started with Generative BI](#)
- [Augmenting Amazon Quick Sight insights with Amazon Q Business](#)
- [The Generative BI authoring experience](#)
- [Creating executive summaries](#)
- [Authoring Q&A](#)
- [Manage topic permissions through dashboards in Amazon Quick Sight](#)
- [Turn on the Dashboard Q&A experience in Amazon Quick Sight](#)
- [Q&A null support](#)
- [Improve Q&A accuracy with custom instructions](#)
- [Asking and answering questions of data with Generative BI](#)
- [Opting out of Generative BI](#)
- [Working with Amazon Quick Sight Topics](#)
- [Working with data stories in Amazon Quick Sight](#)
- [Working with scenarios in Amazon Quick Sight](#)

Get started with Generative BI

To get started with Quick Sight Generative BI capabilities, upgrade your account's users to Admin Pro, Author Pro, or Reader Pro roles. Pro roles grant users access to all Generative BI capabilities that are relevant to the role that's assigned to the user. Pro users can share generative Q&A legacy Topics with another user. To understand which Generative BI capabilities are available to the different user roles in Quick, see the table below. To understand how subscription names map to user roles, see [Understanding Amazon Quick subscriptions and roles](#).

 **Note**

Non-Pro Authors and Readers can still access Generative Q&A legacy Topics if an Author Pro or Admin Pro user shares the legacy Topic with them. Non-Pro Authors and Readers can also access data stories if a Reader Pro, Author Pro, or Admin Pro shares one with them.

Feature name	Feature description	Reader	Author	Admin	Reader Pro	Author Pro	Admin Pro
Creating a data story with Generative BI	Build data stories that explain your data with visuals, insights, and ideas to help improve your business.	⊗ No	⊗ No	⊗ No	✔ Yes	✔ Yes	✔ Yes
Viewing a	View narrative	✔ Yes*	✔ Yes*	✔ Yes*	✔ Yes	✔ Yes	✔ Yes

Authoring Q&A	Create and refine legacy Topics that utilize Generative Q&A for QuickSight dashboards.	⊗ No	⊗ No	⊗ No	⊗ No	✓ Yes	✓ Yes
Asking and answering questions of data with Generative BI	Ask questions about data to accelerate data driven decisions with multi-visual answers.	✓ Yes*	✓ Yes*	✓ Yes*	✓ Yes	✓ Yes	✓ Yes

Feature name	Feature description	Reader	Author	Admin	Reader Pro	Author Pro	Admin Pro
Creating executive summaries	Get an executive summary of key insights from a Quick Sight dashboard.	⊗ No	⊗ No	⊗ No	✓ Yes	✓ Yes	✓ Yes
The Generative BI authoring experience	Create an analysis to build visuals, calculations, and refine existing visuals with natural language.	⊗ No	⊗ No	⊗ No	⊗ No	✓ Yes	✓ Yes

*Non-pro roles in accounts that were created on or after April 30, 2024 can access Q&A legacy Topics that are shared with them. If your Quick account was created before April 30, 2024 and you want to opt-in to this new feature, contact your AWS account team.

Any Quick administrator can upgrade a user to a Pro role with the following procedure.

To upgrade a user to a Pro role

1. Open the [Quick console](#).

2. Choose the user icon at the top right, and then choose **Manage Quick**.
3. Choose **Manage users** to open the **Manage Users** page.
4. To change the role of an existing user, locate that user on the **Manage Users** table and choose the role that you want to grant them from the **Role** dropdown.

For more information about managing Quick users, see [Managing user access inside Amazon Quick](#).

Augmenting Amazon Quick Sight insights with Amazon Q Business

Amazon Quick account admins can connect their Quick account to Amazon Q Business to augment insights with unstructured data sources. [Amazon Q Business](#) is a generative AI assistant that helps your team work smarter. It can answer questions, provide summaries, generate content, and securely complete tasks based on the information in your enterprise systems.

When an Quick account is integrated with Amazon Q Business, users can now leverage this vast repository of organizational knowledge alongside their structured data analytics. This integration allows for more comprehensive and context-rich insights, as it combines quantitative data from Quick with qualitative information from various business documents and applications.

For more information about connecting your Amazon Q Business account with Quick, see [Creating an Quick-integrated application](#).

Use the following topics to configure an Amazon Q Business application in Quick.

Topics

- [Considerations](#)
- [Configuring an Amazon Q Business application in Amazon Quick Sight](#)
- [Connect a Quick account to an existing Amazon Q Business application](#)
- [Disconnect an Amazon Q Business application from an Amazon Quick account](#)

Considerations

The following limitations apply to the Amazon Q Business application.

- Quick and Amazon Q Business must exist in the same AWS account. Cross account calls are not supported.

- Quick and Amazon Q Business accounts need to exist in the same AWS Region. Cross Region calls are not supported. For a list of all supported Quick Regions, see [Supported AWS Regions for Amazon Q in Quick](#). For a list of all supported Amazon Q Business Regions, see [Service quotas for Amazon Q Business](#).

If your Quick account exists in more than one Region, you can connect one Amazon Q Business application from each Region to the Quick account. For example, if your Quick account exists in US East (N. Virginia) and US West (Oregon), one Amazon Q Business application located in US East (N. Virginia) and one Amazon Q Business application located in US West (Oregon) can be connected to the Quick account.

- Quick and Amazon Q Business accounts that are integrated need to use the same identity methods. For example, if a Quick account uses IAM Identity Center for identity management, the Amazon Q Business account that it is integrating with must also use IAM Identity Center for identity management.
- Email addresses that are associated with Quick users and groups are used to perform authorization checks in Amazon Q Business.

Configuring an Amazon Q Business application in Amazon Quick Sight

Use the following procedure to connect an Amazon Quick account with Amazon Q Business

1. Open the [Quick console](#).
2. Choose the user icon at the top right, and then choose **Manage Quick**.
3. Choose **Security & permissions**.
4. On the **Quick access to AWS services** page, choose the **Amazon Q Business application** checkbox.
5. On the **Create an Amazon Q Business connection to unstructured data** popup that appears, choose the Quick Region that you want your connection to be in.
6. Choose **Done**.
7. When you choose **Done**, your Amazon Q Business account is created and you are redirected to a new tab that shows the **Applications** page of the Amazon Q Business console.
8. For **Applications**, choose the Amazon Q Business connection that you created in Quick.
9. The **Application details** page of your connection opens. Choose the **Index** tab, and then choose **Select index**.

10. In the popup that appears, choose the **Index provisioning** option that you want to use, and then choose **Confirm**. For more information about indexes in Amazon Q Business, see [Creating a retriever for an Amazon Q Business application](#).
11. After you choose an index, set up a data source connection. To set up a data source connection, choose the **Data sources** section of the **Enhancements** menu in the left side pane.
12. Choose **Add data source**.
13. Choose the data source that you want to add. The data source that you choose determines the steps that are required to configure the data source connection. For more information about adding a data source to an Amazon Q Business account, see [Connecting Amazon Q Business data sources](#). When you finish setting up the data source configuration, choose **Add data source**.

After you choose an index, a retriever, and a data source for your Amazon Q Business account, your connection to Amazon Q Business is complete and you can return to the Quick console.

Connect a Quick account to an existing Amazon Q Business application

If you already have an Amazon Q Business application that uses the same identity management and exists in the same Region as your Quick account, use the following procedure to link the existing Amazon Q Business account to Quick.

1. Open the [Quick console](#).
2. Choose the user icon at the top right, and then choose **Manage Quick**.
3. Choose **Security & permissions**.
4. On the **Quick access to AWS services** page, choose the **Amazon Q Business application** checkbox.
5. On the **Create an Amazon Q Business connection to unstructured data** popup that appears, choose the Quick Region that you want your connection to be in.
6. Choose your existing Amazon Q Business application from the dropdown.

Note

Your Amazon Q Business application does not appear if the application exists in a different Region than your Quick account or if the application uses a different identity management option than your Quick account.

After you choose your Amazon Q Business application from the dropdown, the connection between Quick and Amazon Q Business is configured.

Disconnect an Amazon Q Business application from an Amazon Quick account

Quick account admins can use the following procedure to disconnect an Amazon Q Business application from a Quick account.

1. Open the [Quick console](#).
2. Choose the user icon at the top right, and then choose **Manage Quick**.
3. Choose **Security & permissions**.
4. On the **Quick access to AWS services** page, choose **SELECT APPLICATION**.
5. Perform one of the following options:
 - a. To disconnect a single Amazon Q Business application from a Quick account, navigate to the application that you want to remove, open the dropdown, and choose **NONE**.
 - b. To disconnect all Amazon Q Business applications from a Quick account, uncheck the **Amazon Q Business application** checkbox.

When you disconnect an Amazon Q Business application from a Quick account, the Amazon Q Business application that you created for Quick is not deleted. The application, index, retriever, and any unstructured data source connections that you configured remain in your Amazon Q Business account.

The Generative BI authoring experience

With Quick chat, authors can use new Generative BI capabilities to build calculated fields and to build and refine visuals. You can also generate complete multi-sheet analyses from natural language prompts. For more information, see [Generating an analysis with natural language prompts](#).

Use the following topics to learn more about the Generative BI authoring experience.

Topics

- [Build visuals with Generative BI](#)
- [Build calculations with Generative BI](#)
- [Refine visuals with generative BI](#)

Build visuals with Generative BI

Quick authors can use the **Build a visual** button to build a custom visual that's generated from author input. The author's input uses natural language to describe the desired outcome for the new visual. You can enter a custom description, or you can choose from a list of generated suggestions that Amazon Q has generated for the topic that's attached to the analysis. The following image shows a custom visual that's created with the **Build a visual** menu.

To build a visual with Generative BI

1. Navigate to the analysis that you want to work in and choose **Ask to build a visual**.
2. In the **Build a visual** panel that appears, perform the following steps.
 - a. Describe the data that you want to visualize. You can enter a custom description, or you can choose from the **Suggested** questions that are generated based on the analysis' data.

When you describe the data that you want to visualize, you can phrase it as a question, or you can use conversational phrases or filters. For example, you can enter "How many people signed up for a free trial last month?" or "Free trial sign ups by month." Both statements generate a visual that shows the number of free trial sign-ups by month. You can also get responses to vague language or keyword style requests.

Suggested questions can include a mix of artificial intelligence (AI) generated questions and human verified questions. Human verified questions appear with a check mark next to the suggestion.

- b. Choose **Build**.
- c. Review the visual that generates. To refine the data presented in the visual, enter a new description into the **Build** bar, and then choose **Build**. Use the forward and back arrows to review the changes made to the visual without losing any progress.
- d. When you're satisfied with the visual, choose **ADD TO ANALYSIS**.

Build calculations with Generative BI

With Generative BI, you can use natural language prompts to create calculated fields in Amazon Quick Sight, as shown in the following image. For more information about calculated fields in analyses, see [Adding calculated fields](#).

To build a calculated field with Generative BI

1. Navigate to the analysis that you want to work in and choose **Data** from the toolbar at the top of the page. Then choose **Add calculated field**.
2. In the calculation editor that appears, choose **Build**.
3. Describe the calculation outcome that you want to achieve. For example, "year over year percent change in daily sales."
4. Choose **BUILD**.
5. Review the expression that's returned, and then choose **Insert** to add it to the expression editor. You can also choose the **Copy** icon to copy the expression to your clipboard. To delete the expression and start over, choose the **Delete** icon next to the expression.
6. When you're finished, close the editor.

After you add a calculation to the expression editor, you must name the calculation before you can save it.

Refine visuals with generative BI

Quick authors can also use natural language prompts to edit visuals in an analysis, as shown in the following visual. Authors can use this functionality to edit visuals without performing manual tasks in the Quick UI. Authors can only use Generative BI to perform formatting tasks that are currently supported in Quick.

The following types of edit are supported:

- Change a visual's type.
- Show or hide axis titles, axis labels, or data labels.
- Show, hide, or change the title of a chart.
- Change axis and table column names.
- Add fields or field wells to a visual.

- Remove fields from a visual.
- Change the aggregation of an axis.
- Show or hide legends and grid lines.
- Show or hide data zoom.
- Add fields or field wells to a visual.
- Change or remove a visual's sort controls.
- Update the conditional formatting of a visual's colors, color gradients, background color, or text color.
- Change the time granularity of a visual.
- Adjust axis scaling and range, as well as maximum and minimum values.
- Change font sizes of titles and subtitles.
- Show, hide, and adjust data labels.
- Adjust column formatting (change between number, percent, date, and currency).

To edit a visual with Generative BI

1. Navigate to the visual that you want to edit, and then choose **Edit with Q**.
2. Describe the task that you want performed, and then choose **APPLY**.
3. Review the visual changes. If you're satisfied with the generated changes, close the **Edit visual** modal. To undo the changes, choose **Undo** and enter a new prompt.

Creating executive summaries

With Quick chat, you can leverage large language models (LLMs) to generate executive summaries of dashboards. Executive summaries are based on Quick Sight's suggested insights for a dashboard. Executive summaries help readers find key insights at a glance without the need to pinpoint specific data from a dashboard's visuals.

To turn on executive summaries for a dashboard, turn on **Allow executive summary** on the **Publish a dashboard** modal.

For more information about how readers can interact with executive summaries, see [Generate an executive summary of an Amazon Quick Sight dashboard](#).

Executive summaries work best when an analysis has multiple suggested insights. To see a list of all suggested insights for an analysis, navigate to the analysis that you want to work in, and then open the **Insights** pane.

Authoring Q&A

Note

The topics referenced in this section refer to legacy Topics. For information about the new multi-dataset Topics experience, which supports cross-dataset relationships and runtime joins for both chat and analysis, see [Working with Amazon Quick Sight Topics](#).

Converting to the Generative Q&A experience

If you have existing topics, you can easily convert these to leverage our new generative capabilities. Navigate to a topic, and then choose **Convert** next to the topic name. You will then be prompted to **Duplicate & Convert Topic** in a dialog box. We duplicate your topic for you so that the conversion to our beta experience does not impact your end users. Once you are satisfied with topic performance in the new experience, you can unshare the original topic and share the new one.

Named entities

Named entities are one of the most important components of topic curation. The information contained in named entities — specifically, the ordering of fields and their ranking — is what makes it possible to present contextual, multi-visual answers in response to even vague questions. Authors can find named entities by navigating to a topic, choosing the **Data** tab, and then choosing the **Named Entities**. From here, authors can preview or edit existing named entities, and create new ones.

Authors can configure the following facets of named entities:

1. **Fields:** Choose a dataset, and then choose which fields from that dataset to include. This defines the scope of data that will be considered when using this named entity to answer enduser questions.
2. **Field Rank and Presentation:** The relative rank of the dimensions and measures in a named entity determines how those fields are used when generating contextual, multi-visual answers. Note in the following demo that adjusting the relative rank of **Profit** so that it is higher than

Sales leads to different data being displayed. By default, the order of fields in the table visual is the same as the field rank. However, you can control these two individually by turning off **Sync table view with field ranking**.

3. **Show / Hide in Presentation:** Fields that are included in named entities can simultaneously be hidden from the tabular presentation of the named entity, while still providing additional context in other components of the answer.

Measure aggregations

Authors have fine-grained control over aggregated measures in topics. Across Quick Sight, measures are defaulted to SUM, unless they have custom aggregations defined in a calculated expression. To change this, navigate to the measure in the list of data fields, and specify a different default aggregation. You can also disallow aggregations, which will prevent them from being applied even if a user specifically asks for them. Lastly, you can specify that a measure is non-additive. This is useful for pre-computed metrics, such as percentages, which should not be re-combined in any way. Doing so will force MEDIAN or AVG depending on your use case.

Manage topic permissions through dashboards in Amazon Quick Sight

Note

The topics referenced in this section refer to legacy Topics that are linked to dashboards for Q&A. For information about the new multi-dataset Topics experience, see [Working with Amazon Quick Sight Topics](#).

Quick enables Authors to manage permissions for dashboards and their linked topics from a single location. When sharing dashboards with Q&A enabled, Authors can control topic viewer access directly from a dashboard's sharing preferences, eliminating the need to manage permissions in multiple locations.

To enable Q&A on a dashboard with a linked topic:

1. Open the [Quick console](#).
2. Open the analysis of the dashboard with Q&A enabled and topic linked that you want to publish.
3. Choose **Publish**.

4. Check the **Allow data Q&A** check box.
5. Choose **MANAGE Q&A** and select **Use a linked topic for Build visual and Q&A**.
6. Select the desired linked topic from the dropdown menu.
7. Choose **APPLY CHANGES**, then choose **Publish dashboard**.

To conveniently manage topic access from a dashboard:

1. Open the [Quick console](#).
2. Open the dashboard with a linked topic that you are a co-owner of.
3. Select the share icon and choose **Share dashboard**.
4. In the row of your selected user, flip on/off the **Share as "topic viewer"** toggle to grant/revoke viewer access to the linked topic.
5. In the row of your selected shared folder, flip on/off the **Add topic to folder** toggle to add/remove the linked topic to/from the shared folder.

To share the dashboard and its linked topic to all users and groups:

1. Open the [Quick console](#).
2. Open the dashboard with a linked topic that you are a co-owner of.
3. Select the share icon and choose **Share dashboard**.
4. On the bottom-left of the panel, under **Auto-share linked topic for**, flip the **All dashboard users and groups** toggle on. This will grant viewer access to the linked topic when the dashboard is shared. Flip the toggle off to cancel this behavior.

After the dashboard with a linked topic has been shared, users will immediately be able to ask questions about their data. Navigate to **Ask a question about <topic name>** at the top of the dashboard to start asking questions.

Turn on the Dashboard Q&A experience in Amazon Quick Sight

Quick allows any Author to enable Q&A directly from their dashboards in one click without the need to create a Topic in Quick Sight. To do this, publish your dashboard and check the **Allow data Q&A** checkbox from the dashboard publishing menu. When you turn on dashboard Q&A, you can choose which datasets to use for dashboard Q&A to ensure that your end users get the answers they need.

Dashboard Q&A queries all rows and columns in the included datasets - beyond what is visible in the dashboard. To protect sensitive or confidential data, enable [row-level security \(RLS\)](#) and/or [column-level security \(CLS\)](#).

The following table compares feature availability between dashboard Q&A and topic Q&A.

Q&A feature	Dashboard Q&A	Topic Q&A
Allows users in all roles to ask and answer questions of data	✔ Yes	✔ Yes
Allows author and admin roles to enable data Q&A on dashboards	✔ Yes	✘ No (Pro users only)
Supported in Quick console embedding	✘ No	✔ Yes
Ability to add reviewed answers	✘ No	✔ Yes
Ability to customize Q&A-specific metadata	✘ No	✔ Yes
Ability to support autocomplete for data values	✘ No	✔ Yes

Use the procedure below to enable dashboard Q&A on a Quick Sight dashboard.

To enable dashboard Q&A on a dashboard

1. Open the [Quick console](#).
2. Open the analysis that the dashboard that you want to publish with Q&A enabled.
3. Choose **Publish**.
4. Check the **Allow data Q&A** check box.
5. (Optional) Choose **MANAGE Q&A** to choose which datasets you want to include in the dashboard Q&A experience. By default, all datasets that are used by the dashboard are included.

6. Choose **APPLY CHANGES**, and then choose **Publish dashboard**.

After you publish a dashboard with the dashboard Q&A experience enabled, users can ask questions about their data with the **Ask a question about this dashboard** input at the top of the dashboard.

Quick allows any user to ask questions on dashboards that have dashboard Q&A enabled. However, dashboard Q&A is a feature that incurs the associated enablement fee. Quick admins can disable this feature at the account level at any time. Use the following procedure to disable dashboard Q&A across an entire Quick account.

1. Open the [Quick console](#).
2. Choose the user icon in the top right, and then choose **Manage Quick**.
3. Choose **Security & permissions**.
4. Navigate to the Amazon Q section, and then choose **Manage**.
5. Toggle **Manage Dashboard Q&A** off.

When you toggle **Manage Dashboard Q&A** off, dashboard Q&A is removed from any dashboards that have dashboard Q&A enabled. If your Quick account does not have Pro users or topics, this action stops the Amazon Q enablement fee from billing your Quick account. This setting does not impact Pro users or existing topics in Quick. For more information about opting out of Generative BI, see [Opting out of Generative BI](#).

Q&A null support

Amazon Quick Sight Q&A has comprehensive support for null value handling, enabling users to create more sophisticated analyses and answer complex business questions. This functionality allows for precise filtering of null values, intuitive queries about missing data, and dynamic chart interactions.

Add a filter to include or exclude null values

To add a filter to include or exclude null values

1. Open the [Quick console](#).
2. Choose **Topics** and then open the topic you want to add a filter to.

3. Choose the **Data** tab.
4. Under **Data Fields**, choose **Add filter**.
5. On the **Filter configuration** page that opens, do the following:
 - a. For **Name**, enter a name for the filter.
 - b. For **Dataset**, choose a dataset that you want to apply the filter to.
 - c. For **Field**, choose the field that you want to filter for.
 - d. For **Null Option**, choose one of the dropdown options:
 - **No null option selected** - No option is selected to filter nulls.
 - **Include nulls only** - Filter for only nulls on the field selected.
 - **Exclude nulls only** - Filter for only non nulls on the field selected.
 - e. (Optional) To specify when the filter is applied, choose **Apply the filter anytime the dataset is used**, and then choose one of the following:
 - i. **Apply always** - Filter is applied whenever a column from the specified dataset is linked to a question.
 - ii. **Apply always, unless a question results in an explicit filter from the dataset** - Filter is applied whenever a column from the specified dataset is linked to a question, unless the question contains its own explicit filter for the same field.
 - f. Choose **Save**.

The filter is added to the list of fields in the topic. You can edit the description for it or adjust it when the filter is applied.

Ask a question on null values

You can use Q&A to directly ask questions about null values, such as:

- What is the total sales amount for records where the segment is null?
- Display accounts without assigned representatives.
- List projects with no completion date.
- Show inventory items without category assignments.
- What percentage of total orders have non null values in the license field by segment?
- Which orders do not have a customer assigned?

Manage null values in visualizations

After generating visualizations through the Q&A bar, you can interact with the charts using various null value actions, including focusing only on null values or excluding null values. These chart actions help you analyze and filter your data dynamically based on null value presence.

Choose either **Focus only on null** or **Exclude null** to appropriately filter the results.

Refine query interpretations for null value handling

Once the visualizations are generated based on your query, you can adjust how null values are handled.

1. Locate the **Interpreted as** section below your query.
2. Select the field you wish to modify.
3. From the dropdown menu, choose **Null Options** to adjust null value handling.

For categorical fields, empty values are not the same as null values. To convert empty values into nulls:

1. Open the [Quick console](#).
2. Choose **Topics** and then open the topic you want to add a filter to.
3. Choose the **Data** tab.
4. Choose **Add calculated field**.
5. Enter a name for the **Add name** field.
6. Choose a categorical field and enter an expression to convert empty values to null values: `ifelse({Segment}="", NULL, {Segment})`.
7. Choose **Save**.

Improve Q&A accuracy with custom instructions

Custom Instructions enables Authors to curate Amazon Q's responses to questions by adding domain-specific knowledge that can't be captured through a topic's metadata settings, such as synonyms or semantic types. By providing these metadata descriptions or custom instructions, Authors can guide Amazon Q to align its responses with distinct definitions, preferences, and expert knowledge—ensuring more accurate, relevant, and tailored answers that are better suited for their business needs.

Use the following table to understand when and how to apply different types of metadata to improve Q&A answer accuracy. Each metadata type plays a unique role in clarifying context,

resolving ambiguity, and ensuring that answers are aligned with business rules or domain-specific terminology.

Metadata Type	When to Use	How it Improves Answer Accuracy
Field-Level Description	When the Q&A system needs to understand ambiguous or domain-specific column names (for example, DTC Spend).	Clarifies field semantics so the model can answer more precisely (for example, interpreting DTC Spend as Direct-to-Consumer marketing expense).
Topic-Level Description	When users may ask broad or ambiguous questions and Amazon Q needs more context about the topic's overall purpose (for example, sales performance vs. clinical trial data).	Helps disambiguate general terms and steer answers toward the right domain (for example, sales vs. marketing).
Dataset Description	When users have access to multiple datasets and the Q&A system needs to identify which one best fits the question.	Enables dataset selection logic by providing context about each dataset's purpose and content.
Topic-Level Custom Instructions	When a topic has specific business rules, timeframes, or definitions (for example, fiscal year ≠ calendar year).	Applies custom logic or definitions (for example, defining Q1 as August-October) to tailor answers appropriately.

Adding field-level descriptions

To add field-level descriptions:

1. Open the [Quick console](#).
2. Choose **Topics** and then open the topic you want to add descriptions for.
3. From the topic details page, select the **Data** tab then choose the **Data Fields** sub-tab.
4. Add a description to improve answer accuracy for each included field. This is especially important for field names that contain bespoke corporate knowledge to understand.

If you have multiple date fields, for example, clear descriptions can help Amazon Q distinguish between them and choose the most relevant one based on the user’s question. In the sample below, an Author added descriptions for **Solution Create** and **Topic Create**, which enables Amazon Q to more accurately select the appropriate date field in context.

Include

☐

Friendly name

Solution Create

Field name: solution_create

Field type: Time

Need help understanding these settings? [Learn more](#)

Description

The timestamp when an approver user marks their reply as a solution on a post.

Include	Friendly name
☐ 	 Topic Create 

Field name: topic_create Field type: Time Need help understanding these settings? [Learn more](#)

Description

The timestamp when a new Community tag is first created. Tags categorize posts into meaningful buckets for the product team, like AI/ML, calculated fields, data connectors, etc.

Adding topic-level descriptions

To add topic-level descriptions:

1. Open the [Quick console](#).
2. Choose **Topics** and then open the topic you want to add descriptions for.
3. From the topic details page, select the **Summary** tab.
4. Under **Topic Details**, add a description to provide more context about the topic's overall purpose.

Adding dataset descriptions

To add dataset descriptions:

1. Open the [Quick console](#).
2. Choose **Topics** and then open the topic you want to add descriptions for.
3. From the topic details page, select the **Data** tab then choose the **Datasets** sub-tab.
4. Add a description to help improve dataset selection logic.

Adding topic-level custom instructions

To add custom instructions:

1. Open the [Quick console](#).
2. Choose **Topics** and then open the topic you want to add descriptions for.
3. From the topics details page, select the **Custom Instructions** tab.
4. Add topic-level guidance to help the chat better understand the context, terminology, or intent that is specific to the selected topic. This can include disambiguation tips, field relationships, definitions for terms that can't be captured in a calculated field or topic filter, or instructions for customizing relative date ranges.

Best practices for writing custom instructions

Match cell values precisely

- Use the exact cell value from the database, including casing and formatting.
- If the value is ambiguous, reference its source column to clarify.

Examples:

- Instead of: *"AMZ are Amazon customers"*

Use: *"AMZ are 'Amazon.com, Inc.' customers"*

- Instead of: *"ETPs are enterprise customers"*

Use: *"ETPs are customers from the enterprise Segment"*

Be specific and quantitative

Avoid vague language—be clear about filters, thresholds, and source columns.

Example:

- Instead of: *"Filter large customers when talking about sales"*

Use: *"Filter customers where Annual Revenue > \$1M when talking about sales"*

Use formatting for clarity, not function

Spacing and line breaks do not affect model behavior, but help authors read and maintain instructions more easily.

Understand what custom instructions cannot do

Custom instructions improve the understanding of your business context, but they do not add new capabilities. These instructions will not:

- Change chart type selections
- Perform calculations or fill nulls
- Create new fields
- Control formatting, colors, or legends
- Alter the narrative or number/type of visuals

Adding field-level descriptions in data preparation for dashboard-based Q&A

In addition to Topic-based descriptions, you can create field-level definitions to enhance [Dashboard Q&A](#) functionality. Adding specific definitions to individual fields during the data preparation phase improves the answer accuracy when users ask questions about particular dashboard elements.

To add field-level descriptions for dashboard-based Q&A:

1. Open the [Quick console](#).
2. Choose **Data**, open a dataset that you have access to, and select **EDIT DATASET**.
3. For each relevant field, choose the three-dot menu and select **Edit name & description**.
4. Add a description to enhance answers for dashboard-related questions.
5. Choose **Apply** to save your changes.

Asking and answering questions of data with Generative BI

Note

The Q&A experience described in this section uses legacy Topics. To view the multi-visual experience, the legacy Topic author must add named entities and convert an existing topic

to use generative capabilities or create a new generative topic. For more information, see [Authoring Q&A](#).

For the new multi-dataset Topics experience, which uses an LLM-powered chat agent to generate cross-dataset SQL queries with runtime joins, see [Using Topics in Amazon Quick chat](#).

Accelerate data-driven decisions with humanistic Q&A that includes:

- AI-generated narrative that highlights key insights
- Multi-visual answer that provides the answer to your question along with supporting visuals to add valuable context
- Home page for every topic with AI-generated and author-reviewed suggested questions and automated data previews to see what data you can ask about

Choose the sparkle icon at the top right. Once you open your topic, there is a home page with a list of suggested questions and **What's in your topic** to see what data you can ask about.

When there are multiple dates available, choose **more...** to view them. For example, in this Student Enrollment Trends topic, there is data available for enrollment data spanning from 2018 to 2023, but there is also student Date of Birth (DOB) data ranging from 1973 to 2005.

Choose a suggested question or type your own question to get started. By hovering over a sentence in the AI-generated narrative, you can clearly identify the source visualization and verify the values. Each visualization is interactive and can be added to your pinboard.

You can get answers to a variety of questions from vague to precise.

If you don't have a precise question in mind, you can ask a vague question that is only one word or a short phrase, like *"sales"* or *"top students."* You can include additional filter criteria with these vague questions like *"top students last semester."*

Question examples include:

- Entity name: *"Order Details"*

- **Note**
You can find the entities from the topic home page and in the **What's in *topic*** tab at the top of the list.
- Field name: "Segment"
- Field values: "Acme Inc.," "Washington DC"
- Vague (or implicit) filters: "best account managers," "bottom products"

For precise questions that are supported, see this table of question types: [Types of questions supported by Q](#). Examples include "product with largest WoW growth %" or "forecast sales for APAC customers by quarter." It covers a range of filters, like top/bottom, relative and absolute date filters, period-to-date and period-over-period, and more. It also supports analytical questions, like percent of total, or "why did sales drop in October 2023?"

- **Tip**
To help you form questions, think *Who, What, Where, When* and *Why*.

Unpacking your answer:

- **Interpreted as:** – This is how Amazon Q interpreted your question. It will map your words to the underlying data so you can verify that you were correctly understood. If not, adjust your question or leave feedback for your author.
- **AI-generated narrative:** – A summary of the visuals that highlights key insights. If your Quick account is connected to an Amazon Q application, you may receive additional insights from unstructured data sources under **Insights from Q Business**. You can see the unstructured sources that are used in the **Sources** collapsible. For more information about connecting a Quick account to a Amazon Q Business application, see [Augmenting Amazon Quick Sight insights with Amazon Q Business](#).
- **Visuals:** – Visuals consist of: center visual that directly answers the question, supporting visual on the right that provides context, relevant KPIs, and a details table at the bottom.

Note

If the field is not included in a named entity, then it will display as a single visual.

- **Did you mean:** – When there are multiple interpretations to your question, it will display a list of alternate answers that you can select to align with your intended question.
- In the following example, the question "top customers" can be interpreted in several ways, including by "Total Sales," "Total Profit," or "number of customers."

Other tips

- To re-size the panel, drag the left side.
- Add important visuals to your pinboard for quick access. View your pinboard from the top of the Amazon Q pane.
- Provide feedback for your topic author to see and make improvements.

Opting out of Generative BI

Quick accounts are charged if Generative BI is active in the account. Generative BI is considered active if your account uses any of the following capabilities:

- Pro users
- Topics

- Dashboard and visual indexing
- Dashboard Q&A

To avoid being charged for Generative BI by completely deactivating it, perform the following steps.

Warning

Opting out of Generative BI will disable AI-powered features and stop related charges. This process involves:

- Removing or changing Pro user roles to standard roles
- Deleting all topics in your account
- Disabling dashboard indexing and Q&A features

Before proceeding: Review the steps carefully and ensure you understand which features will be disabled.

To opt out of Generative BI

1. Ensure there are no Pro users or user groups mapped to Pro roles in the account by performing the following steps:
 - To update or remove Pro users using APIs:
 - If you use Quick identity (with or without IAM federation):
 - a. Find users that have Pro roles using the [ListUsers](#) API.
 - b. Either change the users' roles using the [UpdateUser](#) API, or remove the users from the account using the [DeleteUser](#) API.
 - If you use IAM Identity Center or Microsoft Active Directory:
 - a. Find group of users mapped to Pro roles using the [ListRoleMemberships](#) API.
 - b. Create new user groups with the same users, but mapped to different roles, using the [CreateRoleMemberships](#) API.
 - c. Delete the previous user groups mapped to Pro roles using the [DeleteRoleMemberships](#) API.

- To update or remove Pro users using the Quick console:
 - a. Open the [Quick console](#).
 - b. Choose the profile icon, then choose **Manage Quick**.
 - c. If necessary, in the left navigation pane, choose **Manage users**.
 - If you use Quick identity (with or without IAM federation), update user roles or delete users using the steps in [Viewing Amazon Quick account details](#) or [Deleting a Amazon Quick user account](#).
 - If you use IAM Identity Center or Microsoft Active Directory, update group and role mappings or delete user groups using the steps in [Managing user access](#).
- 2. Ensure there are no topics in the account by performing the following steps:
 - a. Use the [ListTopics](#) API to list all topics in the account for each AWS Region where topics are used.
 - b. For each topic, do one of the following:
 - If you are an owner or co-owner of the topics, delete the topics using the [DeleteTopic](#) API.
 - If you're not an owner or co-owner of the topics:
 - Identify the owners of each topic using the [DescribeTopicPermissions](#) API, then ask them to delete their topics using the [DeleteTopic](#) API.
 - Make yourself a co-owner of the topics using the [UpdateTopicPermissions](#) API , then delete the topics using the [DeleteTopic](#) API.
- 3. Ensure that dashboard and visual indexing and Dashboard Q&A are disabled by performing the following steps:
 - To disable dashboard and visual indexing and Dashboard Q&A using APIs:
 - a. Disable dashboard and visual indexing using the [UpdateQuickSightQSearchConfiguration](#) API.
 - b. Disable Dashboard Q&A using the [UpdateDashboardsQAConfiguration](#) API.
 - To disable dashboard and visual indexing and Dashboard Q&A using the Quick console:
 - a. Open the [Quick console](#).
 - b. Choose the profile icon, then choose **Manage Quick**.
 - c. Under the **Account** section, choose **Amazon Q**.

- d. Disable each of the options.

Working with Amazon Quick Sight Topics

Applies to: Enterprise Edition

Intended audience: Amazon Quick administrators and authors

A *Topic* in Quick Sight is the multi-dataset semantic layer that brings multiple enriched datasets together into a unified data model. Topics let you define relationships between datasets so that Quick Sight can perform runtime joins across them — whether you're building analysis visuals or asking natural language questions through Amazon Quick chat.

With Topics, you can:

- Add up to 12 datasets to a single Topic and define relationships (join keys) between them.
- Add custom instructions that guide the AI engine on cross-dataset logic, disambiguation rules, and business definitions.
- Use the Topic as a data model in Quick Sight analysis sheets to build visuals with fields from multiple datasets — Quick Sight performs runtime inner joins automatically.
- Use the Topic in Amazon Quick chat where the LLM-powered chat agent traverses relationships across datasets, generates cross-dataset SQL with appropriate joins, and returns unified answers.
- Preserve each dataset at its native granularity — no pre-joining or denormalization required.

Each dataset in a Topic should be independently enriched with semantic metadata (column descriptions, synonyms, semantic types, and custom instructions) before being added to the Topic. For more information about enriching datasets, see [Data Preparation Experience \(New\)](#).

Note

If you have existing Topics that were created before this release, they are now classified as *legacy Topics*. Legacy Topics continue to work as before. For more information, see [Working with legacy Topics](#).

To learn more about working with Topics, continue to the following sections.

Topics

- [How Topics work](#)
- [Creating Quick Sight Topics](#)
- [Defining relationships between datasets in a Topic](#)
- [Adding custom instructions to a Topic](#)
- [Using Topics in Quick Sight analysis](#)
- [Using Topics in Amazon Quick chat](#)
- [Sharing Quick Sight Topics](#)
- [Working with legacy Topics](#)
- [Work with Quick Sight Topics using the Amazon Quick Sight APIs](#)

How Topics work

A Topic in Quick Sight consists of four layers:

1. **Data sources.** Your normalized datasets connect to Quick Sight from supported sources. Topics support SPICE datasets and Direct Query datasets against Amazon Redshift, Athena, Amazon S3 Tables, Snowflake, and Databricks. You cannot combine SPICE and Direct Query datasets within a single Topic.
2. **Dataset enrichment.** Each dataset is independently enriched with semantic metadata that improves natural language query accuracy. Enrichment includes column descriptions, synonyms, semantic types, calculated fields, and field exclusions. You can enrich datasets directly in Quick Sight or bring metadata in using catalogs from AWS Glue (AWS Glue Data Catalog) and Databricks Unity Catalog.
3. **Multi-dataset Topic.** The Topic serves as the unified container that brings datasets together. It holds:
 - **Datasets** (up to 12). Each dataset maintains its own enrichment and connects to its own data source.
 - **Relationships.** Join keys defined between dataset pairs tell Quick Sight how tables relate. You upload a JSON file that maps columns between datasets.

- **Custom instructions.** Persistent natural language rules that guide the AI in interpreting domain-specific terminology. These handle disambiguation, custom date logic, and business definitions.
 - **Permissions.** Owners can modify the Topic. Viewers can ask questions and use the Topic in analysis but cannot change its configuration.
4. **Consumption.** Business users interact with the Topic through multiple surfaces:
- **Chat.** Users ask natural language questions in the Amazon Quick chat interface. The LLM-powered chat agent parses the question, identifies relevant columns across datasets, constructs SQL with appropriate joins based on your defined relationships, and returns a unified answer.
 - **Analysis sheets.** Authors build visuals using fields from multiple datasets within the Topic. Quick Sight performs runtime inner joins automatically when a visual references fields from more than one dataset.

Row-level security (RLS) is enforced at the dataset level during runtime joins. Users see only the data they are authorized to access, even when queries span multiple datasets.

Creating Quick Sight Topics

Applies to: Enterprise Edition

Intended audience: Amazon Quick administrators and authors

To create a Topic, you add one or more enriched datasets, define relationships between them, and optionally add custom instructions that guide how the AI interprets cross-dataset queries.

Creating a Topic

Use the following procedure to create a Topic.

To create a Topic

1. On the Quick homepage, choose **Data** in the navigation pane at left.
2. Choose the **Topics** tab, and then choose **Create topic**.

3. Enter a topic name (for example, "Retail Sales Analytics") and an optional description, then choose **Create**.
4. Choose **Add dataset** and select the datasets you want to include in the Topic (up to 12 datasets).
5. After adding datasets, define the relationships between them. For more information, see [Defining relationships between datasets in a Topic](#).
6. (Optional) Add custom instructions that provide cross-dataset business rules. For more information, see [Adding custom instructions to a Topic](#).
7. Choose **Publish** to make the Topic available to users.

After publishing, share the Topic with business users so they can ask natural language questions or use it in analysis. For more information, see [Sharing Quick Sight Topics](#).

Prerequisites

Before creating a Topic, confirm that you have the following:

- Amazon Quick Enterprise Edition enabled with Author or Admin role.
- One or more datasets enriched with semantic metadata (column descriptions, synonyms, and semantic types). For more information, see [Data Preparation Experience \(New\)](#).
- Datasets representing a dimensional model (fact tables and dimension tables) loaded into SPICE or accessible through a supported Direct Query source.
- Permissions to create Topics and manage datasets.

Defining relationships between datasets in a Topic

Applies to: Enterprise Edition

Intended audience: Amazon Quick administrators and authors

Relationships tell Quick Sight how to join datasets when a question or visual spans multiple tables. You define relationships by specifying join keys between dataset pairs using a JSON configuration file.

The relationship graph must be a directed acyclic graph (DAG) — circular relationships are not supported. We recommend modeling your datasets in a star schema with one or more central fact tables joined to shared dimension tables.

To define relationships between datasets

1. Open the Topic that you want to configure.
2. Navigate to the **Relationships** tab.
3. Choose **Upload file** or **Create manually**.
4. Upload a JSON file defining your relationships (see the following example). After uploading, the relationship graph displays visually at left and the join key details appear at right. Select a join to verify the relationship mapping.
5. To edit a relationship, choose **Edit**, update the join columns using the dropdown selectors, and choose **Save**.

Relationship JSON format

The following example shows a star schema configuration with a central SALES_FACT table joined to dimension tables:

```
{
  "datasetPairs": [
    {
      "datasetLeft": { "datasetName": "SALES_FACT", "joinColumnNames":
["CUSTOMER_ID"] },
      "datasetRight": { "datasetName": "CUSTOMER_DIM", "joinColumnNames":
["CUSTOMER_ID"] }
    },
    {
      "datasetLeft": { "datasetName": "SALES_FACT", "joinColumnNames":
["PRODUCT_ID"] },
      "datasetRight": { "datasetName": "PRODUCT_DIM", "joinColumnNames":
["PRODUCT_ID"] }
    },
  ]
}
```

```
    "datasetLeft": { "datasetName": "SALES_FACT", "joinColumnNames": ["STORE_ID"] },
    "datasetRight": { "datasetName": "STORE_DIM", "joinColumnNames": ["STORE_ID"] }
  }
]
```

Each entry in `datasetPairs` specifies a pair of datasets and the columns used to join them. Composite keys are supported by including multiple column names in the `joinColumnNames` array.

Best practices for relationships

- **Start with a star schema.** A central fact table surrounded by dimension tables minimizes join complexity and maximizes query performance.
- **Use clean join keys.** Use integer surrogate keys where possible. Confirm matching data types on both sides. Remove null values from join key columns (nulls never match in inner joins).
- **Validate referential integrity.** Every foreign key in the fact table should exist in the dimension table.
- **Avoid circular joins.** The relationship graph must be acyclic. If your model creates a cycle, break it by removing one leg and denormalizing the redundant path.
- **Pre-join snowflake chains when feasible.** If a dimension has sub-dimensions (for example, Customer → Geography → Region), consider flattening them into a single dimension dataset to reduce join hops.

Current limitations

The following limitations apply to defined relationships:

- Relationships use *inner join* semantics for analysis sheets. Only rows with matching keys in both datasets appear in results.
- The relationship graph must be acyclic (no circular joins).
- Self-relationships (a dataset related to itself) are not supported.
- All datasets in a Topic must use the same query mode (SPICE or Direct Query).
- A Topic cannot exceed 12 datasets.

Note

When using Topics in Amazon Quick chat, the LLM-powered chat agent is not limited to inner joins. It can generate SQL with left joins, outer joins, unions, and subqueries based on your custom instructions. These join-type limitations apply only to the analysis sheet consumption path.

Adding custom instructions to a Topic

Applies to: Enterprise Edition

Intended audience: Amazon Quick administrators and authors

Custom instructions are persistent natural language rules that guide the AI engine in interpreting domain-specific terminology and cross-dataset logic. Without them, the engine interprets terms literally. For example, "this year" defaults to the calendar year. However, if your organization runs on a fiscal year starting April 1, you need an instruction to override that default.

Custom instructions are especially useful for:

- **Disambiguation rules.** When the same business term could map to multiple datasets or fields, tell the AI which one to prefer. For example: "When the user asks about 'sales', use SALES_FACT. When the user asks about 'returns' or 'refunds', use RETURNS_FACT."
- **Cross-dataset definitions.** Define metrics that span multiple datasets. For example: "Net Revenue = SUM(SALES_FACT.total_amount) - SUM(RETURNS_FACT.refund_amount)."
- **Default join behavior.** Specify the join direction that preserves intended semantics. For example: "Prefer LEFT JOIN from fact tables to dimension tables so that facts without matching dimension records are not silently dropped."
- **Custom date logic.** For example: "Fiscal year starts April 1. Interpret 'this year' using fiscal year boundaries."

To add custom instructions

1. Open the Topic that you want to configure.

2. Navigate to the **Custom instructions** tab.
3. Choose **Edit**.
4. Enter your instructions as natural language rules. Use bullet-point style for clarity.
5. Choose **Save changes**.

Example custom instructions

The following example shows a production-ready set of topic-level instructions for a retail analytics Topic:

Disambiguation:

- "sales", "revenue", "orders" -> use SALES_FACT
- "returns", "refunds" -> use RETURNS_FACT
- "net sales", "net revenue" -> join SALES_FACT LEFT JOIN RETURNS_FACT on order_line_id

Cross-dataset metrics:

- Net Revenue = SUM(SALES_FACT.total_amount) - SUM(RETURNS_FACT.refund_amount)
- Return Rate = COUNT(RETURNS_FACT.return_id) / COUNT(SALES_FACT.order_line_id)

Default joins:

- SALES_FACT LEFT JOIN CUSTOMER_DIM on customer_id
- SALES_FACT LEFT JOIN PRODUCT_DIM on product_id

Date handling:

- Fiscal year starts April 1. Interpret "this year" using fiscal year boundaries.
- YTD: current fiscal year up to and including today.

Best practices for custom instructions

- Keep instructions concise. Prefer bullet-point rule lists over prose paragraphs.
- Use topic-level instructions for cross-dataset logic only. Single-dataset semantics (grain, keys, aggregation rules) belong in the dataset's own enrichment metadata.
- Avoid contradictions between dataset-level and topic-level instructions.
- Test your instructions by asking questions in chat and reviewing the generated SQL in the Explanation panel.

Using Topics in Quick Sight analysis

Applies to: Enterprise Edition

Intended audience: Amazon Quick administrators and authors

You can use a Topic as the data model for your Quick Sight analysis. When you create an analysis from a Topic, you can select fields from any of the datasets in the Topic. Quick Sight automatically performs runtime inner joins based on the relationships you defined, assembling precisely the join it needs for each visual.

This means you no longer need to pre-join all your tables into a single flat dataset before building an analysis. Each dataset maintains its own level of detail, and Quick Sight joins only the relevant tables at analysis time.

Creating an analysis from a Topic

To create an analysis from a Topic

1. Navigate to the Topic and choose **Create analysis**.
2. Select **Interactive sheet** and choose **Create**.
3. In the analysis, select fields from multiple datasets and add them to a visual. Quick Sight performs runtime joins automatically based on the defined relationships.
4. (Optional) Create calculated fields that reference columns from different datasets.

How runtime joins work in analysis

When a visual references fields from multiple datasets:

1. Quick Sight identifies which datasets contain the fields used in the visual.
2. It uses the defined relationships to determine the join path between datasets.
3. It performs inner joins at runtime using the specified join keys.
4. The result is displayed in the visual with the correct aggregation and grouping.

Note

Runtime joins in analysis use inner join semantics. Only rows with matching keys in both datasets appear in results. If you need outer join behavior for analytical scenarios, use the Topic in Amazon Quick chat instead, where the chat agent can generate SQL with outer joins based on your custom instructions.

Benefits of using Topics in analysis

- **Less upfront data preparation.** Define relationships once. Quick Sight joins only the relevant tables at analysis time.
- **Preserved native granularity.** Each dataset maintains its own level of detail, avoiding measure duplication across grains.
- **Reuse across analyses.** A single Topic with defined relationships serves multiple analytical use cases without rebuilding datasets.
- **Independent refresh schedules.** Each dataset can be refreshed at different cadences (hourly, daily, monthly) based on data volatility.
- **Row-level security at runtime.** RLS rules are enforced during runtime joins, so data-access policies apply consistently across datasets.

Using Topics in Amazon Quick chat

Applies to: Enterprise Edition

You can use Topics in Amazon Quick chat to ask natural language questions that span multiple datasets. The LLM-powered chat agent uses your defined relationships, dataset enrichment metadata, and custom instructions to generate cross-dataset SQL queries and return unified answers.

How cross-dataset chat queries work

When you ask a natural language question against a Topic, the chat agent performs the following steps:

1. **Intent parsing.** The agent identifies which columns map to your terms by matching against column names, descriptions, and synonyms from the enrichment metadata. It determines which datasets contain the relevant measures and dimensions.
2. **Relationship traversal.** Using the defined join keys and custom instructions, the agent determines the join path between identified datasets. It can traverse relationships to connect fact tables to the necessary dimension tables.
3. **SQL generation.** The agent constructs a SQL query with appropriate JOIN clauses, aggregation, and GROUP BY for the requested dimensions.
4. **Result presentation.** The answer is returned as a visualization or table, with the generated SQL available for inspection in the Explanation panel.

Chat capabilities with Topics

The LLM-powered chat agent supports richer SQL generation than the defined relationship path used in analysis sheets. When you configure a Topic for chat with custom instructions, the agent can generate:

- Inner, left, right, and full outer joins
- Union queries across tables with the same schema
- Subqueries for negation patterns (for example, "customers who have never ordered")
- Cross-grain comparisons (for example, daily actuals versus monthly targets)
- Self-joins for recursive hierarchies (for example, employee-manager relationships)

The richer your enrichment metadata and custom instructions, the more accurately the agent interprets ambiguous questions.

Starting a chat with a Topic

To chat with a Topic:

- Navigate to the Topic and choose the chat icon. Your Topic is automatically available as the context.
- Or, from Amazon Quick chat, use the data filter to select **Specific data and apps** and choose your Topic.

Ask natural language questions that span multiple datasets. For example:

- "Show total sales by customer segment and store region"
- "What is the return rate by product category?"
- "Which stores are below 80% of their monthly target?"

Use the Explanation panel to view the generated SQL and verify that the correct datasets and joins were used.

Differences from legacy Topics in chat

The chat experience differs significantly between new Topics and legacy Topics:

Aspect	New Topics	Legacy Topics
AI model	LLM-powered chat agent	Legacy ML-based fuzzy search model
Cross-dataset queries	Yes — traverses relationships and generates cross-dataset SQL with runtime joins	No — selects one dataset and queries only that dataset
Join types	Inner, left, right, full outer, union, subquery	Not applicable (single dataset)
SQL visibility	Generated SQL shown in Explanation panel	Not available

 Note

You can chat with both new Topics and legacy Topics. However, legacy Topics use the legacy ML-based model and do not support cross-dataset queries. For information about legacy Topics, see [Working with legacy Topics](#).

Sharing Quick Sight Topics

Applies to: Enterprise Edition

Intended audience: Amazon Quick administrators and authors

After you create and publish a Topic, share it with others in your organization. Sharing a Topic allows your users to ask questions in Amazon Quick chat and use the Topic as a data model in analysis sheets.

To share a Topic

1. From the Topic page, select the ellipsis menu and choose **Share**.
2. Search for and add specific users or groups.
3. Set permission levels (**Owner** or **Viewer**) and choose **Done**.

Permission Level	Can Ask Questions	Can Modify Topic	Can Use in Analysis
Owner	Yes	Yes	Yes
Viewer	Yes	No	Yes

Quick Sight enforces row-level security (RLS) and column-level security (CLS) at the dataset level. Access controls are preserved through the Topic's semantic layer, regardless of how users access the Topic.

Working with legacy Topics

Applies to: Enterprise Edition

Intended audience: Amazon Quick administrators and authors

If you created Topics before the multi-dataset Topics feature launched, your existing Topics are now classified as *legacy Topics*. Legacy Topics continue to work as before — their behavior and capabilities are unchanged.

Differences between legacy Topics and new Topics

Feature	New Topics	Legacy Topics
Purpose	Multi-dataset semantic layer with cross-dataset relationships, runtime joins for both chat and analysis	Single-dataset semantic layer for natural language Q&A
Datasets	Up to 12 datasets with defined relationships	Multiple datasets can be added, but no cross-dataset joins at query time
Chat behavior	LLM-powered chat agent generates cross-dataset SQL with runtime joins	ML-based fuzzy search model selects one dataset, then queries only that dataset
Analysis support	Use as data model for analysis sheets with runtime joins	Limited to NLQ search bar in analysis
Metadata location	Dataset enrichment lives in the dataset itself; Topic holds cross-dataset logic	Metadata (synonyms, calculated fields, named entities, filters) stored in the separate legacy Topic object
Relationships	Explicit join keys defined between dataset pairs	Not supported

Migrating from legacy Topics

You can migrate your business context from legacy Topics into enriched datasets using Dataset Enrichment in the new data preparation experience. This moves column descriptions, synonyms, calculated fields, named entities, filters, and custom instructions from the separate legacy Topic object into the dataset itself.

After migrating your dataset-intrinsic metadata into Dataset Enrichment, you can create a new multi-dataset Topic that uses the enriched datasets with defined relationships.

For detailed migration guidance, see [Data Preparation Experience \(New\)](#).

Navigating legacy Topics

From your Quick start page, you can view and manage legacy Topics by selecting **Data** in the navigation pane at left, then choosing the **Topics** tab. Legacy Topics are labeled as such in the topics list.

You can also access a legacy Topic from within an Amazon Quick Sight analysis by choosing the topic icon in the top navigation bar.

Creating a legacy Topic

Note

New Topics created going forward use the multi-dataset Topic experience. The following information applies to legacy Topics that were created before this feature launched.

Legacy Topics are collections of one or more datasets that represent a subject area that your business users can ask questions about. When you create a legacy Topic, Quick Sight uses ML-powered automated data prep to help select fields, assign friendly names and synonyms, and detect semantic types.

There are two ways to create a legacy Topic:

- Create the Topic by selecting a dataset from the Topics page.
- Create the Topic using an analysis, where automated data prep learns from how you analyze your data.

Legacy Topic workspace

After you open a legacy Topic, the workspace displays four tabs:

- **Summary** — Shows suggestions for improving the Topic, engagement metrics and KPIs, and the datasets included in the Topic.
- **Data** — Shows all the fields included in the Topic. Configure field metadata (names, descriptions, synonyms, semantic types, aggregations) to make the Topic natural-language-friendly.
- **User Activity** — Shows all questions received and the overall feedback for each question.
- **Verified Answers** — Shows questions that you have preconfigured visuals for.

Working with datasets in a legacy Topic

You can add additional datasets to a legacy Topic, remove datasets, set refresh schedules, and add calculated fields, filters, and named entities.

- **Adding datasets** — On the Summary page, choose Data, then under Datasets, choose Add datasets.
- **Removing datasets** — On the Summary page, choose Data, then under Datasets, choose the dataset menu and select Remove from topic.
- **Refreshing datasets** — You can set a refresh schedule or manually refresh datasets in a legacy Topic. For SPICE datasets, you can sync with the SPICE refresh schedule.
- **Calculated fields** — Create new fields using combinations of existing fields with supported functions.
- **Filters** — Add filters to support questions that map to multiple values in the data.
- **Named entities** — Create collections of fields that display together in an answer (for example, an "Address" entity combining Branch Name, State, and City).

Making legacy Topics natural-language-friendly

To improve the accuracy of answers in a legacy Topic, configure the following metadata:

1. **Dataset names and descriptions** — Give datasets friendly names so readers can identify them.
2. **Date fields** — Specify default dates and time basis for each dataset.
3. **Exclude unused fields** — Remove irrelevant fields from the Topic to improve accuracy.
4. **Rename fields** — Give fields user-friendly names and descriptions.
5. **Synonyms** — Add alternative names that readers might use to refer to fields or values.
6. **Semantic types** — Specify the type of information in each field (location, currency, date, person, etc.).
7. **Field roles and aggregations** — Specify whether fields are dimensions or measures, and set default aggregations.

Sharing legacy Topics

You can share legacy Topics with other users by assigning them as Viewers or Co-owners. Viewers can see the Topic in the search bar and ask questions. Co-owners can also change the Topic configuration.

Reviewing legacy Topic performance

After sharing a legacy Topic, you can review its performance on the Summary and User Activity tabs. This shows how many questions were asked, feedback received, and any questions that were unanswerable or disambiguated.

Refreshing legacy Topic indexes

When you create a legacy Topic, Quick Sight creates and maintains an index of unique string values for fields included in the Topic. This index is used to generate correct answers, provide autocomplete suggestions, and suggest mappings of terms to columns or data values.

To refresh a legacy Topic index, refresh the datasets in the Topic. You can manually refresh all datasets or set a recurring refresh schedule.

Work with Quick Sight Topics using the Amazon Quick Sight APIs

Applies to: Enterprise Edition

Intended audience: Amazon Quick developers

Use this section to learn how to work with Quick Sight Topics using the Amazon Quick Sight command line interface (CLI).

Prerequisites

Before you begin, make sure that you have an AWS Identity and Access Management (IAM) role that grants the CLI user access to call the Quick Sight API operations. The following table shows which permissions must be added to the IAM policy to use specific API operations.

API operation	IAM policy
CreateTopic	quicksight:CreateTopic quicksight:PassDataSet
ListTopics	quicksight:ListTopics

API operation	IAM policy
DescribeTopic	quicksight:DescribeTopic
UpdateTopic	quicksight:UpdateTopic quicksight:PassDataSet
DeleteTopic	quicksight>DeleteTopic
UpdateTopicPermissions	quicksight:UpdateTopicPermissions
DescribeTopicPermissions	quicksight:DescribeTopicPermissions
CreateTopicRefreshSchedule	quicksight:CreateTopicRefreshSchedule
ListTopicRefreshSchedules	quicksight:ListTopicRefreshSchedules
DescribeTopicRefreshSchedule	quicksight:DescribeTopicRefreshSchedule
UpdateTopicRefreshSchedule	quicksight:UpdateTopicRefreshSchedule
DeleteTopicRefreshSchedule	quicksight>DeleteTopicRefreshSchedule

The following example creates a new Topic.

```
aws quicksight create-topic
--aws-account-id AWSACCOUNTID
--topic-id TOPICID
--topic TOPIC
```

The following example updates a Topic.

```
aws quicksight update-topic  
--aws-account-id AWSACCOUNTID  
--topic-id TOPICID  
--topic TOPIC
```

The following example provides a list of all Topics in an account.

```
aws quicksight list-topics  
--aws-account-id AWSACCOUNTID
```

The following example deletes a Topic.

```
aws quicksight delete-topic  
--aws-account-id AWSACCOUNTID  
--topic-id TOPICID
```

The following example provides information about how a Topic was configured.

```
aws quicksight describe-topic  
--aws-account-id AWSACCOUNTID  
--topic-id TOPICID
```

Working with data stories in Amazon Quick Sight

With Generative BI with Quick Sight, authors and readers can generate a first draft of their data story quickly. Use prompts and visuals to produce a draft that incorporates the details that you provide. Data story drafts are not meant to replace your own ideas or to perform analysis. Rather, data stories are a starting point to customize and expand on as needed. The contextual recommendations and suggestions combine your prompt with selected visuals to provide relevant details that are tailored to your data story. For more information about this, see [Generative BI with Quick Sight](#).

Use the following topics to create, modify, and share a data story.

Topics

- [Creating a data story with Generative BI](#)
- [Personalize data stories in Amazon Quick Sight](#)
- [Viewing a generated data story in Amazon Quick Sight](#)

- [Editing a generated data story in Amazon Quick Sight](#)
- [Adding themes and animations to a data story in Amazon Quick Sight](#)
- [Sharing a data story in Amazon Quick Sight](#)

Creating a data story with Generative BI

Use the following procedure to create a data story with Generative BI.

To create a data story

1. Open the [Quick console](#).
2. At left, choose **Stories**.
3. On the **Data stories** page, choose **New Data Story**.
4. In the **Story** screen that appears, navigate to the **Build story** modal and input a data story prompt that you would like to generate. For the best results, don't phrase the prompt like a question. Instead, type the data story that you want Quick Sight to build. For example, say you want to create a data story about the most commonly performed medical procedures by region. A good prompt for this use case is "Build a data story about most commonly performed procedures by physicians in various regions. Also, show the specialties where patients are admitted the most. Recommend where we need to staff more physicians by specialty, and include at least four points of supporting data."

You can optionally skip this step and manually create your data story. If you choose to forego entering a prompt, you still need to add a visual to the data story.

5. Under **Select visuals**, choose **Add**.
6. Choose the dashboard that contains the visuals that you want to use, and then choose the visuals that you want. You can add up to 20 visuals to a data story.

If you don't see the dashboard that you want to use, use the **Find your dashboards** search bar at the top of the modal.

You can choose visuals from any number of dashboards that you have sharing permissions to. Visuals that show a **Restricted** badge have permissions that restrict them from being added to a data story. A visual might be restricted for one of the following reasons:

- The dataset is connected to a data source that uses trusted identity propagation with Amazon Redshift.

- The dataset is located inside of a restricted folder.
7. (Optional) Use the **Select documents** section to upload up to 5 documents to be used in the data story. Each document can't exceed 10MB. These documents are only used to generate the data story and are not stored in Quick Sight. The following image shows the **Select documents** section of the **Build story** screen.
 8. (Optional) If your Quick account is connected to an Amazon Q Business application, check the **Use insights from Amazon Q Business** checkbox to augment your data story with unstructured data sources from Amazon Q Business. For more information about connecting a Quick account to a Amazon Q Business application, see [Augmenting Amazon Quick Sight insights with Amazon Q Business](#).
 9. Choose **Build**.

After the data story generates, review the data story and choose from the following options:

- **Keep** – Saves the generated content to the canvas. When you choose this option, the **Build story** modal closes and you can start editing your data story.
- **Try again** – Allows users to edit the prompt and generate a new data story.
- **Discard** – Deletes the generated data story.

Personalize data stories in Amazon Quick Sight

User location and job-related information from your IAM Identity Center instance are leveraged to generate personalized data stories that are more relevant to authors and readers. For example, when an author in the US issues the prompt "Write a business strategy focusing on a plan on how to increase the revenue in my location", insights related to the US in the data story's narrative are automatically included. If the author wants the data story to focus on another country such as Canada, they can specify this in the prompt.

For personalization to work, you must add country and job title for users in the IAM Identity Center instance that is connected to your Quick account. For more information, see [Add users to your IAM Identity Center directory](#) in the IAM Identity Center User Guide.

User data in your IAM Identity Center instance is connected to your application environment by default. This means that all data stories are personalized by default. You can choose to [opt out of personalization](#) at any time in the Account settings menu in the QuickSight administration console.

Note

Personalization in data stories is currently available in the US East (N. Virginia) and US West (Oregon) AWS Regions.

Viewing a generated data story in Amazon Quick Sight

After you generate and keep a data story, you can access that data story from the **Data stories** page. To view a data story, choose the data story that you want to view to open the story editor.

As you create and modify a data story, you can preview how the data story looks to readers. To preview a generated data story, choose the **Preview** icon at the top of the page. To exit the preview, choose **BACK TO EDITOR**.

Editing a generated data story in Amazon Quick Sight

After you create and keep a data story, you can modify its content to better fit your needs. You can format data story text, add images, edit visuals, and add new blocks.

Stories are made up of different *blocks* that act as containers for text, visuals, and images that you want to include in your data story. Each block can be formatted independently from other blocks in the data story, similar to the sections of a pixel perfect report.

To format the text of a data story, use the toolbar at the top of the page. The toolbar offers font settings so you can customize the font type, style, color, size, spacing, text highlights, and alignment. You can also use the toolbar to add columns to a data story block.

Use one of the following options to add a visual to a data story.

- Use the **Visuals** pane to drag and drop a visual into a data story. Only the visuals that you chose when you generated the data story are shown in the **Visuals** pane.

You can also choose the **Add (+)** icon in the **Visuals** pane to add new visuals that can be dragged and dropped into the data story. Each data story can contain up to 20 visuals.

- Choose the data story block that you want to add an image to. When a cursor appears, enter a forward slash ("/") to insert an image or visual to that data story block.

To edit a visual in a data story, choose the visual that you want to change, and then choose the **Properties** icon. In the properties pane that appears, you can perform the following actions:

- Change, hide, or show the visual's title. By default, the visual title is displayed.
- Change, hide, or show the visual's subtitle. By default, the visual subtitle is hidden.
- Hide or show data labels. By default, data labels are hidden.
- Hide, show, or change the position of the legend. By default, the legend is hidden.

To add a new block to a data story, choose the plus (+) icon at the bottom of any existing block. Then choose the layout option that you want. You can also move, duplicate, or delete a block from the **Block options** (three dots) icon at the top of each block.

To change the layout of items in a block, you can drag and drop the items wherever you want with the six-dot icon next to each item.

Adding themes and animations to a data story in Amazon Quick Sight

You can add themes and animations to the stories that you generate. To add a theme or animation to a data story, choose the **Story style** icon.

In the **Story style** pane that appears, you can perform the following actions:

- For **THEMES**, choose a theme that you think best fits your data story.
- For **ANIMATIONS**, choose an animation style and speed. For animation types, you can choose **None**, **Fade**, or **Slide**. The default animation is **None**. For **Speed**, choose **Slow**, **Medium**, or **Fast**. The default speed is **Medium**.

Sharing a data story in Amazon Quick Sight

Use the following procedure to share a data story.

To share a data story

1. In the story editor of the data story that you want to share, choose the **Share** icon at the top right.

Alternatively, you can choose the **Share** icon at the top of a data story preview.

2. In the **Share data story** modal that appears, enter the users or groups that you want to share the data story with.
3. (Optional) To save a link for the published data story to your clipboard, choose **Copy Link**.
4. Choose **Publish & Share**.

If you try to share a story and receive a message that the story cannot be shared, contact the owner of the dashboard ask them to toggle on the **Allow sharing data stories** switch. For more information about this switch, see [Tutorial: Create an Amazon Quick Sight dashboard](#).

If you try to share a data story and receive an error message, contact the owner of the dashboard or your Quick account admin for assistance.

After you share a data story, users you shared the story with receive a notification email with a link to the story. You can access the data story from the **Data stories** page of their Quick accounts. You can also share the copied link to the data story with users that can access the data story.

You can't share a data story that contains restricted data. If you try to share a story that contains restricted data, an error message appears that lists all restricted visuals that are a part of the story. If desired, remove the restricted visuals from your data story before sharing it with users.

When you edit a published data story, republish the data story for the changes to propagate to your end users.

Working with scenarios in Amazon Quick Sight

Quick users with Admin Pro, Author Pro, or Reader Pro roles can use scenarios to analyze complex business problems with simple natural language.

To get started with scenarios, a Quick user describes a problem that they want to solve and adds relevant data from Quick Sight or from their computer to be used in the data analysis. Alternatively, users can let Amazon Q search for all relevant data that can be used to solve the problem. Amazon Q returns a series of analyses or prompts to dive deeper into the data. Users can also enter their own prompts to create a custom analysis. After a new prompt is received, Amazon Q breaks down the analysis into steps and executes them. Outputs include specific data insights, interactive visuals, and an analysis of what the findings might mean for the business with suggested next actions.

Scenarios can help Quick Pro users to perform the following tasks:

- Automate tedious, error-prone, and inefficient manual data tasks
- Modify, extend, or reuse past analyses to quickly adapt to business changes
- Dive deeper into data than spreadsheets allow

Use the following topics to create and work with scenarios in Amazon Quick Sight.

Topics

- [Considerations for Quick Sight scenarios](#)
- [Creating an Amazon Quick Sight scenario](#)
- [Working with threads in an Amazon Quick Sight scenario](#)
- [Working with data in an Amazon Quick Sight scenario](#)

Considerations for Quick Sight scenarios

The following considerations apply to Amazon Quick Sight scenarios.

- Amazon Quick Sight scenarios are available to users that have Admin Pro, Author Pro, or Reader Pro roles in Amazon Quick. For information about updating a user to a Quick Pro role, see [Get started with Generative BI](#).
- Scenarios are available in specific AWS Regions listed in [Supported AWS Regions for Amazon Q in Quick](#).

After you review the considerations for Quick Sight scenarios, see [Creating an Amazon Quick Sight scenario](#) to get started with scenarios in Amazon Quick Sight.

Creating an Amazon Quick Sight scenario

Amazon Quick Pro users can create scenarios from Quick Sight dashboards, or from the **Scenarios** section on the Quick Sight home page. Users can create as many scenarios as they need. Each user can have up to 3 active scenarios at a time. Each Quick Sight account supports up to 10 active scenarios at a time. Use the following procedure to create a scenario in Amazon Quick Sight.

Create a new scenario

1. Open the [Quick console](#).
2. Perform one of the following actions:
 - a. Open any dashboard, and look for one of the following:
 - Choose **Analyze this dashboard in a Scenario**, if available, at the top of the dashboard.
 - From a visual on the dashboard, open the drop-down menu and choose **Explore scenario**.
 - Choose **Build**, and then choose **Scenario**.

- b. On the Quick home page, choose **Scenarios**. On the **Scenarios**, choose **New Scenario**.
3. The new scenario appears. In the text box, describe the problem that you want to solve. This input is the starting point for all of the data pivots and manipulations that will occur in the scenario. The description that you provide can be as broad or as specific as you want, for example "analyze usage trends" or "compute month-over-month and year-over-year changes in usage based on last month's data."
4. Add the data that you want to use in the scenario. You can choose data from Quick Sight dashboards, or you can upload files from your computer. When you choose data from a dashboard, a preview of the selected data is generated for you to review. For more information about previewing and editing data in Quick Sight scenarios, see [Working with data in an Amazon Quick Sight scenario](#).

The following limits apply to the data that is used in a scenario:

- You can add up to 10 data sources to a scenario.
- Up to 20 visuals can be selected from a dashboard at a time.
- Uploaded files must be in .xlsx or .csv format and can't exceed 1 GB.
- Data sources can have up to 200 columns.

If you don't add data to the scenario, Amazon Q automatically searches your Quick Sight dashboards to find data related to your problem statement from the previous step.

5. Choose **Start analysis**.

When you start an analysis in a Quick Sight scenario, Quick Sight prepares your data for analysis and returns a new *thread*. The thread contains generated prompts that can be used to solve the problem that you described in the scenario. A thread is a turn based contextual conversation that consists of user prompts and Amazon Q responses that you can use to drill down on a specific scenario. You can use threads to write prompts that assume that Amazon Q remembers what was previously discussed in the thread. You can choose a prompt to continue the thread, or you can choose the plus sign (+) above the thread to start a new thread. The new thread uses a different prompt than the first thread that you created. For more information about working with threads, see [Working with threads in an Amazon Quick Sight scenario](#).

Working with threads in an Amazon Quick Sight scenario

After you create a scenario in Quick Sight, the data that Amazon Q generates is presented in *threads* and *blocks*. A thread is a vertical chain of prompts and responses. A block is a single prompt and response pair. Each thread can contain up to 15 blocks, and each scenario can contain up to 50 blocks total across multiple threads.

When a new thread is created, a list of Amazon Q-generated prompts appears inside of a new block. When you choose one of the prompts to drill down on, Amazon Q analyzes the data that is relevant to the chosen prompt and returns a summary of all data findings, forecasts, and conclusions that can be drawn from the analysis.

To continue the thread and dive deeper into the prompt, choose the plus sign (+) located below the block to create a new block that contains a new list of generated prompts that factor in the findings from the previous block. To start a new thread that analyzes a different aspect of the data, choose the plus sign (+) above any block in the scenario to create a new thread.

Blocks can be collapsed, duplicated, or deleted from a scenario, as long as the block that you want to change has finished loading. Use the following procedures to make changes to a scenario block.

To collapse, duplicate, or delete a block

1. Open the [Quick console](#).
2. Choose **Scenarios** from the options pane, and then choose the scenario that you want to change.
3. Navigate to the block that you want to change and choose the ellipsis (...) in the top right of the block.
4. Perform one of the following actions:
 - To collapse the block, choose **Collapse**. To expand a collapsed block, choose the ellipsis in the top right of the block, and then choose **Expand**.
 - To duplicate the block, choose **Duplicate**. The block is duplicated and placed in a new thread next to the original block.
 - To delete the block, choose **Delete**.

You can also modify the prompt of a block to better match your use case. Use the following procedure to modify a block prompt.

To modify the prompt of a block

1. Open the [Quick console](#).
2. Choose **Scenarios** from the options pane, and then choose the scenario that you want to change.
3. Navigate to the block that you want to change and choose **Modify block**.
4. In the **Modify block** popup that appears, enter a new description for the block, and then choose **Apply**.

After you modify a prompt, Amazon Q analyzes the data and returns a new generated analysis that reflects the changes that were made to the prompt.

Working with data in an Amazon Quick Sight scenario

When you create a scenario in Amazon Quick Sight, you can preview and modify the data that the scenario uses to generate summaries. Use the following sections to learn about the ways Quick users can interact with data in a scenario.

Topics

- [Adding more data to a scenario](#)
- [Editing data in a preview](#)
- [Editing data in a snapshot](#)

Adding more data to a scenario

After you create a scenario in Amazon Quick Sight, you can add more data to the scenario at any time. Use the following procedure to add data to an Amazon Quick Sight scenario.

To add data to an existing Amazon Quick Sight scenario

1. Open the [Quick console](#).
2. Choose **Scenarios** from the options pane, and then choose the scenario that you want to add more data to.
3. Choose the **Data Source** icon in the actions bar to open the **Data** pane.
4. Perform one of the following actions:

- a. To add Quick Sight data to the scenario, choose **Find Data**, and then choose the dataset or dashboard visuals that you want to add to the scenario. After you have selected all of the Quick Sight data that you want to add to the scenario, choose **Add**.
- b. To upload a file from your computer to the scenario, choose **Upload File**.

The following limits apply to the data that is added to a scenario:

- You can add up to 10 data sources to a scenario.
- Up to 20 visuals can be selected from a dashboard at a time.
- Uploaded files must be in .xlsx or .csv format and can't exceed 1 GB.
- Data sources can have up to 200 columns.

After you add new data to a scenario, Amazon Q includes the data in all new analyses.

Editing data in a preview

When you choose data from a Quick Sight dashboard to be used in a scenario, a preview of the data is generated for review before it's added to the analysis. If needed, the following changes can be made to dashboard data in the preview state:

- **Filters** – If you only want to analyze a subset of the available data or if you need to reduce the number of rows that are included in the scenario, you can apply filters to the data.
- **Sort** – If the available data exceeds 1 million rows and you want to prioritize the retention of the values in a specific column, you can sort the data to fit your needs.

Editing data in a snapshot

When you add dashboard or external data to a scenario, Quick Sight creates a snapshot of the data sources to be reviewed. To see a snapshot of the data used in a scenario, choose the **Data Source** icon in the actions bar. This opens the **Data** pane, and then you can choose the data snapshot that you want to review.

You can perform the following actions on a data snapshot:

- To update the title of the data snapshot, choose the pencil icon next to the title and enter a new title for the snapshot.

- Choose the **Filter** icon to filter the data that is used in the scenario. This option can be used if you want the scenario to only use a subset of the data that is added to the scenario.
- Choose the **Sort** icon to sort the data that is used in the scenario. This option can be used to prioritize the retention of specific columns if the data exceeds 1 million rows.
- Choose the **Fields list** icon to choose which fields are included in the scenario. This option can be used to control which columns are used in the scenario.

When you are finished updating the scenario data, close the **Data** pane.

Troubleshooting Amazon Quick Sight

Use this information to help you diagnose and fix common issues that you can encounter when using Amazon Quick Sight.

Note

Need more help? You can visit the Amazon Quick Sight [User Community](#) or the [AWS forums](#). See also the [Quick Sight Resource Library](#).

Topics

- [Resolving Amazon Quick Sight issues and error messages](#)
- [Connectivity issues when using Amazon Athena with Amazon Quick Sight](#)
- [Data source connectivity issues for Amazon Quick Sight](#)
- [Login issues with Quick Sight](#)
- [Visual issues with Quick Sight](#)

Resolving Amazon Quick Sight issues and error messages

If you are having difficulties or receiving an error message, there's a few ways that you can go about resolving the issue. Following are some resources that can help:

- For errors during dataset ingestion (importing data), see [SPICE ingestion error codes](#).
- For technical user questions, visit the [User Community](#).
- For administrator questions, see the [AWS forums](#).

- If you need more customized assistance, contact AWS Support. To do this while you are signed in to your AWS account, choose **Support** at upper right, and then choose **Support Center**.

Connectivity issues when using Amazon Athena with Amazon Quick Sight

Following, you can find information about troubleshooting issues that you might encounter when using Amazon Athena with Amazon Quick Sight.

Before you try troubleshooting anything else for Athena, make sure that you can connect to Athena. For information about troubleshooting Athena connection issues, see [I can't connect to Amazon Athena](#).

If you can connect but have other issues, it can be useful to run your query in the Athena console (<https://console.aws.amazon.com/athena/>) before adding your query to Amazon Quick Sight. For additional troubleshooting information, see [Troubleshooting](#) in the *Athena User Guide*.

Topics

- [Column not found when using Athena with Amazon Quick Sight](#)
- [Invalid data when using Athena with Amazon Quick Sight](#)
- [Query timeout when using Athena with Amazon Quick Sight](#)
- [Staging bucket no longer exists when using Athena with Amazon Quick Sight](#)
- [Table incompatible when using AWS Glue with Athena in Amazon Quick Sight](#)
- [Table not found when using Athena with Amazon Quick Sight](#)
- [Workgroup and output errors when using Athena with Quick Sight](#)

Column not found when using Athena with Amazon Quick Sight

You can receive a "column not found" error if the columns in an analysis are missing from the Athena data source.

In Amazon Quick Sight, open your analysis. On the **Visualize** tab, choose **Choose dataset**, **Edit analysis data sets**.

On the **Data sets in this analysis** screen, choose **Edit** near your dataset to refresh the dataset. Amazon Quick Sight caches the schema for two minutes. So it can take two minutes before the latest changes display.

To investigate how the column was lost in the first place, you can go to the Athena console (<https://console.aws.amazon.com/athena/>) and check the query history to find queries that edited the table.

If this error happened when you were editing a custom SQL query in preview, verify that the name of the column in the query, and check for any other syntax errors. For example, check that the column name isn't enclosed in single quotation marks, which are reserved for strings.

If you still have the issue, verify that your tables, columns, and queries comply with Athena requirements. For more information, see [Names for Tables, Databases, and Columns](#) and [Troubleshooting](#) in the *Athena User Guide*.

Invalid data when using Athena with Amazon Quick Sight

An invalid data error can occur when you use any operator or function in a calculated field. To address this, verify that the data in the table is consistent with the format that you supplied to the function.

For example, suppose that you are using the function `parseDate(expression, ['format'], ['time_zone'])` as `parseDate(date_column, 'MM/dd/yyyy')`. In this case, all values in `date_column` must conform to 'MM/dd/yyyy' format ('05/12/2016'). Any value that isn't in this format ('2016/12/05') can cause an error.

Query timeout when using Athena with Amazon Quick Sight

If your query times out, you can try these options to resolve your problem.

If the failure was generated while working on an analysis, remember that the Amazon Quick Sight timeout for generating any visual is two minutes. If you're using a custom SQL query, you can simplify your query to optimize running time.

If you are in direct query mode (not using SPICE), you can try importing your data to SPICE. However, if your query exceeds the Athena 30-minute timeout, you might get another timeout while importing data into SPICE. For the most current information on Athena limits, see [Amazon Athena Limits](#) in the *AWS General Reference*.

Staging bucket no longer exists when using Athena with Amazon Quick Sight

Use this section to help solve this error: **"The staging bucket for this query result no longer exists in the underlying data source."**

When you create a dataset using Athena, Amazon Quick Sight creates an Amazon S3 bucket. By default, this bucket has a name similar to "aws-athena-query-results-*<REGION>*-*<ACCOUNTID>*". If you remove this bucket, then your next Athena query might fail with an error saying the staging bucket no longer exists.

To fix this error, create a new bucket with the same name in the correct AWS Region.

Table incompatible when using AWS Glue with Athena in Amazon Quick Sight

If you are getting errors when using AWS Glue tables in Athena with Amazon Quick Sight, it might be because you're missing some metadata. Follow these steps to find out if your tables don't have the `TableType` attribute that Amazon Quick Sight needs for the Athena connector to work. Usually, the metadata for these tables wasn't migrated to the AWS Glue Data Catalog. For more information, see [Upgrading to the AWS Glue Data Catalog Step-by-Step](#) in the *AWS Glue Developer Guide*.

If you don't want to migrate to the AWS Glue Data Catalog at this time, you have two options. You can recreate each AWS Glue table through the AWS Glue Management Console. Or you can use the AWS CLI scripts listed in the following procedure to identify and update tables with missing `TableType` attributes.

If you prefer to use the CLI to do this, use the following procedure to help you design your scripts.

To use the CLI to design scripts

1. Use the CLI to learn which AWS Glue tables have no `TableType` attributes.

```
aws glue get-tables --database-name <your_database_name>;
```

For example, you can run the following command in the CLI.

```
aws glue get-table --database-name "test_database" --name  
"table_missing_table_type"
```

Following is a sample of what the output looks like. You can see that the table "table_missing_table_type" doesn't have the `TableType` attribute declared.

```
{  
  "TableList": [  
    {
```

```
"Retention": 0,
"UpdateTime": 1522368588.0,
"PartitionKeys": [
  {
    "Name": "year",
    "Type": "string"
  },
  {
    "Name": "month",
    "Type": "string"
  },
  {
    "Name": "day",
    "Type": "string"
  }
],
"LastAccessTime": 1513804142.0,
"Owner": "owner",
"Name": "table_missing_table_type",
"Parameters": {
  "delimiter": ",",
  "compressionType": "none",
  "skip.header.line.count": "1",
  "sizeKey": "75",
  "averageRecordSize": "7",
  "classification": "csv",
  "objectCount": "1",
  "typeOfData": "file",
  "CrawlerSchemaDeserializerVersion": "1.0",
  "CrawlerSchemaSerializerVersion": "1.0",
  "UPDATED_BY_CRAWLER": "crawl_date_table",
  "recordCount": "9",
  "columnsOrdered": "true"
},
"StorageDescriptor": {
  "OutputFormat": "org.apache.hadoop.hive ql.io.HiveIgnoreKeyTextOutputFormat",
  "SortColumns": [],
  "StoredAsSubDirectories": false,
  "Columns": [
    {
      "Name": "col1",
      "Type": "string"
    }
  ]
}
```

```

        "Name": "col2",
        "Type": "bigint"
    }
],
"Location": "s3://myAthenatest/test_dataset/",
"NumberOfBuckets": -1,
"Parameters": {
    "delimiter": ",",
    "compressionType": "none",
    "skip.header.line.count": "1",
    "columnsOrdered": "true",
    "sizeKey": "75",
    "averageRecordSize": "7",
    "classification": "csv",
    "objectCount": "1",
    "typeOfData": "file",
    "CrawlerSchemaDeserializerVersion": "1.0",
    "CrawlerSchemaSerializerVersion": "1.0",
    "UPDATED_BY_CRAWLER": "crawl_date_table",
    "recordCount": "9"
},
"Compressed": false,
"BucketColumns": [],
"InputFormat": "org.apache.hadoop.mapred.TextInputFormat",
"SerdeInfo": {
    "Parameters": {
        "field.delim": ",",
    },
    "SerializationLibrary": "org.apache.hadoop.hive.serde2.lazy.LazySimpleSerDe"
}
}
}
]
}

```

2. Edit the table definition in your editor to add `"TableType": "EXTERNAL_TABLE"` to the table definition, as shown in the following example.

```

{
  "Table": {
    "Retention": 0,
    "TableType": "EXTERNAL_TABLE",
    "PartitionKeys": [

```

```

{
  "Name": "year",
  "Type": "string"
},
{
  "Name": "month",
  "Type": "string"
},
{
  "Name": "day",
  "Type": "string"
}
],
"UpdateTime": 1522368588.0,
"Name": "table_missing_table_type",
"StorageDescriptor": {
  "BucketColumns": [],
  "SortColumns": [],
  "StoredAsSubDirectories": false,
  "OutputFormat": "org.apache.hadoop.hive ql.io.HiveIgnoreKeyTextOutputFormat",
  "SerdeInfo": {
    "SerializationLibrary": "org.apache.hadoop.hive.serde2.lazy.LazySimpleSerDe",
    "Parameters": {
      "field.delim": ",",
    }
  },
},
"Parameters": {
  "classification": "csv",
  "CrawlerSchemaSerializerVersion": "1.0",
  "UPDATED_BY_CRAWLER": "crawl_date_table",
  "columnsOrdered": "true",
  "averageRecordSize": "7",
  "objectCount": "1",
  "sizeKey": "75",
  "delimiter": ",",
  "compressionType": "none",
  "recordCount": "9",
  "CrawlerSchemaDeserializerVersion": "1.0",
  "typeOfData": "file",
  "skip.header.line.count": "1"
},
"Columns": [
  {
    "Name": "col1",

```

```

    "Type": "string"
  },
  {
    "Name": "col2",
    "Type": "bigint"
  }
],
"Compressed": false,

```

Table not found when using Athena with Amazon Quick Sight

You can receive a "table not found" error if the tables in an analysis are missing from the Athena data source.

In the Athena console (<https://console.aws.amazon.com/athena/>), check for your table under the corresponding schema. You can recreate the table in Athena and then create a new dataset in Amazon Quick Sight on that table. To investigate how the table was lost in the first place, you can use the Athena console to check the query history. Doing this helps you find the queries that dropped the table.

If this error happened when you were editing a custom SQL query in preview, verify that the name of the table in the query, and check for any other syntax errors. Amazon Quick Sight can't infer the schema from the query. The schema must be specified in the query.

For example, the following statement works.

```
select from my_schema.my_table
```

The following statement fails because it's missing the schema.

```
select from my_table
```

If you still have the issue, verify that your tables, columns, and queries comply with Athena requirements. For more information, see [Names for Tables, Databases, and Columns](#) and [Troubleshooting](#) in the *Athena User Guide*.

Workgroup and output errors when using Athena with Quick Sight

To verify that workgroups are set up properly, check the following settings:

- **The Athena workgroup that's associated with the data source must exist.**

To fix this, you can return to the Athena data source settings and choose a different workgroup. For more information, see [Setting Up Workgroups](#) in the *Athena User Guide*.

Another solution is to have the AWS account administrator recreate the workgroup in the Athena console.

- **The Athena workgroup that's associated with the data source must be enabled.**

An AWS account administrator needs to enable the workgroup in the Athena console. Open the Athena console by using this direct link: <https://console.aws.amazon.com/athena/>. Then choose the appropriate workgroup in the **Workgroup** panel and view its settings. Choose **Enable workgroup**.

- **Make sure that you have access to the Amazon S3 output location that's associated with the Athena workgroup.**

To grant Amazon Quick Sight permissions to access the S3 output location, the Amazon Quick Sight administrator can edit **Security & Permissions** in the **Manage QuickSight** screen.

- **The Athena workgroup must have an associated S3 output location.**

An AWS account administrator needs to associate an S3 bucket with the workgroup in the Athena console. Open the Athena console by using this direct link: <https://console.aws.amazon.com/athena/>. Then choose the appropriate workgroup in the **Workgroup** panel and view its settings. Set **Query result location**.

Data source connectivity issues for Amazon Quick Sight

Use the following section to help you troubleshoot connections to data sources. Before you continue, verify that your database is currently available. Also, verify that you have the correct connection information and valid credentials.

Topics

- [I can't connect although my data source connection options look right \(SSL\)](#)
- [I can't connect to Amazon Athena](#)
- [I can't connect to Amazon S3](#)
- [I can't create or refresh a dataset from an existing Adobe Analytics data source](#)
- [I need to validate the connection to my data source, or change data source settings](#)
- [I can't connect to MySQL \(issues with SSL and authorization\)](#)
- [I can't connect to RDS](#)

I can't connect although my data source connection options look right (SSL)

Problems connecting can occur when Secure Sockets Layer (SSL) is incorrectly configured. The symptoms can include the following:

- You can connect to your database in other ways or from other locations but not in this case.
- You can connect to a similar database but not this one.

Before continuing, rule out the following circumstances:

- Permissions issues
- Availability issues
- An expired or invalid certificate

- A self-signed certificate
- Certificate chain in the wrong order
- Ports not enabled
- Firewall blocking an IP address
- Web Sockets are blocked
- A virtual private cloud (VPC) or security group not configured correctly.

To help find issues with SSL, you can use an online SSL checker, or a tool like OpenSSL.

The following steps walk through troubleshooting a connection where SSL is suspect. The administrator in this example has already installed OpenSSL.

Example

1. The user finds an issue connecting to the database. The user verifies that they can connect a different database in another AWS Region. They check other versions of the same database and can connect easily.
2. The administrator reviews the issue and decides to verify that the certificates are working correctly. The administrator searches online for an article on using OpenSSL to troubleshoot or debug SSL connections.
3. Using OpenSSL, the administrator verifies the SSL configuration in the terminal.

```
echo quit  
openssl s_client -connect <host>:port
```

The result shows that the certificate is not working.

```
...  
...  
...  
CONNECTED(00000003)  
012345678901234:error:140770FC:SSL routines:SSL23_GET_SERVER_HELLO:unknown  
  protocol:s23_clnt.c:782:  
---  
no peer certificate available
```

```
---
No client certificate CA names sent
---
SSL handshake has read 7 bytes and written 278 bytes
---
New, (NONE), Cipher is (NONE)
Secure Renegotiation IS NOT supported
SSL-Session:
    Protocol  : TLSv1.2
    Cipher    : 0000
    Session-ID:
    Session-ID-ctx:
    Master-Key:
    Key-Arg   : None
    PSK identity: None
    PSK identity hint: None
    Start Time: 1497569068
    Timeout   : 300 (sec)
    Verify return code: 0 (ok)
---
```

4. The administrator corrects the problem by installing the SSL certificate on the user's database server.

For more detail on the solution in this example, see [Using SSL to Encrypt a Connection to a DB Instance](#) in the *Amazon RDS User Guide*.

I can't connect to Amazon Athena

Intended audience: Amazon Quick administrators

Use this section to help troubleshoot connecting to Athena.

If you can't connect to Amazon Athena, you might get an insufficient permissions error when you run a query, showing that the permissions aren't configured. To verify that you can connect Amazon Quick Sight to Athena, check the following settings:

- AWS resource permissions inside of Amazon Quick Sight
- AWS Identity and Access Management (IAM) policies

- Amazon S3 location
- Query results location
- AWS KMS key policy (for encrypted datasets only)

For details, see following. For information about troubleshooting other Athena issues, see [Connectivity issues when using Amazon Athena with Amazon Quick Sight](#).

Make sure that you authorized Amazon Quick Sight to use Athena

Intended audience: Amazon Quick administrators

Use the following procedure to make sure that you successfully authorized Amazon Quick Sight to use Athena. Permissions to AWS resources apply to all Amazon Quick Sight users.

To perform this action, you must be an Amazon Quick Sight administrator. To check if you have access, verify that you see the **Manage QuickSight** option when you open the menu from your profile at upper right.

To authorize Amazon Quick Sight to access Athena

1. Choose your profile name (upper right). Choose **Manage Quick Sight**, and then scroll down to the **Custom permissions** section.
2. Choose **AWS resources** then choose **Add or remove**.
3. Find Athena in the list. Clear the box by Athena, then select it again to enable Athena.

Then choose **Connect both**.

4. Choose the buckets that you want to access from Amazon Quick Sight.

The settings for S3 buckets that you access here are the same ones that you access by choosing Amazon S3 from the list of AWS services. Be careful that you don't inadvertently disable a bucket that someone else uses.

5. Choose **Finish** to confirm your selection. Or choose **Cancel** to exit without saving.
6. Choose **Update** to save your new settings for Amazon Quick Sight access to AWS services. Or choose **Cancel** to exit without making any changes.
7. Make sure that you are using the correct AWS Region when you are finished.

If you had to change your AWS Region as part of the first step of this process, change it back to the AWS Region that you were using before.

Make sure that your IAM policies grant the right permissions

Intended audience: System administrators

Your AWS Identity and Access Management (IAM) policies must grant permissions to specific actions. Your IAM user or role must be able to read and write both the input and the output of the S3 buckets that Athena uses for your query.

If the dataset is encrypted, the IAM user needs to be a key user in the specified AWS KMS key's policy.

To verify that your IAM policies have permission to use S3 buckets for your query

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. Locate the IAM user or role that you are using. Choose the user or role name to see the associated policies.
3. Verify that your policy has the correct permissions. Choose a policy that you want to verify, and then choose **Edit policy**. Use the visual editor, which opens by default. If you have the JSON editor open instead, choose the **Visual editor** tab.
4. Choose the S3 entry in the list to see its contents. The policy needs to grant permissions to list, read, and write. If S3 is not in the list, or it doesn't have the correct permissions, you can add them here.

For examples of IAM policies that work with Quick Sight, see [IAM policy examples for Quick](#).

Make sure that the IAM user has read/write access to your S3 location

Intended audience: Amazon Quick administrators

To access Athena data from Quick Sight, first make sure that Athena and its S3 location are authorized in **Manage QuickSight** screen. For more information, see [Make sure that you authorized Amazon Quick Sight to use Athena](#).

Next, verify the relevant IAM permissions. The IAM user for your Athena connection needs read/write access to the location where your results go in S3. Start by verifying that the IAM user has an attached policy that [allows access to Athena](#), such as AmazonAthenaFullAccess. Let Athena create the bucket using the name that it requires, and then add this bucket to the list of buckets that QuickSight can access. If you change the default location of the results bucket (aws-athena-query-results-*), be sure that the IAM user has permission to read and write to the new location.

Verify that you don't include the AWS Region code in the S3 URL. For example, use s3://awsexamplebucket/path and not s3://us-east-1.amazonaws.com/awsexamplebucket/path. Using the wrong S3 URL causes an Access Denied error.

Also verify that the bucket policies and object access control lists (ACLs) [allow the IAM user to access the objects in the buckets](#). If the IAM user is in a different AWS account, see [Cross-account Access](#) in the *Amazon Athena User Guide*.

If the dataset is encrypted, verify that the IAM user is a key user in the specified AWS KMS key's policy. You can do this in the AWS KMS console at <https://console.aws.amazon.com/kms>.

To set permissions to your Athena query results location

1. Open the Athena console at <https://console.aws.amazon.com/athena/>.
2. Verify that you have selected the workgroup you want to use:
 - Examine the **Workgroup** option at the top. It has the format **Workgroup: *group-name***. If the group name is the one that you want to use, skip to the next step.
 - To choose a different workgroup, chose **Workgroup** at the top. Choose the workgroup that you want to use, and choose **Switch workgroup**.
3. Choose **Settings** at upper right.

(Not common) If you get an error that your workgroup is not found, use these steps to fix it:

- a. Ignore the error message for now, and instead find **Workgroup: *group-name*** on the **Settings** page. Your workgroup's name is a hyperlink. Open it.

- b. On the **Workgroup: <groupname>** page, choose **Edit workgroup** at left. Now close the error message.
- c. Near **Query result location**, open the S3 location selector by choosing the **Select** button that has the file folder icon.
- d. Choose the small arrow at the end of the name of the S3 location for Athena. The name must begin with `aws-athena-query-results`.
- e. (Optional) Encrypt query results by selecting the **Encrypt results stored in S3** check box.
- f. Choose **Save** to confirm your choices.
- g. If the error doesn't reappear, return to **Settings**.

Occasionally, the error might appear again. If so, take the following steps:

1. Choose the workgroup and then choose **View details**.
 2. (Optional) To preserve your settings, take notes or a screenshot of the workgroup configuration.
 3. Choose **Create workgroup**.
 4. Replace the workgroup with a new one. Configure the correct S3 location and encryption options. Note the S3 location because you need it later.
 5. Choose **Save** to proceed.
 6. When you no longer need the original workgroup, disable it. Make sure to carefully read the warning that appears, because it tells you what you lose if you choose to disable it.
4. If you didn't get this by troubleshooting in the previous step, choose **Settings** at upper right and get the S3 location value shown as **Query result location**.
 5. If **Encrypt query results** is enabled, check whether it uses SSE-KMS or CSE-KMS. Note the key.
 6. Open the S3 console at <https://console.aws.amazon.com/s3/>, open the correct bucket, and then choose the **Permissions** tab.
 7. Check that your IAM user has access by viewing **Bucket Policy**.

If you manage access with ACLs, make sure that the access control lists (ACLs) are set up by viewing **Access Control List**.

8. If your dataset is encrypted (**Encrypt query results** is selected in the workgroup settings), make sure that the IAM user or role is added as a key user in that AWS KMS key's policy. You can access AWS KMS settings at <https://console.aws.amazon.com/kms>.

To grant access to the S3 bucket used by Athena

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. Choose the S3 bucket used by Athena in the **Query result location**.
3. On the **Permissions** tab, verify the permissions.

For more information, see the AWS Support article [When I run an Athena query, I get an "Access Denied" error](#).

I can't connect to Amazon S3

To successfully connect to Amazon S3, make sure that you configure authentication and create a valid manifest file inside the bucket you are trying to access. Also, make sure that the file described by the manifest is available.

To verify authentication, make sure that you authorized Amazon Quick Sight to access the S3 account. It's not enough that you, the user, are authorized. Amazon Quick Sight must be authorized separately.

To authorize Amazon Quick Sight to access your Amazon S3 bucket

1. In the AWS Region list at upper right, choose the US East (N. Virginia) Region. You use this AWS Region temporarily while you edit your account permissions.
2. Inside Amazon Quick Sight, choose your profile name (upper right). Choose **Manage Quick Sight**, and then scroll down to the **Custom permissions** section.
3. Choose **AWS resources** then choose **Add or remove**.
4. Locate Amazon S3 in the list. Choose one of the following actions to open the screen where you can choose S3 buckets:
 - If the check box is clear, select the check box next to Amazon S3.
 - If the check box is selected, choose **Details**, and then choose **Select S3 buckets**.
5. Choose the buckets that you want to access from Amazon Quick Sight. Then choose **Select**.
6. Choose **Update**.
7. If you changed your AWS Region during the first step of this process, change it back to the AWS Region that you want to use.

We strongly recommend that you make sure that your manifest file is valid. If Amazon Quick Sight can't parse your file, it gives you an error message. That might be something like "We can't parse the manifest file as valid JSON" or "We can't connect to the S3 bucket."

To verify your manifest file

1. Open your manifest file. You can do this directly from the Amazon S3 console at <https://console.aws.amazon.com/s3/>. Go to your manifest file and choose **Open**.
2. Make sure that the URI or URLs provided inside the manifest file indicate the file or files that you want connect to.
3. Make sure that your manifest file is formed correctly, if you use a link to the manifest file rather than uploading the file. The link shouldn't have any additional phrases after the word `.json`. You can get the correct link to an S3 file by viewing its **Link** value in the details on the S3 console.
4. Make sure that the content of the manifest file is valid by using a JSON validator, like the one at <https://jsonlint.com>.
5. Verify permissions on your bucket or file. In the <https://console.aws.amazon.com/s3/>, navigate to your Amazon S3 bucket, choose the **Permissions** tab, and add the appropriate permissions. Make sure that the permissions are at the right level, either on the bucket or on the file or files.
6. If you are using the `s3://` protocol, rather than `https://`, make sure that you reference your bucket directly. For example, use `s3://awsexamplebucket/myfile.csv` instead of `s3://s3-us-west-2.amazonaws.com/awsexamplebucket/myfile.csv`. Doubly specifying Amazon S3, by using `s3://` and also `s3-us-west-2.amazonaws.com`, causes an error.

For more information about manifest files and connecting to Amazon S3, see [Supported formats for Amazon S3 manifest files](#).

In addition, verify that your Amazon S3 dataset was created according to the steps in [Creating a dataset using Amazon S3 files](#).

If you use Athena to connect to Amazon S3, see [I can't connect to Amazon Athena](#).

I can't create or refresh a dataset from an existing Adobe Analytics data source

As of May 1, 2022, Quick Sight no longer supports legacy OAuth and version 1.3 and SOAP API operations in Adobe Analytics. If you experience failures while trying to create or refresh a dataset from an existing Adobe Analytics data source, you might have a stale access token.

To troubleshoot failures while creating or refreshing a dataset from an existing Adobe Analytics data source

1. Open Quick Sight and choose **Data** at left.
2. Choose **New** then **Dataset**.
3. On the **Create a dataset** page, choose the Adobe Analytics data source that you want to update from the list of existing data sources.
4. Choose **Edit data source**.
5. On the **Edit Adobe Analytics data source** page that opens, choose **Update data source** to reauthorize the Adobe Analytics connection.
6. Try recreating or refreshing the dataset again. The dataset creation or refresh should succeed.

I need to validate the connection to my data source, or change data source settings

In some cases, you might need to update your data source, or you got a connection error and need to check your settings. If so, take the following steps.

To validate your connection to the data source

1. From the Quick Sight homepage, choose **Data** at left.
2. Choose **New** then **Dataset**.
3. You will see a list of existing data sources.
4. Choose the data source that you want to test or change.
5. If the option is offered, choose **Edit/Preview data**.
6. Choose **Validate connection**.
7. Make any changes that you want to make, then choose **Update data source**.

I can't connect to MySQL (issues with SSL and authorization)

To check on some common connection issues in MySQL, use the following steps. This procedure helps you find out if you have enabled SSL and granted usage rights.

To find solutions for some common connection issues in MySQL

1. Check `/etc/my.cnf` to make sure SSL is enabled for MySQL.

2. In MySQL, run the following command.

```
show status like 'Ssl%';
```

If SSL is working, you see results like the following.

Variable_name	Value
Ssl_accept_renegotiates	0
Ssl_accepts	1
Ssl_callback_cache_hits	0
Ssl_cipher	
Ssl_cipher_list	
Ssl_client_connects	0
Ssl_connect_renegotiates	0
Ssl_ctx_verify_depth	18446744073709551615
Ssl_ctx_verify_mode	5
Ssl_default_timeout	0
Ssl_finished_accepts	0
Ssl_finished_connects	0
Ssl_session_cache_hits	0
Ssl_session_cache_misses	0
Ssl_session_cache_mode	SERVER
Ssl_session_cache_overflows	0
Ssl_session_cache_size	128
Ssl_session_cache_timeouts	0
Ssl_sessions_reused	0
Ssl_used_session_cache_entries	0
Ssl_verify_depth	0
Ssl_verify_mode	0
Ssl_version	

If SSL is disabled, you see results like the following.

```
+-----+-----+
```

Variable_name	Value
Ssl_accept_renegotiates	0
Ssl_accepts	0
Ssl_callback_cache_hits	0
Ssl_cipher	
Ssl_cipher_list	
Ssl_client_connects	0
Ssl_connect_renegotiates	0
Ssl_ctx_verify_depth	0
Ssl_ctx_verify_mode	0
Ssl_default_timeout	0
Ssl_finished_accepts	0
Ssl_finished_connects	0
Ssl_session_cache_hits	0
Ssl_session_cache_misses	0
Ssl_session_cache_mode	NONE
Ssl_session_cache_overflows	0
Ssl_session_cache_size	0
Ssl_session_cache_timeouts	0
Ssl_sessions_reused	0
Ssl_used_session_cache_entries	0
Ssl_verify_depth	0
Ssl_verify_mode	0
Ssl_version	

3. Make sure that you have installed a supported SSL certificate on the database server.
4. Grant usage for the specific user to connect using SSL.

```
GRANT USAGE ON *.* TO 'encrypted_user'@'%' REQUIRE SSL;
```

Note

TLS 1.2 for MySQL connections requires MySQL version 5.7.28 or higher. If your MySQL server enforces TLS 1.2 only (for example, `tls_version = TLSv1.2`) and the server version is below 5.7.28, the SSL handshake fails with a Communications link failure

error. To resolve this, upgrade your MySQL or Aurora MySQL database to version 5.7.28 or higher.

For more detail on the solution in this example, see the following:

- [SSL Support for MySQL DB Instances](#) in the *Amazon RDS User Guide*.
- [Using SSL to Encrypt a Connection to a DB Instance](#) in the *Amazon RDS User Guide*.
- [MySQL documentation](#)

I can't connect to RDS

For details on troubleshooting connections to Amazon RDS, see [Creating a dataset from a database](#).

You can also refer to the Amazon RDS documentation on troubleshooting connections, [Cannot Connect to Amazon RDS DB Instance](#).

Login issues with Quick Sight

Use the following section to help you troubleshoot login and access issues with the Quick Sight console.

Topics

- [Insufficient permissions when using Athena with Amazon Quick Sight](#)
- [Amazon Quick Sight isn't working in my browser](#)
- [How do I delete my Amazon Quick Sight account?](#)
- [Individuals in my organization get an "External Login is Unauthorized" message when they try to access Quick Sight](#)
- [My email sign-in stopped working](#)

Insufficient permissions when using Athena with Amazon Quick Sight

If you receive an error message that says you have insufficient permissions, try the following steps to resolve your problem.

You need administrator permissions to troubleshoot this issue.

To resolve an insufficient permissions error

1. Make sure that Amazon Quick Sight can access the Amazon S3 buckets used by Athena:
 - a. To do this, choose your profile name (upper right). Choose **Manage Quick Sight**, and then scroll down to the **Custom permissions** section.
 - b. Choose **AWS resources** then choose **Add or remove**.
 - c. Locate Athena in the list. Clear the check box by Athena, then select it again to enable Athena.

Choose **Connect both**.

- d. Choose the buckets that you want to access from Amazon Quick Sight.

The settings for S3 buckets that you access here are the same ones that you access by choosing Amazon S3 from the list of AWS services. Be careful that you don't inadvertently disable a bucket that someone else uses.

- e. Choose **Select** to save your S3 buckets.
 - f. Choose **Update** to save your new settings for Amazon Quick Sight access to AWS services. Or choose **Cancel** to exit without making any changes.
2. If your data file is encrypted with an AWS KMS key, grant permissions to the Amazon Quick Sight IAM role to decrypt the key. The easiest way to do this is to use the AWS CLI.

You can run the [create-grant](#) command in AWS CLI to do this.

```
aws kms create-grant --key-id <AWS KMS key ARN> --grantee-principal <Your Amazon Quick Sight Role ARN> --operations Decrypt
```

The Amazon Resource Name (ARN) for the Amazon Quick Sight role has the format `arn:aws:iam::<account id>:role/service-role/aws-quicksight-service-role-v<version number>` and can be accessed from the IAM console. To find your AWS KMS key ARN, use the S3 console. Go to the bucket that contains your data file and choose the **Overview** tab. The key is located near **KMS key ID**.

For Amazon Athena, Amazon S3, and Athena Query Federation connections, Quick Sight uses the following IAM role by default:

```
arn:aws:iam::AWS-ACCOUNT-ID:role/service-role/aws-quicksight-s3-consumers-role-v0
```

If the `aws-quicksight-s3-consumers-role-v0` is not present, then Quick Sight uses:

```
arn:aws:iam::AWS-ACCOUNT-ID:role/service-role/aws-quicksight-service-role-v0
```

Amazon Quick Sight isn't working in my browser

If you can't view Amazon Quick Sight correctly in your Google Chrome browser, take the following steps to fix the problem.

To view Amazon Quick Sight in your Chrome browser

1. Open Chrome and go to `chrome://flags/#touch-events`.
2. If the option is set to **Automatic**, change it to **Disabled**.
3. Close and reopen Chrome.

How do I delete my Amazon Quick Sight account?

In some cases, you might need to delete your Amazon Quick Sight account even when you can't access Amazon Quick Sight to unsubscribe. If so, sign in to AWS and use the following link to open [the unsubscribe screen](https://us-east-1.quicksight.aws.amazon.com/sn/console/unsubscribe): `https://us-east-1.quicksight.aws.amazon.com/sn/console/unsubscribe`. This approach works no matter what AWS Regions that you use. It deletes all data, analyses, Amazon Quick Sight users, and Amazon Quick Sight administrators. If you have further difficulty, contact support.

Individuals in my organization get an "External Login is Unauthorized" message when they try to access Quick Sight

Intended audience: Amazon Quick administrators

When an individual in your organization is federating into Quick Sight using **AssumeRoleWithWebIdentity**, Quick Sight maps a single role-based user to a single external login. In some cases, that individual might be authenticated through an external login (such as Amazon Cognito) that's different from the originally mapped user. If so, they can't access Quick Sight and get the following unexpected error message.

The external login used for federation is unauthorized for the Quick Sight user.

To learn how to troubleshoot this issue, see the following sections:

- [Why is this happening?](#)
- [How can I fix it?](#)

Why is this happening?

You are using a simplified Amazon Cognito flow

If you're using Amazon Cognito to federate into Quick Sight, the single sign-on (IAM Identity Center) setup might use the `CognitoIdentityCredentials` API operation to assume the Quick Sight role. This method maps all users in the Amazon Cognito identity pool to a single Quick Sight user and isn't supported by Quick Sight.

We recommend that you use the `AssumeRoleWithWebIdentity` API operation instead, which specifies the role session name.

You're using unauthenticated Amazon Cognito users

Amazon Cognito IAM Identity Center is set up for unauthenticated users in the Amazon Cognito identity pool. The Quick Sight role trust policy is set up like the following example.

This setup allows a temporary Amazon Cognito user to assume a role session mapped to a unique Quick Sight user. Because unauthenticated identities are temporary, they aren't supported by Quick Sight.

We recommend that you don't use this setup, which setup isn't supported by Quick Sight. For Quick Sight, make sure that the Amazon Cognito IAM Identity Center uses authenticated users.

You deleted and recreated an Amazon Cognito user with the same user name attributes

In this case, the associated Amazon Cognito user that's mapped to the Quick Sight user was deleted and recreated. The newly created Amazon Cognito user has a different underlying subject. Depending on how the role session name is mapped to the Quick Sight user, the session name might correspond to the same Quick Sight role-based user.

We recommend that you remap the Quick Sight user to the updated Amazon Cognito user subject by using the `UpdateUser` API operation. For more information, see the following [UpdateUser API example](#).

You're mapping multiple Amazon Cognito user pools in different AWS accounts to one identity pool and with Quick Sight

Mapping multiple Amazon Cognito user pools in different AWS accounts to one identity pool and Quick Sight isn't supported by Quick Sight.

How can I fix it?

You can use Quick Sight public API operations to update the external login information for your users. Use the following options to learn how.

Use RegisterUser to create users with external login information

If the external login provider is Amazon Cognito, use the following CLI code to create users.

```
aws quicksight register-user --aws-account-id account-id --namespace namespace --email user-email --user-role user-role --identity-type IAM --iam-arn arn:aws:iam::account-id:role/cognito-associated-iam-role --session-name cognito-username --external-login-federation-provider-type COGNITO --external-login-id cognito-identity-id --region identity-region
```

The external-login-id should be the identity ID for the Amazon Cognito user. The format is <identity-region>:<cognito-user-sub>, as shown in the following example.

```
aws quicksight register-user --aws-account-id 111222333 --namespace default --email cognito-user@amazon.com --user-role ADMIN --identity-type IAM --iam-arn arn:aws:iam::111222333:role/CognitoQuickSightRole --session-name cognito-user --external-login-federation-provider-type COGNITO --external-login-id us-east-1:12345678-1234-1234-abc1-a1b1234567 --region us-east-1
```

If the external login provider is a custom OpenID Connect (OIDC) provider, use the following CLI code to create users.

```
aws quicksight register-user --aws-account-id account-id --namespace namespace --email user-email --user-role user-role --identity-type IAM --iam-arn arn:aws:iam::account-id:role/identity-provider-associated-iam-role --session-name identity-username --external-login-federation-provider-type CUSTOM_OIDC --custom-federation-provider-url custom-identity-provider-url --external-login-id custom-provider-identity-id --region identity-region
```

The following is an example.

```
aws quicksight register-user --aws-account-id 111222333 --namespace default
--email identity-user@amazon.com --user-role ADMIN --identity-type IAM
--iam-arn arn:aws:iam::111222333:role/CustomIdentityQuickSightRole
--session-name identity-user --external-login-federation-provider-type CUSTOM_OIDC
--custom-federation-provider-url idp.us-east-1.amazonaws.com/us-east-1_ABCDE
--external-login-id 12345678-1234-1234-abc1-a1b1234567 --region us-east-1
```

To learn more about using RegisterUser in the CLI, see [RegisterUser](#) in the *Amazon Quick API Reference*.

Use DescribeUser to check external login information for users

If a user is a role-based federated user from an external login provider, use the DescribeUser API operation to check the external login information for it, as shown in the following code.

```
aws quicksight describe-user --aws-account-id account-id --namespace namespace
--user-name identity-provider-associated-iam-role/identity-username
--region identity-region
```

The following is an example.

```
aws quicksight describe-user --aws-account-id 111222333 --namespace default --user-name
IdentityQuickSightRole/user --region us-west-2
```

The result contains the external login information fields if there are any. Following is an example.

```
{
  "Status": 200,
  "User": {
    "Arn": "arn:aws:quicksight:us-east-1:111222333:user-default-
IdentityQuickSightRole-user",
    "UserName": "IdentityQuickSightRole-user",
    "Email": "user@amazon.com",
    "Role": "ADMIN",
    "IdentityType": "IAM",
    "Active": true,
    "PrincipalId": "federated-iam-AR0AAAAAAAAAAAAAAAAA:user",
    "ExternalLoginFederationProviderType": "COGNITO",
    "ExternalLoginFederationProviderUrl": "cognito-identity.amazonaws.com",
    "ExternalLoginId": "us-east-1:123abc-1234-123a-b123-12345678a"
  },
}
```

```
"RequestId": "12345678-1234-1234-abc1-a1b1234567"
}
```

To learn more about using `DescribeUser` in the CLI, see [DescribeUser](#) in the *Amazon Quick API Reference*.

Use `UpdateUser` to update external login information for users

In some cases, you might find that the external login information saved for the user from the `DescribeUser` result isn't correct or the external login information is missing. If so, you can use the `UpdateUser` API operation to update it. Use the following examples.

For Amazon Cognito users, use the following.

```
aws quicksight update-user --aws-account-id account-id --namespace namespace
--user-name cognito-associated-iam-role/cognito-username
--email user-email --role user-role
--external-login-federation-provider-type COGNITO
--external-login-id cognito-identity-id --region identity-region
```

The following is an example.

```
aws quicksight update-user --aws-account-id 111222333 --namespace default
--user-name CognitoQuickSightRole/cognito-user --email cognito-user@amazon.com
--role ADMIN --external-login-federation-provider-type COGNITO
--external-login-id us-east-1:12345678-1234-1234-abc1-a1b1234567 --region us-west-2
```

For custom OIDC provider users, use the following.

```
aws quicksight update-user --aws-account-id account-id --namespace namespace
--user-name identity-provider-associated-iam-role/identity-username
--email user-email --role user-role
--external-login-federation-provider-type CUSTOM_OIDC
--custom-federation-provider-url custom-identity-provider-url
--external-login-id custom-provider-identity-id --region identity-region
```

The following is an example.

```
aws quicksight update-user --aws-account-id 111222333 --namespace default
--user-name IdentityQuickSightRole/user --email user@amazon.com --role ADMIN
```

```
--external-login-federation-provider-type CUSTOM_OIDC
--custom-federation-provider-url idp.us-east-1.amazonaws.com/us-east-1_ABCDE
--external-login-id 123abc-1234-123a-b123-12345678a --region us-west-2
```

If you want to delete the external login information for the user, use `NONE` external login federation provider type. Use the following CLI command to delete external login information.

```
aws quicksight update-user --aws-account-id account-id --namespace namespace
--user-name identity-provider-associated-iam-role/identity-username
--email user-email --role user-role
--external-login-federation-provider-type NONE --region identity-region
```

The following is an example.

```
aws quicksight update-user --aws-account-id 111222333 --namespace default
--user-name CognitoQuickSightRole/cognito-user --email cognito-user@amazon.com --role
ADMIN --external-login-federation-provider-type NONE --region us-west-2
```

To learn more about using `UpdateUser` in the CLI, see the [UpdateUser](#) in the *Amazon Quick API Reference*.

My email sign-in stopped working

Currently, emails are case-sensitive. If yours isn't working, ask your administrator to check it for a mix of upper and lowercase letters. Use your email as it was entered.

Visual issues with Quick Sight

Use the following section to help you troubleshoot problems with visuals and their formatting.

Topics

- [I can't see my visuals](#)
- [I get a feedback bar across my printed documents](#)
- [My map charts don't show locations](#)
- [My pivot table stops working](#)
- [My visual can't find missing columns](#)

- [My visual can't find the query table](#)
- [My visual doesn't update after I change a calculated field](#)
- [Values in a Microsoft Excel file with scientific notation don't format correctly in Quick Sight](#)

I can't see my visuals

Use the following section to help you troubleshoot missing visuals. Before you continue, check to make sure you can still access your data source. If you can't connect to your data source, see [Data source connectivity issues for Amazon Quick Sight](#).

- If you are having trouble adding a visual to an analysis, try the following:
 - Check your connectivity and confirm that you have access to all domains that Quick Sight uses for access. To see a list of all URLs Quick Sight uses, see [Domains accessed by Quick Sight](#).
 - Check that you aren't trying to add more objects than the quota allows. Amazon Quick Sight supports up to 30 datasets in a single analysis, up to 30 visuals in a single sheet, and a limit of 20 sheets per analysis.
 - Suppose that you are editing an analysis for a selected data source and the connection to the data source ends unexpectedly. The resulting error state can prevent further changes to the analysis. In this case, you can't add more visuals to the analysis. Check for this state.
- If your visuals don't load, try the following:
 - If you are using a corporate network, seek out help from your network administrator and verify that the network's firewall settings permit traffic from *.aws.amazon.com, amazonaws.com, wss://*.aws.amazon.com, and cloudfront.net.
 - Add exceptions to your ad blocker for *.aws.amazon.com, amazonaws.com, wss://*.aws.amazon.com, and cloudfront.net.
 - If you are using a proxy server, verify that *.quicksight.aws.amazon.com and cloudfront.net are added to the list of approved domains (the allow list).

I get a feedback bar across my printed documents

The browser sometimes prints the document feedback bar across the page, blocking some printed content.

To avoid this problem, use the twirl-down icon on the bottom left of the screen (shown following) to minimize the feedback bar. Then print your document.

My map charts don't show locations

For automatic mapping, called geocoding, to work on map charts, make sure that your data is prepared following specific rules. For help with geospatial issues, see [Geospatial troubleshooting](#). For help with preparing data for geospatial charts, see [Adding geospatial data](#).

My pivot table stops working

If your pivot table exceeds the computational limitations of the underlying database, this is usually caused by the combination of items in the field wells. That is, it's caused by a combination of rows, columns, metrics, and table calculations. To reduce the level of complexity and the potential for errors, simplify your pivot table. For more information, see [Pivot table best practices](#).

My visual can't find missing columns

The visuals in my analysis aren't working as expected. The error message says "The column(s) used in this visual do not exist."

The most common cause of this error is that your data source schema changed. For example, it's possible a column name changed from a_column to b_column.

Depending on how your dataset accesses the data source, choose one of the following.

- If the dataset is based on custom SQL, do one or more of the following:
 - Edit the dataset.
 - Edit the SQL statement.

For example, if the table name changed from a_column to b_column, you can update the SQL statement to create an alias: `SELECT b_column as a_column`. By using the alias to maintain the same field name in the dataset, you avoid having to add the column to your visuals as a new entity.

When you're done, choose **Save & visualize**.

- If the dataset isn't based on custom SQL, do one or more of the following:
 - Edit the dataset.

- For fields that now have different names, rename them in the dataset. You can use the field names from your original dataset. Then open your analysis and add the renamed fields to the affected visuals.

When you're done, choose **Save & visualize**.

My visual can't find the query table

In this case, the visuals in your analysis aren't working as expected. The error message says "Amazon Quick Sight can't find the query table."

The most common cause of this error is that your data source schema changed. For example, it's possible a table name changed from `x_table` to `y_table`.

Depending on how the dataset accesses the data source, choose one of the following.

- If the dataset is based on custom SQL, do one or more of the following:
 - Edit the dataset.
 - Edit the SQL statement.

For example, if the table name changed from `x_table` to `y_table`, you can update the FROM clause in the SQL statement to refer to the new table instead.

When you're done, choose **Save & visualize**, then choose each visual and readd the fields as needed.

- If the dataset isn't based on custom SQL, do the following:
 1. Create a new dataset using the new table, `y_table` for example.
 2. Open your analysis.
 3. Replace the original dataset with the newly created dataset. If there are no column changes, all the visuals should work after you replace the dataset. For more information, see [Replacing datasets](#).

My visual doesn't update after I change a calculated field

When you update a calculated field that many other fields depend on, the consuming entities might not update as expected. For example, when you update a calculated field that's used by a field being visualized, the visual doesn't update as expected.

To resolve this issue, refresh your internet browser.

Values in a Microsoft Excel file with scientific notation don't format correctly in Quick Sight

When you connect to a Microsoft Excel file that has a number column that contains values with scientific notation, they might not format correctly in Quick Sight. For example, the value 1.59964E+11, which is actually 159964032802, formats as 159964000000 in Quick Sight. This can lead to an incorrect analysis.

To resolve this issue, format the column as Text in Microsoft Excel, and then upload the file to Quick Sight.

Developing with Amazon Quick Sight

We provide API operations for Amazon Quick Sight, and also software development kits (SDKs) for AWS that enable you to access Amazon Quick Sight from your preferred programming language. Currently, you can manage users and groups. In Enterprise edition, you can also embed dashboards in your webpage or app.

To monitor the calls made to the Amazon Quick Sight API for your account, including calls made by the AWS Management Console, command line tools, and other services, use AWS CloudTrail. For more information, see the [AWS CloudTrail User Guide](#).

Required knowledge

If you plan to access Amazon Quick Sight through an API, you should be familiar with the following:

- JSON
- Web services
- HTTP requests
- One or more programming languages, such as JavaScript, Java, Python, or C#.

We recommend visiting the AWS [Getting Started Resource Center](#) for a tour of what AWS SDKs and toolkits have to offer.

Although you can use a terminal and your favorite text editor, you might benefit from the more visual UI experience you get in an integrated development environment (IDE). We provide a list

of IDEs in the *AWS Getting Started Resource Center* in the [IDE and IDE Toolkits](#) section. This site provides AWS toolkits that you can download for your preferred IDE. Some IDEs also offer tutorials to help you learn more about programming languages.

Available API operations for Amazon Quick Sight

AWS provides libraries, sample code, tutorials, and other resources for software developers who prefer to build applications using language-specific API operations instead of submitting a request over HTTPS. These libraries provide basic functions that automatically take care of tasks such as cryptographically signing your requests, retrying requests, and handling error responses. These libraries help make it easier for you to get started.

For more information about downloading the AWS SDKs, see [AWS SDKs and Tools](#). The following links are a sample of the language-specific API documentation available.

Terminology and concepts

This section provides a list of terms for development in Amazon Quick Sight.

Anonymous Amazon Quick Sight User: – A temporary Amazon Quick Sight user identity that virtually belongs to a namespace, and is usable only with embedding. You can use tag-based rules to implement row-level security for such users.

Caller identity: – The identity of the AWS Identity and Access Management user making an API request. The identity of the caller is determined by Amazon Quick Sight using the signature attached to the request. Through the use of our provided SDK clients, no manual steps are necessary to generate the signature or attach it to the requests. However, you can do it manually if you want to.

Invoker identity: – In addition to the caller identity, but not as a replacement for it, you can assume a caller's identity through the IAM AssumeRole API when making calls to Amazon Quick Sight. AWS approves callers through their invoker's identity. This is done to avoid having to explicitly add multiple accounts belonging to the same Amazon Quick Sight subscription.

Namespace: – a logical container that allows you to isolate user pools so that you can organize clients, subsidiaries, teams, and so on. For more information, see [Supporting multitenancy with isolated namespaces](#)

QuickSight ARN: – Amazon Resource Name (ARN). Amazon Quick Sight resources are identified using their name or ARN. For example, these are the ARNs for a group named MyGroup1, a user named User1, and a dashboard with the ID 1a1ac2b2-3fc3-4b44-5e5d-c6db6778df89:

```
arn:aws:quicksight:us-east-1:111122223333:group/default/MyGroup1
arn:aws:quicksight:us-east-1:111122223333:user/default/User1
arn:aws:quicksight:us-west-2:111122223333:dashboard/1a1ac2b2-3fc3-4b44-5e5d-
c6db6778df89
```

The following examples show ARNs for a template named MyTemplate and a dashboard named MyDashboard.

1. Sample ARN for a template

```
arn:aws:quicksight:us-east-1:111122223333:template/MyTemplate
```

2. Sample ARN for a template, referencing a specific version of the template

```
arn:aws:quicksight:us-east-1:111122223333:template/MyTemplate/version/10
```

3. Sample ARN for a template alias

```
arn:aws:quicksight:us-east-1:111122223333:template/MyTemplate/alias/STAGING
```

4. Sample ARN for a dashboard

```
arn:aws:quicksight:us-east-1:111122223333:dashboard/MyDashboard
```

5. Sample ARN for a dashboard, referencing a specific version of the dashboard

```
arn:aws:quicksight:us-east-1:111122223333:dashboard/MyDashboard/version/10
```

Depending on the scenario, you might need to provide an entity's name, ID, or ARN. You can retrieve the ARN if you have the name, using some of the Amazon Quick Sight API operations.

Amazon Quick Sight dashboard: – An entity which identifies Amazon Quick Sight reports, created from analyses or templates. Amazon Quick Sight dashboards are sharable. With the right permissions, scheduled email reports can be created from them. The CreateDashboard and DescribeDashboard API Operations act on the dashboard entity.

Amazon Quick Sight template: – An entity which encapsulates the metadata required to create an analysis or a dashboard. It abstracts the dataset associated with the analysis by replacing it with placeholders. Templates can be used to create dashboards by replacing dataset placeholders with datasets that follow the same schema that was used to create the source analysis and template.

Amazon Quick Sight user: – This is an Amazon Quick Sight user identity acted upon by your API call. This user isn't identical to the caller identity but might be the one that maps to the user within Amazon Quick Sight.

Developing applications with the Amazon Quick Sight API

You can manage most aspects of your deployment by using the AWS SDKs to access an API that's tailored to the programming language or platform that you're using. For more information, see [AWS SDKs](#).

For more information on the API operations, see [Amazon Quick Sight API Reference](#).

Before you can call the Amazon Quick Sight API operations, you need the `quicksight:operation-name` permission in a policy attached to your IAM identity. For example, to call `list-users`, you need the permission `quicksight:ListUsers`. The same pattern applies to all operations.

If you're not sure what the necessary permission is, you can attempt to make a call. The client then tells you what the missing permission is. You can use asterisk (*) in the Resource field of your permission policy instead of specifying explicit resources. However, we recommended that you restrict each permission as much as possible. You can restrict user access by specifying or excluding resources in the policy, using their Amazon Quick Sight Amazon Resource Name (ARN) identifier.

For more information, see the following:

- [IAM policy examples for Amazon Quick Sight](#)
- [Actions, Resources, and Condition Keys](#)
- [IAM JSON Policy Elements](#)

To retrieve the ARN of a user or a group, use the `Describe` operation on the relevant resource. You can also add conditions in IAM to further restrict access to an API in some scenarios. For instance, when adding `User1` to `Group1`, the main resource is `Group1`, so you can allow or deny access to certain groups, but you can also add a condition by using the IAM Amazon Quick Sight key `quicksight:UserName` to allow or prevent certain users from being added to that group.

Following is an example policy. It means that the caller with this policy attached, is able to invoke the `CreateGroupMembership` operation on any group, provided that the user name they are adding to the group is not `user1`.

```
{
  "Effect": "Allow",
  "Action": "quicksight:CreateGroupMembership",
  "Resource": "arn:aws:quicksight:us-east-1:aws-account-id:group/default/*",
  "Condition": {
    "StringNotEquals": {
      "quicksight:UserName": "user1"
    }
  }
}
```

AWS CLI

The following procedure explains how to interact with Amazon Quick Sight API operations through the AWS CLI. The following instructions have been tested in Bash but should be identical or similar in other command-line environments.

1. Install AWS SDK in your environment. Instructions on how to do that are located here: [AWS Command line Interface](#).
2. Set up your AWS CLI identity and region using the following command and follow-up instructions. Use the credentials for an IAM identity or role that has the proper permissions.

```
aws configure
```

3. Look at the Amazon Quick Sight SDK help by issuing the following command:

```
aws quicksight help
```

4. To get detailed instructions on how to use an API, enter its name followed by help, like so:

```
aws quicksight list-users help
```

5. Now you can call an Amazon Quick Sight API operation. This example returns a list of Amazon Quick Sight users in your account.

```
aws quicksight list-users --aws-account-id aws-account-id --namespace default --  
region us-east-1
```

Java SDK

Use the following procedure to set up a Java app that interacts with Amazon Quick Sight.

1. To get started, create a Java project in your IDE.
2. Import the Amazon Quick Sight SDK into your new project, for example:
`AWSQuickSightJavaClient-1.11.x.jar`
3. Once your IDE indexes the Amazon Quick Sight SDK, you should be able to add an import line as follows:

```
import com.amazonaws.services.quicksight.AmazonQuickSight;
```

If your IDE doesn't recognize this as valid, verify that you imported the SDK.

4. Like other AWS SDKs, Amazon Quick Sight SDK requires external dependencies to perform many of its functions. You need to download and import those into the same project. The following dependencies are required:
 - `aws-java-sdk-1.11.402.jar` (AWS Java SDK and credentials setup) — See [Set up the AWS SDK for Java](#)
 - `commons-logging-1.2.jar` — See https://commons.apache.org/proper/commons-logging/download_logging.cgi
 - `jackson-annotations-2.9.6.jar`, `jackson-core-2.9.6.jar`, and `jackson-databind-2.9.6.jar` — See <http://repo1.maven.org/maven2/com/fasterxml/jackson/core/>
 - `httpclient-4.5.6.jar`, `httpcore-4.4.10.jar` — See <https://hc.apache.org/downloads.cgi>
 - `joda-time-2.1.jar` — See <https://mvnrepository.com/artifact/joda-time/joda-time/2.1>
5. Now, you are ready to create an Amazon Quick Sight client. You can use a default public endpoint that the client can communicate with or you can reference the endpoint explicitly. There are multiple ways to provide your AWS credentials. In the following example, we

provide a direct, simple approach. The following client method is used to make all the API calls that follow:

```
private static AmazonQuickSight getClient() {
    final AWSCredentialsProvider credsProvider = new AWSCredentialsProvider() {
        @Override
        public AWSCredentials getCredentials() {
            // provide actual IAM access key and secret key here
            return new BasicAWSCredentials("access-key", "secret-key");
        }

        @Override
        public void refresh() {}
    };

    return AmazonQuickSightClientBuilder
        .standard()
        .withRegion(Regions.US_EAST_1.getName())
        .withCredentials(credsProvider)
        .build();
}
```

6. Now, we can use the above client to list all the users in our Amazon Quick Sight account.

 Note

You have to provide the AWS account ID that you used to subscribe to Amazon Quick Sight. This must match the AWS account ID of the caller's identity. Cross-account calls aren't supported at this time. Furthermore, the required parameter namespace should always be set to *default*.

```
getClient().listUsers(new ListUsersRequest()
    .withAwsAccountId("relevant_AWS_account_ID")
    .withNamespace("default"))
    .getUserList().forEach(user -> {
        System.out.println(user.getArn());
    });
```

7. To see a list of all possible API operations and the request objects they use, you can **CTRL-click** on the client object in your IDE in order to view the Amazon Quick Sight interface.

Alternatively, find it within the `com.amazonaws.services.quicksight` package in the Amazon Quick Sight JavaClient JAR file.

JavaScript (Node.js) SDK

Use the following procedure to interact with Amazon Quick Sight using Node.js.

1. Set up your node environment using the following commands:
 - `npm install aws-sdk`
 - `npm install aws4`
 - `npm install request`
 - `npm install url`
2. For information on configuring the Node.js with AWS SDK and setting your credentials, see--> the [AWS SDK for JavaScript Developer Guide for SDK v2](#).
3. Use the following code sample to test your setup. HTTPS is required. The sample displays a full listing of Amazon Quick Sight operations along with their URL request parameters, followed by a list of Amazon Quick Sight users in your account.

```
const AWS = require('aws-sdk');
const https = require('https');

var quicksight = new AWS.Service({
  apiConfig: require('./quicksight-2018-04-01.min.json'),
  region: 'us-east-1',
});

console.log(quicksight.config.apiConfig.operations);

quicksight.listUsers({
  // Enter your actual AWS account ID
  'AwsAccountId': 'relevant_AWS_account_ID',
  'Namespace': 'default',
}, function(err, data) {
  console.log('---');
  console.log('Errors: ');
  console.log(err);
  console.log('---');
  console.log('Response: ');
  console.log(data);
});
```

```
});
```

Python3 SDK

Use the following procedure to create a custom built botocore package to interact with Amazon Quick Sight.

1. Create a credentials file in the AWS directory for your environment. In a Linux/Mac-based environment, that file is called `~/.aws/credentials` and looks like this:

```
[default]
aws_access_key_id = Your_IAM_access_key
aws_secret_access_key = Your_IAM_secret_key
```

2. Unzip the folder `botocore-1.12.10`. Change directory into `botocore-1.12.10` and enter the Python3 interpreter environment.
3. Responses come back as a dictionary object. They each have a `ResponseMetadata` entry that contains request IDs and response status. Other entries are based on what type of operation you run.
4. The following example is a sample app that first creates, deletes, and lists groups. Then, it lists users in a Quicksight account:

```
import botocore.session
default_namespace = 'default'
account_id = 'relevant_AWS_Account'

session = botocore.session.get_session()
client = session.create_client("quicksight", region_name='us-east-1')

print('Creating three groups: ')
client.create_group(AwsAccountId = account_id, Namespace=default_namespace,
    GroupName='MyGroup1')
client.create_group(AwsAccountId = account_id, Namespace=default_namespace,
    GroupName='MyGroup2')
client.create_group(AwsAccountId = account_id, Namespace=default_namespace,
    GroupName='MyGroup3')

print('Retrieving the groups and listing them: ')
response = client.list_groups(AwsAccountId = account_id,
    Namespace=default_namespace)
```

```
for group in response['GroupList']:
    print(group)

print('Deleting our groups: ')
client.delete_group(AwsAccountId = account_id, Namespace=default_namespace,
    GroupName='MyGroup1')
client.delete_group(AwsAccountId = account_id, Namespace=default_namespace,
    GroupName='MyGroup2')
client.delete_group(AwsAccountId = account_id, Namespace=default_namespace,
    GroupName='MyGroup3')

response = client.list_users(AwsAccountId = account_id,
    Namespace=default_namespace)
for user in response['UserList']:
    print(user)
```

.NET/C# SDK

Use the following procedure to interact with Amazon Quick Sight using C#.NET. This example is constructed on Microsoft Visual for Mac; the instructions can vary slightly based on your IDE and platform. However, they should be similar.

1. Unzip the `nuget.zip` file into a folder called `nuget`.
2. Create a new **Console app** project in Visual Studio.
3. Under your solution, locate app **Dependencies**, then open the context (right-click menu) and choose **Add Packages**.
4. In the sources list, choose **Configure Sources**.
5. Choose **Add**, and name the source `QuickSightSDK`. Browse to the `nuget` folder and choose **Add Source**.
6. Choose **OK**. Then, with `QuickSightSDK` selected, select all three Amazon Quick Sight packages:
 - `AWSSDK.QuickSight`
 - `AWSSDK.Extensions.NETCore.Setup`
 - `AWSSDK.Extensions.CognitoAuthentication`
7. Click **Add Package**.
8. Copy and paste the following sample app into your console app editor.

```
using System;
using Amazon.QuickSight.Model;
using Amazon.QuickSight;

namespace DotNetQuickSightSDKTest
{
    class Program
    {
        private static readonly string AccessKey = "insert_your_access_key";
        private static readonly string SecretAccessKey =
            "insert_your_secret_key";
        private static readonly string AccountID = "AWS_account_ID";
        private static readonly string Namespace = "default"; // leave this as
        default

        static void Main(string[] args)
        {
            var client = new AmazonQuickSightClient(
                AccessKey,
                SecretAccessKey,
                Amazon.RegionEndpoint.USEast1);

            var listUsersRequest = new ListUsersRequest
            {
                AwsAccountId = AccountID,
                Namespace = Namespace
            };

            client.ListUsersAsync(listUsersRequest).Result.UserList.ForEach(
                user => Console.WriteLine(user.Arn)
            );

            var listGroupsRequest = new ListGroupsRequest
            {
                AwsAccountId = AccountID,
                Namespace = Namespace
            };

            client.ListGroupsAsync(listGroupsRequest).Result.GroupList.ForEach(
                group => Console.WriteLine(group.Arn)
            );
        }
    }
}
```

```
}

```

Amazon Quick Sight events integration

With Amazon EventBridge, you can respond automatically to events in Amazon Quick Sight such as new dashboard creation or updates. These events are delivered to EventBridge in near real time. As a developer, you can write simple rules to indicate which events are of interest, and what actions to take when an event matches a rule. By using events, you can complete use cases such as continuous backup and deployment.

Example event payload

All events follow the standard EventBridge [object structure](#). The detail field is a JSON object that contains more information about the event.

```
{
  "version": "0",
  "id": "3acb26c8-397c-4c89-a80a-ce672a864c55",
  "detail-type": "QuickSight Dashboard Creation Successful",
  "source": "aws.quicksight",
  "account": "123456789012",
  "time": "2023-10-30T22:06:31Z",
  "region": "us-east-1",
  "resources": ["arn:aws:quicksight:us-east-1:123456789012:dashboard/6fdb328-ebbd-457f-aa02-9780173afc83"],
  "detail": {
    "dashboardId": "6fdb328-ebbd-457f-aa02-9780173afc83",
    "versionNumber": 1
  }
}
```

Creating rules to send Amazon Quick Sight events to Amazon CloudWatch

You can write simple rules to indicate which Amazon Quick Sight events interest you and which automated actions to take when an event matches a rule. For example, you can configure Amazon Quick Sight to send events to Amazon CloudWatch whenever a Amazon Quick Sight asset is placed in a folder. For more information, see the [Amazon EventBridge user guide](#).

1. Sign in to the AWS Management Console and open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. Under **Events** in the navigation pane, choose **Rules**.
3. Choose **Create rule**.
4. Enter a name and description for the rule. The rule name must be unique within this Region. For example, enter QuickSightAssetChangeRuleCloudWatch.
5. Choose **default** Event bus.
6. Choose **Rule with an event pattern**, and then choose **Next**.
7. For **Event source**, choose **AWS events or EventBridge partner events**.
8. In the **Creation method** section, choose **Custom pattern (JSON editor)**.

9. In the **Event pattern** text box, enter the following snippet and choose **Next**.

```
{
  "source": ["aws.quicksight"]
}
```

Alternatively, you can create the rule that only subscribes to a subset of event types in Amazon Quick Sight. For example, the following rule will only triggered when an asset is added to or removed from a folder with id 77e307e8-b41b-472a-90e8-fe3f471537be.

```
{
  "source": ["aws.quicksight"],
  "detail-type": ["QuickSight Folder Membership Updated"],
  "detail": {
    "folderId": "77e307e8-b41b-472a-90e8-fe3f471537be"
  }
}
```

10. For **Targets**, choose **AWS service > CloudWatch log group**.
11. Choose from an existing log group or create a new one by entering a new log group name.
12. Optionally, you can add another target for this rule.
13. In **Configure tags**, choose **Next**.
14. Choose **Create rule**.

For more information, see [Creating Amazon EventBridge rule that reacts To events](#) in the Amazon EventBridge user guide.

Creating rules to send Amazon Quick Sight events to AWS Lambda

In this tutorial, you create an AWS Lambda function that logs the asset events in the Amazon Quick Sight account. You then create a rule that runs the function whenever there is an asset change. This tutorial assumes that you already signed up for Amazon Quick Sight.

Step 1: Create a Lambda function

Create a Lambda function to log the state change events. You specify this function when you create your rule.

1. Sign in to the AWS Management Console and open the AWS Lambda console at <https://console.aws.amazon.com/lambda/>.
2. If you're new to Lambda, you see a welcome page. Choose **Get Started Now**. Otherwise, choose **Create function**.
3. Choose **Author from scratch**.
4. On the Create function page, enter a name and description for the Lambda function. For example, name the function `QuickSightAssetChangeFn`.
5. In **Runtime**, select **Node.js 18.x**.
6. For **Architecture**, choose **x86_64**.
7. For **Execution role**, choose either **Create a new role with basic Lambda permissions** or **Use an existing role** and choose the role you want.
8. Choose **Create function**.
9. On the **QuickSightAssetChange** page, choose **index.js**.
10. In the **index.js** pane, delete the existing code.
11. Enter the following code snippet.

```
console.log('Loading function');
exports.handler = async (event, context) => {
  console.log('Received QuickSight event:', JSON.stringify(event));
};
```

12. Choose **Deploy**.

Step 2: Create a rule

Create a rule to run your Lambda function whenever you create/update/delete a Amazon Quick Sight asset.

1. Sign in to the AWS Management Console and open the Amazon EventBridge console at <https://console.aws.amazon.com/events/>.
2. In the navigation pane, choose **Rules**.
3. Choose **Create rule**.
4. Enter a name and description for the rule. For example, enter `QuickSightAssetChangeRule`.
5. Select **default** Event bus.

6. Choose **Rule with an event pattern**, and then choose **Next**.
7. For **Event source**, choose **AWS events or EventBridge partner events**.
8. In the **Creation method** section, choose **Custom pattern (JSON editor)**.
9. In the **Event pattern** text box, enter the following snippet and choose **Next**.

```
{
  "source": ["aws.quicksight"]
}
```

Alternatively, you can create the rule that only subscribes to a subset of event types in Amazon Quick Sight. For example, the following rule will only triggered when an asset is added to or removed from a folder with id 77e307e8-b41b-472a-90e8-fe3f471537be.

```
{
  "source": ["aws.quicksight"],
  "detail-type": ["QuickSight Folder Membership Updated"],
  "detail": {
    "folderId": "77e307e8-b41b-472a-90e8-fe3f471537be"
  }
}
```

10. For **Target types**, choose **AWS service** and **Lambda function**.
11. For **Function**, choose the Lambda function that you created. Then choose **Next**.
12. In **Configure tags**, choose **Next**.
13. Review the steps in your rule. Then choose **Create rule**.

Step 3: Test the rule

To test your rule, create an analysis. After waiting a minute, verify that your Lambda function was invoked.

1. Open the Amazon Quick Sight console at <https://quicksight.aws.amazon.com/>.
2. Create a new analysis.
3. In the navigation pane, choose **Rules**, choose the name of the rule that you created.
4. In **Rule details**, choose **Monitoring**.
5. You will be redirected to the Amazon CloudWatch console. If you are not redirected, choose **View the metrics in CloudWatch**.

6. In **All metrics**, choose the name of the rule that you created. The graph indicates that the rule was invoked.
7. In the navigation pane, choose **Log groups**.
8. Choose the name of the log group for your Lambda function. For example, `/aws/lambda/function-name`.
9. Choose the name of the log stream to view the data provided by the function for the instance that you launched. You should see a received event similar to the following:

```
{
  "version": "0",
  "id": "3acb26c8-397c-4c89-a80a-ce672a864c55",
  "detail-type": "QuickSight Analysis Creation Successful",
  "source": "aws.quicksight",
  "account": "123456789012",
  "time": "2023-10-30T22:06:31Z",
  "region": "us-east-1",
  "resources": ["arn:aws:quicksight:us-east-1:123456789012:analysis/e5f37119-e24c-4874-901a-af9032b729b5"],
  "detail": {
    "analysisId": "e5f37119-e24c-4874-901a-af9032b729b5"
  }
}
```

For an example of Amazon Quick Sight event in JSON format, see [Overview of events for Amazon Quick Sight](#).

Embedded analytics for Amazon Quick Sight

Important

Amazon Quick Sight has new API operations for embedding analytics: `GenerateEmbedUrlForAnonymousUser` and `GenerateEmbedUrlForRegisteredUser`. You can still use the `GetDashboardEmbedUrl` and `GetSessionEmbedUrl` API operations to embed dashboards and the Amazon Quick Sight console, but they don't contain the latest embedding capabilities. For more information about embedding using the old API operations, see [Embedding analytics using the `GetDashboardEmbedURL` and `GetSessionEmbedURL` API operations](#).

Applies to: Enterprise Edition

Intended audience: Amazon Quick developers

With Amazon Quick Sight embedded analytics, you can seamlessly integrate data-driven experiences into your software applications. You can style the embedded components to match your brand. This capability brings the power of Amazon Quick Sight to your end users, where they can analyze and interact with data without ever leaving the application. Improving the user experience by reducing cognitive complexity gives users a better opportunity for deeper understanding and effectiveness.

Amazon Quick Sight supports embedding for these elements:

- Amazon Quick Sight console (full authoring experience for registered users)
- Amazon Quick Sight dashboards and visuals (for registered users, anonymous users, public end users)
- Amazon Quick Sight Q search bar (for registered users and anonymous users)

With an embedded Amazon Quick Sight console, you embed the full Amazon Quick Sight experience. Doing this makes it possible to use Amazon Quick Sight authoring tools as part of your application, rather than in the context of the AWS Management Console or a standalone website. Users of an embedded Amazon Quick Sight console need to be registered as Amazon Quick Sight authors or admins in your AWS account. They also need to be authenticated into the same AWS account, using any of the Amazon Quick Sight-supported authentication methods.

With an embedded Amazon Quick Sight dashboard or visual, readers get the same functionality and interactivity as they do in a published dashboard or visual. To use an embedded dashboard or visual, readers (viewers) can include any of the following:

- Amazon Quick Sight users authenticated in your AWS account by any method supported by Amazon Quick Sight.
- Unauthenticated visitors to a website or application – This option requires session packs with capacity pricing . For information about subscription types, see [Understanding Amazon Quick Sight subscriptions and roles](#).

- Multiple end users viewing a display on monitors or large screens by programmatic access.

If your app also resides in AWS, the app doesn't need to reside on the same AWS account as the Amazon Quick Sight subscription. However, the app needs to be able to assume the AWS Identity and Access Management (IAM) role that you use for the API calls.

Before you can embed content, make sure that you're using Amazon Quick Sight Enterprise edition in the AWS account where you plan to use embedding.

Amazon Quick Sight embedding is available in all supported AWS Regions.

Embedding Amazon Quick Sight analytics into your applications

Applies to: Enterprise Edition

To embed analytics, you can run the Amazon Quick Sight embedding API to generate the embed code. Alternatively for dashboards, you can copy an embed code when you share the dashboard in Amazon Quick Sight. Each option is described below.

1-click embedding for registered users

When you share a dashboard with registered users in your account, you can copy an embed code for the dashboard and paste it into your internal application's HTML.

Using 1-click enterprise embedding is best for when you want to embed a Amazon Quick Sight dashboard in an internal application that users need to authenticate in to. When you copy the embed code, you get a static embed code that doesn't change.

For more information, see [Embedding Amazon Quick Sight visuals and dashboards for registered users with a 1-click embed code](#).

Embedding with the Amazon Quick Sight APIs

Embedding with the Amazon Quick Sight API is best for when you want to embed the Amazon Quick Sight experience in an internal application that users must authenticate in to, or an external application that anyone can access. When you use the embedding API operations to generate an embed code, you get a one-time code.

For more information, see [Embedding with the Amazon Quick Sight APIs](#).

Embedding custom Amazon Quick Sight assets into your application

You can use Amazon Quick Sight embedded analytics to embed custom Amazon Quick Sight assets into your application that are tailored to meet your business needs. For embedded dashboards and visuals, Amazon Quick Sight authors can add filters and drill downs that readers can access as they navigate the dashboard or visual. Amazon Quick Sight developers can also use the Amazon Quick Sight SDKs to build tighter integrations between their SaaS applications and their Amazon Quick Sight embedded assets to add datapoint callback actions to visuals on a dashboard at runtime.

For more information about the Amazon Quick Sight SDKs, see the `amazon-quicksight-embedding-sdk` on [GitHub](#) or [NPM](#).

Following, you can find descriptions of how to use the Amazon Quick Sight SDKs to customize your Amazon Quick Sight embedded analytics.

- [Adding embedded callback actions at runtime in Amazon Quick Sight](#)
- [Filtering data at runtime for Amazon Quick Sight embedded dashboards and visuals](#)
- [Customize the look and feel of Amazon Quick Sight embedded dashboards and visuals](#)
- [Using the Amazon Quick Sight Embedding SDK to enable shareable links to embedded dashboard views](#)

Adding embedded callback actions at runtime in Amazon Quick Sight

Use embedded datapoint callback actions to build tighter integrations between your software as a service (SaaS) application and your Amazon Quick Sight embedded dashboards and visuals. Developers can register datapoints to be called back with the Amazon Quick Sight embedding SDK. When you register a callback action for a visual, readers can select a datapoint on the visual to receive a callback that provides data specific to the selected data point. This information can be

used to flag key records, compile raw data specific to the datapoint, capture records, and compile data for backend processes.

Embedded callbacks aren't supported for custom visual content, text boxes, or insights.

Before you begin registering datapoints for callback, update the Embedding SDK to version 2.3.0. For more information about using the Amazon Quick Sight Embedding SDK, see the [amazon-quicksight-embedding-sdk](#) on GitHub.

A datapoint callback can be registered to one or more visuals at runtime through the Amazon Quick Sight SDK. You can also register a datapoint callback to any interaction supported by the [VisualCustomAction](#) API structure. This allows the datapoint callback to initiate when the user selects the datapoint on the visual or when the datapoint is selected from the datapoint context menu. The following example registers a datapoint callback that the reader initiates when they select a datapoint on the visual.

```
/const MY_GET_EMBED_URL_ENDPOINT =  
  "https://my.api.endpoint.domain/MyGetEmbedUrlApi"; // Sample URL  
  
// The dashboard id to embed  
const MY_DASHBOARD_ID = "my-dashboard"; // Sample ID  
  
// The container element in your page that will have the embedded dashboard  
const MY_DASHBOARD_CONTAINER = "#experience-container"; // Sample ID  
  
// SOME HELPERS  
  
const ActionTrigger = {  
  DATA_POINT_CLICK: "DATA_POINT_CLICK",  
  DATA_POINT_MENU: "DATA_POINT_MENU",  
};  
  
const ActionStatus = {  
  ENABLED: "ENABLED",  
  DISABLED: "DISABLED",  
};  
  
// This function makes a request to your endpoint to obtain an embed url for a given  
// dashboard id  
// The example implementation below assumes the endpoint takes dashboardId as request  
// data  
// and returns an object with EmbedUrl property
```

```
const myGetEmbedUrl = async (dashboardId) => {
  const apiOptions = {
    dashboardId,
  };
  const apiUrl = new URL(MY_GET_EMBED_URL_ENDPOINT);
  apiUrl.search = new URLSearchParams(apiOptions).toString();
  const apiResponse = await fetch(apiUrl.toString());
  const apiResponseData = await apiResponse.json();
  return apiResponseData.EmbedUrl;
};

// This function constructs a custom action object
const myConstructCustomActionModel = (
  customActionId,
  actionName,
  actionTrigger,
  actionStatus
) => {
  return {
    Name: actionName,
    CustomActionId: customActionId,
    Status: actionStatus,
    Trigger: actionTrigger,
    ActionOperations: [
      {
        CallbackOperation: {
          EmbeddingMessage: {},
        },
      },
    ],
  };
};

// This function adds a custom action on the first visual of first sheet of the
// embedded dashboard
const myAddVisualActionOnFirstVisualOfFirstSheet = async (
  embeddedDashboard
) => {
  // 1. List the sheets on the dashboard
  const { SheetId } = (await embeddedDashboard.getSheets())[0];
  // If you'd like to add action on the current sheet instead, you can use
  // getSelectedSheetId method
  // const SheetId = await embeddedDashboard.getSelectedSheetId();
```

```

// 2. List the visuals on the specified sheet
const { VisualId } = (await embeddedDashboard.getSheetVisuals(SheetId))[0];

// 3. Add the custom action to the visual
try {
  const customActionId = "custom_action_id"; // Sample ID
  const actionName = "Flag record"; // Sample name
  const actionTrigger = ActionTrigger.DATA_POINT_CLICK; // or
ActionTrigger.DATA_POINT_MENU
  const actionStatus = ActionStatus.ENABLED;
  const myCustomAction = myConstructCustomActionModel(
    customActionId,
    actionName,
    actionTrigger,
    actionStatus
  );
  const response = await embeddedDashboard.addVisualActions(
    SheetId,
    VisualId,
    [myCustomAction]
  );
  if (!response.success) {
    console.log("Adding visual action failed", response.errorCode);
  }
} catch (error) {
  console.log("Adding visual action failed", error);
}
};

const parseDatapoint = (visualId, datapoint) => {
  datapoint.Columns.forEach((Column, index) => {
    // FIELD | METRIC
    const columnType = Object.keys(Column)[0];

    // STRING | DATE | INTEGER | DECIMAL
    const valueType = Object.keys(Column[columnType])[0];
    const { Column: columnMetadata } = Column[columnType][valueType];

    const value = datapoint.RawValues[index][valueType];
    const formattedValue = datapoint.FormattedValues[index];

    console.log(
      `Column: ${columnMetadata.ColumnName} has a raw value of ${value}
        and formatted value of ${formattedValue.Value} for visual: ${visualId}`
    );
  });
};

```

```

    );
  });
};

// This function is used to start a custom workflow after the end user selects a
// datapoint
const myCustomDatapointCallbackWorkflow = (callbackData) => {
  const { VisualId, Datapoints } = callbackData;

  parseDatapoint(VisualId, Datapoints);
};

// EMBEDDING THE DASHBOARD

const main = async () => {
  // 1. Get embed url
  let url;
  try {
    url = await myGetEmbedUrl(MY_DASHBOARD_ID);
  } catch (error) {
    console.log("Obtaining an embed url failed");
  }

  if (!url) {
    return;
  }

  // 2. Create embedding context
  const embeddingContext = await createEmbeddingContext();

  // 3. Embed the dashboard
  const embeddedDashboard = await embeddingContext.embedDashboard(
    {
      url,
      container: MY_DASHBOARD_CONTAINER,
      width: "1200px",
      height: "300px",
      resizeHeightOnSizeChangedEvent: true,
    },
    {
      onMessage: async (messageEvent) => {
        const { eventName, message } = messageEvent;
        switch (eventName) {
          case "CONTENT_LOADED": {

```

```

        await myAddVisualActionOnFirstVisualOfFirstSheet(embeddedDashboard);
        break;
    }
    case "CALLBACK_OPERATION_INVOKED": {
        myCustomDatapointCallbackWorkflow(message);
        break;
    }
    },
    },
    );
};

main().catch(console.error);

```

You can also configure the preceding example to initiate datapoint callback when the user opens the context menu. To do this with the preceding example, set the value of `actionTrigger` to `ActionTrigger.DATA_POINT_MENU`.

After a datapoint callback is registered, it's applied to most datapoints on the specified visual or visuals. Callbacks don't apply to totals or subtotals on visuals. When a reader interacts with a datapoint, a `CALLBACK_OPERATION_INVOKED` message is emitted to the Amazon Quick Sight embedding SDK. This message is captured by the `onMessage` handler. The message contains the raw and display values for the full row of data associated with the datapoint that is selected. It also contains the column metadata for all columns in the visual that the datapoint is contained in. The following is an example of a `CALLBACK_OPERATION_INVOKED` message.

```

{
  CustomActionId: "custom_action_id",
  DashboardId: "dashboard_id",
  SheetId: "sheet_id",
  VisualId: "visual_id",
  DataPoints: [
    {
      RawValues: [
        {
          String: "Texas" // 1st raw value in row
        },
        {
          Integer: 1000 // 2nd raw value in row
        }
      ],
    },
  ],
}

```

```

FormattedValues: [
    {Value: "Texas"}, // 1st formatted value in row
    {Value: "1,000"} // 2nd formatted value in row
],
Columns: [
    { // 1st column metadata
      Dimension: {
        String: {
          Column: {
            ColumnName: "State",
            DatsetIdentifier: "..."
          }
        }
      },
    },
    { // 2nd column metadata
      Measure: {
        Integer: {
          Column: {
            ColumnName: "Cancelled",
            DatsetIdentifier: "..."
          },
          AggregationFunction: {
            SimpleNumericalAggregation: "SUM"
          }
        }
      },
    },
  ],
]
}

```

Filtering data at runtime for Amazon Quick Sight embedded dashboards and visuals

You can use filter methods in the Amazon Quick Sight embedding SDK to leverage the power of Amazon Quick Sight filters within your software as a service (SaaS) application at runtime. Runtime filters allow business owners to integrate their application with their embedded Amazon Quick Sight dashboards and visuals. To accomplish this, create customized filter controls in your application and apply filter presets based on data from your application. Then, developers can personalize filter configurations for end users at runtime.

Developers can create, query, update, and remove Amazon Quick Sight filters on an embedded dashboard or visual from their application with the Amazon Quick Sight Embedding SDK. Create Amazon Quick Sight filter objects in your application with the [FilterGroup](#) data model and apply them to embedded dashboards and visuals using the filter methods. For more information about using the Amazon Quick Sight Embedding SDK, see the [amazon-quicksight-embedding-sdk](#) on GitHub.

Prerequisites

Before you can get started, make sure that you are using the Amazon Quick Sight Embedding SDK version 2.5.0 or higher.

Terminology and concepts

The following terminology can be useful when working with embedded runtime filtering.

- *Filter group* – A group of individual filters. Filters that are located within a `FilterGroup` are OR-ed with each other. Filters within a [FilterGroup](#) are applied to the same sheets or visuals.
- *Filter* – A single filter. The filter can be a category, numeric, or datetime filter type. For more information on filters, see [Filter](#).

Setting up

Before you begin, make sure that you have the following assets and information prepared.

- The sheet ID of the sheet that you want to scope the `FilterGroup` to. This can be obtained with the `getSheets` method in the Embedding SDK.
- The dataset and column identifier of the dataset that you want to filter. This can be obtained through the [DescribeDashboardDefinition](#) API operation.

Depending on the column type that you use, there might be restrictions on the types of filters that can be added to an embedded asset. For more information on filter restrictions, see [Filter](#).

- The visual ID of the visual that you want to scope the `FilterGroup` to, if applicable. This can be obtained by using the `getSheetVisuals` method in the Embedding SDK.

In addition to the `getSheetVisuals` method, the `FilterGroup` that you add can only be scoped to the currently selected sheet.

To use this feature, you must already have a dashboard or visual embedded into your application through the Amazon Quick Sight Embedding SDK. For more information about using the Amazon Quick Sight Embedding SDK, see the [amazon-quicksight-embedding-sdk](#) on GitHub.

SDK method interface

Dashboard embedding getter methods

The following table describes different dashboard embedding getter methods that developers can use.

Method	Description
<code>getFilterGroupsForSheet(sheetId: string)</code>	Returns all <code>FilterGroups</code> that are currently scoped to the sheet that is supplied in the parameter.
<code>getFilterGroupsForVisual(sheetId: string, visualId: string)</code>	Returns all <code>FilterGroups</code> that are scoped to the visual that is supplied in the parameter.

If the sheet that is supplied in the parameter is not the currently selected sheet of the embedded dashboard, the above methods return an error.

Visual embedding getter methods

The following table describes different visual embedding getter methods that developers can use.

Method	Description
<code>getFilterGroups()</code>	Returns all <code>FilterGroups</code> that are currently scoped to the embedded visual.

Setter methods

The following table describes different setter methods that developers can use for dashboard or visual embedding.

Method	Description
<code>addFilterGroups(filterGroups: FilterGroup[])</code>	Adds and applies the supplied FilterGroups to the embedded dashboard or visual. A <code>ResponseMessage</code> that indicates whether the addition was successful is returned.
<code>updateFilterGroups(filterGroups: FilterGroup[])</code>	Updates the <code>FilterGroups</code> on the embedded experience that contains the same <code>FilterGroupId</code> as the <code>FilterGroup</code> that is supplied in the parameter. A <code>ResponseMessage</code> that indicates whether the update was successful is returned.
<code>removeFilterGroups(filterGroupsOrIds: FilterGroup[] string[])</code>	Removes the supplied <code>FilterGroups</code> from the dashboard and returns a <code>ResponseMessage</code> that indicates whether the removal attempt is successful.

The `FilterGroup` that is supplied must be scoped to the embedded sheet or visual that is currently selected.

Customize the look and feel of Amazon Quick Sight embedded dashboards and visuals

You can use the Amazon Quick Sight Embedding SDK (version 2.5.0 and higher) to make changes to the theming of your embedded Amazon Quick Sight dashboards and visuals at runtime. Runtime theming makes it easier to integrate your Software as a service (SaaS) application with your Amazon Quick Sight embedded assets. Runtime theming allows you to synchronize the theme of your embedded content with the themes of the parent application that your Amazon Quick Sight assets are embedded into. You can also use runtime theming to add customization options for readers. Theming changes can be applied to embedded assets at initialization or throughout the lifetime of your embedded dashboard or visual.

For more information about themes, see [Using themes in Amazon Quick Sight](#). For more information about using the Amazon Quick Sight Embedding SDK, see the [amazon-quicksight-embedding-sdk](#) on GitHub.

Prerequisites

Before you can get started, make sure that you have the following prerequisites.

- You are using the Amazon Quick Sight Embedding SDK version 2.5.0 or higher.
- Permissions to access the theme that you want to work with. To grant permissions to a theme in Amazon Quick Sight, make a `UpdateThemePermissions` API call or use the **Share** icon next to the theme in the Amazon Quick Sight console's analysis editor.

Terminology and concepts

The following terminology can be useful when working with embedded runtime theming.

- *Theme* – A collection of settings that you can apply to multiple analyses and dashboards that change how the content is displayed.
- *ThemeConfiguration* – A configuration object that contains all of the display properties for a theme.
- *Theme Override* – A *ThemeConfiguration* object that is applied to the active theme to override some or all aspects of how content is displayed.
- *Theme ARN* – An Amazon Resource Name (ARN) that identifies a Amazon Quick Sight theme. Following is an example of custom theme ARN.

```
arn:aws:quicksight:region:account-id:theme/theme-id
```

Amazon Quick Sight provided starter themes don't have a region in their theme ARN. Following is an example of a starter theme ARN.

```
arn:aws:quicksight::aws:theme/CLASSIC
```

Setting up

Make sure that you have the following information ready to get started working with runtime theming.

- The theme ARNs of the themes that you want to use. You can choose an existing theme, or you can create a new one. To obtain a list all themes and theme ARNs in your Amazon Quick Sight account, make a call to the [ListThemes](#) API operation. For information on preset Amazon Quick Sight themes, see [Setting a default theme for Amazon Quick analyses with the Amazon Quick APIs](#).

- If you are using registered user embedding, make sure that the user has access to the themes that you want to use.

If you are using anonymous user embedding, pass a list of theme ARNs to the `AuthorizedResourceArns` parameter of the `GenerateEmbedUrlForAnonymousUser` API. Anonymous users are granted access to any theme that is listed in the `AuthorizedResourceArns` parameter.

SDK method interface

Setter methods

The following table describes different setter methods that developers can use for runtime theming.

Method	Description
<code>setTheme(themeArn: string)</code>	Replaces the active theme of a dashboard or visual with another theme. If applied, the theme override is removed. An error is returned if you don't have access to the theme or if the theme doesn't exist.
<code>setThemeOverride(themeOverride: ThemeConfiguration)</code>	Sets a dynamic <code>ThemeConfiguration</code> to override the current active theme. This replaces the previously set theme override. Any values that are not supplied in the new <code>ThemeConfiguration</code> are defaulted to the values in the currently active theme. An error is returned if the <code>ThemeConfiguration</code> that you supply is invalid.

Initializing embedded content with a theme

To initialize an embedded dashboard or visual with a non-default theme, define a `themeOptions` object on the `DashboardContentOptions` or `VisualContentOptions` parameters, and set the `themeArn` property within `themeOptions` to the desired theme ARN.

The following example initializes an embedded dashboard with the MIDNIGHT theme.

```
import { createEmbeddingContext } from 'amazon-quicksight-embedding-sdk';

const embeddingContext = await createEmbeddingContext();

const {
  embedDashboard,
} = embeddingContext;

const frameOptions = {
  url: '<YOUR_EMBED_URL>',
  container: '#experience-container',
};

const contentOptions = {
  themeOptions: {
    themeArn: "arn:aws:quicksight::aws:theme/MIDNIGHT"
  }
};

// Embedding a dashboard experience
const embeddedDashboardExperience = await embedDashboard(frameOptions, contentOptions);
```

Initializing embedded content with a theme override

Developers can use theme overrides to define the theme of an embedded dashboard or visual at runtime. This allows the dashboard or visual to inherit a theme from a third-party application without the need to pre-configure a theme within Amazon Quick Sight. To initialize an embedded dashboard or visual with a theme override, set the `themeOverride` property within `themeOptions` in either the `DashboardContentOptions` or `VisualContentOptions` parameters. The following example overrides the font of a dashboard's theme from the default font to Amazon Ember.

```
import { createEmbeddingContext } from 'amazon-quicksight-embedding-sdk';

const embeddingContext = await createEmbeddingContext();
```

```
const {
  embedDashboard,
} = embeddingContext;

const frameOptions = {
  url: '<YOUR_EMBED_URL>',
  container: '#experience-container',
};
const contentOptions = {
  themeOptions: {
    "themeOverride":{"Typography":{"FontFamilies":[{"FontFamily":"Comic Neue"]}}}
  }
};

// Embedding a dashboard experience
const embeddedDashboardExperience = await embedDashboard(frameOptions, contentOptions);
```

Initializing embedded content with preloaded themes

Developers can configure a set of dashboard themes to be preloaded on initialization. This is most beneficial for quick toggling between different views, for example dark and light modes. An embedded dashboard or visual can be initialized with up to 5 preloaded themes. To use preloaded themes, set the `preloadThemes` property in either `DashboardContentOptions` or `VisualContentOptions` with an array of up to 5 theme ARNs. The following example preloads the Midnight and Rainier starter themes to a dashboard.

```
import { createEmbeddingContext } from 'amazon-quicksight-embedding-sdk';

const embeddingContext = await createEmbeddingContext();

const {
  embedDashboard,
} = embeddingContext;

const frameOptions = {
  url: '<YOUR_EMBED_URL>',
  container: '#experience-container',
};
const contentOptions = {
  themeOptions: {
    "preloadThemes": ["arn:aws:quicksight::aws:theme/RAINIER",
    "arn:aws:quicksight::aws:theme/MIDNIGHT"]
  }
};
```

```
    }  
};  
  
// Embedding a dashboard experience  
const embeddedDashboardExperience = await embedDashboard(frameOptions, contentOptions);
```

Using the Amazon Quick Sight Embedding SDK to enable shareable links to embedded dashboard views

Amazon Quick Sight developers can use the Amazon Quick Sight Embedding SDK (version 2.8.0 and higher) to allow readers of embedded dashboards to receive and distribute shareable links to their view of an embedded dashboard. Developers can use dashboard or console embedding to generate a shareable link to their application page with Amazon Quick Sight's reference encapsulated using the Amazon Quick Sight Embedding SDK. Amazon Quick Sight Readers can then send this shareable link to their peers. When their peer accesses the shared link, they are taken to the page on the application that contains the embedded Amazon Quick Sight dashboard. Developers can also generate and save shareable links of dashboard views that can be used as a bookmarks for anonymous readers of Amazon Quick Sight when using anonymous embedding.

Prerequisites

Before you get started, make sure that you are using the Amazon Quick Sight Embedding SDK version 2.8.0 or higher

Topics

- [Enabling the SharedView feature configuration for Amazon Quick Sight embedded analytics](#)
- [Creating a shared view with the Amazon Quick Sight createSharedView API](#)
- [Consuming a shared Amazon Quick Sight view](#)

Enabling the SharedView feature configuration for Amazon Quick Sight embedded analytics

When you create an the embedded instance with the Amazon Quick Sight API, set the value of SharedView in the FeatureConfigurations payload to true, as shown in the example below. SharedView overrides the StatePersistence configurations for registered users who access embedded dashboards. If a dashboard user has StatePersistence disabled and SharedView enabled, their state will persist.

```
const generateNewEmbedUrl = async () => {  
    const generateUrlPayload = {
```

```

    experienceConfiguration: {
      QuickSightConsole: {
        FeatureConfigurations: {
          "SharedView": {
            "Enabled": true
          },
        },
      },
    },
  },
}
const result: GenerateEmbedUrlResult = await
generateEmbedUrlForRegisteredUser(generateUrlPayload);
return result.url;
};

```

Creating a shared view with the Amazon Quick Sight createSharedView API

After you update the Embedding SDK to version 2.8.0 or higher, use the `createSharedView` API to create a new shared view. Record the `sharedViewId` and the `dashboardId` that the operation returns. The example below creates a new shared view.

```

const response = await embeddingFrame.createSharedView();
const sharedViewId = response.message.sharedViewId;
const dashboardId = response.message.dashboardId;

```

`createSharedView` can only be called when a user views a dashboard. For console-specific shared view creation, make sure that users are on the dashboard page before you enable the `createSharedView` action. You can do this with the `PAGE_NAVIGATION` event, shown in the example below.

```

const contentOptions = {
  onMessage: async (messageEvent, metadata) => {
    switch (messageEvent.eventName) {
      case 'CONTENT_LOADED': {
        console.log("Do something when the embedded experience is fully
loaded.");
        break;
      }
      case 'ERROR_OCCURRED': {
        console.log("Do something when the embedded experience fails
loading.");
        break;
      }
    }
  }
}

```

```

        case 'PAGE_NAVIGATION': {
            setPageType(messageEvent.message.pageType);
            if (messageEvent.message.pageType === 'DASHBOARD') {
                setShareEnabled(true);
            } else {
                setShareEnabled(false);
            }
            break;
        }
    }
}
};

```

Consuming a shared Amazon Quick Sight view

After you create a new shared view, use the Embedding SDK to make the shared view consumable for other users. The examples below set up a consumable shared view for an embedded dashboard in Amazon Quick Sight.

With an appended URL

Append the `sharedViewId` to the embed URL, under `/views/{viewId}`, and expose this URL to your users. Users can use this URL to will navigate to that shared view.

```

const response = await dashboardFrame.createSharedView();
const newEmbedUrl = await generateNewEmbedUrl();
const formattedUrl = new URL(newEmbedUrl);
formattedUrl.pathname = formattedUrl.pathname.concat('/views/' +
    response.message.sharedViewId);
const baseUrl = formattedUrl.href;
alert("Click to view this QuickSight shared view", baseUrl);

```

With the contentOptions SDK

Pass a `viewId` to the `contentOptions` to open the experience with the given `viewId`.

```

const contentOptions = {
    toolbarOptions: {
        ...
    },
    viewId: sharedViewId,
};

```

```
const embeddedDashboard = await embeddingContext.embedDashboard(
  {container: containerRef.current},
  contentOptions
);
```

With the InitialPath property

```
const shareView = async() => {
  const returnValue = await consoleFrame.createSharedView();
  const {dashboardId, sharedViewId} = returnValue.message;
  const newEmbedUrl = await generateNewEmbedUrl(`/dashboards/${dashboardId}/views/
${sharedViewId}`);
  setShareUrl(newEmbedUrl);
};

const generateNewEmbedUrl = async (initialPath) => {
  const generateUrlPayload = {
    experienceConfiguration: {
      QuickSightConsole: {
        InitialPath: initialPath,
        FeatureConfigurations: {
          "SharedView": {
            "Enabled": true
          },
        },
      },
    },
  }
  const result: GenerateEmbedUrlResult = await
  generateEmbedUrlForRegisteredUser(generateUrlPayload);
  return result.url;
};
```

Embedding Amazon Quick Sight visuals and dashboards with a 1-click embed code

You can embed a visual or dashboard in your application using an embed code. You get this code when you share the dashboard or from the **Embed visual** menu in Amazon Quick Sight.

You can embed a visual or dashboard in your internal application for your registered users. Or you can turn on public sharing in the Amazon Quick Sight console. Doing this grants anyone on the

internet access to a shared visual or dashboard that is embedded in a public application, wiki, or portal.

Following, you can find descriptions about how to embed visuals and dashboards using the 1-click visual or dashboard embed code.

Topics

- [Embedding Amazon Quick Sight visuals and dashboards for registered users with a 1-click embed code](#)
- [Embedding Amazon Quick Sight visuals and dashboards for anonymous users with a 1-click embed code](#)

Embedding Amazon Quick Sight visuals and dashboards for registered users with a 1-click embed code

Applies to: Enterprise Edition

You can embed a visual or dashboard in your internal application for registered users of your Amazon Quick Sight account. You do so using the embed code that you get when you share the dashboard or from the **Embed visual** menu in Amazon Quick Sight. You don't have to run the Amazon Quick Sight embedding API to generate the embed code. You can copy the embed code from Amazon Quick Sight and paste it in your internal application's HTML code.

When users and groups (or all users on your Amazon Quick Sight account) who have access to the dashboard that you want to embed or that holds the visual that you want to embed access your internal application, they're prompted to sign in to the Amazon Quick Sight account with their credentials. After they are authenticated, they can access the visual or dashboard on their internal page. If you have single sign-on enabled, users aren't prompted to sign in again.

Following, you can find descriptions about how to embed a visual or dashboard for registered users using the visual or dashboard embed code.

Before you start

Before you get started, make sure of the following:

- Your internet browser settings contain one of the following to allow communication between the popup and the iframe:

- Native support for the Mozilla Broadcast Channel API. For more information, see [Broadcast Channel API](#) in the Mozilla documentation.
- IndexedDB support.
- LocalStorage support.
- Your internet browser's "block all cookies" settings is turned off.

Step 1: Grant access to the dashboard

For users to access your embedded dashboard, grant them access to view it. You can grant individual users and groups access to a dashboard, or you can grant everyone in your account access. Visual permissions are determined at the dashboard level. To grant access to embedded visuals, grant access to the dashboard that the visual belongs to. For more information, see [Granting access to a dashboard](#).

Step 2: Put the domain where you want to embed the visual or dashboard on your allow list

To embed visuals and dashboards in your internal application, make sure that the domain where you're embedding is allow-listed in your Amazon Quick Sight account. For more information, see [Allow listing static domains](#).

Step 3: Get the embed code

Use the following procedure to get the visual or dashboard embed code.

To get the dashboard embed code

1. Open the published dashboard in Amazon Quick Sight and choose **Share** at upper right. Then choose **Share dashboard**.
2. In the **Share dashboard** page that opens, choose **Copy embed code** at upper left.

The embed code is copied to your clipboard and is similar to the following. The *quicksightdomain* in this example is the URL that you use to access your Amazon Quick Sight account.

```
<iframe
  width="960"
  height="720"
  src="https://quicksightdomain/sn/embed/share/accounts/accountid/
dashboards/dashboardid?directory_alias=account_directory_alias">
```

```
</iframe>
```

To get the visual embed code

1. Open the published dashboard in Amazon Quick Sight and choose the visual that you want to embed. Then open the on-visual menu at the upper right of the visual and choose **Embed visual**.
2. In the **Embed visual** pane that opens, choose **Copy code**.

The embed code is copied to your clipboard and is similar to the following. The *quicksightdomain* in this example is the URL that you use to access your Amazon Quick Sight account.

```
<iframe
  width="600"
  height="400"
  src="https://quicksightdomain/sn/embed/share/accounts/111122223333/
dashboards/DASHBOARDID/sheets/SHEETID>/visuals/VISUALID">
</iframe>
```

Step 4: Paste the code into your internal application's HTML page

Use the following procedure to paste the embed code into your internal application's HTML page

To paste the code in your internal application's HTML page

- Open the HTML code for any page where you want to embed the dashboard and paste the embed code in.

The following example shows what this might look like for an embedded dashboard. The *quicksightdomain* in this example is the URL that you use to access your Amazon Quick Sight account.

```
<!DOCTYPE html>
<html>
<body>

<h2>Example.com - Employee Portal</h2>
<h3>Current shipment stats</h3>
```

```
<iframe
width="960"
height="720"
src="https://quicksightdomain/sn/embed/share/accounts/accountid/
dashboards/dashboardid?directory_alias=account_directory_alias">
</iframe>

</body>
</html>
```

The following example shows what this might look like for an embedded visual. The *quicksightdomain* in this example is the URL that you use to access your Amazon Quick Sight account.

```
<!DOCTYPE html>
<html>
<body>

<h2>Example.com - Employee Portal</h2>
<h3>Current shipment stats</h3>
<iframe
width="600"
height="400"
src="https://quicksightdomain/sn/embed/share/accounts/111122223333/
dashboards/DASHBOARDID/sheets/SHEETID>/visuals/VISUALID?
directory_alias=account_directory_alias">
</iframe>

</body>
</html>
```

For example, let's say that you want to embed your visual or dashboard in an internal Google Sites page. You can open the page on Google Sites and paste the embed code in an embed widget.

If you want to embed your visual or dashboard in an internal Microsoft SharePoint site, you can create a new page and then paste the embed code in an Embed web part.

Embedding Amazon Quick Sight visuals and dashboards for anonymous users with a 1-click embed code

Applies to: Enterprise Edition

You can embed a visual or dashboard in public sites using the embed code that you get when you share the visual or dashboard in Amazon Quick Sight. You can also turn on public sharing by using the Amazon Quick Sight console and automatically grant access to a shared visual or dashboard to anyone on the internet.

Following, you can find how to turn on public sharing for a visual or dashboard and embed the visual or dashboard for anyone on the internet to see. In both cases, you do this by using the 1-click embed code.

Before you start

Before you get started, make sure of the following:

- Your internet browser settings contain one of the following to allow communication between the popup and the iframe that sharing uses:
 - Native support for the Mozilla Broadcast Channel API. For more information, see [Broadcast Channel API](#) in the Mozilla documentation.
 - IndexedDB support.
 - LocalStorage support.
- Your internet browser's "block all cookies" settings is turned off.

Step 1: Turn on public access for the dashboard

For anyone on the internet to access your embedded visual or dashboard, first turn on public access for the dashboard. Visual permissions are determined at the dashboard level. To grant access to embedded visuals, grant access to the dashboard that the visual belongs to. For more information, see [Granting anyone on the internet access to an Amazon Quick Sight dashboard](#).

Step 2: Put the domain where you want to embed the visual or dashboard on your allow list

To embed visuals and dashboards in a public application, wiki, or portal, make sure that the domain where you're embedding it is on the allow list for your Amazon Quick Sight account.

Step 3: Get the embed code

Use the following procedure to get the visual or dashboard embed code.

To get the dashboard embed code

1. Open the published dashboard in Amazon Quick Sight and choose **Share** at upper right. Then choose **Share dashboard**.
2. In the **Share dashboard** page that opens, choose **Copy embed code** at upper left.

The embed code is copied to your clipboard and is similar to the following. The *quicksightdomain* in this example is the URL that you use to access your Amazon Quick Sight account.

```
<iframe
  width="960"
  height="720"
  src="https://quicksightdomain/sn/
    embed/share/accounts/accountid/dashboards/dashboardid">
</iframe>
```

To get the visual embed code

1. Open the published dashboard in Amazon Quick Sight and choose the visual that you want to embed. Then open the on-visual menu in the top right corner of the visual and choose **Embed visual**.
2. In the **Embed visual** pane that opens, choose **Copy code**.

The embed code is copied to your clipboard and is similar to the following. The *quicksightdomain* in this example is the URL that you use to access your Amazon Quick Sight account.

```
<iframe
  width="600"
  height="400"
  src="https://quicksightdomain/sn/embed/share/accounts/111122223333/
dashboards/DASHBOARDID/sheets/SHEETID>/visuals/VISUALID">
</iframe>
```

Step 4: Paste the embed code into an HTML page, wiki page, or portal

Use the following procedure to paste the embed code into an HTML page, wiki page, or portal.

To paste the embed code

- Open the HTML code for the location where you want to embed the visual or dashboard, and paste the embed code in.

The following example shows what this might look like for an embedded dashboard. The *quicksightdomain* in this example is the URL that you use to access your Amazon Quick Sight account.

```
<!DOCTYPE html>
<html>
<body>

<h2>Example.com - Employee Portal</h2>
<h3>Current shipment stats</h3>
  <iframe
    width="960"
    height="720"
    src="https://quicksightdomain/sn/
      embed/share/accounts/accountid/dashboards/dashboardid">
  </iframe>

</body>
</html>
```

The following example shows what this might look like for an embedded visual. The *quicksightdomain* in this example is the URL that you use to access your Amazon Quick Sight account.

```
<!DOCTYPE html>
<html>
<body>

<h2>Example.com - Employee Portal</h2>
<h3>Current shipment stats</h3>
  <iframe
    width="600"
    height="400"
```

```
src="https://quicksightdomain/sn/embed/share/accounts/111122223333/
dashboards/DASHBOARDID/sheets/SHEETID>/visuals/VISUALID">
</iframe>

</body>
</html>
```

If your public-facing applications are built on Google Sites, open the page on Google Sites and then paste the embed code using the embed widget.

Make sure that the following domains in Amazon Quick Sight are on your allow list when you embed in Google Sites:

- <https://googleusercontent.com> (turns on subdomains)
- <https://www.gstatic.com>
- <https://sites.google.com>

After you embed the visual or dashboard in your application, anyone who can access your application can access the embedded visual or dashboard. To update a dashboard that's shared with the public, see [Updating a publicly shared dashboard](#). To turn off public sharing, see [Turning off public sharing settings](#).

When you turn off public sharing, no one from the internet can access a dashboard or dashboards that you have embedded on a public application or shared with a link. The next time anyone tries to view such a dashboard from the internet, they receive a message that they don't have access to view it.

Embedding with the Amazon Quick Sight APIs

Applies to: Enterprise Edition

Intended audience: Amazon Quick developers

There are only a few steps involved in the actual process of embedding analytics using the Amazon Quick Sight APIs.

Before you begin, make sure to have the following items in place:

- Set up the required IAM permissions for the caller identity used by your application that will use the AWS SDK to make API calls. For example, grant permission to allow the `quicksight:GenerateEmbedUrlForAnonymousUser` or `quicksight:GenerateEmbedUrlForRegisteredUser` action.
- To embed for registered users, share Amazon Quick Sight assets with them beforehand. For new authenticating users, know how to grant access to the assets. One way to do this is by adding all the assets to a Amazon Quick Sight folder. If you prefer to use the Amazon Quick Sight API, use the `DescribeDashboardPermissions` and `UpdateDashboardPermissions` API operations. For more information, see [DescribeDashboardPermissions](#) or [UpdateDashboardPermissions](#) in the *Amazon Quick API Reference*. If you want to share the dashboard with all users in a namespace or group, you can share the dashboard with namespace or group.
- If you're embedding dashboards, make sure to have the ID of the dashboards you want to embed. The dashboard ID is the code in the URL of the dashboard. You can also get it from the dashboard URL.
- A Amazon Quick Sight administrator must explicitly enable domains where you plan to embed your Amazon Quick Sight analytics. You can do this by using the **Manage Amazon Quick Sight, Domains and Embedding** from the profile menu, or you can use the `AllowedDomains` parameter of a `GenerateEmbedUrlForAnonymousUser` or `GenerateEmbedUrlForRegisteredUser` API call.

This option is only visible to Amazon Quick Sight administrators. You can also add subdomains as part of a domain. For more information, see [Allow listing domains at runtime with the Amazon Quick API](#).

All domains in your static allow list (such as development, staging, and production) must be explicitly allowed, and they must use HTTPS. You can add up to 100 domains to the allow list. You can add domains at runtime with Amazon Quick Sight API operations.

After all the prerequisites are complete, embedding Amazon Quick Sight involves the following steps, which are explained in greater detail later:

1. For authentication, use your application server to authenticate the user. After authentication in your server, generate the embedded dashboard URL using the AWS SDK that you need.
2. In your web portal or application, embed Amazon Quick Sight using the generated URL. To simplify this process, you can use the Amazon Quick Sight Embedding SDK, available on [NPMJS](#)

and [GitHub](#). This customized JavaScript SDK is designed to help you efficiently integrate Amazon Quick Sight into your application pages, set defaults, connect controls, get callbacks, and handle errors.

You can use AWS CloudTrail auditing logs to get information about the number of embedded dashboards, users of an embedded experience, and access rates.

Embedding Amazon Quick Sight dashboards with the Amazon Quick Sight API

Use the following topics to learn about embedding dashboards with the Amazon Quick Sight API.

Topics

- [Embedding Amazon Quick Sight dashboards for registered users](#)
- [Embedding Amazon Quick Sight dashboards for anonymous \(unregistered\) users](#)
- [Enabling executive summaries in embedded dashboards](#)

Embedding Amazon Quick Sight dashboards for registered users

Important

Amazon Quick Sight has new API operations for embedding analytics: `GenerateEmbedUrlForAnonymousUser` and `GenerateEmbedUrlForRegisteredUser`. You can still use the `GetDashboardEmbedUrl` and `GetSessionEmbedUrl` API operations to embed dashboards and the Amazon Quick Sight console, but they don't contain the latest embedding capabilities. For more information about embedding using the

old API operations, see [Embedding analytics using the GetDashboardEmbedURL and GetSessionEmbedURL API operations](#).

Applies to: Enterprise Edition

Intended audience: Amazon Quick developers

In the following sections, you can find detailed information about how to set up embedded Amazon Quick Sight dashboards for registered users of Amazon Quick Sight.

Topics

- [Step 1: Set up permissions](#)
- [Step 2: Generate the URL with the authentication code attached](#)
- [Step 3: Embed the dashboard URL](#)

Step 1: Set up permissions

In the following section, you can find out how to set up permissions for the backend application or web server. This task requires administrative access to IAM.

Each user who accesses a dashboard assumes a role that gives them Amazon Quick Sight access and permissions to the dashboard. To make this possible, create an IAM role in your AWS account. Associate an IAM policy with the role to provide permissions to any user who assumes it. The IAM role needs to provide permissions to retrieve embedding URLs for a specific user pool. With the help of the wildcard character *, you can grant the permissions to generate a URL for all users in a specific namespace, or for a subset of users in specific namespaces. For this, you add `quicksight:GenerateEmbedUrlForRegisteredUser`.

You can create a condition in your IAM policy that limits the domains that developers can list in the `AllowedDomains` parameter of a `GenerateEmbedUrlForRegisteredUser` API operation. The `AllowedDomains` parameter is an optional parameter. It grants you as a developer the option to override the static domains that are configured in the **Manage Amazon Quick Sight** menu. Instead, you can list up to three domains or subdomains that can access the generated URL. This URL is then embedded in the website that you create. Only the domains that are listed in the parameter

can access the embedded visual. Without this condition, you can list any domain on the internet in the `AllowedDomains` parameter.

To limit the domains that developers can use with this parameter, add an `AllowedEmbeddingDomains` condition to your IAM policy. For more information about the `AllowedDomains` parameter, see [GenerateEmbedUrlForRegisteredUser](#) in the *Amazon Quick Sight API Reference*.

Security best practice for IAM condition operators

Improperly configured IAM condition operators can allow unauthorized access to your embedded Quick resources through URL variations. When using the `quicksight:AllowedEmbeddingDomains` condition key in your IAM policies, use condition operators that either allow specific domains or deny all domains that are not specifically allowed. For more information about IAM condition operators, see [IAM JSON policy elements: Condition operators](#) in the IAM User Guide.

Many different URL variations can point to the same resource. For example, the following URLs all resolve to the same content:

- `https://example.com`
- `https://example.com/`
- `https://Example.com`

If your policy uses operators that do not account for these URL variations, an attacker can bypass your restrictions by providing equivalent URL variations.

You must validate that your IAM policy uses appropriate condition operators to prevent bypass vulnerabilities and ensure that only your intended domains can access your embedded resources.

The following sample policy provides these permissions.

Additionally, if you are creating first-time users who will be Amazon Quick Sight readers, make sure to add the `quicksight:RegisterUser` permission in the policy.

The following sample policy provides permission to retrieve an embedding URL for first-time users who are to be Amazon Quick Sight readers.

Finally, your application's IAM identity must have a trust policy associated with it to allow access to the role that you just created. This means that when a user accesses your application, your application can assume the role on the user's behalf and provision the user in Amazon Quick Sight. The following example shows a sample trust policy.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowLambdaFunctionsToAssumeThisRole",
      "Effect": "Allow",
      "Principal": {
        "Service": "lambda.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    },
    {
      "Sid": "AllowEC2InstancesToAssumeThisRole",
      "Effect": "Allow",
      "Principal": {
        "Service": "ec2.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

For more information regarding trust policies for OpenID Connect or SAML authentication, see the following sections of the *IAM User Guide*:

- [Creating a Role for Web Identity or OpenID Connect Federation \(Console\)](#)
- [Creating a Role for SAML 2.0 Federation \(Console\)](#)

Step 2: Generate the URL with the authentication code attached

In the following section, you can find out how to authenticate your user and get the embeddable dashboard URL on your application server. If you plan to embed dashboards for IAM or Amazon Quick Sight identity types, share the dashboard with the users.

When a user accesses your app, the app assumes the IAM role on the user's behalf. Then it adds the user to Amazon Quick Sight, if that user doesn't already exist. Next, it passes an identifier as the unique role session ID.

Performing these steps ensures that each viewer of the dashboard is uniquely provisioned in Amazon Quick Sight. It also enforces per-user settings, such as the row-level security and dynamic defaults for parameters.

The following examples perform the IAM authentication on the user's behalf. This code runs on your app server.

Java

```
import com.amazonaws.auth.AWSCredentials;
import com.amazonaws.auth.BasicAWSCredentials;
import com.amazonaws.auth.AWSCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.quicksight.AmazonQuickSight;
import com.amazonaws.services.quicksight.AmazonQuickSightClientBuilder;
import
com.amazonaws.services.quicksight.model.GenerateEmbedUrlForRegisteredUserRequest;

    } else {
        const result = {
            "statusCode": 200,
            "headers": {
                "Access-Control-Allow-Origin": "*", // Use your website
domain to secure access to GetEmbedUrl API
                "Access-Control-Allow-Headers": "Content-Type"
            },
            "body": JSON.stringify(data),
            "isBase64Encoded": false
        }
        getEmbedUrlCallback(result);
    }
});
    }
});
}

```

Python3

```

import json
import boto3
from botocore.exceptions import ClientError

sts = boto3.client('sts')

# Function to generate embedded URL
# accountId: AWS account ID

```

```

# dashboardId: Dashboard ID to embed
# userArn: arn of registered user
# allowedDomains: Runtime allowed domain for embedding
# roleArn: IAM user role to use for embedding
# sessionName: session name for the roleArn assume role
def getEmbeddingURL(accountId, dashboardId, userArn, allowedDomains, roleArn,
    sessionName):
    try:
        assumedRole = sts.assume_role(
            RoleArn = roleArn,
            RoleSessionName = sessionName,
        )
    except ClientError as e:
        return "Error assuming role: " + str(e)
    else:
        assumedRoleSession = boto3.Session(
            aws_access_key_id = assumedRole['Credentials']['AccessKeyId'],
            aws_secret_access_key = assumedRole['Credentials']['SecretAccessKey'],
            aws_session_token = assumedRole['Credentials']['SessionToken'],
        )
        try:
            quicksightClient = assumedRoleSession.client('quicksight', region_name='us-
west-2')
            response = quicksightClient.generate_embed_url_for_registered_user(
                AwsAccountId=accountId,
                ExperienceConfiguration = {
                    "Dashboard": {
                        "InitialDashboardId": dashboardId
                    }
                },
                UserArn = userArn,
                AllowedDomains = allowedDomains,
                SessionLifetimeInMinutes = 600
            )

            return {
                'statusCode': 200,
                'headers': {"Access-Control-Allow-Origin": "*", "Access-Control-Allow-
Headers": "Content-Type"},
                'body': json.dumps(response),
                'isBase64Encoded': bool('false')
            }
        except ClientError as e:

```

```
return "Error generating embedding url: " + str(e)
```

Node.js

The following example shows the JavaScript (Node.js) that you can use on the app server to generate the URL for the embedded dashboard. You can use this URL in your website or app to display the dashboard.

Example

```
const AWS = require('aws-sdk');
const https = require('https');

var quicksightClient = new AWS.Service({
  apiConfig: require('./quicksight-2018-04-01.min.json'),
  region: 'us-east-1',
});

quicksightClient.generateEmbedUrlForRegisteredUser({
  'AwsAccountId': '111122223333',
  'ExperienceConfiguration': {
    'Dashboard': {
      'InitialDashboardId': '1c1fe111-e2d2-3b30-44ef-a0e111111cde'
    }
  },
  'UserArn': 'REGISTERED_USER_ARN',
  'AllowedDomains': allowedDomains,
  'SessionLifetimeInMinutes': 100
}, function(err, data) {
  console.log('Errors: ');
  console.log(err);
  console.log('Response: ');
  console.log(data);
});
```

Example

```
//The URL returned is over 900 characters. For this example, we've shortened the string
for
  //readability and added ellipsis to indicate that it's incomplete.
  {
    Status: 200,
```

```
        EmbedUrl: 'https://quicksightdomain/embed/12345/dashboards/67890...'
        RequestId: '7bee030e-f191-45c4-97fe-d9faf0e03713'
    }
```

.NET/C#

The following example shows the .NET/C# code that you can use on the app server to generate the URL for the embedded dashboard. You can use this URL in your website or app to display the dashboard.

Example

```
using System;
using Amazon.QuickSight;
using Amazon.QuickSight.Model;

namespace GenerateDashboardEmbedUrlForRegisteredUser
{
    class Program
    {
        static void Main(string[] args)
        {
            var quicksightClient = new AmazonQuickSightClient(
                AccessKey,
                SecretAccessKey,
                SessionToken,
                Amazon.RegionEndpoint.USEast1);
            try
            {
                RegisteredUserDashboardEmbeddingConfiguration
registeredUserDashboardEmbeddingConfiguration
                = new RegisteredUserDashboardEmbeddingConfiguration
                {
                    InitialDashboardId = "dashboardId"
                };
                RegisteredUserEmbeddingExperienceConfiguration
registeredUserEmbeddingExperienceConfiguration
                = new RegisteredUserEmbeddingExperienceConfiguration
                {
                    Dashboard = registeredUserDashboardEmbeddingConfiguration
                };

                Console.WriteLine(
```

```

        quicksightClient.GenerateEmbedUrlForRegisteredUserAsync(new
GenerateEmbedUrlForRegisteredUserRequest
        {
            AwsAccountId = "111122223333",
            ExperienceConfiguration =
registeredUserEmbeddingExperienceConfiguration,
            UserArn = "REGISTERED_USER_ARN",
            AllowedDomains = allowedDomains,
            SessionLifetimeInMinutes = 100
        }).Result.EmbedUrl
    );
} catch (Exception ex) {
    Console.WriteLine(ex.Message);
}
}
}
}

```

AWS CLI

To assume the role, choose one of the following AWS Security Token Service (AWS STS) API operations:

- [AssumeRole](#) – Use this operation when you're using an IAM identity to assume the role.
- [AssumeRoleWithWebIdentity](#) – Use this operation when you're using a web identity provider to authenticate your user.
- [AssumeRoleWithSaml](#) – Use this operation when you're using SAML to authenticate your users.

The following example shows the CLI command to set the IAM role. The role needs to have permissions enabled for `quicksight:GenerateEmbedUrlForRegisteredUser`. If you are taking a just-in-time approach to add users when they first open a dashboard, the role also needs permissions enabled for `quicksight:RegisterUser`.

```

aws sts assume-role \
    --role-arn "arn:aws:iam::111122223333:role/embedding_quicksight_dashboard_role"
\
    --role-session-name john.doe@example.com

```

The `assume-role` operation returns three output parameters: the access key, the secret key, and the session token.

Note

If you get an `ExpiredToken` error when calling the `AssumeRole` operation, this is probably because the previous `SESSION_TOKEN` is still in the environment variables. Clear this by setting the following variables:

- `AWS_ACCESS_KEY_ID`
- `AWS_SECRET_ACCESS_KEY`
- `AWS_SESSION_TOKEN`

The following example shows how to set these three parameters in the CLI. If you're using a Microsoft Windows machine, use `set` instead of `export`.

```
export AWS_ACCESS_KEY_ID      = "access_key_from_assume_role"
export AWS_SECRET_ACCESS_KEY  = "secret_key_from_assume_role"
export AWS_SESSION_TOKEN      = "session_token_from_assume_role"
```

Running these commands sets the role session ID of the user visiting your website to `embedding_quicksight_dashboard_role/john.doe@example.com`. The role session ID is made up of the role name from `role-arn` and the `role-session-name` value. Using the unique role session ID for each user ensures that appropriate permissions are set for each user. It also prevents any throttling of user access. *Throttling* is a security feature that prevents the same user from accessing Amazon Quick Sight from multiple locations.

The role session ID also becomes the user name in Amazon Quick Sight. You can use this pattern to provision your users in Amazon Quick Sight ahead of time, or to provision them the first time they access the dashboard.

The following example shows the CLI command that you can use to provision a user. For more information about [RegisterUser](#), [DescribeUser](#), and other Amazon Quick Sight API operations, see the [Amazon Quick Sight API Reference](#).

```
aws quicksight register-user \
  --aws-account-id 111122223333 \
  --namespace default \
  --identity-type IAM \
  --iam-arn "arn:aws:iam::111122223333:role/embedding_quicksight_dashboard_role" \
```

```
--user-role READER \
--user-name jhnd \
--session-name "john.doe@example.com" \
--email john.doe@example.com \
--region us-east-1 \
--custom-permissions-name TeamA1
```

If your user is authenticated through Microsoft AD, you don't need to use `RegisterUser` to set them up. Instead, they should be automatically subscribed the first time they access Amazon Quick Sight. For Microsoft AD users, you can use `DescribeUser` to get the user ARN.

The first time a user accesses Amazon Quick Sight, you can also add this user to the group that the dashboard is shared with. The following example shows the CLI command to add a user to a group.

```
aws quicksight create-group-membership \
  --aws-account-id=111122223333 \
  --namespace=default \
  --group-name=financeusers \
  --member-name="embedding_quicksight_dashboard_role/john.doe@example.com"
```

You now have a user of your app who is also a user of Amazon Quick Sight, and who has access to the dashboard.

Finally, to get a signed URL for the dashboard, call `generate-embed-url-for-registered-user` from the app server. This returns the embeddable dashboard URL. The following example shows how to generate the URL for an embedded dashboard using a server-side call for users authenticated through AWS Managed Microsoft AD or single sign-on (IAM Identity Center).

```
aws quicksight generate-embed-url-for-registered-user \
  --aws-account-id 111122223333 \
  --session-lifetime-in-minutes 600 \
  --user-arn arn:aws:quicksight:us-east-1:111122223333:user/default/  
embedding_quicksight_visual_role/embeddingsession \
  --allowed-domains '["domain1", "domain2"]' \
  --experience-configuration  
Dashboard={InitialDashboardId=1a1ac2b2-3fc3-4b44-5e5d-c6db6778df89}
```

For more information about using this operation, see [GenerateEmbedUrlForRegisteredUser](#). You can use this and other API operations in your own code.

Step 3: Embed the dashboard URL

In the following section, you can find out how you can use the [Amazon Quick Sight Embedding SDK](#) (JavaScript) to embed the dashboard URL from step 3 in your website or application page. With the SDK, you can do the following:

- Place the dashboard on an HTML page.
- Pass parameters into the dashboard.
- Handle error states with messages that are customized to your application.

Call the `GenerateEmbedUrlForRegisteredUser` API operation to generate the URL that you can embed in your app. This URL is valid for 5 minutes, and the resulting session is valid for up to 10 hours. The API operation provides the URL with an `auth_code` that enables a single-sign on session.

The following shows an example response from `generate-embed-url-for-registered-user`.

```
//The URL returned is over 900 characters. For this example, we've shortened the string
for
//readability and added ellipsis to indicate that it's incomplete.
{
  "Status": "200",
  "EmbedUrl": "https://quicksightdomain/embed/12345/dashboards/67890..",
  "RequestId": "7bee030e-f191-45c4-97fe-d9faf0e03713"
}
```

Embed this dashboard in your webpage by using the [Amazon Quick Sight Embedding SDK](#) or by adding this URL into an `iframe`. If you set a fixed height and width number (in pixels), Amazon Quick Sight uses those and doesn't change your visual as your window resizes. If you set a relative percent height and width, Amazon Quick Sight provides a responsive layout that is modified as your window size changes. By using the Amazon Quick Sight Embedding SDK, you can also control parameters within the dashboard and receive callbacks in terms of page load completion and errors.

The domain that is going to host embedded dashboards must be on the *allow list*, the list of approved domains for your Quick subscription. This requirement protects your data by keeping unapproved domains from hosting embedded dashboards. For more information about adding domains for embedded dashboards, see [Allow listing domains at runtime with the Amazon Quick Sight API](#).

The following example shows how to use the generated URL. This code is generated on your app server.

SDK 2.0

```
<!DOCTYPE html>
<html>

  <head>
    <title>Dashboard Embedding Example</title>
    <script src="https://unpkg.com/amazon-quicksight-embedding-sdk@2.0.0/dist/
quicksight-embedding-js-sdk.min.js"></script>
    <script type="text/javascript">
      const embedDashboard = async() => {
        const {
          createEmbeddingContext,
        } = QuickSightEmbedding;

        const embeddingContext = await createEmbeddingContext({
          onChange: (changeEvent, metadata) => {
            console.log('Context received a change', changeEvent,
metadata);
          },
        });

        const frameOptions = {
          url: '<YOUR_EMBED_URL>',
          container: '#experience-container',
          height: "700px",
          width: "1000px",
          onChange: (changeEvent, metadata) => {
            switch (changeEvent.eventName) {
              case 'FRAME_MOUNTED': {
                console.log("Do something when the experience frame is
mounted.");
                break;
              }
              case 'FRAME_LOADED': {
                console.log("Do something when the experience frame is
loaded.");
                break;
              }
            }
          },
        },
```

```

};

        <select id="country" name="country">

```

```

        <option value="United States">United States</option>
        <option value="Mexico">Mexico</option>
        <option value="Canada">Canada</option>
    </select>
</span>
<div id="experience-container"></div>
</body>

</html>

```

SDK 1.0

```

<!DOCTYPE html>
<html>

    <head>
        <title>Basic Embed</title>
        <script src="https://unpkg.com/amazon-quicksight-embedding-sdk@1.0.15/dist/
quicksight-embedding-js-sdk.min.js"></script>
        <script type="text/javascript">
            var dashboard
            function onDashboardLoad(payload) {
                console.log("Do something when the dashboard is fully loaded.");
            }

            function onError(payload) {
                console.log("Do something when the dashboard fails loading");
            }

            function embedDashboard() {
                var containerDiv = document.getElementById("embeddingContainer");
                var options = {
                    // replace this dummy url with the one generated via embedding API
                    url: "https://us-east-1.quicksight.aws.amazon.com/sn/dashboards/
dashboardId?isauthcode=true&identityprovider=quicksight&code=authcode",
                    container: containerDiv,
                    parameters: {
                        country: "United States"
                    },
                    scrolling: "no",
                    height: "700px",
                    width: "1000px",
                    locale: "en-US",

```

```
        footerPaddingEnabled: true
    };
    dashboard = QuickSightEmbedding.embedDashboard(options);
    dashboard.on("error", onError);
    dashboard.on("load", onDashboardLoad);
}

function onCountryChange(obj) {
    dashboard.setParameters({country: obj.value});
}
</script>
</head>

<body onload="embedDashboard()">
    <span>
        <label for="country">Country</label>
        <select id="country" name="country" onchange="onCountryChange(this)">
            <option value="United States">United States</option>
            <option value="Mexico">Mexico</option>
            <option value="Canada">Canada</option>
        </select>
    </span>
    <div id="embeddingContainer"></div>
</body>

</html>
```

For this example to work, make sure to use the Amazon Quick Sight Embedding SDK to load the embedded dashboard on your website using JavaScript. To get your copy, do one of the following:

- Download the [Amazon Quick Sight Embedding SDK](#) from GitHub. This repository is maintained by a group of Amazon Quick Sight developers.
- Download the latest embedding SDK version from <https://www.npmjs.com/package/amazon-quicksight-embedding-sdk>.
- If you use npm for JavaScript dependencies, download and install it by running the following command.

```
npm install amazon-quicksight-embedding-sdk
```

Embedding Amazon Quick Sight dashboards for anonymous (unregistered) users

Important

Amazon Quick Sight has new API operations for embedding analytics: `GenerateEmbedUrlForAnonymousUser` and `GenerateEmbedUrlForRegisteredUser`. You can still use the `GetDashboardEmbedUrl` and `GetSessionEmbedUrl` API operations to embed dashboards and the Amazon Quick Sight console, but they don't contain the latest embedding capabilities. For more information about embedding using the old API operations, see [Embedding analytics using the `GetDashboardEmbedURL` and `GetSessionEmbedURL` API operations](#).

Applies to: Enterprise Edition

Intended audience: Amazon Quick developers

In the following sections, you can find detailed information about how to set up embedded Amazon Quick Sight dashboards for anonymous (unregistered) users.

Topics

- [Step 1: Set up permissions](#)
- [Step 2: Generate the URL with the authentication code attached](#)
- [Step 3: Embed the dashboard URL](#)

Step 1: Set up permissions

Applies to: Enterprise Edition

Intended audience: Amazon Quick developers

In the following section, you can find out how to set up permissions for the backend application or web server. This task requires administrative access to IAM.

Each user who accesses a dashboard assumes a role that gives them Amazon Quick Sight access and permissions to the dashboard. To make this possible, create an IAM role in your AWS account. Associate an IAM policy with the role to provide permissions to any user who assumes it.

You can create a condition in your IAM policy that limits the domains that developers can list in the `AllowedDomains` parameter of a `GenerateEmbedUrlForAnonymousUser` API operation. The `AllowedDomains` parameter is an optional parameter. It grants you as a developer the option to override the static domains that are configured in the **Manage Amazon Quick Sight** menu. Instead, you can list up to three domains or subdomains that can access a generated URL. This URL is then embedded in the website that you create. Only the domains that are listed in the parameter can access the embedded dashboard. Without this condition, you can list any domain on the internet in the `AllowedDomains` parameter.

To limit the domains that developers can use with this parameter, add an `AllowedEmbeddingDomains` condition to your IAM policy. For more information about the `AllowedDomains` parameter, see [GenerateEmbedUrlForAnonymousUser](#) in the *Amazon Quick Sight API Reference*.

Security best practice for IAM condition operators

Improperly configured IAM condition operators can allow unauthorized access to your embedded Quick resources through URL variations. When using the `quicksight:AllowedEmbeddingDomains` condition key in your IAM policies, use condition operators that either allow specific domains or deny all domains that are not specifically allowed. For more information about IAM condition operators, see [IAM JSON policy elements: Condition operators](#) in the IAM User Guide.

Many different URL variations can point to the same resource. For example, the following URLs all resolve to the same content:

- `https://example.com`
- `https://example.com/`
- `https://Example.com`

If your policy uses operators that do not account for these URL variations, an attacker can bypass your restrictions by providing equivalent URL variations.

You must validate that your IAM policy uses appropriate condition operators to prevent bypass vulnerabilities and ensure that only your intended domains can access your embedded resources.

The following sample policy provides these permissions for use with `GenerateEmbedUrlForAnonymousUser`. For this approach to work, you also need a session pack, or session capacity pricing, for your AWS account. Otherwise, when a user tries to access the dashboard, the error `UnsupportedPricingPlanException` is returned.

Your application's IAM identity must have a trust policy associated with it to allow access to the role that you just created. This means that when a user accesses your application, your application can assume the role on the user's behalf to open the dashboard. The following example shows a sample trust policy.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowLambdaFunctionsToAssumeThisRole",
      "Effect": "Allow",
      "Principal": {
        "Service": "lambda.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    },
    {
      "Sid": "AllowEC2InstancesToAssumeThisRole",
      "Effect": "Allow",
      "Principal": {
        "Service": "ec2.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

For more information regarding trust policies, see [Temporary security credentials in IAM](#) in the *IAM User Guide*.

Step 2: Generate the URL with the authentication code attached

Applies to: Enterprise Edition

Intended audience: Amazon Quick developers

In the following section, you can find how to authenticate on behalf of the anonymous visitor and get the embeddable dashboard URL on your application server.

When a user accesses your app, the app assumes the IAM role on the user's behalf. Then it adds the user to Amazon Quick Sight, if that user doesn't already exist. Next, it passes an identifier as the unique role session ID.

The following examples perform the IAM authentication on the user's behalf. It passes an identifier as the unique role session ID. This code runs on your app server.

Java

```
import java.util.List;
import com.amazonaws.auth.AWSCredentials;
import com.amazonaws.auth.AWSCredentialsProvider;
import com.amazonaws.auth.BasicAWSCredentials;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.quicksight.AmazonQuickSight;
import com.amazonaws.services.quicksight.AmazonQuickSightClientBuilder;
import
com.amazonaws.services.quicksight.model.RegisteredUserDashboardEmbeddingConfiguration;
import
com.amazonaws.services.quicksight.model.AnonymousUserEmbeddingExperienceConfiguration;
import
com.amazonaws.services.quicksight.model.GenerateEmbedUrlForAnonymousUserRequest;
import
com.amazonaws.services.quicksight.model.GenerateEmbedUrlForAnonymousUserResult;
import com.amazonaws.services.quicksight.model.SessionTag;
```

```

/**
 * Class to call QuickSight AWS SDK to generate embed url for anonymous user.
 */
public class GenerateEmbedUrlForAnonymousUserExample {

    private final AmazonQuickSight quickSightClient;

    public GenerateEmbedUrlForAnonymousUserExample() {
        quickSightClient = AmazonQuickSightClientBuilder
            .standard()
            .withRegion(Regions.US_EAST_1.getName())
            .withCredentials(new AWSCredentialsProvider() {
                @Override
                public AWSCredentials getCredentials() {
                    // provide actual IAM access key and secret key here
                    return new BasicAWSCredentials("access-key", "secret-key");
                }

                @Override
                public void refresh() {
                }
            })
            .build();
    }

    public String GenerateEmbedUrlForAnonymousUser(
        final String accountId, // YOUR AWS ACCOUNT ID
        final String initialDashboardId, // DASHBOARD ID TO WHICH THE CONSTRUCTED
        URL POINTS.
        final String namespace, // ANONYMOUS EMBEDDING REQUIRES SPECIFYING A VALID
        NAMESPACE FOR WHICH YOU WANT THE EMBEDDING URL
        final List<String> authorizedResourceArns, // DASHBOARD ARN LIST TO EMBED
        final List<String> allowedDomains, // RUNTIME ALLOWED DOMAINS FOR EMBEDDING
        final List<SessionTag> sessionTags // SESSION TAGS USED FOR ROW-LEVEL
        SECURITY
    ) throws Exception {
        AnonymousUserEmbeddingExperienceConfiguration experienceConfiguration = new
        AnonymousUserEmbeddingExperienceConfiguration();
        AnonymousUserDashboardEmbeddingConfiguration dashboardConfiguration = new
        AnonymousUserDashboardEmbeddingConfiguration();
        dashboardConfiguration.setInitialDashboardId(initialDashboardId);
        experienceConfiguration.setDashboard(dashboardConfiguration);
    }
}

```

```

        GenerateEmbedUrlForAnonymousUserRequest
generateEmbedUrlForAnonymousUserRequest = new
GenerateEmbedUrlForAnonymousUserRequest()
    .withAwsAccountId(accountId)
    .withNamespace(namespace)
    .withAuthorizedResourceArns(authorizedResourceArns)
    .withExperienceConfiguration(experienceConfiguration)
    .withSessionTags(sessionTags)
    .withSessionLifetimeInMinutes(600L); // OPTIONAL: VALUE CAN BE
[15-600]. DEFAULT: 600
    .withAllowedDomains(allowedDomains);

```

Node.js

The following example shows the JavaScript (Node.js) that you can use on the app server to generate the URL for the embedded dashboard. You can use this URL in your website or app to display the dashboard.

Example

```
const AWS = require('aws-sdk');
const https = require('https');

var quicksightClient = new AWS.Service({
  apiConfig: require('./quicksight-2018-04-01.min.json'),
  region: 'us-east-1',
});

quicksightClient.generateEmbedUrlForAnonymousUser({
  'AwsAccountId': '111122223333',
  'Namespace' : 'default',
  'AuthorizedResourceArns': authorizedResourceArns,
  'AllowedDomains': allowedDomains,
  'ExperienceConfiguration': experienceConfiguration,
  'SessionTags': sessionTags,
  'SessionLifetimeInMinutes': 600

}, function(err, data) {
  console.log('Errors: ');
  console.log(err);
  console.log('Response: ');
  console.log(data);
});
```

Example

```
//The URL returned is over 900 characters. For this example, we've shortened the string
for
  //readability and added ellipsis to indicate that it's incomplete.
  {
    Status: 200,
    EmbedUrl: 'https://quicksightdomain/embed/12345/dashboards/67890..',
    RequestId: '7bee030e-f191-45c4-97fe-d9faf0e03713'
```

```
}
```

.NET/C#

The following example shows the .NET/C# code that you can use on the app server to generate the URL for the embedded dashboard. You can use this URL in your website or app to display the dashboard.

Example

```
using System;
using Amazon.QuickSight;
using Amazon.QuickSight.Model;

var quicksightClient = new AmazonQuickSightClient(
    AccessKey,
    SecretAccessKey,
    sessionToken,
    Amazon.RegionEndpoint.USEast1);

try
{
    Console.WriteLine(
        quicksightClient.GenerateEmbedUrlForAnonymousUserAsync(new
GenerateEmbedUrlForAnonymousUserRequest
    {
        AwsAccountId = "111122223333",
        Namespace = default,
        AuthorizedResourceArns = authorizedResourceArns,
        AllowedDomains = allowedDomains,
        ExperienceConfiguration = experienceConfiguration,
        SessionTags = sessionTags,
        SessionLifetimeInMinutes = 600,
    }).Result.EmbedUrl
    );
} catch (Exception ex) {
    Console.WriteLine(ex.Message);
}
```

AWS CLI

To assume the role, choose one of the following AWS Security Token Service (AWS STS) API operations:

- [AssumeRole](#) – Use this operation when you're using an IAM identity to assume the role.
- [AssumeRoleWithWebIdentity](#) – Use this operation when you're using a web identity provider to authenticate your user.
- [AssumeRoleWithSaml](#) – Use this operation when you're using Security Assertion Markup Language (SAML) to authenticate your users.

The following example shows the CLI command to set the IAM role. The role needs to have permissions enabled for `quicksight:GenerateEmbedUrlForAnonymousUser`.

```
aws sts assume-role \  
  --role-arn "arn:aws:iam::11112222333:role/QuickSightEmbeddingAnonymousPolicy" \  
  --role-session-name anonymous caller
```

The `assume-role` operation returns three output parameters: the access key, the secret key, and the session token.

Note

If you get an `ExpiredToken` error when calling the `AssumeRole` operation, this is probably because the previous `SESSION_TOKEN` is still in the environment variables. Clear this by setting the following variables:

- `AWS_ACCESS_KEY_ID`
- `AWS_SECRET_ACCESS_KEY`
- `AWS_SESSION_TOKEN`

The following example shows how to set these three parameters in the CLI. If you're using a Microsoft Windows machine, use `set` instead of `export`.

```
export AWS_ACCESS_KEY_ID      = "access_key_from_assume_role"  
export AWS_SECRET_ACCESS_KEY = "secret_key_from_assume_role"  
export AWS_SESSION_TOKEN     = "session_token_from_assume_role"
```

Running these commands sets the role session ID of the user visiting your website to `embedding_quicksight_dashboard_role/QuickSightEmbeddingAnonymousPolicy`. The role session ID is made up of the role name from `role-arn` and the `role-session-name` value.

Using the unique role session ID for each user ensures that appropriate permissions are set for each visiting user. It also keeps each session separate and distinct. If you're using an array of web servers, for example for load balancing, and a session is reconnected to a different server, a new session begins.

To get a signed URL for the dashboard, call `generate-embed-url-for-anonymous-user` from the app server. This returns the embeddable dashboard URL. The following example shows how to generate the URL for an embedded dashboard using a server-side call for users who are making anonymous visits to your web portal or app.

```
aws quicksight generate-embed-url-for-anonymous-user \
--aws-account-id 111122223333 \
--namespace default-or-something-else \
--session-lifetime-in-minutes 15 \
--authorized-resource-arns '["dashboard-arn-1","dashboard-arn-2"]' \
--allowed-domains '["domain1","domain2"]' \
--session-tags '["Key": tag-key-1,"Value": tag-value-1,{"Key": tag-key-1,"Value": tag-
value-1}]' \
--experience-configuration
'DashboardVisual={InitialDashboardVisualId={DashboardId=dashboard_id,SheetId=sheet_id,VisualId=
```

For more information about using this operation, see [GenerateEmbedUrlForAnonymousUser](#). You can use this and other API operations in your own code.

Step 3: Embed the dashboard URL

Applies to: Enterprise Edition

Intended audience: Amazon Quick developers

In the following section, you can find out how you can use the [Amazon Quick Sight Embedding SDK](#) (JavaScript) to embed the dashboard URL from step 2 in your website or application page. With the SDK, you can do the following:

- Place the dashboard on an HTML page.
- Pass parameters into the dashboard.
- Handle error states with messages that are customized to your application.

Call the `GenerateEmbedUrlForAnonymousUser` API operation to generate the URL that you can embed in your app. This URL is valid for 5 minutes, and the resulting session is valid for 10 hours. The API operation provides the URL with an `auth_code` that enables a single-sign on session.

The following shows an example response from `generate-embed-url-for-anonymous-user`.

```
//The URL returned is over 900 characters. For this example, we've shortened the string
//for
//readability and added ellipsis to indicate that it's incomplete.
{
  "Status": "200",
  "EmbedUrl": "https://quicksightdomain/embed/12345/dashboards/67890..",
  "RequestId": "7bee030e-f191-45c4-97fe-d9faf0e03713"
}
```

Embed this dashboard in your web page by using the [Amazon Quick Sight Embedding SDK](#) or by adding this URL into an `iframe`. If you set a fixed height and width number (in pixels), Amazon Quick Sight uses those and doesn't change your visual as your window resizes. If you set a relative percent height and width, Amazon Quick Sight provides a responsive layout that is modified as your window size changes. By using the Amazon Quick Sight Embedding SDK, you can also control parameters within the dashboard and receive callbacks in terms of page load completion and errors.

The domain that is going to host embedded dashboards must be on the *allow list*, the list of approved domains for your Quick subscription. This requirement protects your data by keeping unapproved domains from hosting embedded dashboards. For more information about adding domains for embedded dashboards, see [Allow listing domains at runtime with the Amazon Quick Sight API](#).

The following example shows how to use the generated URL. This code resides on your app server.

SDK 2.0

```
<!DOCTYPE html>
<html>

<head>
  <title>Dashboard Embedding Example</title>
  <script src="https://unpkg.com/amazon-quicksight-embedding-sdk@2.0.0/dist/
quicksight-embedding-js-sdk.min.js"></script>
  <script type="text/javascript">
```

```

const embedDashboard = async() => {
  const {
    createEmbeddingContext,
  } = QuickSightEmbedding;

  const embeddingContext = await createEmbeddingContext({
    onChange: (changeEvent, metadata) => {
      console.log('Context received a change', changeEvent, metadata);
    },
  });

  const frameOptions = {
    url: '<YOUR_EMBED_URL>',
    container: '#experience-container',
    height: "700px",
    width: "1000px",
    onChange: (changeEvent, metadata) => {
      switch (changeEvent.eventName) {
        case 'FRAME_MOUNTED': {
          console.log("Do something when the experience frame is
mounted.");
          break;
        }
        case 'FRAME_LOADED': {
          console.log("Do something when the experience frame is
loaded.");
          break;
        }
      }
    },
  };

  const contentOptions = {
    parameters: [
      {
        Name: 'country',
        Values: [
          'United States'
        ],
      },
      {
        Name: 'states',
        Values: [
          'California',

```

```

        'Washington'
    ]
}
],

    }
}
}

```

```

        }
        case 'MODAL_OPENED': {
            window.scrollTo({
                top: 0 // iframe top position
            });
            break;
        }
    },
    },
    };
    const embeddedDashboardExperience = await
embeddingContext.embedDashboard(frameOptions, contentOptions);

    const selectCountryElement = document.getElementById('country');
    selectCountryElement.addEventListener('change', (event) => {
        embeddedDashboardExperience.setParameters([
            {
                Name: 'country',
                Values: event.target.value
            }
        ]);
    });
});
</script>
</head>

<body onload="embedDashboard()">
    <span>
        <label for="country">Country</label>
        <select id="country" name="country">
            <option value="United States">United States</option>
            <option value="Mexico">Mexico</option>
            <option value="Canada">Canada</option>
        </select>
    </span>
    <div id="experience-container"></div>
</body>

</html>

```

SDK 1.0

```
<!DOCTYPE html>
```

```
<html>

<head>
  <title>Basic Embed</title>
  <script src="https://unpkg.com/amazon-quicksight-embedding-sdk@1.0.15/dist/
quicksight-embedding-js-sdk.min.js"></script>
  <script type="text/javascript">
    var dashboard
    function onDashboardLoad(payload) {
      console.log("Do something when the dashboard is fully loaded.");
    }

    function onError(payload) {
      console.log("Do something when the dashboard fails loading");
    }

    function embedDashboard() {
      var containerDiv = document.getElementById("embeddingContainer");
      var options = {
        // replace this dummy url with the one generated via embedding API
        url: "https://us-east-1.quicksight.aws.amazon.com/sn/dashboards/
dashboardId?isauthcode=true&identityprovider=quicksight&code=authcode",
        container: containerDiv,
        parameters: {
          country: "United States"
        },
        scrolling: "no",
        height: "700px",
        width: "1000px",
        locale: "en-US",
        footerPaddingEnabled: true
      };
      dashboard = QuickSightEmbedding.embedDashboard(options);
      dashboard.on("error", onError);
      dashboard.on("load", onDashboardLoad);
    }

    function onCountryChange(obj) {
      dashboard.setParameters({country: obj.value});
    }
  </script>
</head>

<body onload="embedDashboard()">
```

```
<span>
  <label for="country">Country</label>
  <select id="country" name="country" onchange="onCountryChange(this)">
    <option value="United States">United States</option>
    <option value="Mexico">Mexico</option>
    <option value="Canada">Canada</option>
  </select>
</span>
<div id="embeddingContainer"></div>
</body>

</html>
```

For this example to work, make sure to use the Amazon Quick Sight Embedding SDK to load the embedded dashboard on your website using JavaScript. To get your copy, do one of the following:

- Download the [Amazon Quick Sight Embedding SDK](#) from GitHub. This repository is maintained by a group of Amazon Quick Sight developers.
- Download the latest Amazon Quick Sight Embedding SDK version from <https://www.npmjs.com/package/amazon-quicksight-embedding-sdk>.
- If you use npm for JavaScript dependencies, download and install it by running the following command.

```
npm install amazon-quicksight-embedding-sdk
```

Enabling executive summaries in embedded dashboards

Applies to: Enterprise Edition

Intended audience: Amazon Quick developers

You can enable executive summaries in your embedded dashboards. When enabled, registered users can generate executive summaries that provide a summary of all insights that Amazon Quick Sight has generated for the dashboard. Executive summaries make it easier for readers to find key insights and information about a dashboard. For more information about how users generate an

executive summary of a dashboard, see [Generate an executive summary of an Amazon Quick Sight dashboard](#).

Note

Executive summaries are only available in embedded dashboards for registered users, and cannot be enabled in embedded dashboards for anonymous or unregistered users.

To enable executive summaries in embedded dashboards for registered users

- Follow the steps in [Embedding Amazon Quick Sight dashboards for registered users](#) to embed a dashboard with the following changes:
 - When generating the URL in Step 2, set `Enabled: true` in the `ExecutiveSummary` parameter in the [GenerateEmbedUrlForRegisteredUser](#) or [GenerateEmbedUrlForRegisteredUserWithIdentity](#) as shown in the following example:

```
ExperienceConfiguration: {
  Dashboard: {
    InitialDashboardId: dashboard_id,
    FeatureConfigurations: {
      AmazonQInQuickSight: {
        ExecutiveSummary: {
          Enabled: true
        }
      }
    }
  }
}
```

- When embedding the dashboard URL with the Amazon Quick Sight Embedding SDK in Step 3, set `executiveSummary: true` in `contentOptions`, as shown in the following example:

```
const contentOptions = {
  toolbarOptions: {
    executiveSummary: true
  }
};
```

Embedding Amazon Quick Sight visuals with the Amazon Quick Sight APIs

You can embed individual visuals that are a part of a published dashboard in your application with the Amazon Quick Sight API.

Topics

- [Embedding Amazon Quick Sight visuals for registered users](#)
- [Embedding Amazon Quick Sight visuals for anonymous \(unregistered\) users](#)

Embedding Amazon Quick Sight visuals for registered users

Applies to: Enterprise Edition

Intended audience: Amazon Quick developers

In the following sections, you can find detailed information about how to set up embedded Amazon Quick Sight visuals for registered users of Amazon Quick Sight.

Topics

- [Step 1: Set up permissions](#)
- [Step 2: Generate the URL with the authentication code attached](#)
- [Step 3: Embed the visual URL](#)

Step 1: Set up permissions

In the following section, you can find out how to set up permissions for the backend application or web server. This task requires administrative access to IAM.

Each user who accesses a visual assumes a role that gives them Amazon Quick Sight access and permissions to the visual. To make this possible, create an IAM role in your AWS account. Associate an IAM policy with the role to provide permissions to any user who assumes it. The IAM role needs to provide permissions to retrieve embedding URLs for a specific user pool. With the help of the wildcard character *, you can grant the permissions to generate a URL for all users in a specific namespace, or for a subset of users in specific namespaces. For this, you add `quicksight:GenerateEmbedUrlForRegisteredUser`.

You can create a condition in your IAM policy that limits the domains that developers can list in the `AllowedDomains` parameter of a `GenerateEmbedUrlForAnonymousUser` API operation. The `AllowedDomains` parameter is an optional parameter. It grants you as a developer the option to override the static domains that are configured in the **Manage Amazon Quick Sight** menu. Instead, you can list up to three domains or subdomains that can access a generated URL. This URL is then embedded in the website that you create. Only the domains that are listed in the parameter can access the embedded dashboard. Without this condition, you can list any domain on the internet in the `AllowedDomains` parameter.

To limit the domains that developers can use with this parameter, add an `AllowedEmbeddingDomains` condition to your IAM policy. For more information about the `AllowedDomains` parameter, see [GenerateEmbedUrlForRegisteredUser](#) in the *Amazon Quick Sight API Reference*.

Security best practice for IAM condition operators

Improperly configured IAM condition operators can allow unauthorized access to your embedded Quick resources through URL variations. When using the `quicksight:AllowedEmbeddingDomains` condition key in your IAM policies, use condition operators that either allow specific domains or deny all domains that are not specifically allowed. For more information about IAM condition operators, see [IAM JSON policy elements: Condition operators](#) in the IAM User Guide.

Many different URL variations can point to the same resource. For example, the following URLs all resolve to the same content:

- `https://example.com`
- `https://example.com/`
- `https://Example.com`

If your policy uses operators that do not account for these URL variations, an attacker can bypass your restrictions by providing equivalent URL variations.

You must validate that your IAM policy uses appropriate condition operators to prevent bypass vulnerabilities and ensure that only your intended domains can access your embedded resources.

The following sample policy provides these permissions.

Additionally, if you are creating first-time users who will be Amazon Quick Sight readers, make sure to add the `quicksight:RegisterUser` permission in the policy.

The following sample policy provides permission to retrieve an embedding URL for first-time users who are to be Amazon Quick Sight readers.

Finally, your application's IAM identity must have a trust policy associated with it to allow access to the role that you just created. This means that when a user accesses your application, your application can assume the role on the user's behalf and provision the user in Amazon Quick Sight. The following example shows a sample trust policy.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowLambdaFunctionsToAssumeThisRole",
      "Effect": "Allow",
      "Principal": {
        "Service": "lambda.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    },
    {
      "Sid": "AllowEC2InstancesToAssumeThisRole",
      "Effect": "Allow",
      "Principal": {
        "Service": "ec2.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

For more information regarding trust policies for OpenID Connect or SAML authentication, see the following sections of the *IAM User Guide*:

- [Creating a Role for Web Identity or OpenID Connect Federation \(Console\)](#)
- [Creating a Role for SAML 2.0 Federation \(Console\)](#)

Step 2: Generate the URL with the authentication code attached

In the following section, you can find out how to authenticate your Amazon Quick Sight user and get the embeddable visual URL on your application server. If you plan to embed visuals for IAM or Amazon Quick Sight identity types, share the visual with the Amazon Quick Sight users.

When a Amazon Quick Sight user accesses your app, the app assumes the IAM role on the Amazon Quick Sight user's behalf. Then it adds the user to Amazon Quick Sight, if that Amazon Quick Sight user doesn't already exist. Next, it passes an identifier as the unique role session ID.

Performing the described steps ensures that each viewer of the visual is uniquely provisioned in Amazon Quick Sight. It also enforces per-user settings, such as the row-level security and dynamic defaults for parameters.

The following examples perform the IAM authentication on the Amazon Quick Sight user's behalf. This code runs on your app server.

Java

```
import com.amazonaws.auth.AWSCredentials;
import com.amazonaws.auth.BasicAWSCredentials;
import com.amazonaws.auth.AWSCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.quicksight.AmazonQuickSight;
import com.amazonaws.services.quicksight.AmazonQuickSightClientBuilder;
import com.amazonaws.services.quicksight.model.DashboardVisualId;
import
    com.amazonaws.services.quicksight.model.GenerateEmbedUrlForRegisteredUserRequest;

Node.js

The following example shows the JavaScript (Node.js) that you can use on the app server to generate the URL for the embedded dashboard. You can use this URL in your website or app to display the dashboard.

Example

```

const AWS = require('aws-sdk');
const https = require('https');

var quicksightClient = new AWS.Service({
    apiConfig: require('./quicksight-2018-04-01.min.json'),
    region: 'us-east-1',
});

```

```
quicksightClient.generateEmbedUrlForRegisteredUser({
  'AwsAccountId': '111122223333',
  'ExperienceConfiguration': {
    'DashboardVisual': {
      'InitialDashboardVisualId': {
        'DashboardId': 'dashboard_id',
        'SheetId': 'sheet_id',
        'VisualId': 'visual_id'
      }
    }
  },
  'UserArn': 'REGISTERED_USER_ARN',
  'AllowedDomains': allowedDomains,
  'SessionLifetimeInMinutes': 100
}, function(err, data) {
  console.log('Errors: ');
  console.log(err);
  console.log('Response: ');
  console.log(data);
});
```

Example

```
//The URL returned is over 900 characters. For this example, we've shortened the string
//for
//readability and added ellipsis to indicate that it's incomplete.
{
  "Status": "200",
  "EmbedUrl": "https://quicksightdomain/embed/12345/dashboards/67890/
sheets/12345/visuals/67890...",
  "RequestId": "7bee030e-f191-45c4-97fe-d9faf0e03713"
}
```

.NET/C#

The following example shows the .NET/C# code that you can use on the app server to generate the URL for the embedded dashboard. You can use this URL in your website or app to display the dashboard.

Example

```
using System;
```

```

using Amazon.QuickSight;
using Amazon.QuickSight.Model;

namespace GenerateDashboardEmbedUrlForRegisteredUser
{
    class Program
    {
        static void Main(string[] args)
        {
            var quicksightClient = new AmazonQuickSightClient(
                AccessKey,
                SecretAccessKey,
                SessionToken,
                Amazon.RegionEndpoint.USEast1);

            try
            {
                DashboardVisualId dashboardVisual = new DashboardVisualId
                {
                    DashboardId = "dashboard_id",
                    SheetId = "sheet_id",
                    VisualId = "visual_id"
                };

                RegisteredUserDashboardVisualEmbeddingConfiguration
registeredUserDashboardVisualEmbeddingConfiguration
                    = new RegisteredUserDashboardVisualEmbeddingConfiguration
                    {
                        InitialDashboardVisualId = dashboardVisual
                    };

                RegisteredUserEmbeddingExperienceConfiguration
registeredUserEmbeddingExperienceConfiguration
                    = new RegisteredUserEmbeddingExperienceConfiguration
                    {
                        DashboardVisual =
registeredUserDashboardVisualEmbeddingConfiguration
                    };

                Console.WriteLine(
                    quicksightClient.GenerateEmbedUrlForRegisteredUserAsync(new
GenerateEmbedUrlForRegisteredUserRequest
                    {
                        AwsAccountId = "111122223333",

```

```

        ExperienceConfiguration =
registeredUserEmbeddingExperienceConfiguration,
        UserArn = "REGISTERED_USER_ARN",
        AllowedDomains = allowedDomains,
        SessionLifetimeInMinutes = 100
    })).Result.EmbedUrl
    );
} catch (Exception ex) {
    Console.WriteLine(ex.Message);
}
}
}
}

```

AWS CLI

To assume the role, choose one of the following AWS Security Token Service (AWS STS) API operations:

- [AssumeRole](#) – Use this operation when you're using an IAM identity to assume the role.
- [AssumeRoleWithWebIdentity](#) – Use this operation when you're using a web identity provider to authenticate your user.
- [AssumeRoleWithSaml](#) – Use this operation when you're using SAML to authenticate your users.

The following example shows the CLI command to set the IAM role. The role needs to have permissions enabled for `quicksight:GenerateEmbedUrlForRegisteredUser`. If you are taking a just-in-time approach to add users when they first open a dashboard, the role also needs permissions enabled for `quicksight:RegisterUser`.

```

aws sts assume-role \
  --role-arn "arn:aws:iam::111122223333:role/embedding_quicksight_visual_role" \
  --role-session-name john.doe@example.com

```

The `assume-role` operation returns three output parameters: the access key, the secret key, and the session token.

Note

If you get an `ExpiredToken` error when calling the `AssumeRole` operation, this is probably because the previous `SESSION_TOKEN` is still in the environment variables. Clear this by setting the following variables:

- `AWS_ACCESS_KEY_ID`
- `AWS_SECRET_ACCESS_KEY`
- `AWS_SESSION_TOKEN`

The following example shows how to set these three parameters in the CLI. If you're using a Microsoft Windows machine, use `set` instead of `export`.

```
export AWS_ACCESS_KEY_ID      = "access_key_from_assume_role"
export AWS_SECRET_ACCESS_KEY  = "secret_key_from_assume_role"
export AWS_SESSION_TOKEN      = "session_token_from_assume_role"
```

Running these commands sets the role session ID of the user visiting your website to `embedding_quicksight_visual_role/john.doe@example.com`. The role session ID is made up of the role name from `role-arn` and the `role-session-name` value. Using the unique role session ID for each user ensures that appropriate permissions are set for each user. It also prevents any throttling of user access. *Throttling* is a security feature that prevents the same user from accessing Amazon Quick Sight from multiple locations.

The role session ID also becomes the user name in Amazon Quick Sight. You can use this pattern to provision your users in Amazon Quick Sight ahead of time, or to provision them the first time they access the dashboard.

The following example shows the CLI command that you can use to provision a user. For more information about [RegisterUser](#), [DescribeUser](#), and other Amazon Quick Sight API operations, see the [Amazon Quick Sight API Reference](#).

```
aws quicksight register-user \
  --aws-account-id 111122223333 \
  --namespace default \
  --identity-type IAM \
  --iam-arn "arn:aws:iam::111122223333:role/embedding_quicksight_visual_role" \
  --user-role READER \
```

```
--user-name jhnd \
--session-name "john.doe@example.com" \
--email john.doe@example.com \
--region us-east-1 \
--custom-permissions-name TeamA1
```

If the user is authenticated through Microsoft AD, you don't need to use `RegisterUser` to set them up. Instead, they should be automatically subscribed the first time they access Amazon Quick Sight. For Microsoft AD users, you can use `DescribeUser` to get the user ARN.

The first time a user accesses Amazon Quick Sight, you can also add this user to the group that the visual is shared with. The following example shows the CLI command to add a user to a group.

```
aws quicksight create-group-membership \
  --aws-account-id=111122223333 \
  --namespace=default \
  --group-name=financeusers \
  --member-name="embedding_quicksight_visual_role/john.doe@example.com"
```

You now have a user of your app who is also a user of Amazon Quick Sight, and who has access to the visual.

Finally, to get a signed URL for the visual, call `generate-embed-url-for-registered-user` from the app server. This returns the embeddable visual URL. The following example shows how to generate the URL for an embedded visual using a server-side call for users authenticated through AWS Managed Microsoft AD or single sign-on (IAM Identity Center).

```
aws quicksight generate-embed-url-for-registered-user \
  --aws-account-id 111122223333 \
  --session-lifetime-in-minutes 600 \
  --user-arn arn:aws:quicksight:us-east-1:111122223333:user/default/
embedding_quicksight_visual_role/embeddingsession \
  --allowed-domains '["domain1", "domain2"]' \
  --experience-configuration
'DashboardVisual={InitialDashboardVisualId={DashboardId=dashboard_id, SheetId=sheet_id, VisualId=
```

For more information about using this operation, see [GenerateEmbedUrlForRegisteredUser](#). You can use this and other API operations in your own code.

Step 3: Embed the visual URL

In the following section, you can find out how you can use the [Amazon Quick Sight Embedding SDK](#) (JavaScript) to embed the visual URL from step 3 in your website or application page. With the SDK, you can do the following:

- Place the visual on an HTML page.
- Pass parameters into the visual.
- Handle error states with messages that are customized to your application.

Call the `GenerateEmbedUrlForRegisteredUser` API operation to generate the URL that you can embed in your app. This URL is valid for 5 minutes, and the resulting session is valid for up to 10 hours. The API operation provides the URL with an `auth_code` that enables a single-sign on session.

The following shows an example response from `generate-embed-url-for-registered-user`. The *quicksightdomain* in this example is the URL that you use to access your Amazon Quick Sight account.

```
//The URL returned is over 900 characters. For this example, we've shortened the string
//for
//readability and added ellipsis to indicate that it's incomplete.
{
  "Status": "200",
  "EmbedUrl": "https://quicksightdomain/embed/12345/dashboards/67890/
sheets/12345/visuals/67890...",
  "RequestId": "7bee030e-f191-45c4-97fe-d9faf0e03713"
}
```

Embed this visual in your webpage by using the [Amazon Quick Sight Embedding SDK](#) or by adding this URL into an `iframe`. If you set a fixed height and width number (in pixels), Amazon Quick Sight uses those and doesn't change your visual as your window resizes. If you set a relative percent height and width, Amazon Quick Sight provides a responsive layout that is modified as your window size changes. By using the Amazon Quick Sight Embedding SDK, you can also control parameters within the visual and receive callbacks in terms of page load completion and errors.

The domain that is going to host embedded visuals and dashboards must be on the *allow list*, the list of approved domains for your Quick subscription. This requirement protects your data

by keeping unapproved domains from hosting embedded visuals and dashboards. For more information about adding domains for embedded visuals and dashboards, see [Allow listing domains at runtime with the Amazon Quick Sight API](#).

The following example shows how to use the generated URL. This code is generated on your app server.

```

    <!-- Or you can do "npm install amazon-quicksight-embedding-sdk", if you use
    npm for javascript dependencies -->
    <script src="./quicksight-embedding-js-sdk.min.js"></script>
    <script type="text/javascript">
        let embeddedVisualExperience;
        function onVisualLoad(payload) {
            console.log("Do something when the visual is fully loaded.");
        }

        function onError(payload) {
            console.log("Do something when the visual fails loading");
        }

        function embedVisual() {
            const containerDiv = document.getElementById("embeddingContainer");
            const options = {
                url: "<YOUR_EMBED_URL>", // replace this value with the url
generated via embedding API
                container: containerDiv,
                parameters: {
                    country: "United States"
                },
                height: "700px",
                width: "1000px",
                locale: "en-US"
            };
            embeddedVisualExperience = QuickSightEmbedding.embedVisual(options);
            embeddedVisualExperience.on("error", onError);
            embeddedVisualExperience.on("load", onVisualLoad);
        }

        function onCountryChange(obj) {
            embeddedVisualExperience.setParameters({country: obj.value});
        }
    </script>
</head>

<body onload="embedVisual()">
    <span>
        <label for="country">Country</label>
        <select id="country" name="country" onchange="onCountryChange(this)">
            <option value="United States">United States</option>
            <option value="Mexico">Mexico</option>
            <option value="Canada">Canada</option>

```

```
        </select>
    </span>
    <div id="embeddingContainer"></div>
</body>

</html>
```

For this example to work, make sure to use the Amazon Quick Sight Embedding SDK to load the embedded visual on your website using JavaScript. To get your copy, do one of the following:

- Download the [Amazon Quick Sight Embedding SDK](#) from GitHub. This repository is maintained by a group of Amazon Quick Sight developers.
- Download the latest embedding SDK version from <https://www.npmjs.com/package/amazon-quicksight-embedding-sdk>.
- If you use npm for JavaScript dependencies, download and install it by running the following command.

```
npm install amazon-quicksight-embedding-sdk
```

Embedding Amazon Quick Sight visuals for anonymous (unregistered) users

Applies to: Enterprise Edition

Intended audience: Amazon Quick developers

In the following sections, you can find detailed information about how to set up embedded Amazon Quick Sight visuals for anonymous (unregistered) users.

Topics

- [Step 1: Set up permissions](#)
- [Step 2: Generate the URL with the authentication code attached](#)
- [Step 3: Embed the visual URL](#)

Step 1: Set up permissions

Applies to: Enterprise Edition

Intended audience: Amazon Quick developers

In the following section, you can find out how to set up permissions for the backend application or web server. This task requires administrative access to IAM.

Each user who accesses a visual assumes a role that gives them Amazon Quick Sight access and permissions to the visual. To make this possible, create an IAM role in your AWS account. Associate an IAM policy with the role to provide permissions to any user who assumes it.

You can create a condition in your IAM policy that limits the domains that developers can list in the `AllowedDomains` parameter of a `GenerateEmbedUrlForAnonymousUser` API operation. The `AllowedDomains` parameter is an optional parameter. It grants you as a developer the option to override the static domains that are configured in the **Manage Amazon Quick Sight** menu. Instead, you can list up to three domains or subdomains that can access a generated URL. This URL is then embedded in the website that you create. Only the domains that are listed in the parameter can access the embedded dashboard. Without this condition, you can list any domain on the internet in the `AllowedDomains` parameter.

To limit the domains that developers can use with this parameter, add an `AllowedEmbeddingDomains` condition to your IAM policy. For more information about the `AllowedDomains` parameter, see [GenerateEmbedUrlForAnonymousUser](#) in the *Amazon Quick Sight API Reference*.

Security best practice for IAM condition operators

Improperly configured IAM condition operators can allow unauthorized access to your embedded Quick resources through URL variations. When using the `quicksight:AllowedEmbeddingDomains` condition key in your IAM policies, use condition operators that either allow specific domains or deny all domains that are not specifically allowed. For more information about IAM condition operators, see [IAM JSON policy elements: Condition operators](#) in the IAM User Guide.

Many different URL variations can point to the same resource. For example, the following URLs all resolve to the same content:

- `https://example.com`
- `https://example.com/`
- `https://Example.com`

If your policy uses operators that do not account for these URL variations, an attacker can bypass your restrictions by providing equivalent URL variations.

You must validate that your IAM policy uses appropriate condition operators to prevent bypass vulnerabilities and ensure that only your intended domains can access your embedded resources.

Your application's IAM identity must have a trust policy associated with it to allow access to the role that you just created. This means that when a user accesses your application, your application can assume the role on the user's behalf to open the visual. The following example shows a sample trust policy.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowLambdaFunctionsToAssumeThisRole",
      "Effect": "Allow",
      "Principal": {
        "Service": "lambda.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    },
    {
      "Sid": "AllowEC2InstancesToAssumeThisRole",
      "Effect": "Allow",
      "Principal": {
        "Service": "ec2.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

```
}  
]  
}
```

For more information regarding trust policies, see [Temporary security credentials in IAM](#) in the *IAM User Guide*.

Step 2: Generate the URL with the authentication code attached

Applies to: Enterprise Edition

Intended audience: Amazon Quick developers

In the following section, you can find how to authenticate on behalf of the anonymous visitor and get the embeddable visual URL on your application server.

When a user accesses your app, the app assumes the IAM role on the user's behalf. Then it adds the user to Amazon Quick Sight, if that user doesn't already exist. Next, it passes an identifier as the unique role session ID.

The following examples perform the IAM authentication on the user's behalf. It passes an identifier as the unique role session ID. This code runs on your app server.

Java

```
import com.amazonaws.auth.AWSCredentials;  
import com.amazonaws.auth.BasicAWSCredentials;  
import com.amazonaws.auth.AWSCredentialsProvider;  
import com.amazonaws.regions.Regions;

        }
    except ClientError as e:
        print(e)
        return "Error generating embeddedURL: " + str(e)
```

Node.js

The following example shows the JavaScript (Node.js) that you can use on the app server to generate the URL for the embedded dashboard. You can use this URL in your website or app to display the dashboard.

Example

```
const AWS = require('aws-sdk');
const https = require('https');

var quicksightClient = new AWS.Service({
    apiConfig: require('./quicksight-2018-04-01.min.json'),
    region: 'us-east-1',
});

quicksightClient.generateEmbedUrlForAnonymousUser({
    'AwsAccountId': '111122223333',
```

```

    'Namespace' : 'default',
    // authorizedResourceArns should contain ARN of dashboard used below in
    ExperienceConfiguration
    'AuthorizedResourceArns': authorizedResourceArns,
    'ExperienceConfiguration': {
        'DashboardVisual': {
            'InitialDashboardVisualId': {
                'DashboardId': 'dashboard_id',
                'SheetId': 'sheet_id',
                'VisualId': 'visual_id'
            }
        }
    },
    'AllowedDomains': allowedDomains,
    'SessionTags': sessionTags,
    'SessionLifetimeInMinutes': 600
}, function(err, data) {
    console.log('Errors: ');
    console.log(err);
    console.log('Response: ');
    console.log(data);
});

```

Example

```

//The URL returned is over 900 characters. For this example, we've shortened the string
for
//readability and added ellipsis to indicate that it's incomplete.
{
    "Status": "200",
    "EmbedUrl": "https://quicksightdomain/embed/12345/dashboards/67890/
sheets/12345/visuals/67890...",
    "RequestId": "7bee030e-f191-45c4-97fe-d9faf0e03713"
}

```

.NET/C#

The following example shows the .NET/C# code that you can use on the app server to generate the URL for the embedded dashboard. You can use this URL in your website or app to display the dashboard.

Example

```
using System;
using Amazon.QuickSight;
using Amazon.QuickSight.Model;

namespace GenerateDashboardEmbedUrlForAnonymousUser
{
    class Program
    {
        static void Main(string[] args)
        {
            var quicksightClient = new AmazonQuickSightClient(
                AccessKey,
                SecretAccessKey,
                SessionToken,
                Amazon.RegionEndpoint.USEast1);
            try
            {
                DashboardVisualId dashboardVisual = new DashboardVisualId
                {
                    DashboardId = "dashboard_id",
                    SheetId = "sheet_id",
                    VisualId = "visual_id"
                };

                AnonymousUserDashboardVisualEmbeddingConfiguration
anonymousUserDashboardVisualEmbeddingConfiguration
                    = new AnonymousUserDashboardVisualEmbeddingConfiguration
                    {
                        InitialDashboardVisualId = dashboardVisual
                    };

                AnonymousUserEmbeddingExperienceConfiguration
anonymousUserEmbeddingExperienceConfiguration
                    = new AnonymousUserEmbeddingExperienceConfiguration
                    {
                        DashboardVisual =
anonymousUserDashboardVisualEmbeddingConfiguration
                    };

                Console.WriteLine(
```

```

        quicksightClient.GenerateEmbedUrlForAnonymousUserAsync(new
GenerateEmbedUrlForAnonymousUserRequest
        {
            AwsAccountId = "111222333444",
            Namespace = default,
            // authorizedResourceArns should contain ARN of dashboard used
below in ExperienceConfiguration
            AuthorizedResourceArns = { "dashboard_id" },
            ExperienceConfiguration =
anonymousUserEmbeddingExperienceConfiguration,
            SessionTags = sessionTags,
            SessionLifetimeInMinutes = 600,
        }).Result.EmbedUrl
    );
} catch (Exception ex) {
    Console.WriteLine(ex.Message);
}
}
}
}
}

```

AWS CLI

To assume the role, choose one of the following AWS Security Token Service (AWS STS) API operations:

- [AssumeRole](#) – Use this operation when you're using an IAM identity to assume the role.
- [AssumeRoleWithWebIdentity](#) – Use this operation when you're using a web identity provider to authenticate your user.
- [AssumeRoleWithSaml](#) – Use this operation when you're using Security Assertion Markup Language (SAML) to authenticate your users.

The following example shows the CLI command to set the IAM role. The role needs to have permissions enabled for `quicksight:GenerateEmbedUrlForAnonymousUser`.

```

aws sts assume-role \
    --role-arn "arn:aws:iam::11112222333:role/QuickSightEmbeddingAnonymousPolicy" \
    --role-session-name anonymous caller

```

The `assume-role` operation returns three output parameters: the access key, the secret key, and the session token.

Note

If you get an `ExpiredToken` error when calling the `AssumeRole` operation, this is probably because the previous `SESSION_TOKEN` is still in the environment variables. Clear this by setting the following variables:

- `AWS_ACCESS_KEY_ID`
- `AWS_SECRET_ACCESS_KEY`
- `AWS_SESSION_TOKEN`

The following example shows how to set these three parameters in the CLI. If you're using a Microsoft Windows machine, use `set` instead of `export`.

```
export AWS_ACCESS_KEY_ID      = "access_key_from_assume_role"  
export AWS_SECRET_ACCESS_KEY  = "secret_key_from_assume_role"  
export AWS_SESSION_TOKEN      = "session_token_from_assume_role"
```

Running these commands sets the role session ID of the user visiting your website to `embedding_quicksight_visual_role/QuickSightEmbeddingAnonymousPolicy`. The role session ID is made up of the role name from `role-arn` and the `role-session-name` value. Using the unique role session ID for each user ensures that appropriate permissions are set for each visiting user. It also keeps each session separate and distinct. If you're using an array of web servers, for example for load balancing, and a session is reconnected to a different server, a new session begins.

To get a signed URL for the visual, call `generate-embed-url-for-anonymous-user` from the app server. This returns the embeddable visual URL. The following example shows how to generate the URL for an embedded visual using a server-side call for users who are making anonymous visits to your web portal or app.

```
aws quicksight generate-embed-url-for-anonymous-user \  
  --aws-account-id 111122223333 \  
  --namespace default-or-something-else \  
  --session-lifetime-in-minutes 15 \  
  --authorized-resource-arns '["dashboard-arn-1","dashboard-arn-2"]' \  
  \
```

```
--allowed-domains '["domain1", "domain2"]' \
--session-tags '["Key": tag-key-1, "Value": tag-value-1, {"Key": tag-
key-1, "Value": tag-value-1}]' \
--experience-configuration
'DashboardVisual={InitialDashboardVisualId={DashboardId=dashboard_id, SheetId=sheet_id, VisualId=
```

For more information about using this operation, see [GenerateEmbedUrlForAnonymousUser](#). You can use this and other API operations in your own code.

Step 3: Embed the visual URL

Applies to: Enterprise Edition

Intended audience: Amazon Quick developers

In the following section, you can find out how you can use the [Amazon Quick Sight Embedding SDK](#) (JavaScript) to embed the visual URL from step 2 in your website or application page. With the SDK, you can do the following:

- Place the visual on an HTML page.
- Pass parameters into the visual.
- Handle error states with messages that are customized to your application.

Call the `GenerateEmbedUrlForAnonymousUser` API operation to generate the URL that you can embed in your app. This URL is valid for 5 minutes, and the resulting session is valid for 10 hours. The API operation provides the URL with an authorization (auth) code that enables a single-sign on session.

The following shows an example response from `generate-embed-url-for-anonymous-user`. The *quicksightdomain* in this example is the URL that you use to access your Amazon Quick Sight account.

```
//The URL returned is over 900 characters. For this example, we've shortened the string
for
//readability and added ellipsis to indicate that it's incomplete.
{
    "Status": "200",
```

```
"EmbedUrl": "https://quicksightdomain/embed/12345/dashboards/67890/sheets/12345/visuals/67890...",
"RequestId": "7bee030e-f191-45c4-97fe-d9faf0e03713"
}
```

Embed this visual in your web page by using the Amazon Quick Sight [Embedding SDK](#) or by adding this URL into an iframe. If you set a fixed height and width number (in pixels), Amazon Quick Sight uses those and doesn't change your visual as your window resizes. If you set a relative percent height and width, Amazon Quick Sight provides a responsive layout that is modified as your window size changes. By using the Amazon Quick Sight Embedding SDK, you can also control parameters within the visual and receive callbacks in terms of visual load completion and errors.

The domain that is going to host embedded visual must be on the *allow list*, the list of approved domains for your Quick subscription. This requirement protects your data by keeping unapproved domains from hosting embedded visuals and dashboards. For more information about adding domains for embedded visuals and dashboards, see [Allow listing domains at runtime with the Amazon Quick Sight API](#).

The following example shows how to use the generated URL. This code resides on your app server.

SDK 2.0

```
<!DOCTYPE html>
<html>

  <head>
    <title>Visual Embedding Example</title>
    <script src="https://unpkg.com/amazon-quicksight-embedding-sdk@2.0.0/dist/quicksight-embedding-js-sdk.min.js"></script>
    <script type="text/javascript">
      const embedVisual = async() => {
        const {
          createEmbeddingContext,
        } = QuickSightEmbedding;

        const embeddingContext = await createEmbeddingContext({
          onChange: (changeEvent, metadata) => {
            console.log('Context received a change', changeEvent,
metadata);
          },
        });
      };
```

```

        const frameOptions = {
            url: "<YOUR_EMBED_URL>", // replace this value with the url
generated via embedding API
            container: '#experience-container',
            height: "700px",
            width: "1000px",
            onChange: (changeEvent, metadata) => {

    <title>Visual Embedding Example</title>
    <!-- You can download the latest QuickSight embedding SDK version from https://
www.npmjs.com/package/amazon-quicksight-embedding-sdk -->
    <!-- Or you can do "npm install amazon-quicksight-embedding-sdk", if you use
npm for javascript dependencies -->
    <script src="./quicksight-embedding-js-sdk.min.js"></script>
    <script type="text/javascript">
      let embeddedVisualExperience;
      function onVisualLoad(payload) {
        console.log("Do something when the visual is fully loaded.");
      }

      function onError(payload) {
        console.log("Do something when the visual fails loading");
      }

      function embedVisual() {
        const containerDiv = document.getElementById("embeddingContainer");
        const options = {
          url: "<YOUR_EMBED_URL>", // replace this value with the url
generated via embedding API
          container: containerDiv,
          parameters: {
            country: "United States"
          },
          height: "700px",
          width: "1000px",
          locale: "en-US"
        };
        embeddedVisualExperience = QuickSightEmbedding.embedVisual(options);
        embeddedVisualExperience.on("error", onError);
        embeddedVisualExperience.on("load", onVisualLoad);
      }
    </script>
  </head>
</html>
```

```
        function onCountryChange(obj) {
            embeddedVisualExperience.setParameters({country: obj.value});
        }
    </script>
</head>

<body onload="embedVisual()">
    <span>
        <label for="country">Country</label>
        <select id="country" name="country" onchange="onCountryChange(this)">
            <option value="United States">United States</option>
            <option value="Mexico">Mexico</option>
            <option value="Canada">Canada</option>
        </select>
    </span>
    <div id="embeddingContainer"></div>
</body>

</html>
```

For this example to work, make sure to use the Amazon Quick Sight Embedding SDK to load the embedded visual on your website using JavaScript. To get your copy, do one of the following:

- Download the [Amazon Quick Sight Embedding SDK](#) from GitHub. This repository is maintained by a group of Amazon Quick Sight developers.
- Download the latest QuickSight embedding SDK version from <https://www.npmjs.com/package/amazon-quicksight-embedding-sdk>.
- If you use npm for JavaScript dependencies, download and install it by running the following command.

```
npm install amazon-quicksight-embedding-sdk
```

Embedding the full functionality of the Amazon Quick Sight console for registered users

Important

Amazon Quick Sight has new API operations for embedding analytics:
GenerateEmbedUrlForAnonymousUser and GenerateEmbedUrlForRegisteredUser.

You can still use the `GetDashboardEmbedUrl` and `GetSessionEmbedUrl` API operations to embed dashboards and the Amazon Quick Sight console, but they don't contain the latest embedding capabilities. For more information about embedding using the old API operations, see [Embedding analytics using the `GetDashboardEmbedURL` and `GetSessionEmbedURL` API operations](#).

Applies to: Enterprise Edition

Intended audience: Amazon Quick developers

With Enterprise edition, in addition to providing read-only dashboards you can also provide the Amazon Quick Sight console experience in a custom-branded authoring portal. Using this approach, you allow your users to create data sources, datasets, and analyses. In the same interface, they can create, publish, and view dashboards. If you want to restrict some of those permissions, you can also do that.

Users who access Amazon Quick Sight through an embedded console need to belong to the author or admin security cohort. Readers don't have enough access to use the Amazon Quick Sight console for authoring, regardless of whether it's embedded or part of the AWS Management Console. However, authors and admins can still access embedded dashboards. If you want to restrict permissions to some of the authoring features, you can add a custom permissions profile to the user with the [UpdateUser](#) API operation. Use the [RegisterUser](#) API operation to add a new user with a custom permission profile attached. For more information, see the following sections:

- For information about creating custom roles by defining custom console permissions, see [Customizing Access to the Amazon Quick Sight Console](#).
- For information about using namespaces to isolate multitenancy users, groups, and Amazon Quick Sight assets, see [Amazon Quick Sight Namespaces](#).
- For information about adding your own branding to an embedded Amazon Quick Sight console, see [Using Themes in Amazon Quick Sight](#) and the [QuickSight Theme API Operations](#).

In the following sections, you can find detailed information about how to set up embedded Amazon Quick Sight dashboards for registered users.

Topics

- [Step 1: Set up permissions](#)
- [Step 2: Generate the URL with the authentication code attached](#)
- [Step 3: Embed the console session URL](#)
- [Enabling Generative BI features in embedded consoles for registered users](#)

Step 1: Set up permissions

In the following section, you can find out how to set up permissions for the backend application or web server. This task requires administrative access to IAM.

Each user who accesses a Amazon Quick Sight assumes a role that gives them Amazon Quick Sight access and permissions to the console session. To make this possible, create an IAM role in your AWS account. Associate an IAM policy with the role to provide permissions to any user who assumes it. Add `quicksight:RegisterUser` permissions to ensure that the reader can access Amazon Quick Sight in a read-only fashion, and not have access to any other data or creation capability. The IAM role also needs to provide permissions to retrieve console session URLs. For this, you add `quicksight:GenerateEmbedUrlForRegisteredUser`.

You can create a condition in your IAM policy that limits the domains that developers can list in the `AllowedDomains` parameter of a `GenerateEmbedUrlForAnonymousUser` API operation. The `AllowedDomains` parameter is an optional parameter. It grants you as a developer the option to override the static domains that are configured in the **Manage Amazon Quick Sight** menu. Instead, you can list up to three domains or subdomains that can access a generated URL. This URL is then embedded in the website that you create. Only the domains that are listed in the parameter can access the embedded dashboard. Without this condition, you can list any domain on the internet in the `AllowedDomains` parameter.

Security best practice for IAM condition operators

Improperly configured IAM condition operators can allow unauthorized access to your embedded Quick resources through URL variations. When using the `quicksight:AllowedEmbeddingDomains` condition key in your IAM policies, use condition operators that either allow specific domains or deny all domains that are not specifically allowed. For more information about IAM condition operators, see [IAM JSON policy elements: Condition operators](#) in the IAM User Guide.

Many different URL variations can point to the same resource. For example, the following URLs all resolve to the same content:

- `https://example.com`
- `https://example.com/`
- `https://Example.com`

If your policy uses operators that do not account for these URL variations, an attacker can bypass your restrictions by providing equivalent URL variations.

You must validate that your IAM policy uses appropriate condition operators to prevent bypass vulnerabilities and ensure that only your intended domains can access your embedded resources.

The following sample policy provides these permissions.

The following sample policy provides permission to retrieve a console session URL. You can use the policy without `quicksight:RegisterUser` if you are creating users before they access an embedded session.

Finally, your application's IAM identity must have a trust policy associated with it to allow access to the role that you just created. This means that when a user accesses your application, your application can assume the role on the user's behalf and provision the user in Amazon Quick Sight. The following example shows a sample trust policy.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowLambdaFunctionsToAssumeThisRole",
      "Effect": "Allow",
      "Principal": {
        "Service": "lambda.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    },
    {
```

```
        "Sid": "AllowEC2InstancesToAssumeThisRole",
        "Effect": "Allow",
        "Principal": {
            "Service": "ec2.amazonaws.com"
        },
        "Action": "sts:AssumeRole"
    }
]
```

For more information regarding trust policies for OpenID Connect or SAML authentication, see the following sections of the *IAM User Guide*:

- [Creating a Role for Web Identity or OpenID Connect Federation \(Console\)](#)
- [Creating a Role for SAML 2.0 Federation \(Console\)](#)

Step 2: Generate the URL with the authentication code attached

In the following section, you can find out how to authenticate your user and get the embeddable console session URL on your application server.

When a user accesses your app, the app assumes the IAM role on the user's behalf. Then it adds the user to Amazon Quick Sight, if that user doesn't already exist. Next, it passes an identifier as the unique role session ID.

Performing the described steps ensures that each viewer of the console session is uniquely provisioned in Amazon Quick Sight. It also enforces per-user settings, such as the row-level security and dynamic defaults for parameters.

The following examples perform the IAM authentication on the user's behalf. This code runs on your app server.

Java

Python3

```

import json
import boto3
from botocore.exceptions import ClientError

# Create QuickSight and STS clients
qs = boto3.client('quicksight', region_name='us-east-1')
sts = boto3.client('sts')

# Function to generate embedded URL
# accountId: AWS account ID
# userArn: arn of registered user
# allowedDomains: Runtime allowed domain for embedding
# roleArn: IAM user role to use for embedding
# sessionName: session name for the roleArn assume role
def generateEmbeddingURL(accountId, userArn, allowedDomains, roleArn, sessionName):
    try:
        assumedRole = sts.assume_role(
            RoleArn = roleArn,
            RoleSessionName = sessionName,
        )
    except ClientError as e:
        return "Error assuming role: " + str(e)
    else:
        assumedRoleSession = boto3.Session(
            aws_access_key_id = assumedRole['Credentials']['AccessKeyId'],
            aws_secret_access_key = assumedRole['Credentials']['SecretAccessKey'],
            aws_session_token = assumedRole['Credentials']['SessionToken'],
        )
        try:
            quickSightClient = assumedRoleSession.client('quicksight', region_name='us-
east-1')

            experienceConfiguration = {
                "QuickSightConsole": {

```

```

        "InitialPath": "/start"
    }
}
response = quickSightClient.generate_embed_url_for_registered_user(
    AwsAccountId = accountId,
    ExperienceConfiguration = experienceConfiguration,
    UserArn = userArn,
    AllowedDomains = allowedDomains,
    SessionLifetimeInMinutes = 600
)

return {
    'statusCode': 200,
    'headers': {"Access-Control-Allow-Origin": "*", "Access-Control-Allow-Headers": "Content-Type"},
    'body': json.dumps(response),
    'isBase64Encoded': bool('false')
}
except ClientError as e:
    return "Error generating embedding url: " + str(e)

```

Node.js

The following example shows the JavaScript (Node.js) that you can use on the app server to generate the URL for the embedded console session. You can use this URL in your website or app to display the console session.

Example

```

const AWS = require('aws-sdk');
const https = require('https');

var quicksightClient = new AWS.Service({
    apiConfig: require('./quicksight-2018-04-01.min.json'),
    region: 'us-east-1',
});

quicksightClient.generateEmbedUrlForRegisteredUser({
    'AwsAccountId': '111122223333',
    'ExperienceConfiguration': {
        'QuickSightConsole': {
            'InitialPath': '/start'
        }
    }
}

```

```
    },
    'UserArn': 'REGISTERED_USER_ARN',
    'AllowedDomains': allowedDomains,
    'SessionLifetimeInMinutes': 100
  }, function(err, data) {
    console.log('Errors: ');
    console.log(err);
    console.log('Response: ');
    console.log(data);
  });
```

Example

```
// The URL returned is over 900 characters. For this example, we've shortened the
// string for
// readability and added ellipsis to indicate that it's incomplete.
{
  Status: 200,
  EmbedUrl: 'https://quicksightdomain/embed/12345/dashboards/67890...',
  RequestId: '7bee030e-f191-45c4-97fe-d9faf0e03713'
}
```

.NET/C#

The following example shows the .NET/C# code that you can use on the app server to generate the URL for the embedded console session. You can use this URL in your website or app to display the console.

Example

```
using System;
using Amazon.QuickSight;
using Amazon.QuickSight.Model;

namespace GenerateDashboardEmbedUrlForRegisteredUser
{
    class Program
    {
        static void Main(string[] args)
        {
            var quicksightClient = new AmazonQuickSightClient(
                AccessKey,
                SecretAccessKey,
```

```

        SessionToken,
        Amazon.RegionEndpoint.USEast1);
    try
    {
        RegisteredUserQuickSightConsoleEmbeddingConfiguration
registeredUserQuickSightConsoleEmbeddingConfiguration
        = new RegisteredUserQuickSightConsoleEmbeddingConfiguration
        {
            InitialPath = "/start"
        };
        RegisteredUserEmbeddingExperienceConfiguration
registeredUserEmbeddingExperienceConfiguration
        = new RegisteredUserEmbeddingExperienceConfiguration
        {
            QuickSightConsole =
registeredUserQuickSightConsoleEmbeddingConfiguration
        };

        Console.WriteLine(
            quicksightClient.GenerateEmbedUrlForRegisteredUserAsync(new
GenerateEmbedUrlForRegisteredUserRequest
            {
                AwsAccountId = "111122223333",
                ExperienceConfiguration =
registeredUserEmbeddingExperienceConfiguration,
                UserArn = "REGISTERED_USER_ARN",
                AllowedDomains = allowedDomains,
                SessionLifetimeInMinutes = 100
            }).Result.EmbedUrl
        );
    } catch (Exception ex) {
        Console.WriteLine(ex.Message);
    }
}
}
}
}

```

AWS CLI

To assume the role, choose one of the following AWS Security Token Service (AWS STS) API operations:

- [AssumeRole](#) – Use this operation when you're using an IAM identity to assume the role.

- [AssumeRoleWithWebIdentity](#) – Use this operation when you're using a web identity provider to authenticate your user.
- [AssumeRoleWithSaml](#) – Use this operation when you're using SAML to authenticate your users.

The following example shows the CLI command to set the IAM role. The role needs to have permissions enabled for `quicksight:GenerateEmbedUrlForRegisteredUser`. If you are taking a just-in-time approach to add users when they first open Amazon Quick Sight, the role also needs permissions enabled for `quicksight:RegisterUser`.

```
aws sts assume-role \  
  --role-arn "arn:aws:iam::111122223333:role/embedding_quicksight_dashboard_role" \  
  --role-session-name john.doe@example.com
```

The `assume-role` operation returns three output parameters: the access key, the secret key, and the session token.

Note

If you get an `ExpiredToken` error when calling the `AssumeRole` operation, this is probably because the previous `SESSION_TOKEN` is still in the environment variables. Clear this by setting the following variables:

- `AWS_ACCESS_KEY_ID`
- `AWS_SECRET_ACCESS_KEY`
- `AWS_SESSION_TOKEN`

The following example shows how to set these three parameters in the CLI. If you're using a Microsoft Windows machine, use `set` instead of `export`.

```
export AWS_ACCESS_KEY_ID      = "access_key_from_assume_role"  
export AWS_SECRET_ACCESS_KEY  = "secret_key_from_assume_role"  
export AWS_SESSION_TOKEN      = "session_token_from_assume_role"
```

Running these commands sets the role session ID of the user visiting your website to `embedding_quicksight_console_session_role/john.doe@example.com`. The role session ID is made up of the role name from `role-arn` and the `role-session-name` value. Using the unique role session ID for each user ensures that appropriate permissions are set for each user. It

also prevents any throttling of user access. Throttling is a security feature that prevents the same user from accessing Amazon Quick Sight from multiple locations.

The role session ID also becomes the user name in Amazon Quick Sight. You can use this pattern to provision your users in Amazon Quick Sight ahead of time, or to provision them the first time they access a console session.

The following example shows the CLI command that you can use to provision a user. For more information about [RegisterUser](#), [DescribeUser](#), and other Amazon Quick Sight API operations, see the [Amazon Quick Sight API Reference](#).

```
aws quicksight register-user \  
  --aws-account-id 111122223333 \  
  --namespace default \  
  --identity-type IAM \  
  --iam-arn "arn:aws:iam::111122223333:role/embedding_quicksight_dashboard_role" \  
  --user-role READER \  
  --user-name jhnd \  
  --session-name "john.doe@example.com" \  
  --email john.doe@example.com \  
  --region us-east-1 \  
  --custom-permissions-name TeamA1
```

If the user is authenticated through Microsoft AD, you don't need to use `RegisterUser` to set them up. Instead, they should be automatically subscribed the first time they access Amazon Quick Sight. For Microsoft AD users, you can use `DescribeUser` to get the user ARN.

The first time a user accesses Amazon Quick Sight, you can also add this user to the appropriate group. The following example shows the CLI command to add a user to a group.

```
aws quicksight create-group-membership \  
  --aws-account-id=111122223333 \  
  --namespace=default \  
  --group-name=financeusers \  
  --member-name="embedding_quicksight_dashboard_role/john.doe@example.com"
```

You now have a user of your app who is also a user of Amazon Quick Sight, and who has access to the Amazon Quick Sight console session.

Finally, to get a signed URL for the console session, call `generate-embed-url-for-registered-user` from the app server. This returns the embeddable console session URL. The

following example shows how to generate the URL for an embedded console session using a server-side call for users authenticated through AWS Managed Microsoft AD or single sign-on (IAM Identity Center).

```
aws quicksight generate-embed-url-for-registered-user \
  --aws-account-id 111122223333 \
  --entry-point the-url-for--the-console-session \
  --session-lifetime-in-minutes 600 \
  --user-arn arn:aws:quicksight:us-east-1:111122223333:user/default/
embedding_quicksight_dashboard_role/embeddingsession
--allowed-domains '["domain1","domain2"]' \
--experience-configuration QuickSightConsole={InitialPath="/start"}
```

For more information about using this operation, see [GenerateEmbedUrlForRegisteredUser](#). You can use this and other API operations in your own code.

Step 3: Embed the console session URL

In the following section, you can find out how you can use the [Amazon Quick Sight Embedding SDK](#) (JavaScript) to embed the console session URL from step 3 in your website or application page. With the SDK, you can do the following:

- Place the console session on an HTML page.
- Pass parameters into the console session.
- Handle error states with messages that are customized to your application.

Call the `GenerateEmbedUrlForRegisteredUser` API operation to generate the URL that you can embed in your app. This URL is valid for 5 minutes, and the resulting session is valid for up to 10 hours. The API operation provides the URL with an `auth_code` that enables a single-sign on session.

The following shows an example response from `generate-embed-url-for-registered-user`.

```
//The URL returned is over 900 characters. For this example, we've shortened the string
for
//readability and added ellipsis to indicate that it's incomplete.
{
  "Status": "200",
  "EmbedUrl": "https://quicksightdomain/embedding/12345/start...",
  "RequestId": "7bee030e-f191-45c4-97fe-d9faf0e03713"
```

```
}
```

Embed this console session in your webpage by using the Amazon Quick Sight [Embedding SDK](#) or by adding this URL into an iframe. If you set a fixed height and width number (in pixels), Amazon Quick Sight uses those and doesn't change your visual as your window resizes. If you set a relative percent height and width, Amazon Quick Sight provides a responsive layout that is modified as your window size changes. By using the Amazon Quick Sight Embedding SDK, you can also control parameters within the console session and receive callbacks in terms of page load completion and errors.

The domain that is going to host embedded dashboards must be on the *allow list*, the list of approved domains for your Quick subscription. This requirement protects your data by keeping unapproved domains from hosting embedded dashboards. For more information about adding domains for an embedded console, see [Allow listing domains at runtime with the Amazon Quick Sight API](#).

The following example shows how to use the generated URL. This code is generated on your app server.

SDK 2.0

```
<!DOCTYPE html>
<html>

  <head>
    <title>Console Embedding Example</title>
    <script src="https://unpkg.com/amazon-quicksight-embedding-sdk@2.0.0/dist/
quicksight-embedding-js-sdk.min.js"></script>
    <script type="text/javascript">
      const embedSession = async() => {
        const {
          createEmbeddingContext,
        } = QuickSightEmbedding;

        const embeddingContext = await createEmbeddingContext({
          onChange: (changeEvent, metadata) => {
            console.log('Context received a change', changeEvent,
metadata);
          },
        });

        const frameOptions = {
```

```

        url: "<YOUR_EMBED_URL>", // replace this value with the url
generated via embedding API
        container: '#experience-container',
        height: "700px",
        width: "1000px",
        onChange: (changeEvent, metadata) => {
            switch (changeEvent.eventName) {
                case 'FRAME_MOUNTED': {
                    console.log("Do something when the experience frame is
mounted.");

                    break;
                }
                case 'FRAME_LOADED': {
                    console.log("Do something when the experience frame is
loaded.");

                    break;
                }
            }
        },
    };

    const contentOptions = {
        onMessage: async (messageEvent, experienceMetadata) => {
            switch (messageEvent.eventName) {
                case 'ERROR_OCCURRED': {
                    console.log("Do something when the embedded experience
fails loading.");

                    break;
                }
            }
        }
    };

    const embeddedConsoleExperience = await
embeddingContext.embedConsole(frameOptions, contentOptions);
};
</script>
</head>

<body onload="embedSession()">
    <div id="experience-container"></div>
</body>

</html>

```

SDK 1.0

```
<!DOCTYPE html>
<html>

  <head>
    <title>QuickSight Console Embedding</title>
    <script src="https://unpkg.com/amazon-quicksight-embedding-sdk@1.0.15/dist/
quicksight-embedding-js-sdk.min.js"></script>
    <script type="text/javascript">
      var session

      function onError(payload) {
        console.log("Do something when the session fails loading");
      }

      function embedSession() {
        var containerDiv = document.getElementById("embeddingContainer");
        var options = {
          // replace this dummy url with the one generated via embedding API
          url: "https://us-east-1.quicksight.aws.amazon.com/sn/dashboards/
dashboardId?isauthcode=true&identityprovider=quicksight&code=authcode", // replace this
dummy url with the one generated via embedding API
          container: containerDiv,
          parameters: {
            country: "United States"
          },
          scrolling: "no",
          height: "700px",
          width: "1000px",
          locale: "en-US",
          footerPaddingEnabled: true,
          defaultEmbeddingVisualType: "TABLE", // this option only applies to
QuickSight console embedding and is not used for dashboard embedding
        };
        session = QuickSightEmbedding.embedSession(options);
        session.on("error", onError);
      }

      function onCountryChange(obj) {
        session.setParameters({country: obj.value});
      }
    </script>
  </head>
```

```
<body onload="embedSession()">
  <span>
    <label for="country">Country</label>
    <select id="country" name="country" onchange="onCountryChange(this)">
      <option value="United States">United States</option>
      <option value="Mexico">Mexico</option>
      <option value="Canada">Canada</option>
    </select>
  </span>
  <div id="embeddingContainer"></div>
</body>

</html>
```

For this example to work, make sure to use the Amazon Quick Sight Embedding SDK to load the embedded console session on your website using JavaScript. To get your copy, do one of the following:

- Download the [Amazon Quick Sight Embedding SDK](#) from GitHub. This repository is maintained by a group of Amazon Quick Sight developers.
- Download the latest embedding SDK version from <https://www.npmjs.com/package/amazon-quicksight-embedding-sdk>.
- If you use npm for JavaScript dependencies, download and install it by running the following command.

```
npm install amazon-quicksight-embedding-sdk
```

Enabling Generative BI features in embedded consoles for registered users

Applies to: Enterprise Edition

Intended audience: Amazon Quick developers

You can enable the following Generative BI features in your embedded console:

- **Executive summaries:** When enabled, registered Author Pro and Reader Pro users can generate executive summaries that provide a summary of all insights that Amazon Quick Sight has generated for the dashboard to easily discover key insights.
- **Authoring:** When enabled, Author Pro users can use Generative BI to build calculated fields and build and refine visuals.
- **Q&A:** When enabled, Author Pro and Reader Pro users can use the AI-powered Q&A to both suggest and answer questions related their data.
- **Data stories:** When enabled, Author Pro and Reader Pro users can provide details to quickly generate a first draft of their data story.

To enable Generative BI features in embedded consoles for registered users

- Follow the steps in [Embedding the full functionality of the Amazon Quick Sight console for registered users](#) to embed a console with the following changes:
 - a. When generating the URL in Step 2, set `Enabled: true` in the `FeatureConfigurations` parameter for each of the features you want to enable in the [GenerateEmbedUrlForRegisteredUser](#) or [GenerateEmbedUrlForRegisteredUserWithIdentity](#) APIs, as shown in the following example. If no configuration is provided, the features are disabled by default.

```
ExperienceConfiguration: {
  QuickSightConsole: {
    InitialPath: "initial_path",
    AmazonQInQuickSight: {
      FeatureConfigurations: {
        COMMENT: Enable executive summaries
        ExecutiveSummary: {
          Enabled: true
        },
        COMMENT: Enable Generative BI authoring
        GenerativeAuthoring: {
          Enabled: true
        },
        COMMENT: Enable Q&A
        DataQnA: {
          Enabled: true
        },
        COMMENT: Enable data stories
```

```
DataStories: {  
    Enabled: true  
}  
  
}  
  
}  
  
}  
  
}
```

- b. When embedding the console URL with the Amazon Quick Sight Embedding SDK in Step 3, set the values in the following example as desired. If no configuration is provided, the features are disabled by default.

Note

There is no SDK option for enabling data stories. If data stories are enabled with the API as shown in the previous step, they will be available to registered users.

```
const contentOptions = {
  toolbarOptions: {
    executiveSummary: true, // Enable executive summaries
    buildVisual: true, // Enable Generative BI authoring
    dataQnA: true // Enable Q&A
  }
};
```

Embedding the Amazon Q in Amazon Quick Sight Generative Q&A experience

Intended audience: Amazon Quick developers

In the following sections, you can find detailed information about how to set up an embedded Generative Q&A experience that uses enhanced NLQ capabilities powered by LLMs. The Generative Q&A experience is the recommended replacement for the embedded Q Search Bar and provides an updated BI experience for users.

Topics

- [Embedding the Amazon Q in Amazon Quick Sight Generative Q&A experience for registered users](#)
- [Embedding the Amazon Q in Quick Generative Q&A experience for anonymous \(unregistered\) users](#)

Embedding the Amazon Q in Amazon Quick Sight Generative Q&A experience for registered users

In the following sections, you can find detailed information about how to set up an embedded Generative Q&A experience for registered users of Amazon Quick Sight.

Topics

- [Step 1: Set up permissions](#)
- [Step 2: Generate the URL with the authentication code attached](#)
- [Step 3: Embed the Generative Q&A experience URL](#)
- [Optional embedded Generative Q&A experience functionalities](#)

Step 1: Set up permissions

In the following section, you can find how to set up permissions for your backend application or web server to embed the Generative Q&A experience. This task requires administrative access to AWS Identity and Access Management (IAM).

Each user who accesses a Generative Q&A experience assumes a role that gives them Amazon Quick Sight access and permissions. To make this possible, create an IAM role in your AWS account. Associate an IAM policy with the role to provide permissions to any user who assumes it. The IAM role needs to provide permissions to retrieve embedding URLs for a specific user pool.

With the help of the wildcard character *, you can grant the permissions to generate a URL for all users in a specific namespace. Or you can grant permissions to generate a URL for a subset of users in specific namespaces. For this, you add `quicksight:GenerateEmbedUrlForRegisteredUser`.

You can create a condition in your IAM policy that limits the domains that developers can list in the `AllowedDomains` parameter of a `GenerateEmbedUrlForRegisteredUser` API operation. The `AllowedDomains` parameter is an optional parameter. It grants developers the option to override

the static domains that are configured in the **Manage Amazon Quick Sight** menu and instead list up to three domains or subdomains that can access a generated URL. This URL is then embedded in a developer's website. Only the domains that are listed in the parameter can access the embedded Generative Q&A experience. Without this condition, developers can list any domain on the internet in the `AllowedDomains` parameter.

To limit the domains that developers can use with this parameter, add an `AllowedEmbeddingDomains` condition to your IAM policy. For more information about the `AllowedDomains` parameter, see [GenerateEmbedUrlForRegisteredUser](#) in the *Amazon Quick Sight API Reference*.

Security best practice for IAM condition operators

Improperly configured IAM condition operators can allow unauthorized access to your embedded Quick resources through URL variations. When using the `quicksight:AllowedEmbeddingDomains` condition key in your IAM policies, use condition operators that either allow specific domains or deny all domains that are not specifically allowed. For more information about IAM condition operators, see [IAM JSON policy elements: Condition operators](#) in the IAM User Guide.

Many different URL variations can point to the same resource. For example, the following URLs all resolve to the same content:

- `https://example.com`
- `https://example.com/`
- `https://Example.com`

If your policy uses operators that do not account for these URL variations, an attacker can bypass your restrictions by providing equivalent URL variations.

You must validate that your IAM policy uses appropriate condition operators to prevent bypass vulnerabilities and ensure that only your intended domains can access your embedded resources.

The following sample policy provides these permissions.

Also, if you're creating first-time users who will be Amazon Quick Sight readers, make sure to add the `quicksight:RegisterUser` permission in the policy.

The following sample policy provides permission to retrieve an embedding URL for first-time users who are to be Amazon Quick Sight readers.

Finally, your application's IAM identity must have a trust policy associated with it to allow access to the role that you just created. This means that when a user accesses your application, your application can assume the role on the user's behalf and provision the user in Amazon Quick Sight.

The following example shows a sample trust policy.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowLambdaFunctionsToAssumeThisRole",
      "Effect": "Allow",
      "Principal": {
        "Service": "lambda.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    },
    {
      "Sid": "AllowEC2InstancesToAssumeThisRole",
      "Effect": "Allow",
      "Principal": {
        "Service": "ec2.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

For more information regarding trust policies for OpenID Connect or Security Assertion Markup Language (SAML) authentication, see the following sections of the *IAM User Guide*:

- [Creating a role for web identity or OpenID Connect federation \(console\)](#)
- [Creating a role for SAML 2.0 federation \(console\)](#)

Step 2: Generate the URL with the authentication code attached

In the following section, you can find how to authenticate your user and get the embeddable Q topic URL on your application server. If you plan to embed the Generative Q&A experience for IAM or Amazon Quick Sight identity types, share the Q topic with the users.

When a user accesses your app, the app assumes the IAM role on the user's behalf. Then the app adds the user to Amazon Quick Sight, if that user doesn't already exist. Next, it passes an identifier as the unique role session ID.

Performing the described steps ensures that each viewer of the Q topic is uniquely provisioned in Amazon Quick Sight. It also enforces per-user settings, such as the row-level security and dynamic defaults for parameters. Tag-based row-level security can be used for anonymous user embedding of the Q bar.

The following examples perform the IAM authentication on the user's behalf. This code runs on your app server.

Java

```
import com.amazonaws.auth.AWSCredentials;
import com.amazonaws.auth.BasicAWSCredentials;
import com.amazonaws.auth.AWSCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.quicksight.AmazonQuickSight;
import com.amazonaws.services.quicksight.AmazonQuickSightClientBuilder;
import
    com.amazonaws.services.quicksight.model.GenerateEmbedUrlForRegisteredUserRequest;
import com.amazonaws.services.quicksight.model.GenerateEmbedUrlForRegisteredUserResult;
import
    com.amazonaws.services.quicksight.model.RegisteredUserEmbeddingExperienceConfiguration;
import
    com.amazonaws.services.quicksight.model.RegisteredUserGenerativeQnAEmbeddingConfiguration;

/**
 * Class to call QuickSight AWS SDK to get url for embedding Generative Q&A experience.
 */
public class RegisteredUserGenerativeQnAEmbeddingSample {

    private final AmazonQuickSight quickSightClient;

    public RegisteredUserGenerativeQnAEmbeddingSample() {
        this.quickSightClient = AmazonQuickSightClientBuilder
```

```

        .standard()
        .withRegion(Regions.US_EAST_1.getName())
        .withCredentials(new AWSCredentialsProvider() {
            @Override
            public AWSCredentials getCredentials() {
                // provide actual IAM access key and secret key here
                return new BasicAWSCredentials("access-key", "secret-
key");
            }

            @Override
            public void refresh() {
            }
        })
        .build();
    }

    public String getQuicksightEmbedUrl(
        final String accountId, // AWS Account ID
        final String topicId, // Topic ID to embed
        final List<String> allowedDomains, // Runtime allowed domain for embedding
        final String userArn // Registered user arn to use for embedding. Refer to
Get Embed Url section in developer portal to find how to get user arn for a QuickSight
user.
    ) throws Exception {

        final RegisteredUserEmbeddingExperienceConfiguration experienceConfiguration =
new RegisteredUserEmbeddingExperienceConfiguration()
            .withGenerativeQnA(new
RegisteredUserGenerativeQnAEmbeddingConfiguration().withInitialTopicId(topicId));
        final GenerateEmbedUrlForRegisteredUserRequest
generateEmbedUrlForRegisteredUserRequest = new
GenerateEmbedUrlForRegisteredUserRequest();
        generateEmbedUrlForRegisteredUserRequest.setAwsAccountId(accountId);
        generateEmbedUrlForRegisteredUserRequest.setUserArn(userArn);
        generateEmbedUrlForRegisteredUserRequest.setAllowedDomains(allowedDomains);

        generateEmbedUrlForRegisteredUserRequest.setExperienceConfiguration(experienceConfiguration);

        final GenerateEmbedUrlForRegisteredUserResult
generateEmbedUrlForRegisteredUserResult =
quicksightClient.generateEmbedUrlForRegisteredUser(generateEmbedUrlForRegisteredUserRequest);

```

```
        return generateEmbedUrlForRegisteredUserResult.getEmbedUrl();
    }
}
```

JavaScript

Note

Embed URL generation APIs cannot be called from browsers directly. Refer to the Node.JS example instead.

Python3

```
import json
import boto3
from botocore.exceptions import ClientError

sts = boto3.client('sts')

# Function to generate embedded URL
# accountId: AWS account ID
# topicId: Topic ID to embed
# userArn: arn of registered user
# allowedDomains: Runtime allowed domain for embedding
# roleArn: IAM user role to use for embedding
# sessionName: session name for the roleArn assume role
def getEmbeddingURL(accountId, topicId, userArn, allowedDomains, roleArn, sessionName):
    try:
        assumedRole = sts.assume_role(
            RoleArn = roleArn,
            RoleSessionName = sessionName,
        )
    except ClientError as e:
        return "Error assuming role: " + str(e)
    else:
        assumedRoleSession = boto3.Session(
            aws_access_key_id = assumedRole['Credentials']['AccessKeyId'],
            aws_secret_access_key = assumedRole['Credentials']['SecretAccessKey'],
            aws_session_token = assumedRole['Credentials']['SessionToken'],
        )
        try:
```

```

    quicksightClient = assumedRoleSession.client('quicksight', region_name='us-
west-2')

    response = quicksightClient.generate_embed_url_for_registered_user(
        AwsAccountId=accountId,
        ExperienceConfiguration = {
            'GenerativeQnA': {
                'InitialTopicId': topicId
            }
        },
        UserArn = userArn,
        AllowedDomains = allowedDomains,
        SessionLifetimeInMinutes = 600
    )

    return {
        'statusCode': 200,
        'headers': {"Access-Control-Allow-Origin": "*", "Access-Control-Allow-
Headers": "Content-Type"},
        'body': json.dumps(response),
        'isBase64Encoded': bool('false')}
except ClientError as e:
    return "Error generating embedding url: " + str(e)

```

Node.js

The following example shows the JavaScript (Node.js) that you can use on the app server to generate the URL for the embedded dashboard. You can use this URL in your website or app to display the dashboard.

Example

```

const AWS = require('aws-sdk');
const https = require('https');

var quicksightClient = new AWS.Service({
    region: 'us-east-1'
});

quicksightClient.generateEmbedUrlForRegisteredUser({
    'AwsAccountId': '111122223333',
    'ExperienceConfiguration': {
        'GenerativeQnA': {

```

```

        'InitialTopicId': 'U4zJMVZ2n2stZflc80u3iKySEb3BEV6f'
    }
},
'UserArn': 'REGISTERED_USER_ARN',
'AllowedDomains': allowedDomains,
'SessionLifetimeInMinutes': 100
}, function(err, data) {
    console.log('Errors: ');
    console.log(err);
    console.log('Response: ');
    console.log(data);
});

```

.NET/C#

The following example shows the .NET/C# code that you can use on the app server to generate the URL for the embedded Q search bar. You can use this URL in your website or app to display the Q search bar.

Example

```

using System;
using Amazon.QuickSight;
using Amazon.QuickSight.Model;

namespace GenerateGenerativeQnAEmbedUrlForRegisteredUser
{
    class Program
    {
        static void Main(string[] args)
        {
            var quicksightClient = new AmazonQuickSightClient(
                AccessKey,
                SecretAccessKey,
                SessionToken,
                Amazon.RegionEndpoint.USEast1);

            try
            {
                RegisteredUserGenerativeQnAEmbeddingConfiguration
registeredUserGenerativeQnAEmbeddingConfiguration
                    = new RegisteredUserGenerativeQnAEmbeddingConfiguration
                    {
                        InitialTopicId = "U4zJMVZ2n2stZflc80u3iKySEb3BEV6f"

```

```

        };
        RegisteredUserEmbeddingExperienceConfiguration
registeredUserEmbeddingExperienceConfiguration
        = new RegisteredUserEmbeddingExperienceConfiguration
        {
            GenerativeQnA =
registeredUserGenerativeQnAEmbeddingConfiguration
        };

        Console.WriteLine(
            quicksightClient.GenerateEmbedUrlForRegisteredUserAsync(new
GenerateEmbedUrlForRegisteredUserRequest
            {
                AwsAccountId = "111122223333",
                ExperienceConfiguration =
registeredUserEmbeddingExperienceConfiguration,
                UserArn = "REGISTERED_USER_ARN",
                AllowedDomains = allowedDomains,
                SessionLifetimeInMinutes = 100
            }).Result.EmbedUrl
        );
    } catch (Exception ex) {
        Console.WriteLine(ex.Message);
    }
}
}
}
}

```

AWS CLI

To assume the role, choose one of the following AWS Security Token Service (AWS STS) API operations:

- [AssumeRole](#) – Use this operation when you are using an IAM identity to assume the role.
- [AssumeRoleWithWebIdentity](#) – Use this operation when you are using a web identity provider to authenticate your user.
- [AssumeRoleWithSaml](#) – Use this operation when you are using SAML to authenticate your users.

The following example shows the CLI command to set the IAM role. The role needs to have permissions enabled for `quicksight:GenerateEmbedUrlForRegisteredUser`. If you are

taking a just-in-time approach to add users when they use a topic in the Q search bar, the role also needs permissions enabled for `quicksight:RegisterUser`.

```
aws sts assume-role \  
  --role-arn "arn:aws:iam::111122223333:role/  
embedding_quicksight_q_generative_qna_role" \  
  --role-session-name john.doe@example.com
```

The `assume-role` operation returns three output parameters: the access key, the secret key, and the session token.

Note

If you get an `ExpiredToken` error when calling the `AssumeRole` operation, this is probably because the previous `SESSION_TOKEN` is still in the environment variables. Clear this by setting the following variables:

- `AWS_ACCESS_KEY_ID`
- `AWS_SECRET_ACCESS_KEY`
- `AWS_SESSION_TOKEN`

The following example shows how to set these three parameters in the CLI. For a Microsoft Windows machine, use `set` instead of `export`.

```
export AWS_ACCESS_KEY_ID      = "access_key_from_assume_role"  
export AWS_SECRET_ACCESS_KEY  = "secret_key_from_assume_role"  
export AWS_SESSION_TOKEN      = "session_token_from_assume_role"
```

Running these commands sets the role session ID of the user visiting your website to `embedding_quicksight_q_search_bar_role/john.doe@example.com`. The role session ID is made up of the role name from `role-arn` and the `role-session-name` value. Using the unique role session ID for each user ensures that appropriate permissions are set for each user. It also prevents any throttling of user access. *Throttling* is a security feature that prevents the same user from accessing Amazon Quick Sight from multiple locations.

The role session ID also becomes the user name in Amazon Quick Sight. You can use this pattern to provision your users in Amazon Quick Sight ahead of time, or to provision them the first time that they access the Generative Q&A experience.

The following example shows the CLI command that you can use to provision a user. For more information about [RegisterUser](#), [DescribeUser](#), and other Amazon Quick Sight API operations, see the [Amazon Quick Sight API reference](#).

```
aws quicksight register-user \  
  --aws-account-id 111122223333 \  
  --namespace default \  
  --identity-type IAM \  
  --iam-arn "arn:aws:iam::111122223333:role/  
embedding_quicksight_q_generative_qna_role" \  
  --user-role READER \  
  --user-name jhnd \  
  --session-name "john.doe@example.com" \  
  --email john.doe@example.com \  
  --region us-east-1 \  
  --custom-permissions-name TeamA1
```

If the user is authenticated through Microsoft AD, you don't need to use `RegisterUser` to set them up. Instead, they should be automatically subscribed the first time that they access Amazon Quick Sight. For Microsoft AD users, you can use `DescribeUser` to get the user Amazon Resource Name (ARN).

The first time a user accesses Amazon Quick Sight, you can also add this user to the group that the dashboard is shared with. The following example shows the CLI command to add a user to a group.

```
aws quicksight create-group-membership \  
  --aws-account-id 111122223333 \  
  --namespace default \  
  --group-name financeusers \  
  --member-name "embedding_quicksight_q_generative_qna_role/john.doe@example.com"
```

You now have a user of your app who is also a user of Amazon Quick Sight, and who has access to the dashboard.

Finally, to get a signed URL for the dashboard, call `generate-embed-url-for-registered-user` from the app server. This returns the embeddable dashboard URL. The following example shows how to generate the URL for an embedded dashboard using a server-side call for users authenticated through AWS Managed Microsoft AD or single sign-on (IAM Identity Center).

```
aws quicksight generate-embed-url-for-anonymous-user \  
  --aws-account-id 111122223333 \  
  --region us-east-1
```

```
--namespace default-or-something-else \  
--authorized-resource-arns '["topic-arn-topicId1","topic-arn-topicId2"]' \  
--allowed-domains '["domain1","domain2"]' \  
--experience-configuration 'GenerativeQnA={InitialTopicId="topicId1"}' \  
--session-tags '["Key": tag-key-1, "Value": tag-value-1, {"Key": tag-key-1, "Value": tag-value-1}]' \  
--session-lifetime-in-minutes 15
```

For more information about using this operation, see [GenerateEmbedUrlForRegisteredUser](#). You can use this and other API operations in your own code.

Step 3: Embed the Generative Q&A experience URL

In the following section, you can find how to embed the Generative Q&A experience URL in your website or application page. You do this with the [Amazon Quick Sight embedding SDK](#) (JavaScript). With the SDK, you can do the following:

- Place the Generative Q&A experience on an HTML page.
- Customize the layout and appearance of the embedded experience to fit your application needs.
- Handle error states with messages that are customized to your application.

To generate the URL that you can embed in your app, call the `GenerateEmbedUrlForRegisteredUser` API operation. This URL is valid for 5 minutes, and the resulting session is valid for up to 10 hours. The API operation provides the URL with an `auth_code` value that enables a single-sign on session.

The following shows an example response from `generate-embed-url-for-registered-user`.

```
//The URL returned is over 900 characters. For this example, we've shortened the string  
for  
//readability and added ellipsis to indicate that it's incomplete.  
{  
  "Status": "200",  
  "EmbedUrl": "https://quicksightdomain/embedding/12345/q/search...",  
  "RequestId": "7bee030e-f191-45c4-97fe-d9faf0e03713"  
}
```

Embed the Generative Q&A experience in your webpage by using the [Amazon Quick Sight embedding SDK](#) or by adding this URL into an iframe. If you set a fixed height and width number (in pixels), Amazon Quick Sight uses those and doesn't change your visual as your window resizes. If

you set a relative percent height and width, Amazon Quick Sight provides a responsive layout that is modified as your window size changes.

Make sure that the domain to host the embedded Generative Q&A experience is on the *allow list*, the list of approved domains for your Amazon Quick Sight subscription. This requirement protects your data by keeping unapproved domains from hosting embedded dashboards. For more information about adding domains for an embedded Generative Q&A experience, see [Managing domains](#).

You can use the Amazon Quick Sight Embedding SDK to customize the layout and appearance of the embedded Generative Q&A experience to fit your application. Use the `panelType` property to configure the landing state of the Generative Q&A experience when it renders in your application. Set the `panelType` property to 'FULL' to render the full Generative Q&A experience panel. This panel resembles the experience that Amazon Quick Sight users have in the Amazon Quick Sight console. The frame height of the panel is not changed based on user interaction and respects the value that you set in the `frameOptions.height` property. The image below shows the Generative Q&A experience panel that renders when you set the `panelType` value to 'FULL'.

Set the `panelType` property to 'SEARCH_BAR' to render the Generative Q&A experience as a search bar. This search bar resembles the way that the Q Search Bar renders when it is embedded into an application. The Generative Q&A search bar expands to a larger panel that displays topic selection options, the question suggestion list, the answer panel or the pinboard.

The default minimum height of the Generative Q&A search bar is rendered when the embedded asset loads. It is recommended that you set the `frameOptions.height` value to "38px" to optimize the search bar experience. Use the `focusedHeight` property to set the optimal size of the topic selection dropdown and the question suggestion list. Use the `expandedHeight` property to set the optimal size of the answer panel and pinboard. If you choose the 'SEARCH_BAR' option, it is recommended that you style the parent container with `position: absolute` to avoid unwanted content shifting in your application. The image below shows the Generative Q&A experience search bar that renders when you set the `panelType` value to 'SEARCH_BAR'.

After you configure the `panelType` property, use the Amazon Quick Sight embedding SDK to customize the following properties of the Generative Q&A experience.

- The title of the Generative Q&A panel (Applies only to the `panelType`: FULL option).
- The search bar's placeholder text.
- Whether topic selection is allowed.

- Whether topic names are shown or hidden.
- Whether the Amazon Q icon is shown or hidden (Applies only to the `panelType`: FULL option).
- Whether the pinboard is shown or hidden.
- Whether users can maximize the Generative Q&A panel to fullscreen.
- The theme of the Generative Q&A panel. A custom theme ARN can be passed in the SDK to change the appearance of the frame's content. Amazon Quick Sight starter themes are not supported for embedded Generative BI panels. To use an Amazon Quick Sight starter theme, save it as a custom theme in Amazon Quick Sight.

When you use the Amazon Quick Sight Embedding SDK, the Generative Q&A experience on your page is dynamically resized based on the state. By using the Amazon Quick Sight Embedding SDK, you can also control parameters within the Generative Q&A experience and receive callbacks in terms of page load completion, state changes, and errors.

The following example shows how to use the generated URL. This code is generated on your app server.

SDK 2.0

```
<!DOCTYPE html>
<html>
  <head>
    <title>Generative Q&A Embedding Example</title>
    <script src="https://unpkg.com/amazon-quicksight-embedding-sdk@2.7.0/dist/
quicksight-embedding-js-sdk.min.js"></script>
    <script type="text/javascript">
      const embedGenerativeQnA = async() => {
        const {createEmbeddingContext} = QuickSightEmbedding;

        const embeddingContext = await createEmbeddingContext({
          onChange: (changeEvent, metadata) => {
            console.log('Context received a change', changeEvent,
metadata);
          },
        });

        const frameOptions = {
          url: "<YOUR_EMBED_URL>", // replace this value with the url
generated via embedding API
          container: '#experience-container',
```

```

        height: "700px",
        width: "1000px",
        onChange: (changeEvent, metadata) => {
            switch (changeEvent.eventName) {
                case 'FRAME_MOUNTED': {
                    console.log("Do something when the experience frame is
mounted.");

                    break;
                }
                case 'FRAME_LOADED': {
                    console.log("Do something when the experience frame is
loaded.");

                    break;
                }
            }
        },
    };

    const contentOptions = {
        // Optional panel settings. Default behavior is equivalent to
        {panelType: 'FULL'}
        panelOptions: {
            panelType: 'FULL',
            title: 'custom title', // Optional
            showQIcon: false, // Optional, Default: true
        },
        // Use SEARCH_BAR panel type for the landing state to be similar to
embedQSearchBar
        // with generative capability enabled topics
        /*
        panelOptions: {
            panelType: 'SEARCH_BAR',
            focusedHeight: '250px',
            expandedHeight: '500px',
        },
        */
        showTopicName: false, // Optional, Default: true
        showPinboard: false, // Optional, Default: true
        allowTopicSelection: false, // Optional, Default: true
        allowFullscreen: false, // Optional, Default: true
        searchPlaceholderText: "custom search placeholder", // Optional
        themeOptions: { // Optional
            themeArn: 'arn:aws:quicksight:<Region>:<AWS-Account-ID>:theme/
<Theme-ID>'

```

```

    }
    onMessage: async (messageEvent, experienceMetadata) => {
      switch (messageEvent.eventName) {
        case 'Q_SEARCH_OPENED': {
          // called when pinboard is shown / visuals are rendered
          console.log("Do something when SEARCH_BAR type panel is
expanded");

          break;
        }
        case 'Q_SEARCH_FOCUSED': {
          // called when question suggestions or topic selection
dropdown are shown

          console.log("Do something when SEARCH_BAR type panel is
focused");

          break;
        }
        case 'Q_SEARCH_CLOSED': {
          // called when shrunk to initial bar height
          console.log("Do something when SEARCH_BAR type panel is
collapsed");

          break;
        }
        case 'Q_PANEL_ENTERED_FULLSCREEN': {
          console.log("Do something when panel enters full screen
mode");

          break;
        }
        case 'Q_PANEL_EXITED_FULLSCREEN': {
          console.log("Do something when panel exits full screen
mode");

          break;
        }
        case 'CONTENT_LOADED': {
          console.log("Do something after experience is loaded");
          break;
        }
        case 'ERROR_OCCURRED': {
          console.log("Do something when experience fails to
load");

          break;
        }
      }
    }
  };

```

```
        const embeddedGenerativeQnExperience = await
embeddingContext.embedGenerativeQnA(frameOptions, contentOptions);
    };
</script>
</head>

<body onload="embedGenerativeQnA()">
    <div id="experience-container"></div>
</body>

</html>
```

For this example to work, make sure to use the Amazon Quick Sight Embedding SDK to load the embedded Generative Q&A experience on your website with JavaScript. To get your copy, do one of the following:

- Download the [Amazon Quick Sight embedding SDK](#) from GitHub. This repository is maintained by a group of Amazon Quick Sight developers.
- Download the latest embedding SDK version from <https://www.npmjs.com/package/amazon-quicksight-embedding-sdk>.
- If you use npm for JavaScript dependencies, download and install it by running the following command.

```
npm install amazon-quicksight-embedding-sdk
```

Optional embedded Generative Q&A experience functionalities

The following optional functionalities are available for the embedded Generative Q&A experience with the embedding SDK.

Invoke Generative Q&A search bar actions

- Set a question — This feature sends a question to the Generative Q&A experience and immediately queries the question.

```
embeddedGenerativeQnExperience.setQuestion('show me monthly revenue');
```

- Close the answer panel (applies to the Generative Q&A search bar option) — This feature closes the answer panel and returns the iframe to the original search bar state.

```
embeddedGenerativeQnExperience.close();
```

For more information, see the [Amazon Quick Sight embedding SDK](#).

Embedding the Amazon Q in Quick Generative Q&A experience for anonymous (unregistered) users

Intended audience: Amazon Quick developers

In the following sections, you can find detailed information about how to set up an embedded Generative Q&A experience for anonymous (unregistered) users.

Topics

- [Step 1: Set up permissions](#)
- [Step 2: Generate the URL with the authentication code attached](#)
- [Step 3: Embed the Generative Q&A experience URL](#)
- [Optional embedded Generative Q&A experience functionalities](#)

Step 1: Set up permissions

In the following section, you can find how to set up permissions for your backend application or web server to embed the Generative Q&A experience. This task requires administrative access to AWS Identity and Access Management (IAM).

Each user who accesses a Generative Q&A experience assumes a role that gives them Amazon Quick Sight access and permissions. To make this possible, create an IAM role in your AWS account. Associate an IAM policy with the role to provide permissions to any user who assumes it. The IAM role needs to provide permissions to retrieve embedding URLs for a specific user pool.

With the help of the wildcard character *, you can grant the permissions to generate a URL for all users in a specific namespace. Or you can grant permissions to generate a URL for a subset of users in specific namespaces. For this, you add `quicksight:GenerateEmbedUrlForAnonymousUser`.

You can create a condition in your IAM policy that limits the domains that developers can list in the `AllowedDomains` parameter of a `GenerateEmbedUrlForAnonymousUser` API operation.

The `AllowedDomains` parameter is an optional parameter. It grants developers the option to override the static domains that are configured in the **Manage Amazon Quick Sight** menu and instead list up to three domains or subdomains that can access a generated URL. This URL is then embedded in a developer's website. Only the domains that are listed in the parameter can access the embedded Q search bar. Without this condition, developers can list any domain on the internet in the `AllowedDomains` parameter.

To limit the domains that developers can use with this parameter, add an `AllowedEmbeddingDomains` condition to your IAM policy. For more information about the `AllowedDomains` parameter, see [GenerateEmbedUrlForAnonymousUser](#) in the *Amazon Quick Sight API Reference*.

Security best practice for IAM condition operators

Improperly configured IAM condition operators can allow unauthorized access to your embedded Quick resources through URL variations. When using the `quicksight:AllowedEmbeddingDomains` condition key in your IAM policies, use condition operators that either allow specific domains or deny all domains that are not specifically allowed. For more information about IAM condition operators, see [IAM JSON policy elements: Condition operators](#) in the IAM User Guide.

Many different URL variations can point to the same resource. For example, the following URLs all resolve to the same content:

- `https://example.com`
- `https://example.com/`
- `https://Example.com`

If your policy uses operators that do not account for these URL variations, an attacker can bypass your restrictions by providing equivalent URL variations.

You must validate that your IAM policy uses appropriate condition operators to prevent bypass vulnerabilities and ensure that only your intended domains can access your embedded resources.

Your application's IAM identity must have a trust policy associated with it to allow access to the role that you just created. This means that when a user accesses your application, your application

can assume the role on the user's behalf to load the Generative Q&A experience. The following example shows a sample trust policy.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowLambdaFunctionsToAssumeThisRole",
      "Effect": "Allow",
      "Principal": {
        "Service": "lambda.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    },
    {
      "Sid": "AllowEC2InstancesToAssumeThisRole",
      "Effect": "Allow",
      "Principal": {
        "Service": "ec2.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

For more information regarding trust policies, see [Temporary security credentials in IAM](#) in the *IAM User Guide*

Step 2: Generate the URL with the authentication code attached

In the following section, you can find how to authenticate your user and get the embeddable Q topic URL on your application server.

When a user accesses your app, the app assumes the IAM role on the user's behalf. Then the app adds the user to Amazon Quick Sight, if that user doesn't already exist. Next, it passes an identifier as the unique role session ID.

    private final AmazonQuickSight quickSightClient;

    public GenerateEmbedUrlForAnonymousUserExample() {
        quickSightClient = AmazonQuickSightClientBuilder
            .standard()
            .withRegion(Regions.US_EAST_1.getName())
            .withCredentials(new AWSCredentialsProvider() {
                @Override
                public AWSCredentials getCredentials() {
                    // provide actual IAM access key and secret key here
                    return new BasicAWSCredentials("access-key", "secret-key");
                }

                @Override
                public void refresh() {
                }
            })
            .build();
    }

    public String GenerateEmbedUrlForAnonymousUser(
```

```

        final String accountId, // YOUR AWS ACCOUNT ID
        final String initialTopicId, // Q TOPIC ID TO WHICH THE CONSTRUCTED URL POINTS
        AND EXPERIENCE PREPOPULATES INITIALLY
        final String namespace, // ANONYMOUS EMBEDDING REQUIRES SPECIFYING A VALID
        NAMESPACE FOR WHICH YOU WANT THE EMBEDDING URL
        final List<String> authorizedResourceArns, // Q TOPIC ARN LIST TO EMBED
        final List<String> allowedDomains, // RUNTIME ALLOWED DOMAINS FOR EMBEDDING
        final List<SessionTag> sessionTags // SESSION TAGS USED FOR ROW-LEVEL SECURITY
    ) throws Exception {
        AnonymousUserEmbeddingExperienceConfiguration experienceConfiguration = new
        AnonymousUserEmbeddingExperienceConfiguration();
        AnonymousUserGenerativeQnAEmbeddingConfiguration generativeQnAConfiguration =
        new AnonymousUserGenerativeQnAEmbeddingConfiguration();
        generativeQnAConfiguration.setInitialTopicId(initialTopicId);
        experienceConfiguration.setGenerativeQnA(generativeQnAConfiguration);

        GenerateEmbedUrlForAnonymousUserRequest generateEmbedUrlForAnonymousUserRequest
        = new GenerateEmbedUrlForAnonymousUserRequest()
            .withAwsAccountId(accountId)
            .withNamespace(namespace)
            .withAuthorizedResourceArns(authorizedResourceArns)
            .withExperienceConfiguration(experienceConfiguration)
            .withSessionTags(sessionTags)
            .withSessionLifetimeInMinutes(600L); // OPTIONAL: VALUE CAN BE [15-600].
        DEFAULT: 600
            .withAllowedDomains(allowedDomains);

        GenerateEmbedUrlForAnonymousUserResult result =
        quickSightClient.generateEmbedUrlForAnonymousUser(generateEmbedUrlForAnonymousUserRequest);

        return result.getEmbedUrl();
    }
}

```

JavaScript

Note

Embed URL generation APIs cannot be called from browsers directly. Refer to the Node.JS example instead.

Python3

```
import json
import boto3
from botocore.exceptions import ClientError
import time

# Create QuickSight and STS clients
quicksightClient = boto3.client('quicksight', region_name='us-west-2')
sts = boto3.client('sts')

# Function to generate embedded URL for anonymous user
# accountId: YOUR AWS ACCOUNT ID
# topicId: Topic ID to embed
# quicksightNamespace: VALID NAMESPACE WHERE YOU WANT TO DO NOAUTH EMBEDDING
# authorizedResourceArns: TOPIC ARN LIST TO EMBED
# allowedDomains: RUNTIME ALLOWED DOMAINS FOR EMBEDDING
# sessionTags: SESSION TAGS USED FOR ROW-LEVEL SECURITY
def generateEmbedUrlForAnonymousUser(accountId, quicksightNamespace,
    authorizedResourceArns, allowedDomains, sessionTags):
    try:
        response = quicksightClient.generate_embed_url_for_anonymous_user(
            AwsAccountId = accountId,
            Namespace = quicksightNamespace,
            AuthorizedResourceArns = authorizedResourceArns,
            AllowedDomains = allowedDomains,
            ExperienceConfiguration = {
                'GenerativeQnA': {
                    'InitialTopicId': topicId
                }
            },
            SessionTags = sessionTags,
            SessionLifetimeInMinutes = 600
        )

        return {
            'statusCode': 200,
            'headers': {"Access-Control-Allow-Origin": "*", "Access-Control-Allow-Headers": "Content-Type"},
            'body': json.dumps(response),
            'isBase64Encoded': bool('false')
        }
    except ClientError as e:
        print(e)
```

```
return "Error generating embeddedURL: " + str(e)
```

Node.js

The following example shows the JavaScript (Node.js) that you can use on the app server to generate the URL for the embedded dashboard. You can use this URL in your website or app to display the dashboard.

Example

```
const AWS = require('aws-sdk');
const https = require('https');

var quicksightClient = new AWS.Service({
    region: 'us-east-1',
});

quicksightClient.generateEmbedUrlForAnonymousUser({
    'AwsAccountId': '111122223333',
    'Namespace': 'DEFAULT',
    'AuthorizedResourceArns': '["topic-arn-topicId1","topic-arn-topicId2"]',
    'AllowedDomains': allowedDomains,
    'ExperienceConfiguration': {
        'GenerativeQnA': {
            'InitialTopicId': 'U4zJMVZ2n2stZf1c80u3iKySEb3BEV6f'
        }
    },
    'SessionTags': '["Key": tag-key-1,"Value": tag-value-1,{"Key": tag-key-1,"Value": tag-value-1}]',
    'SessionLifetimeInMinutes': 15
}, function(err, data) {
    console.log('Errors: ');
    console.log(err);
    console.log('Response: ');
    console.log(data);
});
```

.NET/C#

The following example shows the .NET/C# code that you can use on the app server to generate the URL for the embedded Q search bar. You can use this URL in your website or app to display the Q search bar.

Example

```
using System;
using Amazon.QuickSight;
using Amazon.QuickSight.Model;

namespace GenerateGenerativeQnAEmbedUrlForAnonymousUser
{
    class Program
    {
        static void Main(string[] args)
        {
            var quicksightClient = new AmazonQuickSightClient(
                AccessKey,
                SecretAccessKey,
                SessionToken,
                Amazon.RegionEndpoint.USEast1);
            try
            {
                AnonymousUserGenerativeQnAEmbeddingConfiguration
anonymousUserGenerativeQnAEmbeddingConfiguration
                = new AnonymousUserGenerativeQnAEmbeddingConfiguration
                {
                    InitialTopicId = "U4zJMVZ2n2stZflc80u3iKySEb3BEV6f"
                };
                AnonymousUserEmbeddingExperienceConfiguration
anonymousUserEmbeddingExperienceConfiguration
                = new AnonymousUserEmbeddingExperienceConfiguration
                {
                    GenerativeQnA =
anonymousUserGenerativeQnAEmbeddingConfiguration
                };

                Console.WriteLine(
                    quicksightClient.GenerateEmbedUrlForAnonymousUserAsync(new
GenerateEmbedUrlForAnonymousUserRequest
                {
                    AwsAccountId = "111122223333",
                    Namespace = "DEFAULT",
                    AuthorizedResourceArns ["topic-arn-topicId1","topic-arn-
topicId2"]',
                    AllowedDomains = allowedDomains,
                    ExperienceConfiguration =
anonymousUserEmbeddingExperienceConfiguration,
```

```

        SessionTags = '[{"Key": tag-key-1,"Value": tag-value-1,{"Key":
tag-key-1,"Value": tag-value-1}}]',
        SessionLifetimeInMinutes = 15,
    })).Result.EmbedUrl
    );
} catch (Exception ex) {
    Console.WriteLine(ex.Message);
}
}
}
}
}

```

AWS CLI

To assume the role, choose one of the following AWS Security Token Service (AWS STS) API operations:

- [AssumeRole](#) – Use this operation when you are using an IAM identity to assume the role.
- [AssumeRoleWithWebIdentity](#) – Use this operation when you are using a web identity provider to authenticate your user.
- [AssumeRoleWithSaml](#) – Use this operation when you are using SAML to authenticate your users.

The following example shows the CLI command to set the IAM role. The role needs to have permissions enabled for `quicksight:GenerateEmbedUrlForAnonymousUser`.

```

aws sts assume-role \
    --role-arn "arn:aws:iam::111122223333:role/
embedding_quicksight_generative_qna_role" \
    --role-session-name anonymous caller

```

The `assume-role` operation returns three output parameters: the access key, the secret key, and the session token.

Note

If you get an `ExpiredToken` error when calling the `AssumeRole` operation, this is probably because the previous `SESSION_TOKEN` is still in the environment variables. Clear this by setting the following variables:

- `AWS_ACCESS_KEY_ID`

- `AWS_SECRET_ACCESS_KEY`
- `AWS_SESSION_TOKEN`

The following example shows how to set these three parameters in the CLI. For a Microsoft Windows machine, use `set` instead of `export`.

```
export AWS_ACCESS_KEY_ID      = "access_key_from_assume_role"
export AWS_SECRET_ACCESS_KEY  = "secret_key_from_assume_role"
export AWS_SESSION_TOKEN      = "session_token_from_assume_role"
```

Running these commands sets the role session ID of the user visiting your website to `embedding_quicksight_q_search_bar_role/QuickSightEmbeddingAnonymousPolicy`. The role session ID is made up of the role name from `role-arn` and the `role-session-name` value. Using the unique role session ID for each user ensures that appropriate permissions are set for each user. It also prevents any throttling of user access. *Throttling* is a security feature that prevents the same user from accessing Amazon Quick Sight from multiple locations. In addition, it keeps each session separate and distinct. If you're using an array of web servers, for example for load balancing, and a session is reconnected to a different server, a new session begins.

To get a signed URL for the dashboard, call `generate-embed-url-for-anonymous-user` from the app server. This returns the embeddable dashboard URL. The following example shows how to generate the URL for an embedded dashboard using a server-side call for users who are making anonymous visits to your web portal or app.

```
aws quicksight generate-embed-url-for-anonymous-user \
--aws-account-id 111122223333 \
--namespace default-or-something-else \
--authorized-resource-arns '["topic-arn-topicId","topic-arn-topicId2"]' \
--allowed-domains '["domain1","domain2"]' \
--experience-configuration 'GenerativeQnA={InitialTopicId="topicId1"}' \
--session-tags '["Key": tag-key-1,"Value": tag-value-1,{"Key": tag-key-1,"Value": tag-value-1}]' \
--session-lifetime-in-minutes 15
```

For more information about using this operation, see [GenerateEmbedUrlForAnonymousUser](#). You can use this and other API operations in your own code.

Step 3: Embed the Generative Q&A experience URL

In the following section, you can find how to embed the Generative Q&A experience URL in your website or application page. You do this with the [Amazon Quick Sight embedding SDK](#) (JavaScript). With the SDK, you can do the following:

- Place the Generative Q&A experience on an HTML page.
- Customize the layout and appearance of the embedded experience to fit your application needs.
- Handle error states with messages that are customized to your application.

To generate the URL that you can embed in your app, call the `GenerateEmbedUrlForAnonymousUser` API operation. This URL is valid for 5 minutes, and the resulting session is valid for up to 10 hours. The API operation provides the URL with an `auth_code` value that enables a single-sign on session.

The following shows an example response from `generate-embed-url-for-anonymous-user`.

```
//The URL returned is over 900 characters. For this example, we've shortened the string
for
//readability and added ellipsis to indicate that it's incomplete.{
  "Status": "200",
  "EmbedUrl": "https://quicksightdomain/embedding/12345/q/search...",
  "RequestId": "7bee030e-f191-45c4-97fe-d9faf0e03713"
}
```

Embed the Generative Q&A experience in your webpage with the [Amazon Quick Sight embedding SDK](#) or by adding this URL into an `iframe`. If you set a fixed height and width number (in pixels), Amazon Quick Sight uses those and doesn't change your visual as your window resizes. If you set a relative percent height and width, Amazon Quick Sight provides a responsive layout that is modified as your window size changes.

Make sure that the domain to host the Generative Q&A experience is on the *allow list*, the list of approved domains for your Amazon Quick Sight subscription. This requirement protects your data by keeping unapproved domains from hosting embedded Generative Q&A experiences. For more information about adding domains for an embedded Generative Q&A experience, see [Managing domains](#).

You can use the Amazon Quick Sight Embedding SDK to customize the layout and appearance of the embedded Generative Q&A experience to fit your application. Use the `panelType` property to

configure the landing state of the Generative Q&A experience when it renders in your application. Set the `panelType` property to `'FULL'` to render the full Generative Q&A experience panel. This panel resembles the experience that Amazon Quick Sight users have in the Amazon Quick Sight console. The frame height of the panel is not changed based on user interaction and respects the value that you set in the `frameOptions.height` property. The image below shows the Generative Q&A experience panel that renders when you set the `panelType` value to `'FULL'`.

Set the `panelType` property to `'SEARCH_BAR'` to render the Generative Q&A experience as a search bar. This search bar resembles the way that the Q Search Bar renders when it is embedded into an application. The Generative Q&A search bar expands to a larger panel that displays topic selection options, the question suggestion list, the answer panel or the pinboard.

The default minimum height of the Generative Q&A search bar is rendered when the embedded asset loads. It is recommended that you set the `frameOptions.height` value to `"38px"` to optimize the search bar experience. Use the `focusedHeight` property to set the optimal size of the topic selection dropdown and the question suggestion list. Use the `expandedHeight` property to set the optimal size of the answer panel and pinboard. If you choose the `'SEARCH_BAR'` option, it is recommended that you style the parent container with `position; absolute` to avoid unwanted content shifting in your application. The image below shows the Generative Q&A experience search bar that renders when you set the `panelType` value to `'SEARCH_BAR'`.

After you configure the `panelType` property, use the Amazon Quick Sight embedding SDK to customize the following properties of the Generative Q&A experience.

- The title of the Generative Q&A panel (Applies only to the `panelType: FULL` option).
- The search bar's placeholder text.
- Whether topic selection is allowed.
- Whether topic names are shown or hidden.
- Whether the Amazon Q icon is shown or hidden (Applies only to the `panelType: FULL` option).
- Whether the pinboard is shown or hidden.
- Whether users can maximize the Generative Q&A panel to fullscreen.
- The theme of the Generative Q&A panel. A custom theme ARN can be passed in the SDK to change the appearance of the frame's content. Amazon Quick Sight starter themes are not supported for embedded Generative BI panels. To use a Amazon Quick Sight starter theme, save it as a custom theme in Amazon Quick Sight.

When you use the Amazon Quick Sight Embedding SDK, the Generative Q&A experience on your page is dynamically resized based on the state. With the Amazon Quick Sight Embedding SDK, you can also control parameters within the Generative Q&A experience and receive callbacks in terms of page load completion, state changes, and errors.

The following example shows how to use the generated URL. This code is generated on your app server.

SDK 2.0

```
<!DOCTYPE html>
<html>
  <head>
    <title>Generative Q&A Embedding Example</title>
    <script src="https://unpkg.com/amazon-quicksight-embedding-sdk@2.7.0/dist/
quicksight-embedding-js-sdk.min.js"></script>
    <script type="text/javascript">
      const embedGenerativeQnA = async() => {
        const {createEmbeddingContext} = QuickSightEmbedding;

        const embeddingContext = await createEmbeddingContext({
          onChange: (changeEvent, metadata) => {
            console.log('Context received a change', changeEvent,
metadata);
          },
        });

        const frameOptions = {
          url: "<YOUR_EMBED_URL>", // replace this value with the url
generated via embedding API
          container: '#experience-container',
          height: "700px",
          width: "1000px",
          onChange: (changeEvent, metadata) => {
            switch (changeEvent.eventName) {
              case 'FRAME_MOUNTED': {
                console.log("Do something when the experience frame is
mounted.");
                break;
              }
              case 'FRAME_LOADED': {
                console.log("Do something when the experience frame is
loaded.");
            }
```

```

        break;
    }
    },
};

const contentOptions = {
    // Optional panel settings. Default behavior is equivalent to
    {panelType: 'FULL'}
    panelOptions: {
        panelType: 'FULL',
        title: 'custom title', // Optional
        showQIcon: false, // Optional, Default: true
    },
    // Use SEARCH_BAR panel type for the landing state to be similar to
    embedQSearchBar
    // with generative capability enabled topics
    /*
    panelOptions: {
        panelType: 'SEARCH_BAR',
        focusedHeight: '250px',
        expandedHeight: '500px',
    },
    */
    showTopicName: false, // Optional, Default: true
    showPinboard: false, // Optional, Default: true
    allowTopicSelection: false, // Optional, Default: true
    allowFullscreen: false, // Optional, Default: true
    searchPlaceholderText: "custom search placeholder", // Optional
    themeOptions: { // Optional
        themeArn: 'arn:aws:quicksight:<Region>:<AWS-Account-ID>:theme/
<Theme-ID>'
    }
    onMessage: async (messageEvent, experienceMetadata) => {
        switch (messageEvent.eventName) {
            case 'Q_SEARCH_OPENED': {
                // called when pinboard is shown / visuals are rendered
                console.log("Do something when SEARCH_BAR type panel is
expanded");

                break;
            }
            case 'Q_SEARCH_FOCUSED': {
                // called when question suggestions or topic selection
dropdown are shown

```

```

        console.log("Do something when SEARCH_BAR type panel is
focused");
        break;
    }
    case 'Q_SEARCH_CLOSED': {
        // called when shrunk to initial bar height
        console.log("Do something when SEARCH_BAR type panel is
collapsed");
        break;
    }
    case 'Q_PANEL_ENTERED_FULLSCREEN': {
        console.log("Do something when panel enters full screen
mode");
        break;
    }
    case 'Q_PANEL_EXITED_FULLSCREEN': {
        console.log("Do something when panel exits full screen
mode");
        break;
    }
    case 'CONTENT_LOADED': {
        console.log("Do something after experience is loaded");
        break;
    }
    case 'ERROR_OCCURRED': {
        console.log("Do something when experience fails to
load");
        break;
    }
}
}
};
const embeddedGenerativeQnExperience = await
embeddingContext.embedGenerativeQnA(frameOptions, contentOptions);
};
</script>
</head>

<body onload="embedGenerativeQnA()">
    <div id="experience-container"></div>
</body>

</html>

```

For this example to work, make sure to use the Amazon Quick Sight Embedding SDK to load the embedded Generative Q&A experience on your website with JavaScript. To get your copy, do one of the following:

- Download the [Amazon Quick Sight embedding SDK](#) from GitHub. This repository is maintained by a group of Amazon Quick Sight developers.
- Download the latest embedding SDK version from <https://www.npmjs.com/package/amazon-quicksight-embedding-sdk>.
- If you use npm for JavaScript dependencies, download and install it by running the following command.

```
npm install amazon-quicksight-embedding-sdk
```

Optional embedded Generative Q&A experience functionalities

The following optional functionalities are available for the embedded Generative Q&A experience with the embedding SDK.

Invoke Generative Q&A search bar actions

- Set a question — This feature sends a question to the Generative Q&A experience and immediately queries the question.

```
embeddedGenerativeQnExperience.setQuestion('show me monthly revenue');
```

- Close the answer panel (applies to the Generative Q&A search bar option) — This feature closes the answer panel and returns the iframe to the original search bar state.

```
embeddedGenerativeQnExperience.close();
```

For more information, see the [Amazon Quick Sight embedding SDK](#).

Embedding the Amazon Quick Sight Q search bar (Classic)

Intended audience: Amazon Quick developers

Note

The embedded Amazon Quick Sight Q search bar provides the classic Amazon Quick Sight Q&A experience. Amazon Quick Sight integrates with Amazon Q Business to launch a new Generative Q&A experience. Developers are recommended to use the new Generative Q&A experience. For more information on the embedded Generative Q&A experience, see [Embedding the Amazon Q in Amazon Quick Sight Generative Q&A experience](#).

Use the following topics to learn about embedding the Amazon Quick Sight Q search bar with the Amazon Quick Sight APIs.

Topics

- [Embedding the Amazon Quick Sight Q search bar for registered users](#)
- [Embedding the Amazon Quick Sight Q search bar for anonymous \(unregistered\) users](#)

Embedding the Amazon Quick Sight Q search bar for registered users

Applies to: Enterprise Edition

Intended audience: Amazon Quick developers

Note

The embedded Amazon Quick Sight Q search bar provides the classic Amazon Quick Sight Q&A experience. Amazon Quick Sight integrates with Amazon Q Business to launch a new Generative Q&A experience. Developers are recommended to use the new Generative Q&A experience. For more information on the embedded Generative Q&A experience, see [Embedding the Amazon Q in Amazon Quick Sight Generative Q&A experience](#).

In the following sections, you can find detailed information about how to set up an embedded Amazon Quick Sight Q search bar for registered users of Amazon Quick Sight.

Topics

- [Step 1: Set up permissions](#)
- [Step 2: Generate the URL with the authentication code attached](#)
- [Step 3: Embed the Q search bar URL](#)
- [Optional Amazon Quick Sight Q search bar embedding functionalities](#)

Step 1: Set up permissions

Note

The embedded Amazon Quick Sight Q search bar provides the classic Amazon Quick Sight Q&A experience. Amazon Quick Sight integrates with Amazon Q Business to launch a new Generative Q&A experience. Developers are recommended to use the new Generative Q&A experience. For more information on the embedded Generative Q&A experience, see [Embedding the Amazon Q in Amazon Quick Sight Generative Q&A experience](#).

In the following section, you can find how to set up permissions for your backend application or web server to embed the Q search bar. This task requires administrative access to AWS Identity and Access Management (IAM).

Each user who accesses a dashboard assumes a role that gives them Amazon Quick Sight access and permissions to the dashboard. To make this possible, create an IAM role in your AWS account. Associate an IAM policy with the role to provide permissions to any user who assumes it. The IAM role needs to provide permissions to retrieve embedding URLs for a specific user pool.

With the help of the wildcard character *, you can grant the permissions to generate a URL for all users in a specific namespace. Or you can grant permissions to generate a URL for a subset of users in specific namespaces. For this, you add `quicksight:GenerateEmbedUrlForRegisteredUser`.

You can create a condition in your IAM policy that limits the domains that developers can list in the `AllowedDomains` parameter of a `GenerateEmbedUrlForRegisteredUser` API operation. The `AllowedDomains` parameter is an optional parameter. It grants developers the option to override the static domains that are configured in the **Manage Amazon Quick Sight** menu and instead list up to three domains or subdomains that can access a generated URL. This URL is then embedded in a developer's website. Only the domains that are listed in the parameter can access

the embedded Q search bar. Without this condition, developers can list any domain on the internet in the `AllowedDomains` parameter.

To limit the domains that developers can use with this parameter, add an `AllowedEmbeddingDomains` condition to your IAM policy. For more information about the `AllowedDomains` parameter, see [GenerateEmbedUrlForRegisteredUser](#) in the *Amazon Quick Sight API Reference*.

Security best practice for IAM condition operators

Improperly configured IAM condition operators can allow unauthorized access to your embedded Quick resources through URL variations. When using the `quicksight:AllowedEmbeddingDomains` condition key in your IAM policies, use condition operators that either allow specific domains or deny all domains that are not specifically allowed. For more information about IAM condition operators, see [IAM JSON policy elements: Condition operators](#) in the IAM User Guide.

Many different URL variations can point to the same resource. For example, the following URLs all resolve to the same content:

- `https://example.com`
- `https://example.com/`
- `https://Example.com`

If your policy uses operators that do not account for these URL variations, an attacker can bypass your restrictions by providing equivalent URL variations.

You must validate that your IAM policy uses appropriate condition operators to prevent bypass vulnerabilities and ensure that only your intended domains can access your embedded resources.

The following sample policy provides these permissions.

Also, if you're creating first-time users who will be Amazon Quick Sight readers, make sure to add the `quicksight:RegisterUser` permission in the policy.

The following sample policy provides permission to retrieve an embedding URL for first-time users who are to be Amazon Quick Sight readers.

Finally, your application's IAM identity must have a trust policy associated with it to allow access to the role that you just created. This means that when a user accesses your application, your application can assume the role on the user's behalf and provision the user in Amazon Quick Sight.

The following example shows a sample trust policy.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowLambdaFunctionsToAssumeThisRole",
      "Effect": "Allow",
      "Principal": {
        "Service": "lambda.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    },
    {
      "Sid": "AllowEC2InstancesToAssumeThisRole",
      "Effect": "Allow",
      "Principal": {
        "Service": "ec2.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

For more information regarding trust policies for OpenID Connect or Security Assertion Markup Language (SAML) authentication, see the following sections of the *IAM User Guide*:

- [Creating a role for web identity or OpenID Connect federation \(console\)](#)
- [Creating a role for SAML 2.0 federation \(console\)](#)

Step 2: Generate the URL with the authentication code attached

Note

The embedded Amazon Quick Sight Q search bar provides the classic Amazon Quick Sight Q&A experience. Amazon Quick Sight integrates with Amazon Q Business to launch a new Generative Q&A experience. Developers are recommended to use the new Generative Q&A experience. For more information on the embedded Generative Q&A experience, see [Embedding the Amazon Q in Amazon Quick Sight Generative Q&A experience](#).

In the following section, you can find how to authenticate your user and get the embeddable Q topic URL on your application server. If you plan to embed the Q bar for IAM or Amazon Quick Sight identity types, share the Q topic with the users.

When a user accesses your app, the app assumes the IAM role on the user's behalf. Then the app adds the user to Amazon Quick Sight, if that user doesn't already exist. Next, it passes an identifier as the unique role session ID.

Performing the described steps ensures that each viewer of the Q topic is uniquely provisioned in Amazon Quick Sight. It also enforces per-user settings, such as the row-level security and dynamic defaults for parameters.

The following examples perform the IAM authentication on the user's behalf. This code runs on your app server.

Java

```
import com.amazonaws.auth.AWSCredentials;
import com.amazonaws.auth.BasicAWSCredentials;
import com.amazonaws.auth.AWSCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.quicksight.AmazonQuickSight;
import com.amazonaws.services.quicksight.AmazonQuickSightClientBuilder;
import
    com.amazonaws.services.quicksight.model.GenerateEmbedUrlForRegisteredUserRequest;
import com.amazonaws.services.quicksight.model.GenerateEmbedUrlForRegisteredUserResult;
import
    com.amazonaws.services.quicksight.model.RegisteredUserEmbeddingExperienceConfiguration;
import
    com.amazonaws.services.quicksight.model.RegisteredUserQSearchBarEmbeddingConfiguration;
```

```

    /**
     * Class to call QuickSight AWS SDK to get url for embedding the Q search bar.
     */
    public class RegisteredUserQSearchBarEmbeddingConfiguration {

        private final AmazonQuickSight quickSightClient;

        public RegisteredUserQSearchBarEmbeddingConfiguration() {
            this.quickSightClient = AmazonQuickSightClientBuilder
                .standard()

```

Node.js

The following example shows the JavaScript (Node.js) that you can use on the app server to generate the URL for the embedded dashboard. You can use this URL in your website or app to display the dashboard.

Example

```
const AWS = require('aws-sdk');
const https = require('https');

var quicksightClient = new AWS.Service({
    apiConfig: require('./quicksight-2018-04-01.min.json'),
    region: 'us-east-1',
});

quicksightClient.generateEmbedUrlForRegisteredUser({
    'AwsAccountId': '111122223333',
    'ExperienceConfiguration': {
        'QSearchBar': {
            'InitialTopicId': 'U4zJMVZ2n2stZflc80u3iKySEb3BEV6f'
        }
    },
    'UserArn': 'REGISTERED_USER_ARN',
    'AllowedDomains': allowedDomains,
    'SessionLifetimeInMinutes': 100
}, function(err, data) {
    console.log('Errors: ');
    console.log(err);
    console.log('Response: ');
```

```
console.log(data);
});
```

Example

```
//The URL returned is over 900 characters. For this example, we've shortened the string
//for
//readability and added ellipsis to indicate that it's incomplete.
{
    Status: 200,
    EmbedUrl: "https://quicksightdomain/embed/12345/dashboards/67890/sheets/12345/
visuals/67890...",
    RequestId: '7bee030e-f191-45c4-97fe-d9faf0e03713'
}
```

.NET/C#

The following example shows the .NET/C# code that you can use on the app server to generate the URL for the embedded Q search bar. You can use this URL in your website or app to display the Q search bar.

Example

```
using System;
using Amazon.QuickSight;
using Amazon.QuickSight.Model;

namespace GenerateDashboardEmbedUrlForRegisteredUser
{
    class Program
    {
        static void Main(string[] args)
        {
            var quicksightClient = new AmazonQuickSightClient(
                AccessKey,
                SecretAccessKey,
                SessionToken,
                Amazon.RegionEndpoint.USEast1);
            try
            {
                RegisteredUserQSearchBarEmbeddingConfiguration
registeredUserQSearchBarEmbeddingConfiguration
                    = new RegisteredUserQSearchBarEmbeddingConfiguration
```

```

        {
            InitialTopicId = "U4zJMVZ2n2stZflc80u3iKySEb3BEV6f"
        };
        RegisteredUserEmbeddingExperienceConfiguration
registeredUserEmbeddingExperienceConfiguration
        = new RegisteredUserEmbeddingExperienceConfiguration
        {
            QSearchBar = registeredUserQSearchBarEmbeddingConfiguration
        };

        Console.WriteLine(
            quicksightClient.GenerateEmbedUrlForRegisteredUserAsync(new
GenerateEmbedUrlForRegisteredUserRequest
            {
                AwsAccountId = "111122223333",
                ExperienceConfiguration =
registeredUserEmbeddingExperienceConfiguration,
                UserArn = "REGISTERED_USER_ARN",
                AllowedDomains = allowedDomains,
                SessionLifetimeInMinutes = 100
            }).Result.EmbedUrl
        );
    } catch (Exception ex) {
        Console.WriteLine(ex.Message);
    }
}
}
}
}
}

```

AWS CLI

To assume the role, choose one of the following AWS Security Token Service (AWS STS) API operations:

- [AssumeRole](#) – Use this operation when you are using an IAM identity to assume the role.
- [AssumeRoleWithWebIdentity](#) – Use this operation when you are using a web identity provider to authenticate your user.
- [AssumeRoleWithSaml](#) – Use this operation when you are using SAML to authenticate your users.

The following example shows the CLI command to set the IAM role. The role needs to have permissions enabled for `quicksight:GenerateEmbedUrlForRegisteredUser`. If you are

taking a just-in-time approach to add users when they use a topic in the Q search bar, the role also needs permissions enabled for `quicksight:RegisterUser`.

```
aws sts assume-role \  
  --role-arn "arn:aws:iam::111122223333:role/embedding_quicksight_q_search_bar_role" \  
  --role-session-name john.doe@example.com
```

The `assume-role` operation returns three output parameters: the access key, the secret key, and the session token.

Note

If you get an `ExpiredToken` error when calling the `AssumeRole` operation, this is probably because the previous `SESSION_TOKEN` is still in the environment variables. Clear this by setting the following variables:

- `AWS_ACCESS_KEY_ID`
- `AWS_SECRET_ACCESS_KEY`
- `AWS_SESSION_TOKEN`

The following example shows how to set these three parameters in the CLI. For a Microsoft Windows machine, use `set` instead of `export`.

```
export AWS_ACCESS_KEY_ID      = "access_key_from_assume_role" \  
export AWS_SECRET_ACCESS_KEY  = "secret_key_from_assume_role" \  
export AWS_SESSION_TOKEN      = "session_token_from_assume_role"
```

Running these commands sets the role session ID of the user visiting your website to `embedding_quicksight_q_search_bar_role/john.doe@example.com`. The role session ID is made up of the role name from `role-arn` and the `role-session-name` value. Using the unique role session ID for each user ensures that appropriate permissions are set for each user. It also prevents any throttling of user access. *Throttling* is a security feature that prevents the same user from accessing Amazon Quick Sight from multiple locations.

The role session ID also becomes the user name in Amazon Quick Sight. You can use this pattern to provision your users in Amazon Quick Sight ahead of time, or to provision them the first time that they access the Q search bar.

The following example shows the CLI command that you can use to provision a user. For more information about [RegisterUser](#), [DescribeUser](#), and other Amazon Quick Sight API operations, see the [Amazon Quick Sight API reference](#).

```
aws quicksight register-user \  
  --aws-account-id 111122223333 \  
  --namespace default \  
  --identity-type IAM \  
  --iam-arn "arn:aws:iam::111122223333:role/embedding_quicksight_q_search_bar_role" \  
  --user-role READER \  
  --user-name jhnd \  
  --session-name "john.doe@example.com" \  
  --email john.doe@example.com \  
  --region us-east-1 \  
  --custom-permissions-name TeamA1
```

If the user is authenticated through Microsoft AD, you don't need to use `RegisterUser` to set them up. Instead, they should be automatically subscribed the first time that they access Amazon Quick Sight. For Microsoft AD users, you can use `DescribeUser` to get the user Amazon Resource Name (ARN).

The first time a user accesses Amazon Quick Sight, you can also add this user to the group that the dashboard is shared with. The following example shows the CLI command to add a user to a group.

```
aws quicksight create-group-membership \  
  --aws-account-id=111122223333 \  
  --namespace=default \  
  --group-name=financeusers \  
  --member-name="embedding_quicksight_q_search_bar_role/john.doe@example.com"
```

You now have a user of your app who is also a user of Amazon Quick Sight, and who has access to the dashboard.

Finally, to get a signed URL for the dashboard, call `generate-embed-url-for-registered-user` from the app server. This returns the embeddable dashboard URL. The following example shows how to generate the URL for an embedded dashboard using a server-side call for users authenticated through AWS Managed Microsoft AD or single sign-on (IAM Identity Center).

```
aws quicksight generate-embed-url-for-registered-user \  
  --aws-account-id 111122223333 \  
  --session-lifetime-in-minutes 600 \  
  --region us-east-1
```

```
--user-arn arn:aws:quicksight:us-east-1:111122223333:user/default/
embedding_quicksight_q_search_bar_role/embeddingsession
--allowed-domains '["domain1", "domain2"]' \
--experience-configuration QSearchBar={InitialTopicId=U4zJMVZ2n2stZflc80u3iKySEb3BEV6f}
```

For more information about using this operation, see [GenerateEmbedUrlForRegisteredUser](#). You can use this and other API operations in your own code.

Step 3: Embed the Q search bar URL

Note

The embedded Amazon Quick Sight Q search bar provides the classic Amazon Quick Sight Q&A experience. Amazon Quick Sight integrates with Amazon Q Business to launch a new Generative Q&A experience. Developers are recommended to use the new Generative Q&A experience. For more information on the embedded Generative Q&A experience, see [Embedding the Amazon Q in Amazon Quick Sight Generative Q&A experience](#).

In the following section, you can find how to embed the Q search bar URL from step 3 in your website or application page. You do this with the [Amazon Quick Sight embedding SDK](#) (JavaScript). With the SDK, you can do the following:

- Place the Q search bar on an HTML page.
- Pass parameters into the Q search bar.
- Handle error states with messages that are customized to your application.

To generate the URL that you can embed in your app, call the `GenerateEmbedUrlForRegisteredUser` API operation. This URL is valid for 5 minutes, and the resulting session is valid for up to 10 hours. The API operation provides the URL with an `auth_code` value that enables a single-sign on session.

The following shows an example response from `generate-embed-url-for-registered-user`.

```
//The URL returned is over 900 characters. For this example, we've shortened the string
for
//readability and added ellipsis to indicate that it's incomplete.
{
    "Status": "200",
```

```
"EmbedUrl": "https://quicksightdomain/embedding/12345/q/search...",  
"RequestId": "7bee030e-f191-45c4-97fe-d9faf0e03713"  
}
```

Embed the Q search bar in your webpage by using the [Amazon Quick Sight embedding SDK](#) or by adding this URL into an iframe. If you set a fixed height and width number (in pixels), Amazon Quick Sight uses those and doesn't change your visual as your window resizes. If you set a relative percent height and width, Amazon Quick Sight provides a responsive layout that is modified as your window size changes.

To do this, make sure that the domain to host the embedded Q search bar is on the *allow list*, the list of approved domains for your Amazon Quick Sight subscription. This requirement protects your data by keeping unapproved domains from hosting embedded dashboards. For more information about adding domains for an embedded Q search bar, see [Managing domains and embedding](#).

When you use the Amazon Quick Sight Embedding SDK, the Q search bar on your page is dynamically resized based on the state. By using the Amazon Quick Sight Embedding SDK, you can also control parameters within the Q search bar and receive callbacks in terms of page load completion and errors.

The following example shows how to use the generated URL. This code is generated on your app server.

SDK 2.0

```
<!DOCTYPE html>  
<html>  
  
  <head>  
    <title>Q Search Bar Embedding Example</title>  
    <script src="https://unpkg.com/amazon-quicksight-embedding-sdk@2.0.0/dist/  
quicksight-embedding-js-sdk.min.js"></script>  
    <script type="text/javascript">  
      const embedQSearchBar = async() => {  
        const {  
          createEmbeddingContext,  
        } = QuickSightEmbedding;  
  
        const embeddingContext = await createEmbeddingContext({  
          onChange: (changeEvent, metadata) => {  
            console.log('Context received a change', changeEvent,  
metadata);
```

```

        },
    });

    const frameOptions = {
        url: "<YOUR_EMBED_URL>", // replace this value with the url
generated via embedding API
        container: '#experience-container',
        height: "700px",
        width: "1000px",
        onChange: (changeEvent, metadata) => {
            switch (changeEvent.eventName) {
                case 'FRAME_MOUNTED': {
                    console.log("Do something when the experience frame is
mounted.");

                    break;
                }
                case 'FRAME_LOADED': {
                    console.log("Do something when the experience frame is
loaded.");

                    break;
                }
            }
        },
    };

    const contentOptions = {
        hideTopicName: false,
        theme: '<YOUR_THEME_ID>',
        allowTopicSelection: true,
        onMessage: async (messageEvent, experienceMetadata) => {
            switch (messageEvent.eventName) {
                case 'Q_SEARCH_OPENED': {
                    console.log("Do something when Q Search content
expanded");

                    break;
                }
                case 'Q_SEARCH_CLOSED': {
                    console.log("Do something when Q Search content
collapsed");

                    break;
                }
                case 'Q_SEARCH_SIZE_CHANGED': {
                    console.log("Do something when Q Search size changed");
                    break;
                }
            }
        }
    };

```

```

        }
        case 'CONTENT_LOADED': {
            console.log("Do something when the Q Search is
loaded.");

            break;
        }
        case 'ERROR_OCCURRED': {
            console.log("Do something when the Q Search fails
loading.");

            break;
        }
    }
}
};
const embeddedDashboardExperience = await
embeddingContext.embedQSearchBar(frameOptions, contentOptions);
};
</script>
</head>

<body onload="embedQSearchBar()">
    <div id="experience-container"></div>
</body>

</html>

```

SDK 1.0

```

<!DOCTYPE html>
<html>

    <head>
        <title>QuickSight Q Search Bar Embedding</title>
        <script src="https://unpkg.com/amazon-quicksight-embedding-sdk@1.18.0/dist/
quicksight-embedding-js-sdk.min.js"></script>
        <script type="text/javascript">
            var session

            function onError(payload) {
                console.log("Do something when the session fails loading");
            }

            function onOpen() {

```

```

        console.log("Do something when the Q search bar opens");
    }

    function onClose() {
        console.log("Do something when the Q search bar closes");
    }

    function embedQSearchBar() {
        var containerDiv = document.getElementById("embeddingContainer");
        var options = {
            url: "https://us-east-1.quicksight.aws.amazon.com/sn/dashboards/
dashboardId?isauthcode=true&identityprovider=quicksight&code=authcode", // replace this
dummy url with the one generated via embedding API
            container: containerDiv,
            width: "1000px",
            locale: "en-US",
            qSearchBarOptions: {
                expandCallback: onOpen,
                collapseCallback: onClose,
                iconDisabled: false,
                topicNameDisabled: false,
                themeId: 'bdb844d0-0fe9-4d9d-b520-0fe602d93639',
                allowTopicSelection: true
            }
        };
        session = QuickSightEmbedding.embedQSearchBar(options);
        session.on("error", onError);
    }

    function onCountryChange(obj) {
        session.setParameters({country: obj.value});
    }
</script>
</head>

<body onload="embedQSearchBar()">
    <div id="embeddingContainer"></div>
</body>

</html>

```

For this example to work, make sure to use the Amazon Quick Sight Embedding SDK to load the embedded dashboard on your website using JavaScript. To get your copy, do one of the following:

- Download the [Amazon Quick Sight embedding SDK](#) from GitHub. This repository is maintained by a group of Amazon Quick Sight developers.
- Download the latest embedding SDK version from <https://www.npmjs.com/package/amazon-quicksight-embedding-sdk>.
- If you use npm for JavaScript dependencies, download and install it by running the following command.

```
npm install amazon-quicksight-embedding-sdk
```

Optional Amazon Quick Sight Q search bar embedding functionalities

Note

The embedded Amazon Quick Sight Q search bar provides the classic Amazon Quick Sight Q&A experience. Amazon Quick Sight integrates with Amazon Q Business to launch a new Generative Q&A experience. Developers are recommended to use the new Generative Q&A experience. For more information on the embedded Generative Q&A experience, see [Embedding the Amazon Q in Amazon Quick Sight Generative Q&A experience](#).

The following optional functionalities are available for the embedded Q search bar using the embedding SDK.

Invoke Q search bar actions

The following options are only supported for Q search bar embedding.

- Set a Q search bar question — This feature sends a question to the Q search bar and immediately queries the question. It also automatically opens the Q popover.

```
qBar.setQBarQuestion('show me monthly revenue');
```

- Close the Q popover — This feature closes the Q popover and returns the iframe to the original Q search bar size.

```
qBar.closeQPopover();
```

For more information, see the [Amazon Quick Sight embedding SDK](#).

Embedding the Amazon Quick Sight Q search bar for anonymous (unregistered) users

Intended audience: Amazon Quick developers

Note

The embedded Amazon Quick Sight Q search bar provides the classic Amazon Quick Sight Q&A experience. Amazon Quick Sight integrates with Amazon Q Business to launch a new Generative Q&A experience. Developers are recommended to use the new Generative Q&A experience. For more information on the embedded Generative Q&A experience, see [Embedding the Amazon Q in Amazon Quick Sight Generative Q&A experience](#).

In the following sections, you can find detailed information about how to set up an embedded Amazon Quick Sight Q search bar for anonymous (unregistered) users.

Topics

- [Step 1: Set up permissions](#)
- [Step 2: Generate the URL with the authentication code attached](#)
- [Step 3: Embed the Q search bar URL](#)
- [Optional Amazon Quick Sight Q search bar embedding functionalities](#)

Step 1: Set up permissions

Note

The embedded Amazon Quick Sight Q search bar provides the classic Amazon Quick Sight Q&A experience. Amazon Quick Sight integrates with Amazon Q Business to launch a new Generative Q&A experience. Developers are recommended to use the new Generative Q&A experience. For more information on the embedded Generative Q&A experience, see [Embedding the Amazon Q in Amazon Quick Sight Generative Q&A experience](#).

In the following section, you can find how to set up permissions for your backend application or web server to embed the Q search bar. This task requires administrative access to AWS Identity and Access Management (IAM).

Each user who accesses a Q search bar assumes a role that gives them Amazon Quick Sight access and permissions to the Q search bar. To make this possible, create an IAM role in your AWS account. Associate an IAM policy with the role to provide permissions to any user who assumes it. The IAM role needs to provide permissions to retrieve embedding URLs for a specific user pool.

With the help of the wildcard character *, you can grant the permissions to generate a URL for all users in a specific namespace. Or you can grant permissions to generate a URL for a subset of users in specific namespaces. For this, you add `quicksight:GenerateEmbedUrlForAnonymousUser`.

You can create a condition in your IAM policy that limits the domains that developers can list in the `AllowedDomains` parameter of a `GenerateEmbedUrlForAnonymousUser` API operation. The `AllowedDomains` parameter is an optional parameter. It grants developers the option to override the static domains that are configured in the **Manage Amazon Quick Sight** menu and instead list up to three domains or subdomains that can access a generated URL. This URL is then embedded in a developer's website. Only the domains that are listed in the parameter can access the embedded Q search bar. Without this condition, developers can list any domain on the internet in the `AllowedDomains` parameter.

To limit the domains that developers can use with this parameter, add an `AllowedEmbeddingDomains` condition to your IAM policy. For more information about the `AllowedDomains` parameter, see [GenerateEmbedUrlForAnonymousUser](#) in the *Amazon Quick Sight API Reference*.

Security best practice for IAM condition operators

Improperly configured IAM condition operators can allow unauthorized access to your embedded Quick resources through URL variations. When using the `quicksight:AllowedEmbeddingDomains` condition key in your IAM policies, use condition operators that either allow specific domains or deny all domains that are not specifically allowed. For more information about IAM condition operators, see [IAM JSON policy elements: Condition operators](#) in the IAM User Guide.

Many different URL variations can point to the same resource. For example, the following URLs all resolve to the same content:

- `https://example.com`

- <https://example.com/>
- <https://Example.com>

If your policy uses operators that do not account for these URL variations, an attacker can bypass your restrictions by providing equivalent URL variations.

You must validate that your IAM policy uses appropriate condition operators to prevent bypass vulnerabilities and ensure that only your intended domains can access your embedded resources.

Your application's IAM identity must have a trust policy associated with it to allow access to the role that you just created. This means that when a user accesses your application, your application can assume the role on the user's behalf to open the Q search bar. The following example shows a sample trust policy.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowLambdaFunctionsToAssumeThisRole",
      "Effect": "Allow",
      "Principal": {
        "Service": "lambda.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    },
    {
      "Sid": "AllowEC2InstancesToAssumeThisRole",
      "Effect": "Allow",
      "Principal": {
        "Service": "ec2.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

For more information regarding trust policies, see [Temporary security credentials in IAM](#) in the *IAM User Guide*

Step 2: Generate the URL with the authentication code attached

Note

The embedded Amazon Quick Sight Q search bar provides the classic Amazon Quick Sight Q&A experience. Amazon Quick Sight integrates with Amazon Q Business to launch a new Generative Q&A experience. Developers are recommended to use the new Generative Q&A experience. For more information on the embedded Generative Q&A experience, see [Embedding the Amazon Q in Amazon Quick Sight Generative Q&A experience](#).

In the following section, you can find how to authenticate your user and get the embeddable Q topic URL on your application server.

When a user accesses your app, the app assumes the IAM role on the user's behalf. Then the app adds the user to Amazon Quick Sight, if that user doesn't already exist. Next, it passes an identifier as the unique role session ID.

For more information, see [AnonymousUserQSearchBarEmbeddingConfiguration](#).

```

Node.js

The following example shows the JavaScript (Node.js) that you can use on the app server to generate the URL for the embedded dashboard. You can use this URL in your website or app to display the dashboard.

Example

```
const AWS = require('aws-sdk');
const https = require('https');

var quicksightClient = new AWS.Service({
  apiConfig: require('./quicksight-2018-04-01.min.json'),
  region: 'us-east-1',
});

quicksightClient.generateEmbedUrlForAnonymousUser({
  'AwsAccountId': '111122223333',
  'Namespace': 'DEFAULT',
  'AuthorizedResourceArns': '["topic-arn-topicId1","topic-arn-topicId2"]',
  'AllowedDomains': allowedDomains,
  'ExperienceConfiguration': {
    'QSearchBar': {
      'InitialTopicId': 'U4zJMVZ2n2stZflc80u3iKySEb3BEV6f'
    }
  },
  'SessionTags': '["Key": tag-key-1,"Value": tag-value-1,{"Key": tag-key-1,"Value": tag-value-1}]',
  'SessionLifetimeInMinutes': 15
}, function(err, data) {
  console.log('Errors: ');
  console.log(err);
  console.log('Response: ');
  console.log(data);
});
```

Example

```
//The URL returned is over 900 characters. For this example, we've shortened the string
//for
//readability and added ellipsis to indicate that it's incomplete.
```

```
{
  Status: 200,
  EmbedUrl : 'https://quicksightdomain/embed/12345/dashboards/67890/sheets/12345/
visuals/67890...',
  RequestId: '7bee030e-f191-45c4-97fe-d9faf0e03713'
}
```

.NET/C#

The following example shows the .NET/C# code that you can use on the app server to generate the URL for the embedded Q search bar. You can use this URL in your website or app to display the Q search bar.

Example

```
using System;
using Amazon.QuickSight;
using Amazon.QuickSight.Model;

namespace GenerateQSearchBarEmbedUrlForAnonymousUser
{
    class Program
    {
        static void Main(string[] args)
        {
            var quicksightClient = new AmazonQuickSightClient(
                AccessKey,
                SecretAccessKey,
                SessionToken,
                Amazon.RegionEndpoint.USEast1);
            try
            {
                AnonymousUserQSearchBarEmbeddingConfiguration
anonymousUserQSearchBarEmbeddingConfiguration
                = new AnonymousUserQSearchBarEmbeddingConfiguration
                {
                    InitialTopicId = "U4zJMVZ2n2stZflc80u3iKySEb3BEV6f"
                };
                AnonymousUserEmbeddingExperienceConfiguration
anonymousUserEmbeddingExperienceConfiguration
                = new AnonymousUserEmbeddingExperienceConfiguration
                {
                    QSearchBar = anonymousUserQSearchBarEmbeddingConfiguration

```

```
};

Console.WriteLine(
    quicksightClient.GenerateEmbedUrlForAnonymousUserAsync(new
GenerateEmbedUrlForAnonymousUserRequest
    {
        AwsAccountId = "111122223333",
        Namespace = "DEFAULT",
        AuthorizedResourceArns ["topic-arn-topicId1","topic-arn-
topicId2"]',
        AllowedDomains = allowedDomains,
        ExperienceConfiguration =
anonymousUserEmbeddingExperienceConfiguration,
        SessionTags = '[{"Key": tag-key-1,"Value": tag-value-1,{"Key":
tag-key-1,"Value": tag-value-1}}]',
        SessionLifetimeInMinutes = 15,
    }).Result.EmbedUrl
);
} catch (Exception ex) {
    Console.WriteLine(ex.Message);
}
}
```

AWS CLI

To assume the role, choose one of the following AWS Security Token Service (AWS STS) API operations:

- [AssumeRole](#) – Use this operation when you are using an IAM identity to assume the role.
- [AssumeRoleWithWebIdentity](#) – Use this operation when you are using a web identity provider to authenticate your user.
- [AssumeRoleWithSaml](#) – Use this operation when you are using SAML to authenticate your users.

The following example shows the CLI command to set the IAM role. The role needs to have permissions enabled for `quicksight:GenerateEmbedUrlForAnonymousUser`.

```
aws sts assume-role \
    --role-arn "arn:aws:iam::111122223333:role/embedding_quicksight_q_search_bar_role" \
```

```
--role-session-name anonymous caller
```

The `assume-role` operation returns three output parameters: the access key, the secret key, and the session token.

 Note

If you get an `ExpiredToken` error when calling the `AssumeRole` operation, this is probably because the previous `SESSION TOKEN` is still in the environment variables. Clear this by setting the following variables:

- `AWS_ACCESS_KEY_ID`
- `AWS_SECRET_ACCESS_KEY`
- `AWS_SESSION_TOKEN`

The following example shows how to set these three parameters in the CLI. For a Microsoft Windows machine, use `set` instead of `export`.

```
export AWS_ACCESS_KEY_ID      = "access_key_from_assume_role"
export AWS_SECRET_ACCESS_KEY  = "secret_key_from_assume_role"
export AWS_SESSION_TOKEN      = "session_token_from_assume_role"
```

Running these commands sets the role session ID of the user visiting your website to `embedding_quicksight_q_search_bar_role/QuickSightEmbeddingAnonymousPolicy`. The role session ID is made up of the role name from `role-arn` and the `role-session-name` value. Using the unique role session ID for each user ensures that appropriate permissions are set for each user. It also prevents any throttling of user access. *Throttling* is a security feature that prevents the same user from accessing Amazon Quick Sight from multiple locations. In addition, it keeps each session separate and distinct. If you're using an array of web servers, for example for load balancing, and a session is reconnected to a different server, a new session begins.

To get a signed URL for the dashboard, call `generate-embed-url-for-anonymous-user` from the app server. This returns the embeddable dashboard URL. The following example shows how to generate the URL for an embedded dashboard using a server-side call for users who are making anonymous visits to your web portal or app.

```
aws quicksight generate-embed-url-for-anonymous-user \  
--aws-account-id 111122223333 \  

```

```
--namespace default-or-something-else \  
--authorized-resource-arns '["topic-arn-topicId1","topic-arn-topicId2"]' \  
--allowed-domains '["domain1","domain2"]' \  
--experience-configuration 'QSearchBar={InitialTopicId="topicId1"}' \  
--session-tags '["Key": tag-key-1, "Value": tag-value-1, {"Key": tag-key-1, "Value": tag-value-1}]' \  
--session-lifetime-in-minutes 15
```

For more information about using this operation, see [GenerateEmbedUrlForRegisteredUser](#). You can use this and other API operations in your own code.

Step 3: Embed the Q search bar URL

Note

The embedded Amazon Quick Sight Q search bar provides the classic Amazon Quick Sight Q&A experience. Amazon Quick Sight integrates with Amazon Q Business to launch a new Generative Q&A experience. Developers are recommended to use the new Generative Q&A experience. For more information on the embedded Generative Q&A experience, see [Embedding the Amazon Q in Amazon Quick Sight Generative Q&A experience](#).

In the following section, you can find how to embed the Q search bar URL from step 3 in your website or application page. You do this with the [Amazon Quick Sight embedding SDK](#) (JavaScript). With the SDK, you can do the following:

- Place the Q search bar on an HTML page.
- Pass parameters into the Q search bar.
- Handle error states with messages that are customized to your application.

To generate the URL that you can embed in your app, call the `GenerateEmbedUrlForAnonymousUser` API operation. This URL is valid for 5 minutes, and the resulting session is valid for up to 10 hours. The API operation provides the URL with an `auth_code` value that enables a single-sign on session.

The following shows an example response from `generate-embed-url-for-anonymous-user`.

```
//The URL returned is over 900 characters. For this example, we've shortened the string  
for
```

```
//readability and added ellipsis to indicate that it's incomplete.
{
  "Status": "200",
  "EmbedUrl": "https://quicksightdomain/embedding/12345/q/search...",
  "RequestId": "7bee030e-f191-45c4-97fe-d9faf0e03713"
}
```

Embed the Q search bar in your webpage by using the [Amazon Quick Sight embedding SDK](#) or by adding this URL into an iframe. If you set a fixed height and width number (in pixels), Amazon Quick Sight uses those and doesn't change your visual as your window resizes. If you set a relative percent height and width, Amazon Quick Sight provides a responsive layout that is modified as your window size changes.

To do this, make sure that the domain to host the embedded Q search bar is on the *allow list*, the list of approved domains for your Amazon Quick Sight subscription. This requirement protects your data by keeping unapproved domains from hosting embedded Q search bar. For more information about adding domains for an embedded Q search bar, see [Managing domains and embedding](#).

When you use the Amazon Quick Sight Embedding SDK, the Q search bar on your page is dynamically resized based on the state. By using the Amazon Quick Sight Embedding SDK, you can also control parameters within the Q search bar and receive callbacks in terms of page load completion and errors.

The following example shows how to use the generated URL. This code is generated on your app server.

SDK 2.0

```
<!DOCTYPE html>
<html>

  <head>
    <title>Q Search Bar Embedding Example</title>
    <script src="https://unpkg.com/amazon-quicksight-embedding-sdk@2.0.0/dist/
quicksight-embedding-js-sdk.min.js"></script>
    <script type="text/javascript">
      const embedQSearchBar = async() => {
        const {
          createEmbeddingContext,
        } = QuickSightEmbedding;

        const embeddingContext = await createEmbeddingContext({
```

```

        onChange: (changeEvent, metadata) => {
            console.log('Context received a change', changeEvent,
metadata);
        },
    });

    const frameOptions = {
        url: "<YOUR_EMBED_URL>", // replace this value with the url
generated via embedding API
        container: '#experience-container',
        height: "700px",
        width: "1000px",
        onChange: (changeEvent, metadata) => {
            switch (changeEvent.eventName) {
                case 'FRAME_MOUNTED': {
                    console.log("Do something when the experience frame is
mounted.");

                    break;
                }
                case 'FRAME_LOADED': {
                    console.log("Do something when the experience frame is
loaded.");

                    break;
                }
            }
        },
    };

    const contentOptions = {
        hideTopicName: false,
        theme: '<YOUR_THEME_ID>',
        allowTopicSelection: true,
        onMessage: async (messageEvent, experienceMetadata) => {
            switch (messageEvent.eventName) {
                case 'Q_SEARCH_OPENED': {
                    console.log("Do something when Q Search content
expanded");

                    break;
                }
                case 'Q_SEARCH_CLOSED': {
                    console.log("Do something when Q Search content
collapsed");

                    break;
                }
            }
        }
    };

```

```

        case 'Q_SEARCH_SIZE_CHANGED': {
            console.log("Do something when Q Search size changed");
            break;
        }
        case 'CONTENT_LOADED': {
            console.log("Do something when the Q Search is
loaded.");
            break;
        }
        case 'ERROR_OCCURRED': {
            console.log("Do something when the Q Search fails
loading.");
            break;
        }
    }
};
const embeddedDashboardExperience = await
embeddingContext.embedQSearchBar(frameOptions, contentOptions);
    };
</script>
</head>

<body onload="embedQSearchBar()">
    <div id="experience-container"></div>
</body>

</html>

```

SDK 1.0

```

<!DOCTYPE html>
<html>

    <head>
        <title>QuickSight Q Search Bar Embedding</title>
        <script src="https://unpkg.com/amazon-quicksight-embedding-sdk@1.18.0/dist/
quicksight-embedding-js-sdk.min.js"></script>
        <script type="text/javascript">
            var session

            function onError(payload) {
                console.log("Do something when the session fails loading");
            }
        </script>
    </head>
</html>

```

```
    }

    function onOpen() {
        console.log("Do something when the Q search bar opens");
    }

    function onClose() {
        console.log("Do something when the Q search bar closes");
    }

    function embedQSearchBar() {
        var containerDiv = document.getElementById("embeddingContainer");
        var options = {
            url: "https://us-east-1.quicksight.aws.amazon.com/sn/dashboards/
dashboardId?isauthcode=true&identityprovider=quicksight&code=authcode", // replace this
dummy url with the one generated via embedding API
            container: containerDiv,
            width: "1000px",
            locale: "en-US",
            qSearchBarOptions: {
                expandCallback: onOpen,
                collapseCallback: onClose,
                iconDisabled: false,
                topicNameDisabled: false,
                themeId: 'bdb844d0-0fe9-4d9d-b520-0fe602d93639',
                allowTopicSelection: true
            }
        };
        session = QuickSightEmbedding.embedQSearchBar(options);
        session.on("error", onError);
    }

    function onCountryChange(obj) {
        session.setParameters({country: obj.value});
    }
</script>
</head>

<body onload="embedQSearchBar()">
    <div id="embeddingContainer"></div>
</body>

</html>
```

For this example to work, make sure to use the Amazon Quick Sight Embedding SDK to load the embedded Q search bar on your website using JavaScript. To get your copy, do one of the following:

- Download the [Amazon Quick Sight embedding SDK](#) from GitHub. This repository is maintained by a group of Amazon Quick Sight developers.
- Download the latest embedding SDK version from <https://www.npmjs.com/package/amazon-quicksight-embedding-sdk>.
- If you use npm for JavaScript dependencies, download and install it by running the following command.

```
npm install amazon-quicksight-embedding-sdk
```

Optional Amazon Quick Sight Q search bar embedding functionalities

Note

The embedded Amazon Quick Sight Q search bar provides the classic Amazon Quick Sight Q&A experience. Amazon Quick Sight integrates with Amazon Q Business to launch a new Generative Q&A experience. Developers are recommended to use the new Generative Q&A experience. For more information on the embedded Generative Q&A experience, see [Embedding the Amazon Q in Amazon Quick Sight Generative Q&A experience](#).

The following optional functionalities are available for the embedded Q search bar using the embedding SDK.

Invoke Q search bar actions

The following options are only supported for Q search bar embedding.

- Set a Q search bar question — This feature sends a question to the Q search bar and immediately queries the question. It also automatically opens the Q popover.

```
qBar.setQBarQuestion('show me monthly revenue');
```

- Close the Q popover — This feature closes the Q popover and returns the iframe to the original Q search bar size.

```
qBar.closeQPopover();
```

For more information, see the [Amazon Quick Sight embedding SDK](#).

Embedding analytics using the `GetDashboardEmbedURL` and `GetSessionEmbedURL` API operations

Applies to: Enterprise Edition

Intended audience: Amazon Quick developers

The following API operations for embedding Amazon Quick Sight dashboards and the Amazon Quick Sight console have been replaced by the `GenerateEmbedUrlForAnonymousUser` and `GenerateEmbedUrlForRegisteredUser` API operations. You can still use them to embed analytics in your application, but they are no longer maintained and do not contain the latest embedding features or functionality. For the latest up-to-date embedding experience, see [Embedding Amazon Quick Sight analytics into your applications](#)

- The [GetDashboardEmbedUrl](#) API operation embeds interactive dashboards.
- The [GetSessionEmbedUrl](#) API operation embeds the Amazon Quick Sight console.

Topics

- [Embedding dashboards for everyone using `GetDashboardEmbedURL` \(old API\)](#)
- [Embedding dashboards for registered users using `GetDashboardEmbedUrl` \(old API\)](#)
- [Embedding the Amazon Quick Sight console using `GetSessionEmbedUrl` \(old API\)](#)

Embedding dashboards for everyone using `GetDashboardEmbedURL` (old API)

Important

Amazon Quick Sight has new APIs for embedding analytics:
`GenerateEmbedUrlForAnonymousUser` and `GenerateEmbedUrlForRegisteredUser`.

You can still use the `GetDashboardEmbedUrl` and `GetSessionEmbedUrl` APIs to embed dashboards and the Amazon Quick Sight console, but they do not contain the latest embedding capabilities. For the latest up-to-date embedding experience, see [Embedding Amazon Quick Sight analytics into your applications](#).

Applies to: Enterprise Edition

Intended audience: Amazon Quick developers

In the following sections, you can find detailed information on how to set up embedded Amazon Quick Sight dashboards for everyone (nonauthenticated users) using `GetDashboardEmbedURL`.

Topics

- [Step 1: Set up permissions](#)
- [Step 2: Get the URL with the authentication code attached](#)
- [Step 3: Embed the dashboard URL](#)

Step 1: Set up permissions

Important

Amazon Quick Sight has new APIs for embedding analytics: `GenerateEmbedUrlForAnonymousUser` and `GenerateEmbedUrlForRegisteredUser`. You can still use the `GetDashboardEmbedUrl` and `GetSessionEmbedUrl` APIs to embed dashboards and the Amazon Quick Sight console, but they do not contain the latest embedding capabilities. For the latest up-to-date embedding experience, see [Embedding Amazon Quick Sight analytics into your applications](#).

Applies to: Enterprise Edition

Intended audience: Amazon Quick developers

In the following section, you can find out how to set up permissions for the backend application or web server. This task requires administrative access to IAM.

Each user who accesses a dashboard assumes a role that gives them Amazon Quick Sight access and permissions to the dashboard. To make this possible, create an IAM role in your AWS account. Associate an IAM policy with the role to provide permissions to any user who assumes it.

The following sample policy provides these permissions for use with `IdentityType=ANONYMOUS`. For this approach to work, you also need a session pack, or session capacity pricing, on your AWS account. Otherwise, when a user tries to access the dashboard, the error `UnsupportedPricingPlanException` is returned.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "quicksight:GetDashboardEmbedUrl",
        "quicksight:GetAnonymousUserEmbedUrl"
      ],
      "Resource": "*"
    }
  ]
}
```

Your application's IAM identity must have a trust policy associated with it to allow access to the role that you just created. This means that when a user accesses your application, your application can assume the role on the user's behalf to open the dashboard. The following example shows a role called `QuickSightEmbeddingAnonymousPolicy`, which has the sample policy preceding as its resource.

For more information regarding trust policies, see [Temporary security credentials in IAM](#) in the *IAM User Guide*.

Step 2: Get the URL with the authentication code attached

Important

Amazon Quick Sight has new APIs for embedding analytics: `GenerateEmbedUrlForAnonymousUser` and `GenerateEmbedUrlForRegisteredUser`. You can still use the `GetDashboardEmbedUrl` and `GetSessionEmbedUrl` APIs to embed dashboards and the Amazon Quick Sight console, but they do not contain the latest embedding capabilities. For the latest up-to-date embedding experience, see [Embedding Amazon Quick Sight analytics into your applications](#).

Applies to: Enterprise Edition

Intended audience: Amazon Quick developers

In the following section, you can find how to authenticate on behalf of the anonymous visitor and get the embeddable dashboard URL on your application server.

When a user accesses your app, the app assumes the IAM role on the user's behalf. Then it adds the user to Amazon Quick Sight, if that user doesn't already exist. Next, it passes an identifier as the unique role session ID.

The following examples perform the IAM authentication on the user's behalf. It passes an identifier as the unique role session ID. This code runs on your app server.

Java

```

        }
    except ClientError as e:
        print(e)
        return "Error generating embeddedURL: " + str(e)
```

Node.js

The following example shows the JavaScript (Node.js) that you can use on the app server to get the URL for the embedded dashboard. You can use this URL in your website or app to display the dashboard.

Example

```
const AWS = require('aws-sdk');
const https = require('https');

var quicksight = new AWS.Service({
    apiConfig: require('./quicksight-2018-04-01.min.json'),
    region: 'us-east-1',
});

quicksight.getDashboardEmbedUrl({
    'AwsAccountId': '111122223333',
```

```

        'DashboardId': 'dashboard-id',
        'AdditionalDashboardIds': 'added-dashboard-id-1 added-dashboard-id-2
added-dashboard-id-3'
        'Namespace' : 'default',
        'IdentityType': 'ANONYMOUS',
        'SessionLifetimeInMinutes': 100,
        'UndoRedoDisabled': false,
        'ResetDisabled': true

    }, function(err, data) {
        console.log('Errors: ');
        console.log(err);
        console.log('Response: ');
        console.log(data);
    });

```

Example

```

//The URL returned is over 900 characters. For this example, we've shortened the
string for
    //readability and added ellipsis to indicate that it's incomplete.
        { Status: 200,
          EmbedUrl: 'https://dashboards.example.com/
embed/620bef10822743fab329fb3751187d2d...
          RequestId: '7bee030e-f191-45c4-97fe-d9faf0e03713' }

```

.NET/C#

The following example shows the .NET/C# code that you can use on the app server to get the URL for the embedded dashboard. You can use this URL in your website or app to display the dashboard.

Example

```

var client = new AmazonQuickSightClient(
    AccessKey,
    SecretAccessKey,
    sessionToken,
    Amazon.RegionEndpoint.USEast1);
try

```

```

    {
        Console.WriteLine(
            client.GetDashboardEmbedUrlAsync(new GetDashboardEmbedUrlRequest
            {
                AwsAccountId = "111122223333",
                DashboardId = "dashboard-id",
                AdditionalDashboardIds = "added-dashboard-id-1 added-
dashboard-id-2 added-dashboard-id-3",
                Namespace = default,
                IdentityType = IdentityType.ANONYMOUS,
                SessionLifetimeInMinutes = 600,
                UndoRedoDisabled = false,
                ResetDisabled = true
            }).Result.EmbedUrl
        );
    } catch (Exception ex) {
        Console.WriteLine(ex.Message);
    }
}

```

AWS CLI

To assume the role, choose one of the following AWS Security Token Service (AWS STS) API operations:

- [AssumeRole](#) – Use this operation when you are using an IAM identity to assume the role.
- [AssumeRoleWithWebIdentity](#) – Use this operation when you are using a web identity provider to authenticate your user.
- [AssumeRoleWithSaml](#) – Use this operation when you are using Security Assertion Markup Language (SAML) to authenticate your users.

The following example shows the CLI command to set the IAM role. The role needs to have permissions enabled for `quicksight:GetDashboardEmbedURL`.

```

aws sts assume-role \
    --role-arn "arn:aws:iam::111122223333:role/QuickSightEmbeddingAnonymousPolicy" \
    --role-session-name anonymous caller

```

The `assume-role` operation returns three output parameters: the access key, the secret key, and the session token.

Note

If you get an ExpiredToken error when calling the AssumeRole operation, this is probably because the previous SESSION_TOKEN is still in the environment variables. Clear this by setting the following variables:

- `AWS_ACCESS_KEY_ID`
- `AWS_SECRET_ACCESS_KEY`
- `AWS_SESSION_TOKEN`

The following example shows how to set these three parameters in the CLI. If you are using a Microsoft Windows machine, use `set` instead of `export`.

```
export AWS_ACCESS_KEY_ID      = "access_key_from_assume_role"
export AWS_SECRET_ACCESS_KEY  = "secret_key_from_assume_role"
export AWS_SESSION_TOKEN      = "session_token_from_assume_role"
```

Running these commands sets the role session ID of the user visiting your website to `embedding_quicksight_dashboard_role/QuickSightEmbeddingAnonymousPolicy`. The role session ID is made up of the role name from `role-arn` and the `role-session-name` value. Using the unique role session ID for each user ensures that appropriate permissions are set for each visiting user. It also keeps each session separate and distinct. If you're using an array of web servers, for example for load balancing, and a session is reconnected to a different server, a new session begins.

To get a signed URL for the dashboard, call `get-dashboard-embed-url` from the app server. This returns the embeddable dashboard URL. The following example shows how to get the URL for an embedded dashboard using a server-side call for users who are making anonymous visits to your web portal or app.

```
aws quicksight get-dashboard-embed-url \
  --aws-account-id 111122223333 \
  --dashboard-id dashboard-id \
  --additional-dashboard-ids added-dashboard-id-1 added-dashboard-id-2 added-
  dashboard-id-3
  --namespace default-or-something-else \
  --identity-type ANONYMOUS \
  --session-lifetime-in-minutes 30 \
```

```
--undo-redo-disabled true \  
--reset-disabled true \  
--user-arn arn:aws:quicksight:us-east-1:111122223333:user/  
default/QuickSightEmbeddingAnonymousPolicy/embeddingSession
```

For more information on using this operation, see [GetDashboardEmbedUrl](#). You can use this and other API operations in your own code.

Step 3: Embed the dashboard URL

Important

Amazon Quick Sight has new APIs for embedding analytics:

`GenerateEmbedUrlForAnonymousUser` and `GenerateEmbedUrlForRegisteredUser`. You can still use the `GetDashboardEmbedUrl` and `GetSessionEmbedUrl` APIs to embed dashboards and the Amazon Quick Sight console, but they do not contain the latest embedding capabilities. For the latest up-to-date embedding experience, see [Embedding Amazon Quick Sight analytics into your applications](#).

Applies to: Enterprise Edition

Intended audience: Amazon Quick developers

In the following section, you can find out how you can use the [Amazon Quick Sight embedding SDK](#) (JavaScript) to embed the dashboard URL from step 2 in your website or application page. With the SDK, you can do the following:

- Place the dashboard on an HTML page.
- Pass parameters into the dashboard.
- Handle error states with messages that are customized to your application.

Call the `GetDashboardEmbedUrl` API operation to get the URL that you can embed in your app. This URL is valid for 5 minutes, and the resulting session is valid for 10 hours. The API operation provides the URL with an `auth_code` that enables a single-sign on session.

The following shows an example response from `get-dashboard-embed-url`.

```
//The URL returned is over 900 characters. For this example, we've shortened the string
//for
//readability and added ellipsis to indicate that it's incomplete.
{
  "Status": "200",
  "EmbedUrl": "https://dashboards.example.com/
embed/620bef10822743fab329fb3751187d2d...",
  "RequestId": "7bee030e-f191-45c4-97fe-d9faf0e03713"
}
```

Embed this dashboard in your web page by using the Amazon Quick Sight [Embedding SDK](#) or by adding this URL into an `iframe`. If you set a fixed height and width number (in pixels), Amazon Quick Sight uses those and doesn't change your visual as your window resizes. If you set a relative percent height and width, Amazon Quick Sight provides a responsive layout that is modified as your window size changes. By using the Amazon Quick Sight Embedding SDK, you can also control parameters within the dashboard and receive callbacks in terms of page load completion and errors.

The following example shows how to use the generated URL. This code resides on your app server.

```
<!DOCTYPE html>
<html>

<head>
  <title>Basic Embed</title>
  <!-- You can download the latest QuickSight embedding SDK version from https://
www.npmjs.com/package/amazon-quicksight-embedding-sdk -->
  <!-- Or you can do "npm install amazon-quicksight-embedding-sdk", if you use npm
for javascript dependencies -->
  <script src="./quicksight-embedding-js-sdk.min.js"></script>
  <script type="text/javascript">
    var dashboard;

    function embedDashboard() {
      var containerDiv = document.getElementById("embeddingContainer");
```

```
var options = {
    // replace this dummy url with the one generated via embedding API
    url: "https://us-east-1.quicksight.aws.amazon.com/sn/dashboards/
dashboardId?isauthcode=true&identityprovider=quicksight&code=authcode",
    container: containerDiv,
    scrolling: "no",
    height: "700px",
    width: "1000px",
    footerPaddingEnabled: true
};
dashboard = QuickSightEmbedding.embedDashboard(options);
}
</script>
</head>

<body onload="embedDashboard()">
    <div id="embeddingContainer"></div>
</body>

</html>
```

For this example to work, make sure to use the Amazon Quick Sight Embedding SDK to load the embedded dashboard on your website using JavaScript. To get your copy, do one of the following:

- Download the [Amazon Quick Sight embedding SDK](#) from GitHub. This repository is maintained by a group of Amazon Quick Sight developers.
- Download the latest QuickSight embedding SDK version from <https://www.npmjs.com/package/amazon-quicksight-embedding-sdk>.
- If you use npm for JavaScript dependencies, download and install it by running the following command.

```
npm install amazon-quicksight-embedding-sdk
```

Embedding dashboards for registered users using GetDashboardEmbedUrl (old API)

Important

Amazon Quick Sight has new APIs for embedding analytics:

`GenerateEmbedUrlForAnonymousUser` and `GenerateEmbedUrlForRegisteredUser`.

You can still use the `GetDashboardEmbedUrl` and `GetSessionEmbedUrl` APIs to embed dashboards and the Amazon Quick Sight console, but they do not contain the latest embedding capabilities. For the latest up-to-date embedding experience, see [Embedding Amazon Quick Sight analytics into your applications](#).

In the following sections, you can find detailed information on how to set up embedded Amazon Quick Sight dashboards for registered users using `GetDashboardEmbedUrl`.

Topics

- [Step 1: Set up permissions](#)
- [Step 2: Get the URL with the authentication code attached](#)
- [Step 3: Embed the dashboard URL](#)

Step 1: Set up permissions

Important

Amazon Quick Sight has new APIs for embedding analytics: `GenerateEmbedUrlForAnonymousUser` and `GenerateEmbedUrlForRegisteredUser`. You can still use the `GetDashboardEmbedUrl` and `GetSessionEmbedUrl` APIs to embed dashboards and the Amazon Quick Sight console, but they do not contain the latest embedding capabilities. For the latest up-to-date embedding experience, see [Embedding Amazon Quick Sight analytics into your applications](#).

In the following section, you can find out how to set up permissions for the backend application or web server. This task requires administrative access to IAM.

Each user who accesses a dashboard assumes a role that gives them Amazon Quick Sight access and permissions to the dashboard. To make this possible, create an IAM role in your AWS account. Associate an IAM policy with the role to provide permissions to any user who assumes it. The IAM role needs to provide permissions to retrieve dashboard URLs. For this, you add `quicksight:GetDashboardEmbedUrl`.

The following sample policy provides these permissions for use with `IdentityType=IAM`.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "quicksight:GetDashboardEmbedUrl"
      ],
      "Resource": "*"
    }
  ]
}
```

The following sample policy provides permission to retrieve a dashboard URL. You use the policy with `quicksight:RegisterUser` if you are creating first-time users who are to be Amazon Quick Sight readers.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": "quicksight:RegisterUser",
      "Resource": "*",
      "Effect": "Allow"
    },
    {
      "Action": "quicksight:GetDashboardEmbedUrl",
      "Resource": "*",
      "Effect": "Allow"
    }
  ]
}
```

If you use QUICKSIGHT as your `identityType` and provide the user's Amazon Resource Name (ARN), you also need to allow the `quicksight:GetAuthCode` action in your policy. The following sample policy provides this permission.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "quicksight:GetDashboardEmbedUrl",
        "quicksight:GetAuthCode"
      ],
      "Resource": "*"
    }
  ]
}
```

Your application's IAM identity must have a trust policy associated with it to allow access to the role that you just created. This means that when a user accesses your application, your application can assume the role on the user's behalf and provision the user in Amazon Quick Sight. The following example shows a role called `embedding_quicksight_dashboard_role`, which has the sample policy preceding as its resource.

For more information regarding trust policies for OpenID Connect or SAML authentication, see the following sections of the *IAM User Guide*:

- [Creating a role for web identity or OpenID Connect federation \(console\)](#)
- [Creating a role for SAML 2.0 federation \(console\)](#)

Step 2: Get the URL with the authentication code attached

Important

Amazon Quick Sight has new APIs for embedding analytics:
`GenerateEmbedUrlForAnonymousUser` and `GenerateEmbedUrlForRegisteredUser`.

You can still use the `GetDashboardEmbedUrl` and `GetSessionEmbedUrl` APIs to embed dashboards and the Amazon Quick Sight console, but they do not contain the latest embedding capabilities. For the latest up-to-date embedding experience, see [Embedding Amazon Quick Sight analytics into your applications](#).

In the following section, you can find out how to authenticate your user and get the embeddable dashboard URL on your application server.

When a user accesses your app, the app assumes the IAM role on the user's behalf. Then it adds the user to Amazon Quick Sight, if that user doesn't already exist. Next, it passes an identifier as the unique role session ID.

Performing the described steps ensures that each viewer of the dashboard is uniquely provisioned in Amazon Quick Sight. It also enforces per-user settings, such as the row-level security and dynamic defaults for parameters.

The following examples perform the IAM authentication on the user's behalf. This code runs on your app server.

Java

```
import com.amazonaws.auth.AWSCredentials;
import com.amazonaws.auth.AWSStaticCredentialsProvider;
import com.amazonaws.auth.BasicSessionCredentials;
import com.amazonaws.auth.BasicAWSCredentials;
import com.amazonaws.auth.AWSCredentialsProvider;

# undoRedoDisabled: PARAMETER TO ENABLE DISABLE UNDO REDO BUTTONS IN EMBEDDED
# DASHBAORD
def getDashboardURL(accountId, dashboardId, openIdToken, roleArn, sessionName,
    resetDisabled, undoRedoDisabled):
    try:
        assumedRole = sts.assume_role(
            RoleArn = roleArn,
            RoleSessionName = sessionName,
            WebIdentityToken = openIdToken
        )
    except ClientError as e:
        return "Error assuming role: " + str(e)
    else:
        assumedRoleSession = boto3.Session(

```

```

        aws_access_key_id = assumedRole['Credentials']['AccessKeyId'],
        aws_secret_access_key = assumedRole['Credentials']['SecretAccessKey'],
        aws_session_token = assumedRole['Credentials']['SessionToken'],
    )
    try:
        quickSight = assumedRoleSession.client('quicksight', region_name='us-
east-1')

        response = quickSight.get_dashboard_embed_url(
            AwsAccountId = accountId,
            DashboardId = dashboardId,
            IdentityType = 'IAM',
            SessionLifetimeInMinutes = 600,
            UndoRedoDisabled = undoRedoDisabled,
            ResetDisabled = resetDisabled
        )

        return {
            'statusCode': 200,
            'headers': {"Access-Control-Allow-Origin": "*", "Access-Control-
Allow-Headers": "Content-Type"},
            'body': json.dumps(response),
            'isBase64Encoded': bool('false')
        }
    except ClientError as e:
        return "Error generating embeddedURL: " + str(e)

```

Node.js

The following example shows the JavaScript (Node.js) that you can use on the app server to get the URL for the embedded dashboard. You can use this URL in your website or app to display the dashboard.

Example

```

const AWS = require('aws-sdk');
const https = require('https');

var quicksight = new AWS.Service({
    apiConfig: require('./quicksight-2018-04-01.min.json'),
    region: 'us-east-1',
});

```

```
quicksight.getDashboardEmbedUrl({
  'AwsAccountId': '111122223333',
  'DashboardId': '1c1fe111-e2d2-3b30-44ef-a0e111111cde',
  'IdentityType': 'IAM',
  'ResetDisabled': true,
  'SessionLifetimeInMinutes': 100,
  'UndoRedoDisabled': false,
  'StatePersistenceEnabled': true
}, function(err, data) {
  console.log('Errors: ');
  console.log(err);
  console.log('Response: ');
  console.log(data);
});
```

Example

```
//The URL returned is over 900 characters. For this example, we've shortened the
string for
    //readability and added ellipsis to indicate that it's incomplete.
    { Status: 200,
      EmbedUrl: 'https://dashboards.example.com/
embed/620bef10822743fab329fb3751187d2d...
      RequestId: '7bee030e-f191-45c4-97fe-d9faf0e03713' }
```

.NET/C#

The following example shows the .NET/C# code that you can use on the app server to get the URL for the embedded dashboard. You can use this URL in your website or app to display the dashboard.

Example

```
var client = new AmazonQuickSightClient(
    AccessKey,
    SecretAccessKey,
    sessionToken,
    Amazon.RegionEndpoint.USEast1);
try
{
```

```
Console.WriteLine(
    client.GetDashboardEmbedUrlAsync(new GetDashboardEmbedUrlRequest
    {
        AwsAccountId = "111122223333",
        DashboardId = "1c1fe111-e2d2-3b30-44ef-a0e111111cde",
        IdentityType = EmbeddingIdentityType.IAM,
        ResetDisabled = true,
        SessionLifetimeInMinutes = 100,
        UndoRedoDisabled = false,
        StatePersistenceEnabled = true
    }).Result.EmbedUrl
);
} catch (Exception ex) {
    Console.WriteLine(ex.Message);
}
```

AWS CLI

To assume the role, choose one of the following AWS Security Token Service (AWS STS) API operations:

- [AssumeRole](#) – Use this operation when you are using an IAM identity to assume the role.
- [AssumeRoleWithWebIdentity](#) – Use this operation when you are using a web identity provider to authenticate your user.
- [AssumeRoleWithSaml](#) – Use this operation when you are using SAML to authenticate your users.

The following example shows the CLI command to set the IAM role. The role needs to have permissions enabled for `quicksight:GetDashboardEmbedURL`. If you are taking a just-in-time approach to add users when they first open a dashboard, the role also needs permissions enabled for `quicksight:RegisterUser`.

```
aws sts assume-role \
    --role-arn "arn:aws:iam::111122223333:role/embedding_quicksight_dashboard_role" \
    --role-session-name john.doe@example.com
```

The `assume-role` operation returns three output parameters: the access key, the secret key, and the session token.

Note

If you get an `ExpiredToken` error when calling the `AssumeRole` operation, this is probably because the previous `SESSION_TOKEN` is still in the environment variables. Clear this by setting the following variables:

- `AWS_ACCESS_KEY_ID`
- `AWS_SECRET_ACCESS_KEY`
- `AWS_SESSION_TOKEN`

The following example shows how to set these three parameters in the CLI. If you are using a Microsoft Windows machine, use `set` instead of `export`.

```
export AWS_ACCESS_KEY_ID      = "access_key_from_assume_role"
export AWS_SECRET_ACCESS_KEY  = "secret_key_from_assume_role"
export AWS_SESSION_TOKEN     = "session_token_from_assume_role"
```

Running these commands sets the role session ID of the user visiting your website to `embedding_quicksight_dashboard_role/john.doe@example.com`. The role session ID is made up of the role name from `role-arn` and the `role-session-name` value. Using the unique role session ID for each user ensures that appropriate permissions are set for each user. It also prevents any throttling of user access. *Throttling* is a security feature that prevents the same user from accessing Amazon Quick Sight from multiple locations.

The role session ID also becomes the user name in Amazon Quick Sight. You can use this pattern to provision your users in Amazon Quick Sight ahead of time, or to provision them the first time they access the dashboard.

The following example shows the CLI command that you can use to provision a user. For more information about [RegisterUser](#), [DescribeUser](#), and other Amazon Quick Sight API operations, see the [Amazon Quick Sight API reference](#).

```
aws quicksight register-user \
  --aws-account-id 111122223333 \
  --namespace default \
  --identity-type IAM \
  --iam-arn "arn:aws:iam::111122223333:role/embedding_quicksight_dashboard_role" \
```

```
--user-role READER \  
--user-name jhnd \  
--session-name "john.doe@example.com" \  
--email john.doe@example.com \  
--region us-east-1 \  
--custom-permissions-name TeamA1
```

If the user is authenticated through Microsoft AD, you don't need to use `RegisterUser` to set them up. Instead, they should be automatically subscribed the first time they access Amazon Quick Sight. For Microsoft AD users, you can use `DescribeUser` to get the user ARN.

The first time a user accesses Amazon Quick Sight, you can also add this user to the group that the dashboard is shared with. The following example shows the CLI command to add a user to a group.

```
aws quicksight create-group-membership \  
  --aws-account-id=111122223333 \  
  --namespace=default \  
  --group-name=financeusers \  
  --member-name="embedding_quicksight_dashboard_role/john.doe@example.com"
```

You now have a user of your app who is also a user of Amazon Quick Sight, and who has access to the dashboard.

Finally, to get a signed URL for the dashboard, call `get-dashboard-embed-url` from the app server. This returns the embeddable dashboard URL. The following example shows how to get the URL for an embedded dashboard using a server-side call for users authenticated through AWS Managed Microsoft AD or IAM Identity Center.

```
aws quicksight get-dashboard-embed-url \  
  --aws-account-id 111122223333 \  
  --dashboard-id 1a1ac2b2-3fc3-4b44-5e5d-c6db6778df89 \  
  --identity-type IAM \  
  --session-lifetime-in-minutes 30 \  
  --undo-redo-disabled true \  
  --reset-disabled true \  
  --state-persistence-enabled true \  
  --user-arn arn:aws:quicksight:us-east-1:111122223333:user/default/  
embedding_quicksight_dashboard_role/embeddingsession
```

For more information on using this operation, see [GetDashboardEmbedUrl](#). You can use this and other API operations in your own code.

Step 3: Embed the dashboard URL

Important

Amazon Quick Sight has new APIs for embedding analytics: `GenerateEmbedUrlForAnonymousUser` and `GenerateEmbedUrlForRegisteredUser`. You can still use the `GetDashboardEmbedUrl` and `GetSessionEmbedUrl` APIs to embed dashboards and the Amazon Quick Sight console, but they do not contain the latest embedding capabilities. For the latest up-to-date embedding experience, see [Embedding Amazon Quick Sight analytics into your applications](#).

In the following section, you can find out how you can use the [Amazon Quick Sight embedding SDK](#) (JavaScript) to embed the dashboard URL from step 3 in your website or application page. With the SDK, you can do the following:

- Place the dashboard on an HTML page.
- Pass parameters into the dashboard.
- Handle error states with messages that are customized to your application.

Call the `GetDashboardEmbedUrl` API operation to get the URL that you can embed in your app. This URL is valid for 5 minutes, and the resulting session is valid for 10 hours. The API operation provides the URL with an `auth_code` that enables a single-sign on session.

The following shows an example response from `get-dashboard-embed-url`.

```
//The URL returned is over 900 characters. For this example, we've shortened the string
for
//readability and added ellipsis to indicate that it's incomplete.
{
  "Status": "200",
  "EmbedUrl": "https://dashboards.example.com/
embed/620bef10822743fab329fb3751187d2d...",
  "RequestId": "7bee030e-f191-45c4-97fe-d9faf0e03713"
}
```

Embed this dashboard in your webpage by using the [Amazon Quick Sight embedding SDK](#) or by adding this URL into an iframe. If you set a fixed height and width number (in pixels), Amazon Quick Sight uses those and doesn't change your visual as your window resizes. If you set a relative percent height and width, Amazon Quick Sight provides a responsive layout that is modified as your window size changes. By using the Amazon Quick Sight Embedding SDK, you can also control parameters within the dashboard and receive callbacks in terms of page load completion and errors.

The following example shows how to use the generated URL. This code is generated on your app server.

```
<!DOCTYPE html>
<html>

<head>
  <title>Basic Embed</title>

  <script src="./quicksight-embedding-js-sdk.min.js"></script>
  <script type="text/javascript">
    var dashboard;

    function embedDashboard() {
      var containerDiv = document.getElementById("embeddingContainer");
      var options = {
        // replace this dummy url with the one generated via embedding API
        url: "https://us-east-1.quicksight.aws.amazon.com/sn/dashboards/
dashboardId?isauthcode=true&identityprovider=quicksight&code=authcode",
        container: containerDiv,
        scrolling: "no",
        height: "700px",
        width: "1000px",
        footerPaddingEnabled: true
      };
      dashboard = QuickSightEmbedding.embedDashboard(options);
    }
  </script>
</head>

<body onload="embedDashboard()">
  <div id="embeddingContainer"></div>
</body>
```

```
</html>
```

For this example to work, make sure to use the Amazon Quick Sight Embedding SDK to load the embedded dashboard on your website using JavaScript. To get your copy, do one of the following:

- Download the [Amazon Quick Sight embedding SDK](#) from GitHub. This repository is maintained by a group of Amazon Quick Sight developers.
- Download the latest embedding SDK version from <https://www.npmjs.com/package/amazon-quicksight-embedding-sdk>.
- If you use npm for JavaScript dependencies, download and install it by running the following command.

```
npm install amazon-quicksight-embedding-sdk
```

Embedding the Amazon Quick Sight console using GetSessionEmbedUrl (old API)

Important

Amazon Quick Sight has new APIs for embedding analytics:

`GenerateEmbedUrlForAnonymousUser` and `GenerateEmbedUrlForRegisteredUser`.

You can still use the `GetDashboardEmbedUrl` and `GetSessionEmbedUrl` APIs to embed dashboards and the Amazon Quick Sight console, but they do not contain the latest embedding capabilities. For the latest up-to-date embedding experience, see [Embedding Amazon Quick Sight analytics into your applications](#).

Applies to: Enterprise Edition

Intended audience: Amazon Quick developers

In the following sections, you can find detailed information on how to provide the Amazon Quick Sight console experience in a custom-branded authoring portal for registered users using the `GetSessionEmbedUrl` API.

Topics

- [Step 1: Set up permissions](#)
- [Step 2: Get the URL with the authentication code attached](#)
- [Step 3: Embed the console session URL](#)

Step 1: Set up permissions

Important

Amazon Quick Sight has new APIs for embedding analytics:

`GenerateEmbedUrlForAnonymousUser` and `GenerateEmbedUrlForRegisteredUser`. You can still use the `GetDashboardEmbedUrl` and `GetSessionEmbedUrl` APIs to embed dashboards and the Amazon Quick Sight console, but they do not contain the latest embedding capabilities. For the latest up-to-date embedding experience, see [Embedding Amazon Quick Sight analytics into your applications](#).

In the following section, you can find out how to set up permissions for the backend application or web server. This task requires administrative access to IAM.

Each user who accesses a Amazon Quick Sight assumes a role that gives them Amazon Quick Sight access and permissions to the console session. To make this possible, create an IAM role in your AWS account. Associate an IAM policy with the role to provide permissions to any user who assumes it. Add `quicksight:RegisterUser` permissions to ensure that the reader can access Amazon Quick Sight in a read-only fashion, and not have access to any other data or creation capability. The IAM role also needs to provide permissions to retrieve console session URLs. For this, you add `quicksight:GetSessionEmbedUrl`.

The following sample policy provides these permissions for use with `IdentityType=IAM`.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": "quicksight:RegisterUser",
```

```
    "Resource": "*",
    "Effect": "Allow"
  },
  {
    "Action": "quicksight:GetSessionEmbedUrl",
    "Resource": "*",
    "Effect": "Allow"
  }
]
```

The following sample policy provides permission to retrieve a console session URL. You use the policy without `quicksight:RegisterUser` if you are creating users before they access an embedded session.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "quicksight:GetSessionEmbedUrl"
      ],
      "Resource": "*"
    }
  ]
}
```

If you use `QUICKSIGHT` as your `identityType` and provide the user's Amazon Resource Name (ARN), you also need to allow the `quicksight:GetAuthCode` action in your policy. The following sample policy provides this permission.

JSON

```
{
  "Version": "2012-10-17",
```

```
"Statement": [
  {
    "Effect": "Allow",
    "Action": [
      "quicksight:GetSessionEmbedUrl",
      "quicksight:GetAuthCode"
    ],
    "Resource": "*"
  }
]
```

Your application's IAM identity must have a trust policy associated with it to allow access to the role that you just created. This means that when a user accesses your application, your application can assume the role on the user's behalf and provision the user in Amazon Quick Sight. The following example shows a role called `embedding_quicksight_console_session_role`, which has the sample policy preceding as its resource.

For more information regarding trust policies for OpenID Connect or SAML authentication, see the following sections of the *IAM User Guide*:

- [Creating a role for web identity or OpenID Connect federation \(console\)](#)
- [Creating a role for SAML 2.0 federation \(console\)](#)

Step 2: Get the URL with the authentication code attached

Important

Amazon Quick Sight has new APIs for embedding analytics: `GenerateEmbedUrlForAnonymousUser` and `GenerateEmbedUrlForRegisteredUser`. You can still use the `GetDashboardEmbedUrl` and `GetSessionEmbedUrl` APIs to embed dashboards and the Amazon Quick Sight console, but they do not contain the latest embedding capabilities. For the latest up-to-date embedding experience, see [Embedding Amazon Quick Sight analytics into your applications](#).

In the following section, you can find out how to authenticate your user and get the embeddable console session URL on your application server.

When a user accesses your app, the app assumes the IAM role on the user's behalf. Then it adds the user to Amazon Quick Sight, if that user doesn't already exist. Next, it passes an identifier as the unique role session ID.

Performing the described steps ensures that each viewer of the console session is uniquely provisioned in Amazon Quick Sight. It also enforces per-user settings, such as the row-level security and dynamic defaults for parameters.

The following examples perform the IAM authentication on the user's behalf. This code runs on your app server.

Java

```
import com.amazonaws.auth.AWSCredentials;
import com.amazonaws.auth.BasicAWSCredentials;
import com.amazonaws.auth.AWSCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.quicksight.AmazonQuickSight;
import com.amazonaws.services.quicksight.AmazonQuickSightClientBuilder;
import com.amazonaws.services.quicksight.model.GetSessionEmbedUrlRequest;
import com.amazonaws.services.quicksight.model.GetSessionEmbedUrlResult;

/**
 * Class to call QuickSight AWS SDK to get url for session embedding.
 */
public class GetSessionEmbedUrlQSAuth {

    private final AmazonQuickSight quickSightClient;

    public GetSessionEmbedUrlQSAuth() {
        this.quickSightClient = AmazonQuickSightClientBuilder
            .standard()
            .withRegion(Regions.US_EAST_1.getName())
            .withCredentials(new AWSCredentialsProvider() {
                @Override
                public AWSCredentials getCredentials() {
                    // provide actual IAM access key and secret
                    key here
                    return new BasicAWSCredentials("access-
key", "secret-key");
                }
            })
            .build();
    }

    @Override
```

```

        public void refresh() {}
    }

    )
    .build();
}

public String getQuicksightEmbedUrl(
    final String accountId, // YOUR AWS ACCOUNT ID
    final String userArn // REGISTERED USER ARN TO USE FOR EMBEDDING.
    REFER TO GETEMBEDURL SECTION IN DEV PORTAL TO FIND OUT HOW TO GET USER ARN FOR A
    QUICKSIGHT USER
    ) throws Exception {
    GetSessionEmbedUrlRequest getSessionEmbedUrlRequest = new
    GetSessionEmbedUrlRequest()
        .withAwsAccountId(accountId)
        .withEntryPoint("/start")
        .withUserArn(userArn);

    GetSessionEmbedUrlResult sessionEmbedUrl =
    quickSightClient.getSessionEmbedUrl(getSessionEmbedUrlRequest);

    return sessionEmbedUrl.getEmbedUrl();
}
}

```

JavaScript

```

global.fetch = require('node-fetch');
const AWS = require('aws-sdk');

function getSessionEmbedURL(
    accountId, // YOUR AWS ACCOUNT ID
    userArn, // REGISTERED USER ARN TO USE FOR EMBEDDING. REFER TO GETEMBEDURL
    SECTION IN DEV PORTAL TO FIND OUT HOW TO GET USER ARN FOR A QUICKSIGHT USER
    getEmbedUrlCallback, // GETEMBEDURL SUCCESS CALLBACK METHOD
    errorCallback // GETEMBEDURL ERROR CALLBACK METHOD
    ) {
    const getSessionParams = {
        AwsAccountId: accountId,
        EntryPoint: "/start",
        UserArn: userArn,
        SessionLifetimeInMinutes: 600,
    };
};

```

```

const quicksightGetSession = new AWS.QuickSight({
  region: process.env.AWS_REGION,
});

quicksightGetSession.getSessionEmbedUrl(getSessionParams, function(err, data) {
  if (err) {
    console.log(err, err.stack);
    errorCallback(err);
  } else {
    const result = {
      "statusCode": 200,
      "headers": {
        "Access-Control-Allow-Origin": "*", // USE YOUR WEBSITE DOMAIN
        "Access-Control-Allow-Headers": "Content-Type"
      },
      "body": JSON.stringify(data),
      "isBase64Encoded": false
    }
    getEmbedUrlCallback(result);
  }
});
}

```

Python3

```

import json
import boto3
from botocore.exceptions import ClientError
import time

# Create QuickSight and STS clients
qs = boto3.client('quicksight', region_name='us-east-1')
sts = boto3.client('sts')

# Function to generate embedded URL
# accountId: YOUR AWS ACCOUNT ID
# userArn: REGISTERED USER ARN TO USE FOR EMBEDDING. REFER TO GETEMBEDURL SECTION IN
# DEV PORTAL TO FIND OUT HOW TO GET USER ARN FOR A QUICKSIGHT USER
def getSessionEmbedURL(accountId, userArn):
    try:
        response = qs.get_session_embed_url(

```

```

        AwsAccountId = accountId,
        EntryPoint = "/start",
        UserArn = userArn,
        SessionLifetimeInMinutes = 600
    )

    return {
        'statusCode': 200,
        'headers': {"Access-Control-Allow-Origin": "*", "Access-Control-Allow-Headers": "Content-Type"},
        'body': json.dumps(response),
        'isBase64Encoded': bool('false')
    }
except ClientError as e:
    print(e)
    return "Error generating embeddedURL: " + str(e)

```

Node.js

The following example shows the JavaScript (Node.js) that you can use on the app server to get the URL for the embedded console session. You can use this URL in your website or app to display the console session.

Example

```

const AWS = require('aws-sdk');
const https = require('https');

var quicksight = new AWS.Service({
    apiConfig: require('./quicksight-2018-04-01.min.json'),
    region: 'us-east-1',
});

quicksight.getSessionEmbedUrl({
    'AwsAccountId': '111122223333',
    'EntryPoint': 'https://url-for-console-page-to-open',
    'SessionLifetimeInMinutes': 600,
    'UserArn': 'USER_ARN'
}, function(err, data) {
    console.log('Errors: ');
    console.log(err);
    console.log('Response: ');

```

```
        console.log(data);
    });
```

Example

//The URL returned is over 900 characters. For this example, we've shortened the string for

```
    //readability and added ellipsis to indicate that it's incomplete.
    { Status: 200,
      EmbedUrl: 'https://dashboards.example.com/
embed/620bef10822743fab329fb3751187d2d...
      RequestId: '7bee030e-f191-45c4-97fe-d9faf0e03713' }
```

.NET/C#

The following example shows the .NET/C# code that you can use on the app server to get the URL for the embedded console session. You can use this URL in your website or app to display the console.

Example

```
var client = new AmazonQuickSightClient(
    AccessKey,
    SecretAccessKey,
    sessionToken,
    Amazon.RegionEndpoint.USEast1);
try
{
    Console.WriteLine(
        client.GetSessionEmbedUrlAsync(new GetSessionEmbedUrlRequest
        {
            'AwsAccountId': '111122223333',
            'EntryPoint': 'https://url-for-console-page-to-open',
            'SessionLifetimeInMinutes': 600,
            'UserArn': 'USER_ARN'
            AwsAccountId = 111122223333,
            EntryPoint = https://url-for-console-page-to-open,
            SessionLifetimeInMinutes = 600,
            UserArn = 'USER_ARN'
        }).Result.EmbedUrl
    );
```

```
    } catch (Exception ex) {  
        Console.WriteLine(ex.Message);  
    }
```

AWS CLI

To assume the role, choose one of the following AWS Security Token Service (AWS STS) API operations:

- [AssumeRole](#) – Use this operation when you are using an IAM identity to assume the role.
- [AssumeRoleWithWebIdentity](#) – Use this operation when you are using a web identity provider to authenticate your user.
- [AssumeRoleWithSaml](#) – Use this operation when you are using SAML to authenticate your users.

The following example shows the CLI command to set the IAM role. The role needs to have permissions enabled for `quicksight:GetSessionEmbedUrl`. If you are taking a just-in-time approach to add users when they first open Amazon Quick Sight, the role also needs permissions enabled for `quicksight:RegisterUser`.

```
aws sts assume-role \  
    --role-arn "arn:aws:iam::111122223333:role/embedding_quicksight_dashboard_role"  
 \  
    --role-session-name john.doe@example.com
```

The `assume-role` operation returns three output parameters: the access key, the secret key, and the session token.

Note

If you get an `ExpiredToken` error when calling the `AssumeRole` operation, this is probably because the previous `SESSION_TOKEN` is still in the environment variables. Clear this by setting the following variables:

- `AWS_ACCESS_KEY_ID`
- `AWS_SECRET_ACCESS_KEY`
- `AWS_SESSION_TOKEN`

The following example shows how to set these three parameters in the CLI. If you are using a Microsoft Windows machine, use `set` instead of `export`.

```
export AWS_ACCESS_KEY_ID      = "access_key_from_assume_role"
export AWS_SECRET_ACCESS_KEY  = "secret_key_from_assume_role"
export AWS_SESSION_TOKEN      = "session_token_from_assume_role"
```

Running these commands sets the role session ID of the user visiting your website to `embedding_quicksight_console_session_role/john.doe@example.com`. The role session ID is made up of the role name from `role-arn` and the `role-session-name` value. Using the unique role session ID for each user ensures that appropriate permissions are set for each user. It also prevents any throttling of user access. Throttling is a security feature that prevents the same user from accessing Amazon Quick Sight from multiple locations.

The role session ID also becomes the user name in Amazon Quick Sight. You can use this pattern to provision your users in Amazon Quick Sight ahead of time, or to provision them the first time they access a console session.

The following example shows the CLI command that you can use to provision a user. For more information about [RegisterUser](#), [DescribeUser](#), and other Amazon Quick Sight API operations, see the [Amazon Quick Sight API reference](#).

```
aws quicksight register-user \
  --aws-account-id 111122223333 \
  --namespace default \
  --identity-type IAM \
  --iam-arn "arn:aws:iam::111122223333:role/embedding_quicksight_dashboard_role" \
  --user-role READER \
  --user-name jhnd \
  --session-name "john.doe@example.com" \
  --email john.doe@example.com \
  --region us-east-1 \
  --custom-permissions-name TeamA1
```

If the user is authenticated through Microsoft AD, you don't need to use `RegisterUser` to set them up. Instead, they should be automatically subscribed the first time they access Amazon Quick Sight. For Microsoft AD users, you can use `DescribeUser` to get the user ARN.

The first time a user accesses Amazon Quick Sight, you can also add this user to the appropriate group. The following example shows the CLI command to add a user to a group.

```
aws quicksight create-group-membership \  
  --aws-account-id=111122223333 \  
  --namespace=default \  
  --group-name=financeusers \  
  --member-name="embedding_quicksight_dashboard_role/john.doe@example.com"
```

You now have a user of your app who is also a user of Amazon Quick Sight, and who has access to the Amazon Quick Sight console session.

Finally, to get a signed URL for the console session, call `get-session-embed-url` from the app server. This returns the embeddable console session URL. The following example shows how to get the URL for an embedded console session using a server-side call for users authenticated through AWS Managed Microsoft AD or Single Sign-on (IAM Identity Center).

```
aws quicksight get-dashboard-embed-url \  
  --aws-account-id 111122223333 \  
  --entry-point the-url-for--the-console-session \  
  --session-lifetime-in-minutes 600 \  
  --user-arn arn:aws:quicksight:us-east-1:111122223333:user/  
default/embedding_quicksight_dashboard_role/embeddingession
```

For more information on using this operation, see [GetSessionEmbedUrl](#). You can use this and other API operations in your own code.

Step 3: Embed the console session URL

Important

Amazon Quick Sight has new APIs for embedding analytics: `GenerateEmbedUrlForAnonymousUser` and `GenerateEmbedUrlForRegisteredUser`. You can still use the `GetDashboardEmbedUrl` and `GetSessionEmbedUrl` APIs to embed dashboards and the Amazon Quick Sight console, but they do not contain the latest embedding capabilities. For the latest up-to-date embedding experience, see [Embedding Amazon Quick Sight analytics into your applications](#).

In the following section, you can find out how you can use the [Amazon Quick Sight embedding SDK](#) (JavaScript) to embed the console session URL from step 3 in your website or application page. With the SDK, you can do the following:

- Place the console session on an HTML page.
- Pass parameters into the console session.
- Handle error states with messages that are customized to your application.

Call the `GetSessionEmbedUrl` API operation to get the URL that you can embed in your app. This URL is valid for 5 minutes, and the resulting session is valid for 10 hours. The API operation provides the URL with an `auth_code` that enables a single-sign on session.

The following shows an example response from `get-dashboard-embed-url`.

```
//The URL returned is over 900 characters. For this example, we've shortened the string
for
//readability and added ellipsis to indicate that it's incomplete.
{
  "Status": "200",
  "EmbedUrl": "https: //dashboards.example.com/
embed/620bef10822743fab329fb3751187d2d...",
  "RequestId": "7bee030e-f191-45c4-97fe-d9faf0e03713"
}
```

Embed this console session in your webpage by using the Amazon Quick Sight [Embedding SDK](#) or by adding this URL into an `iframe`. If you set a fixed height and width number (in pixels), Amazon Quick Sight uses those and doesn't change your visual as your window resizes. If you set a relative percent height and width, Amazon Quick Sight provides a responsive layout that is modified as your window size changes. By using the Amazon Quick Sight Embedding SDK, you can also control parameters within the console session and receive callbacks in terms of page load completion and errors.

The following example shows how to use the generated URL. This code is generated on your app server.

```
<!DOCTYPE html>
<html>

<head>
  <title>Basic Embed</title>

  <script src="./quicksight-embedding-js-sdk.min.js"></script>
  <script type="text/javascript">
    var dashboard;
```

```
function embedDashboard() {
    var containerDiv = document.getElementById("embeddingContainer");
    var options = {
        // replace this dummy url with the one generated via embedding API
        url: "https://us-east-1.quicksight.aws.amazon.com/sn/dashboards/
dashboardId?isauthcode=true&identityprovider=quicksight&code=authcode",
        container: containerDiv,
        scrolling: "no",
        height: "700px",
        width: "1000px",
        footerPaddingEnabled: true
    };
    dashboard = QuickSightEmbedding.embedDashboard(options);
}
</script>
</head>

<body onload="embedDashboard()">
    <div id="embeddingContainer"></div>
</body>

</html>
```

For this example to work, make sure to use the Amazon Quick Sight Embedding SDK to load the embedded console session on your website using JavaScript. To get your copy, do one of the following:

- Download the [Amazon Quick Sight embedding SDK](#) from GitHub. This repository is maintained by a group of Amazon Quick Sight developers.
- Download the latest embedding SDK version from <https://www.npmjs.com/package/amazon-quicksight-embedding-sdk>.
- If you use npm for JavaScript dependencies, download and install it by running the following command.

```
npm install amazon-quicksight-embedding-sdk
```

Using Amazon Quick Research

Amazon Quick Research is a feature of Amazon Quick that enables you to conduct comprehensive research by analyzing multiple data sources and generating detailed reports. Quick Research uses artificial intelligence to help you gather, analyze, and synthesize information from various sources including web search, uploaded files, connected data spaces, knowledge bases, actions, and third-party data providers.

With Quick Research, you can define research objectives, select relevant data sources, and receive AI-generated research reports with proper citations and source tracing. This helps you make informed decisions based on comprehensive analysis of available information.

What you can do with Quick Research

Quick Research supports a wide range of research activities and use cases:

- Market research and competitive analysis
- Literature reviews and academic research
- Business intelligence and trend analysis
- Product research and feature comparison
- Policy and regulatory research
- Technical documentation and best practices research
- Customer insights and feedback analysis
- Industry reports and white paper synthesis

Quick Research helps you save time by automatically gathering information from multiple sources, analyzing the content, and presenting findings in a structured format with proper citations and source references.

Starting new research

Creating a new research project in Amazon Quick Research involves a structured workflow that guides you from initial objective setting through final report generation. This process ensures comprehensive research coverage while maintaining focus on your specific goals.

Enter research objective

The first step in creating a new research project is to define your research objective. A well-written research objective helps Quick Research understand what information you're looking for and guides the AI in selecting relevant sources and generating focused results.

To enter your research objective

1. In the main navigation bar, choose **Research**.
2. In the Quick Research interface, choose **New Research**.
3. In the **Research objective** field, enter a clear description of what you want to research.

Make your research goal specific and detailed. For example, include the following:

- What you are researching and why
- What industry, region, and timeframe
- Any data sources like dashboards, documents, or internet resources
- Key focus areas such as metrics, competitors, and trends

Share your research objective in a few sentences to describe your goal, frameworks, desired outcomes and any other essential information including your industry context and any specific requirements or constraints.

Example: "Evaluate renewable energy investment opportunities for our corporate sustainability portfolio to support Q1 2025 capital allocation decisions. We're allocating \$50M across North American markets with a 7-year investment horizon. Focus on solar, wind, and battery storage sectors from 2023-2024 performance data. Key metrics: IRR projections, regulatory incentive impacts, market growth trends, and risk-adjusted returns. Cost sensitivity is critical - prioritize solutions under \$2M per MW capacity."

You can also reference internal data sources in your objective. For example:

"Primarily build research on our internal investment analysis from Document: 'Renewable_Portfolio_Performance_2024.pdf' in Knowledge base: 'Investment Research', which is added in Space: 'Financial Analysis', and Chart: 'Investment Performance Trends' in Dashboard: 'Sustainability Portfolio Dashboard'. Use web research to supplement with recent policy changes, emerging technology costs, and competitor strategies not covered in our internal data."

4. (Optional) Choose the **Research mode** button to select a research mode. The following modes are available:
 - **Fast** – Completes research in approximately 4-7 minutes. This mode is suitable for quick insights and time-sensitive research needs.
 - **Deep** – Completes research in approximately 20-30 minutes. This mode provides more thorough analysis and is suitable for complex research topics that require deeper investigation.
5. After entering your research objective, choose what materials to use in **Research materials**, then choose **Review plan** to review a draft plan, or choose **Start researching** to begin research immediately.

Tips for writing a good research objective

Follow these guidelines to create effective research objectives:

- Be specific about what you want to learn or understand
- Include relevant context about your industry, market, or domain
- Specify the time frame if relevant (for example, "recent trends," "2024 data")
- Mention the intended use of the research (for example, "for strategic planning," "to inform product decisions")
- Use clear, concise language and avoid ambiguous terms
- Include any specific aspects or angles you want to explore

Example of a well-written research objective: "Analyze the current state of artificial intelligence adoption in healthcare, focusing on diagnostic imaging applications, regulatory challenges, and market opportunities for 2024-2025."

Select research materials

After defining your research objective, you can select the data sources that Quick Research will use to gather information. Set your preferences and control what sources Quick Research uses. Include files, web search preferences, company assets, and premium and public datasets.

To select research materials

1. In the material selection interface, review the available data source options.

2. Select the types of materials you want to include:

- a. Toggle **Web search** to include online sources
- b. Choose **File upload** to add specific documents

For best results, include key documents that are most relevant to your research goals. Adding more materials may increase research time and lead to less focused insights.

If you're working with larger collections, consider using Spaces to organize and optimize extensive research materials for better results.

- c. Choose **Quick assets** to include data spaces, dashboards, knowledge bases, and integrations in your research. For more information about creating and managing data spaces, see [Organize and collaborate using Amazon Quick spaces](#).
 - d. Choose **Third party data** to incorporate data from premium datasets and trusted public data sources to enhance your research. For more information, see [the section called "Using third party data for research"](#).
3. Choose **Review plan** to review a draft research plan before starting, or choose **Start researching** to begin research immediately.

Web search

Enable web search to allow Quick Research to gather information from publicly available online sources. This includes academic papers, industry reports, news articles, and other relevant web content related to your research objective.

Amazon Quick uses the internet to enhance your results. Web search queries may be processed in a different AWS Region than your primary Region. For more information, see [Cross-Region calls for web search](#).

To prioritize or avoid certain websites, you can expand the web search section to enter a list of preferred websites and a list of websites to avoid. Both fields are optional and can take a maximum of 3,500 characters.

We recommend providing a list of web domains (such as `example.com`), but you can also include types of websites such as `government websites` or `blogs`. If you enter a website address like `example.com/path/to/specific/page`, it will be shortened to `example.com`, so you don't need to enter multiple websites for a single domain.

Note

Adding a domain to the list of preferred websites doesn't guarantee that the website will be used in research. A website might not be used include: the site is behind a paywall, the site doesn't allow agents to access it, or the site's content is found to be less relevant than other sites.

Uploaded files

Upload specific documents, PDFs, spreadsheets, or other files that you want Quick Research to analyze as part of your research. This is useful when you have particular sources or documents that are directly relevant to your research objective.

To upload files

1. Choose **Upload** to open the **File Uploads** window.
2. Add files using one of the following methods:
 - a. Choose **Add Files** to navigate to your files in File Explorer
 - b. Drag and drop up to 20 files into the upload area

If you need to include more than 20 files in your research, consider organizing them in Spaces instead.

3. When you're finished selecting files, choose **Done**.

Accepted file formats include .pdf, .txt, .doc, .xls, and .csv files. The file size limit is 25MB per file.

Quick assets

Connect Quick Research to your existing data spaces to include internal documents, reports, knowledge bases, and integrations in your research. You can combine external web sources with your organization's proprietary information. Quick Research can also fetch data through Quick connectors, enabling it to pull live data from connected systems during the research process.

For optimal results, consider selecting the most relevant assets for your specific research question. Choose **Browse** to add assets from Quick.

To add Quick assets

1. Choose **Browse** to open the **Add assets** window in the right pane.
2. Select from the available resource type tabs:
 - a. **Recent** - Recently accessed assets
 - b. **Space** - Available data spaces (maximum of 2 selections)
 - c. **Dashboard** - Dashboard resources (maximum of 2 selections)
 - d. **Topic** - Topic resources (maximum of 2 selections)
 - e. **Knowledgebase** - Knowledge base resources
 - f. **Integration** - Connectors that can fetch live data from connected systems
3. Review the available assets, which display the Name, Owner, and Last Modified date and time for each asset.
4. Select the assets you want to include in your research.
5. When you're finished specifying all assets, choose **Add**.

Review and finalize research plan

Before Quick Research begins gathering and analyzing information, you have the opportunity to review and refine your research plan. This step helps ensure that the research will meet your specific needs and expectations.

To review and finalize your research plan

1. Review the AI-generated suggestions in the **Revise Plan** pane on the right for improving your research plan.
2. (Optional) To make revisions, enter your changes in the **How should I change the plan?** field. You can add comments and notes to provide additional context or specific instructions for the AI, such as clarifying particular aspects you want emphasized, specifying exclusions, or providing domain-specific guidance that will help generate more relevant results.
3. Choose **Revise plan** to update the plan with your revisions.
4. Choose **Start researching** to begin the analysis process.

Research suggestions

Quick Research analyzes your research objective and selected materials to provide intelligent suggestions for improving your research plan. These suggestions appear in the **Revise Plan** pane and might include additional data sources, refined search terms, or alternative approaches to your research question.

For example, if your research objective is about sustainable packaging for the food industry, suggestions might include specifying geographic regions for regulatory analysis, identifying specific food types requiring temperature maintenance, or providing budget constraints for cost comparison analysis.

Revision history

The revision history section tracks all changes made to your research plan during the review process. This allows you to see what modifications have been applied and provides a record of how your research plan has evolved.

View research report

Once you select to create the research, Quick Research will work through a series of research tasks. Research typically takes 20-40 minutes to complete. The window displays the percentage complete along with the specific tasks Quick Research is working on and which sources are being used for each research task.

After Quick Research completes its analysis, you can view the comprehensive research report that synthesizes information from all selected sources. The report presents findings in a structured format with supporting evidence and source references.

You can use the **Download** button at the top to download the report as a PDF or Word document. There is also a **Summarize** button in the upper right. For more information, see [the section called "Summarizing the research"](#). You can also select **Reading mode** to hide sidebars and focus on the report content.

When you're ready to share your research with others, use the **Share** button. For more information, see [the section called "Sharing the research"](#). If you want to refine the research further before sharing, you can make updates and iterate on the report. For more information, see [the section called "Updating research"](#).

In the left pane, under your research objective you can see a **Topics** tab which lists and allows you to navigate through the major sections of the report.

The **Research** pane on the right of the window accepts comments up to 400 characters. You can now add comments that will be queued for revision, as they require deeper investigation by Quick Research.

Viewing citations

Throughout the report, numbered citations are present. Clicking on a citation shows you a popup window with the source article and a hyperlink to the source page.

Understanding statements

You can also click the **Understand the statement** icon (three horizontal lines and a plus) to launch an explanation window that shows how a statement in the report was determined, including a summary of the evidence and a breakdown of the conclusion.

Updating research

Research is an iterative process that often requires refinement and updates based on new findings or changing requirements. Quick Research provides flexible tools to modify your research objectives, incorporate additional sources, and track changes through version management.

Making updates

After reviewing your initial research report, you can make updates to refine and improve the results. Quick Research provides multiple ways to provide feedback and request modifications to better meet your needs.

Once you've added all your comments to the queue in the Research pane, the **Revise** button becomes available in the upper right. When you choose **Revise**, you see a message that "Review revision started". Quick Research goes back to work through its research tasks with your new comments in mind, analyzing the existing report's structure and content to determine how to apply your comments.

The version increments to Version 2 when the revision is complete.

In-line feedback

Provide specific feedback on individual sections or findings within your research report by highlighting the word or section you want to comment on. In-line feedback allows you to request clarification, additional detail, or corrections for specific parts of the report without affecting the entire document.

High level feedback

Submit broader feedback about the overall direction, focus, or approach of your research. High-level feedback is useful when you want to adjust the research scope, change the emphasis, or request additional analysis across the entire report.

Research versions

Quick Research maintains versions of your research reports as you make updates and refinements. This version control system allows you to track changes, compare different iterations, and revert to previous versions if needed.

Each time you submit feedback or request updates, Quick Research creates a new version of your report while preserving the previous versions. You can view the version history, compare changes between versions, and choose which version to use as your final report.

Version management helps you maintain a clear audit trail of your research process and ensures that you don't lose valuable insights from earlier iterations of your work.

Summarizing the research

After completing your research report, you can create focused summaries for different audiences. To access the summarizing feature, choose the **Summarize** button in the upper right of your research report.

Quick Research provides multiple summary formats to help you present your findings in different contexts and for various audiences. Choose the summary type that best fits your intended use and audience needs.

In the **Options** tab, you can choose to create a custom summary by entering up to 5,000 characters about how you would like to summarize, or select one of two preset summary styles:

- *Executive summary* - VP-oriented tone, 2-page maximum, no citations

- *General share out* - Business-friendly tone, 6-page maximum, essential citations

Once you choose a summary style, you can choose **Begin** to start producing the summary. The **Previous** tab shows previous summary reports. You can download the summary as PDF or Word using the **Download** button at the top.

Custom summary

Create a tailored summary by entering up to 5,000 characters about how you would like to summarize your research. Custom summaries allow you to specify the key points, length, and focus areas you want emphasized for your particular use case.

Executive summary

Generate a concise executive summary with a VP-oriented tone, limited to 2 pages maximum with no citations. This format presents the most important findings and recommendations suitable for senior leadership and decision-makers.

General share out

Create a comprehensive summary document with a business-friendly tone, up to 6 pages maximum with essential citations included. This format balances depth with accessibility for team presentations and stakeholder briefings.

Sharing the research

After completing your research, you can download it in various formats or share it with others. Amazon Quick Research provides flexible options for both downloading and sharing your research findings.

Download the research

You can export your research in multiple formats to suit different needs and workflows.

Export to PDF

PDF format is ideal for sharing formatted documents that maintain their appearance across different devices and platforms.

To export your research to PDF:

- Navigate to your completed research report
- Choose *Download* from the options menu
- Select *PDF* as the export format
- The PDF file will be generated and downloaded to your device

Export to Word

Word format allows for further editing and collaboration using Microsoft Word or compatible applications.

To export your research to Word format:

- Navigate to your completed research report
- Choose *Download* from the options menu
- Select *Word* as the export format
- The Word document will be generated and downloaded to your device

Sharing the research with stakeholders

Quick Research provides several ways to share your research with colleagues and stakeholders, enabling collaboration and knowledge distribution.

To share your research:

- Open the research report you want to share
- Choose *Share* from the options menu
- Select your preferred sharing method from the available options
- Configure sharing permissions and access levels as needed
- Send the share link or invitation to your intended recipients

Shared research maintains all formatting, citations, and interactive elements, allowing recipients to view the complete research experience.

Automating research with Quick Flows

Amazon Quick Research can be integrated into Quick Flows to automate your research workflows. This allows you to standardize research processes, schedule recurring research reports, and share proven research methods across your organization.

When to use research in Quick Flows

Consider using Quick Research as a flow step when you need to:

- **Standardize research processes** across your team by creating reusable workflows
- **Schedule automated research** that runs at specific times (like every Monday 8am)
- **Trigger downstream actions** based on research findings, such as updating records in Salesforce or creating tasks in Jira

Getting started

To add Quick Research as a step in your flows, you'll configure a research agent that defines your research objective, selects data sources, and optionally accepts user inputs. The research results can then be used to drive subsequent actions in your workflow.

For detailed instructions, see [Research](#).

Using third party data in Amazon Quick Research

Amazon Quick Research integrates with third party data providers, such as FactSet, IDC, and S&P Global. The following table shows the current list of providers. The **Premium** data providers require a license to access their data, while the Public data providers do not require a license.

You can use multiple third party data providers in research. The agent will determine which sources to use based on their relevance.

Data provider	Category	Description
FactSet	Premium	Access FactSet's trusted equity prices, news, events, transcripts, fundamentals and consensus estimates - delivered for AI-driven insights.

Data provider	Category	Description
IDC	Premium	The IDC Connector brings verified technology market intelligence into Quick Research for faster, deeper, and more credible insights.
S&P Global Energy	Premium	S&P Global Energy Data provides AI Ready market insights across commodities and energy, refreshed every 30 minutes with rich metadata.
S&P Global Market Intelligence	Premium	Query S&P Global datasets: Capital IQ Financials, Market Data, Transcripts & securities. Saves time for financial services teams
US Patents	Public	20 years of US patents from the US PTO
PubMed	Public	Millions of biomedical and life sciences articles published in PubMed

- [Using third party data in Quick Research \(PubMed\)](#)

Using third party data in Quick Research (FactSet)

Access FactSet's trusted equity prices, fundamentals, events, news, transcripts, pricing and consensus estimates - delivered seamlessly for AI-driven insights. With comprehensive coverage and reliable data, FactSet empowers smarter financial analysis, decision-making, and innovation.

- **Global Prices** - End-of-day pricing data, returns, corporate actions, dividends, and shares outstanding for global equities

- **Fundamentals** - Company financial statements, ratios, and business/geographic segment data from regulatory filings
- **Consensus Estimates** - Earnings estimates, surprise data, and buy/hold/sell ratings consensus
- **Transcripts** – Corporate event data and corresponding transcripts
- **StreetAccount News** – Curated, real-time market-moving news and summaries

Setting up the integration

This integration requires a subscription to FactSet. FactSet will need to authorize your account and someone with an Enterprise subscription to Quick (typically an admin or whomever is responsible for your organization's subscription to FactSet data) will need to set up the integration.

The integration can then be shared with others at your organization who should have access. The instructions below describe these steps in more detail.

To use FactSet in Quick, you (or someone from your organization) will need to:

1. Contact FactSet to get access at AWS.QR.Partnership@factset.com.
2. Create a Quick integration for FactSet.
 - a. Open the Research page and select **New Research**.
 - b. In the **Research Materials** section, find **Third party data** and select **Browse** to display a list of supported third party data integrations.
 - c. Find the integration in the list and select **Connect**. This will display a pop-up with a summary of these setup steps. Select **Continue**.
 - d. Enter a name and description.
 - e. For the client ID, provide the client ID you got from FactSet.
 - f. For the other authentication-related fields you can use the suggestions visible below each input field.
3. Share the integration with anyone else at your organization who should have access.

Using the integration in Quick Research

These instructions assume that you already set up the integration (see details above), or someone at your organization set up the integration and shared it with you.

To use this integration in Quick Research:

1. Navigate to the Quick Research page and select **New Research**.
2. On the left-hand side, under **Research Materials**, there is a section called **Third Party Data**. Select the **Browse** button to display a list of supported integrations.
3. If you need to sign in, there will be a **Sign In** button in the status column. Selecting this button will open a new tab where you can sign in. After you have signed in, navigate back to the tab with Quick Research.
4. Select the check box for the integration you want to use.

Using third party data in Quick Research (IDC)

The IDC Connector integrates IDC's industry-leading technology research and market intelligence directly into Amazon Quick Research, enabling business users to generate deeper, more credible insights in minutes. Through this integration, Quick Research users can securely access IDC's trusted data — including market forecasts, vendor assessments, and emerging technology analyses — alongside their own enterprise data and public web sources.

Setting up the integration

This integration requires a subscription to IDC. IDC will need to enable API access for your account, and someone with an Enterprise subscription to Quick (typically an admin or whomever is responsible for your organization's subscription to IDC) will need to set up the integration and knowledge base. The knowledge base can then be shared with others at your organization who should have access. The instructions below describe these steps in more detail.

Important

Creating an IDC knowledge base incurs storage and indexing costs. You should only create one IDC knowledge base for your organization to avoid unnecessary costs. To avoid users creating duplicate knowledge bases, we recommend not sharing the client ID and client secret with anyone else.

To use IDC in Quick, you (or someone from your organization) will need to:

1. Contact IDC to enable API access at <https://www.idc.com/amazonquickresearch>. IDC will give you a client id and client secret.
2. Create an integration for IDC:

- a. Open the Research page and select **New Research**.
 - b. In the **Research Materials** section, find **Third party data** and select **Browse** to display a list of supported third party data integrations.
 - c. Find the integration in the list and select **Connect**. This will display a pop-up with a summary of these setup steps. Select **Continue**.
 - d. Provide a name and description for the integration.
 - e. Use the client id and client secret you received from IDC.
3. Next, you will be prompted to create a knowledge base. This step could take several hours, depending on how much IDC data needs to be ingested and indexed.
 4. To share the knowledge base with others, scroll to the top of the Integrations page, select the menu icon for IDC, and select **Share**. You can share with individual users or groups. Make sure you only share the knowledge base with users who should have access to IDC data.

Using the integration in Quick Research

These instructions assume that you already set up the integration and knowledge base (see details above), or someone else did this and shared it with you.

To use this integration in Quick Research:

1. Navigate to the Quick Research page and select **New Research**.
2. On the left-hand side, under **Research Materials**, there is a section called **Third Party Data**. Select the **Browse** button to display a list of supported integrations.
3. Select the check box for the integration you want to use.

Using third party data in Quick Research (S&P Global Energy)

S&P Global Energy Data aggregates a vast array of textual content across thousands of documents about commodity and energy markets into an AI Ready data format, updated every 30 minutes. It enables users to ask customized questions on a range of topics such as regulatory challenges, investment opportunities, and trade flows.

Sources include PDF documents, news articles, rationales, commentaries, analyses, and more, all in an LLM-friendly format. This extensive dataset features hundreds of thousands of documents enriched with metadata, embeddings, and citations. The inventory of textual content focuses on different time horizons (from daily news to 1-year outlooks to 20+ year long-term scenario views)

for each of the major industry sectors broken down by subscription packages spanning Oil, Gas, Power, Metals, Clean Energy, Agriculture, Shipping sector, and more.

Users can leverage this integration to answer customized questions, leveraging S&P Global's commodity and energy market expertise. Example prompts include (but not limited to):

- Summarize the current regulatory challenges facing the crude oil industry and how they might impact production and pricing strategies.
- Identify the top investment opportunities in India's wind turbine sector in 2025 and beyond, highlighting emerging technologies or companies that are innovating in this space.
- Discuss recent environmental implications of metals extraction in Africa, and suggest sustainable practices that could be adopted in the industry.
- Summarize the current regulatory challenges facing the US natural gas pipelines in 2025 and how that might impact US gas production through end of this decade.

Setting up the integration

This integration requires a subscription to S&P Global Energy. S&P will need to authorize your account and someone with an Enterprise subscription to Quick (typically an admin or whomever is responsible for your organization's access to S&P data) will need to set up the integration. This person (the 'integration owner') will then share the integration with everyone at your organization who should have access. The instructions below describe these steps in more detail.

To use S&P Global Energy in Quick, you (or someone from your organization) will need to:

1. Contact S&P Global at ai.energy@spglobal.com to ensure your organization subscribes to S&P Global Energy. S&P will provide you a client id and client secret.
 - a. If your organization already subscribes, S&P needs to enable your account so you can access this data in Quick.
 - b. If your organization does not subscribe already, S&P can help you get started with a free trial.
2. Create a Quick integration for S&P Global Energy.
 - a. Open the Research page and select **New Research**.
 - b. In the **Research Materials** section, find **Third party data** and select **Browse** to display a list of supported third party data integrations.
 - c. Find the integration in the list and select **Connect**. This will display a pop-up with a summary of these setup steps. Select **Continue**.

- d. Enter a name and description for the integration. You can enter anything you want to help you identify this integration later.
 - e. Enter the client ID and client secret provided by S&P.
 - f. For the remaining fields, you can use the suggested values displayed below each input field.
3. Share the integration with anyone else at your organization who should have access.

Using the integration in Quick Research

These instructions assume that you already set up the integration (see details above), or someone at your organization set up the integration and shared it with you.

To use this integration in Quick Research:

1. Navigate to the Quick Research page and select **New Research**.
2. On the left-hand side, under **Research Materials**, there is a section called **Third Party Data**. Select the **Browse** button to display a list of supported integrations.
3. If you need to sign in, there will be a **Sign In** button in the status column. Selecting this button will open a new tab where you can sign in. After you have signed in, navigate back to the tab with Quick Research.
4. Select the check box for the integration you want to use.

Using third party data in Quick Research (S&P Global Market Intelligence)

Using S&P Global's MCP Server for the Kensho LLM-Ready API, customers can unlock S&P Global's trusted data and insights using natural language queries, enabling financial professionals to answer complex financial questions and get fast, reliable answers grounded in reliable data from S&P Global.

Query a comprehensive range of S&P Global datasets, including S&P Capital IQ Financials, Market Data, earnings call transcripts, and global securities information. This powerful connector is specifically designed to save time and resources for engineering, product, and business teams in financial services by streamlining access to critical company information, detailed financial statements, historical market data, and comprehensive global securities coverage.

Key capabilities include:

- **Compare Company Financials:** Analyze and benchmark financial performance across companies and time periods. Example: "Compare the gross margins and EBITDA trends for Amazon, Google, and Meta over the past 5 years" to identify competitive positioning and operational efficiency trends.
- **Summarize Earnings Calls:** Extract key insights from earnings transcripts and management commentary. Example: "Summarize the key takeaways from Apple's latest earnings call, focusing on guidance and capital allocation" to quickly understand strategic direction and financial priorities.
- **Deep Financial Research Reports:** Generate comprehensive competitive analysis and market research reports. Example: "Generate a comp table for software companies with \$1B+ revenue and 20%+ growth rates" to identify investment opportunities and market positioning.
- **Develop Due Diligence Briefs:** Develop a due diligence brief in a fraction of the time it would normally take – pulling key financials, generating comps tables, benchmarking peers, and flagging risks in minutes. Example: "Pull key financials for Tesla, generate a peer benchmark analysis, and flag potential risks for an investment committee presentation" to support informed decision-making.

Setting up the integration

This integration requires a subscription to S&P Global Market Intelligence. S&P will need to authorize your account and someone with an Enterprise subscription to Quick (typically an admin or whomever is responsible for your organization's access to this data) will need to set up the integration. The instructions below describe these steps in more detail.

To use S&P Global Market Intelligence in Quick, you (or someone from your organization) will need to:

1. Contact S&P Global to ensure your organization subscribes to S&P Global Market Intelligence data. To learn more about how to access S&P Global data via the Kensho LLM-ready API, email commercial@kensho.com for free trials and pricing, or read more [here](#).
2. Create a Quick integration for S&P Global Market Intelligence.
 - a. Open the Research page and select **New Research**.
 - b. In the **Research Materials** section, find **Third party data** and select **Browse** to display a list of supported third party data integrations.
 - c. Find the integration in the list and select **Connect**. This will display a pop-up with a summary of these setup steps. Select **Continue**.

- d. Provide a name and description for the integration. You can enter anything you like here to help you identify the integration.
3. Share the integration with anyone else at your organization who should have access.

Using the integration in Quick Research

These instructions assume that you already set up the integration (see details above), or someone at your organization set up the integration and shared it with you.

To use this integration in Quick Research:

1. Navigate to the Quick Research page and select **New Research**.
2. On the left-hand side, under **Research Materials**, there is a section called **Third Party Data**. Select the **Browse** button to display a list of supported integrations.
3. If you need to sign in, there will be a **Sign In** button in the status column. Selecting this button will open a new tab where you can sign in. After you have signed in, navigate back to the tab with Quick Research.
4. Select the check box for the integration you want to use.

Using third party data in Quick Research (US Patents)

This integration provides access to 20 years of US patents from the US Patent and Trademark Office (USPTO). For more information, see [USPTO](#).

Setting up the integration

There's no setup required since this is a public dataset.

Using the integration in Quick Research

To use this integration in Quick Research:

1. Navigate to the Quick Research page and select **New Research**.
2. On the left-hand side, under **Research Materials**, there is a section called **Third Party Data**. Select the **Browse** button to display a list of supported integrations.
3. Select the check box for the integration you want to use.

Using third party data in Quick Research (PubMed)

This integration provides access to 10 years of PubMed articles and documents. This includes millions of biomedical and life sciences articles. For more information, see [PubMed](#).

Setting up the integration

There's no setup required since this is a public dataset.

Using the integration in Quick Research

To use this integration in Quick Research:

1. Navigate to the Quick Research page and select **New Research**.
2. On the left-hand side, under **Research Materials**, there is a section called **Third Party Data**. Select the **Browse** button to display a list of supported integrations.
3. Select the check box for the integration you want to use.

Admin controls

Administrators can configure various settings and controls for Quick Research to ensure it meets organizational policies and security requirements.

Turn on/off web search

Administrators can enable or disable web search functionality for their organization. When web search is disabled, Quick Research will only use internal data sources such as uploaded files and connected spaces, ensuring that research remains within the organization's controlled data environment.

This control is useful for organizations with strict data governance policies or when working with sensitive information that should not be supplemented with external web sources.

Status definitions

Quick Research projects progress through various status states during their lifecycle. Understanding these status definitions helps you track the progress of your research and know what actions you can take at each stage.

- *Draft* - Research project is being created and configured but has not yet been submitted for processing
- *In Progress* - Quick Research is actively gathering and analyzing information from your selected sources
- *Review* - Initial research is complete and available for your review and feedback
- *Updating* - Quick Research is processing your feedback and generating an updated version of the report
- *Complete* - Research is finalized and ready for download, sharing, or archiving
- *Error* - An issue occurred during processing that requires attention or retry

You can view the current status of all your research projects from the main Quick Research dashboard.

Using Amazon Quick automations

Quick unifies AI agents for research, business insights, and automation into a single experience, helping business users make better decisions and act on them faster. Quick's automation capabilities handle everything from individual daily tasks to mission-critical enterprise processes, so teams can focus on higher-value work.

Types of automations

Quick offers two automation capabilities designed for different levels of scale and complexity:

- **Amazon Quick Flows** empowers any business user to automate repetitive, routine tasks without needing technical expertise.
- **Amazon Quick Automate** enables power users to orchestrate end-to-end business processes at enterprise scale. Amazon Quick Automate is not available for Free or Plus accounts.

Choosing between Quick Flows and Quick Automate

The right choice depends on the scope and complexity of what you need to automate.

- **User and ownership model.** Choose Quick Flows for personal and team productivity tasks, run by individual users. Choose Quick Automate for centralized, enterprise-wide automations, especially those which need to run independent of an individual user.
- **Workflow scope and duration.** Use Quick Flows for shorter-running tasks such as generating reports, drafting content, or responding to tickets. Use Quick Automate for long-running and high-volume processes such as managing loan applications, processing invoices, and validating new vendor compliance.
- **Customization.** Quick Flows offers a simple but powerful set of no-code building blocks for your workflows. Quick Automate gives additional advanced options for power users such as control flow logic, case management, error handling, custom code, and more.

Getting started

- To get started with Quick Flows, see [the section called “Using Amazon Quick Flows”](#).
- To get started with Quick Automate, see [the section called “Using Amazon Quick Automate”](#).

Using Amazon Quick Flows

Amazon Quick Flows is a capability within Amazon Quick that lets any user create, customize, and share workflows that automate routine tasks. You can generate flows from conversations with chat agents, describe what you need in natural language, or build them manually using the visual editor — no technical skills required. Flows can also be published to an admin-managed library and shared with other Amazon Quick users in your organization.

Each flow is a sequence of steps that can gather user input, generate AI responses from your data or the web, take actions in connected applications, and apply logic to control how steps run.

What are Flows?

A flow is a sequence of *steps* that you define once and run whenever you need it. You build flows in the editor, then run them in either a guided step-by-step mode or a conversational chat mode where you can refine outputs and ask follow-up questions.

Each flow can include the following step types:

AI responses

- Chat agent step that gets a response from a custom agent and can take actions.
- Research step that conducts research on a topic.
- Web search step that gets a response using web search.
- General knowledge step that gets a response directly from base AI models.
- UI agent step to perform tasks on public websites.
- Create image step that generates an image from inputs.

Flow logic

- Reasoning group step that adds run instructions to one or more steps.

Data insights

- Quick data step that gets insights from spaces or knowledge bases.
- Dashboards and topics step that gets responses from dashboards and topics.

Actions

- Application actions step that reads or writes to connected apps.

User input

- Text step to get and use text from users.
- Files step to get and use files from users.

For detailed explanations of each component, see [the section called “Components and features”](#).

Why Flows?

Organizations face business processes that require both human judgment and system interactions. Amazon Quick Flows bridges this gap by combining AI reasoning with direct business actions, so you can automate tasks like generating responses for requests for proposals (RFPs), reviewing statements of work (SOWs), or compiling industry trends into a sales pitch.

Amazon Quick Flows can help across departments:

- *Sales, marketing, and operations*: Qualifying leads, generating personalized proposals, creating marketing content, updating customer relationship management (CRM) records, and supporting processes like RFP responses
- *Human resources (HR)*: Processing employee requests, answering policy questions, and automating onboarding steps
- *Finance*: Analyzing expense reports, flagging anomalies, and processing routine approvals
- *Information technology (IT)*: Automating troubleshooting, system monitoring, and access management

Getting started with Quick Flows

This section covers user personas, prerequisites, and the Amazon Quick Flows landing page interface.

User personas

Amazon Quick Flows serves three types of users:

Creator

Creators are business users who build flows. They understand the repetitive tasks and processes in their domain and translate them into reusable workflows.

End user

End users run flows that creators have built. They interact with flows to complete their daily tasks and provide feedback on how well the automation works.

Admin

Admins configure and manage governance controls for Amazon Quick Flows within Amazon Quick. They can:

- Enable or disable Quick Flows for the account
- Restrict access to Quick Flows for specific users
- Enable or disable Bedrock models for output refinement
- Require approval before users can share flows
- Unpublish shared flows and transfer ownership between users

Prerequisites for Quick Flows

Before you can create and use Amazon Quick Flows, you need to ensure that your Amazon Quick administrator has completed the following prerequisites.

Administrator setup requirements

Your Quick administrator must complete the following tasks before you can create and use Quick Flows:

- Set up and configure Quick for your organization. For more information, see [Setting up and signing in](#).
- (Optional) Restrict access to flows for specific users using custom permissions.

For browser and region requirements, see [the section called "Supported browsers"](#).

Required permissions

Permissions to create, run, share, and govern flows are determined by user subscriptions and any configured custom permissions. For more information, see [the section called “Managing subscriptions”](#) and [the section called “Managing user access”](#).

Amazon Bedrock model access

Quick Flows uses Amazon Bedrock models for AI reasoning in the General knowledge step. Your administrator must enable access in custom permissions for output refinement in flows using Bedrock models. For more information, see [the section called “General knowledge”](#).

Next steps

After ensuring that all prerequisites are met, you can:

- Learn about key concepts in Quick Flows. See [the section called “Key concepts”](#).
- Create your first flow. See [the section called “Creating flows”](#).

Amazon Quick Flows landing page

When you access Amazon Quick Flows, you are directed to the landing page. The landing page has three navigation tabs:

- **Flows library** — Browse, search, and manage your flows and flows that others have shared with you.
- **My schedules** — Monitor and manage scheduled flow runs.
- **Pending approval** — Review and act on flows that are awaiting approval.

Flows library

The Flows library organizes your flows into three views:

- **Recently used** — Flows you have recently opened or modified, sorted by most recent.
- **My Flows** — Flows you own or that have been shared with you directly.
- **All Flows** — Every flow available in your organization.

Use the search bar to find flows by name or description. For each flow, the context menu lets you open, duplicate, or delete it. Choose **Create flow** to start building a new flow. For more information, see [the section called "Creating flows"](#).

Using pre-built flows

Amazon Quick Flows provides pre-built flows and samples to help you get started.

Pre-built flows

Pre-built flows are ready-to-use templates available in **My Flows** on the Flows landing page. You can run them as-is or duplicate and customize them to fit your needs.

- **Blog post generator** — Creates blog content based on a topic, target audience, and key points you provide. The flow produces structured posts with headings, body content, and suggestions for tone and style.
- **Email composer** — Drafts professional emails for common business scenarios such as announcements, requests, and follow-ups. You specify the recipient context and purpose, and the flow generates appropriately toned content with a subject line.
- **Data summarizer** — Analyzes structured data such as CSV or tabular files and extracts key insights, trends, and anomalies. The flow presents findings in a summary format you can share or use in other steps.
- **Chart creator** — Generates visualizations based on your data and analysis goals. The flow recommends chart types based on your data and lets you configure the output for clarity.
- **Meeting summarizer** — Processes meeting notes or transcripts and extracts discussion topics, decisions, and action items. The flow organizes the output into a structured summary you can distribute to attendees.
- **Project status reporter** — Creates project status updates from key metrics and milestones you provide. The flow highlights risks, resource allocation, and next steps in a formatted report.

Flow samples

Flow samples are available on the **Create Flow** page. These are example prompts designed to help you construct your own flows. Each sample provides a detailed natural language description that you can use as a starting point.

For example, the "Find current industry trends and news" sample generates a prompt like:

"Help me prepare for my customer call by fetching latest news on the company. Accept customer name, industry, company size, meeting objective, and previous interaction notes as inputs. For the customer name and previous interaction notes, search from web to obtain key talking points and relevant industry trends. Finally, from the web analysis and previous interaction notes, generate a meeting brief that I can use as talking points along with relevant product recommendations from indexed data."

Customizing a pre-built flow

To customize a pre-built flow, duplicate it and modify the copy:

1. Select the pre-built flow you want to customize.
2. Choose **Duplicate** to create your own copy.
3. Open the duplicated flow in the Flow editor.
4. Modify the steps, prompts, and configuration as needed.
5. Save your customized flow.

For more information about editing flows, see [the section called "Editing flows"](#).

Flow components and features

These topics provide detailed information about individual step types and their capabilities. For configuration instructions, see [the section called "Editing flows"](#).

Terminology and key concepts

Understanding the core terminology and concepts helps you effectively create, run, share, and maintain flows within your organization.

Steps and @ references

A flow is made up of steps that each perform a specific function, such as calling an action, querying your data, or searching the web. Most steps are controlled through a natural language prompt.

Steps pass data to each other using @ references. When you write a prompt inside a step, type @ to see a menu of previous steps. Select one to include that step's output as context in your prompt. For example, if Step 1 collects a customer's issue and Step 3 needs to classify it, Step 3's prompt might say: "Classify the issue in @Customer Issue by severity (low, medium, high)."

The available step types are organized into the following groups:

AI responses

- **Chat agent** — Gets a response from a custom agent and can take actions in connected applications.
- **Research** — Invokes Amazon Quick Research to generate research reports as part of your workflow.
- **Web Search** — Generates responses using internet search results.
- **General knowledge** — Gets a response directly from Amazon Bedrock models, with configurable response preferences for speed or versatility.
- **UI Agent** — Navigates public websites that do not require a login and performs tasks like scrolling to find information or filling forms.
- **Create Image** — Generates AI images from text inputs.

Flow logic

- **Reasoning Group** — Groups related steps together with natural language instructions that define conditions, loops, validation, and execution order.

Data insights

- **Quick data** — Retrieves responses from spaces and knowledge bases.
- **Dashboards and topics** — Gets insights from Amazon Quick Sight dashboards and topics.

Actions

- **Application actions** — Performs read or write operations in connected third-party applications through pre-built connectors.

User input

- **Text** — Collects free-form text input from users.
- **Files** — Accepts file uploads from users for document processing.

Editor and Run mode

Editor mode is where you build your flow. You see all the steps laid out and can select each one to change its configuration. Run mode is where you test and execute your flow, with a chat panel where you can ask follow-up questions or refine the output.

AI response steps

AI response steps generate content using AI models. Amazon Quick Flows provides the following AI response step types.

Chat agent

Amazon Quick Flows allows you to use your chat agents to generate outputs from configured spaces or take action with configured action integrations, all within a workflow step.

Chat agents contain domain-specific knowledge, custom instructions, and connected tools. When you integrate a chat agent into a flow, you can automatically apply this specialized knowledge across multiple workflows without recreating it. For example, if you built a sales assistant chat agent that understands product details and follows brand guidelines, you can embed it in your outreach flow to ensure consistent communication at scale.

For configuration instructions, see [the section called “Editing flows”](#).

Note

The chat agent step is a single-turn interaction. The agent responds to the task you instruct it to do, but does not support a back-and-forth conversation within the same step.

Research

The research step invokes Amazon Quick Research to generate research reports within your flow. This lets you embed research directly into multi-step workflows — for example, creating account plans, conducting policy reviews, researching patent prior art, or generating industry reports.

For full details about Quick Research capabilities and limitations, see [Using Amazon Quick Research](#). For configuration instructions, see [the section called “Editing flows”](#).

You can reference the research output in later steps — for example, to send a summary over email to your team.

Web search

The web search step lets your flows retrieve current information from the internet. This is useful when you need to access real-time data, verify facts, or gather information from public sources beyond your organization's internal knowledge base.

Write a prompt describing what to search for. The search results can be referenced by later steps in your flow using @ references.

For configuration instructions, see [the section called “Editing flows”](#).

Note

Search results may vary over time as internet content changes. Some content may not be accessible through web search.

General knowledge

The General knowledge step generates text responses using Amazon Bedrock models. Instead of selecting a specific model, you choose a response preference, and Amazon Quick Flows automatically selects the most appropriate model based on your preference and the requirements of your flow.

Choose from:

- **Fast responses** — Optimized for speed across image, video, and text inputs.
- **Versatility and performance** — Balanced capabilities for diverse tasks.

Optionally adjust the creativity slider to control the randomness of the response.

If you do not see response preferences, verify that your administrator has enabled "Enable bedrock model usage in General knowledge step for output refinement" in the Custom Permissions page.

For configuration instructions, see [the section called "Editing flows"](#).

UI agent

The UI agent step (Preview) lets your flows interact with public websites that do not require a login. The agent can autonomously navigate websites, click, type, read data, and produce structured outputs — all described in natural language.

Writing effective instructions

- Be clear and specific about the task you want performed.
- Use single, complete URLs (for example, "Go to <https://example.com/reports>").
- Add constraints to narrow the scope (for example, "only look at the pricing section").
- Specify when the agent should stop (for example, "stop after finding the first matching result").
- Define the output format if needed (for example, "return the data as a bulleted list").

For configuration instructions, see [the section called “Editing flows”](#).

 Note

UI agent is currently in Preview. Some websites implement anti-automation measures such as CAPTCHA challenges that may limit UI agent capabilities. Websites that require login are not currently supported.

Create Image

The Create Image step generates AI images from text prompts. You can configure creativity level, exclude terms, and image seed in the advanced settings.

For configuration instructions, see [the section called “Editing flows”](#).

Flow logic steps

Flow logic steps control how your flow runs.

Reasoning Group

Reasoning groups give you control over how parts of your flow run using natural language instructions. A reasoning group contains its own set of steps — like an isolated workflow within your larger workflow — that runs based on conditions you define. You can add most step types to a reasoning group, except reasoning groups and research steps. Templates are available to help you get started.

Loops

You can repeat the steps in a group for each value in a list from a previous step's output. Reference the previous step in your instructions, and the Flows runtime handles the iteration for you. For example, if a previous step returns a list of customer emails, a reasoning group can process each email in turn.

Conditions

You can run the steps in a group based on natural language conditions that evaluate a previous step's output. For example, "Run if @Customer Priority is HIGH PRIORITY" routes only urgent items through the group's steps.

Validation

You can check inputs or outputs before proceeding. For example, a reasoning group can verify that a required field is present before passing data to an action step.

For configuration instructions, see [the section called “Editing flows”](#). For reasoning group limits, see [the section called “Quick Flows limits”](#).

Data insight steps

Data insight steps retrieve information from your Quick data sources.

Quick data

The Quick data step retrieves responses from your spaces and knowledge bases. Write a prompt describing what content to retrieve, and optionally link specific resources. By default, responses are generated from all knowledge sources the user has access to.

The system searches across indexed documents in your spaces, including knowledge bases from connected sources. For more information about setting up spaces and knowledge bases, see [Working with integrations](#).

For configuration instructions, see [the section called “Editing flows”](#).

Dashboards and topics

The Dashboards and topics step generates insights from your existing Amazon Quick Sight dashboards and topics. Responses can include charts, graphs, tables, and other visualizations.

Select a Quick Sight source (Dashboard or Topic) and write a prompt describing the insights you want. You can specify filters, date ranges, and other criteria in natural language.

For configuration instructions, see [the section called “Editing flows”](#).

Action steps

Action steps let your flows perform read or write operations in connected applications. The available operations depend on the action integrations that you have configured or that have been shared with you. For prerequisites, authentication methods, and available integrations, see [Working with integrations](#).

Action parameters

Some actions require or accept parameters such as filters or specific input values. To determine which parameters an action accepts, you can ask Quick — for example, "What parameters does list emails accept when filtering emails?"

Parameters can be:

- Supplied directly in the prompt (for example, "List emails with subject containing 'quarterly report'")
- Referenced from a previous step using @ references (for example, a user input step that collects a search term)
- Acquired dynamically during flow execution based on the flow context

Working with list results

When you use an action that returns a list of items (for example, listing emails or tickets), the results may not include every item or every detail. This is because many applications return results in batches rather than all at once, and Quick retrieves only the first batch to keep your flow fast and responsive.

If you need the full details for each item in a list, you can use a reasoning group to go through the results one at a time and retrieve the complete information for each. For example, you might list your open support tickets in one step, then use a reasoning group to get the full details of each ticket.

When doing this, be mindful of how many items you are processing. A large number of items means more steps to run, which increases the time your flow takes to complete and the amount of data in your results. Where possible, use filters in your initial list action to narrow down the results before processing them.

For configuration instructions, see [the section called “Editing flows”](#).

User input steps

User input steps collect information from users when they run a flow.

Text

The text input step collects free-form text from users. You can set a placeholder, a default value, and allow users to override the default at runtime.

Use placeholder text to guide users on what to enter. For example, you can present a set of options like "Enter 1 for Sales, 2 for Marketing, 3 for Support" to help users provide structured input that your flow can act on.

For configuration instructions, see [the section called "Editing flows"](#).

Files

The file upload step accepts a document, image, or video from users. You can upload a default file and allow users to override it at runtime. You can upload one file per step.

File uploads are subject to the same size and format restrictions as uploading files in chat. If your content exceeds these limits, consider using a space or knowledge base to process the request instead.

For configuration instructions, see [the section called "Editing flows"](#).

Creating and managing flows

This section covers how to create, edit, version, and share flows within your organization.

Creating flows

You can create flows using natural language, the visual editor, by duplicating an existing flow, or from a chat agent conversation.

Prerequisites for creating flows

Before creating a flow, ensure that you meet the requirements described in [the section called "Prerequisites"](#).

Creating a flow using natural language prompt (NLP)

The natural language prompt method lets you describe your desired flow in plain language, and Amazon Quick Flows generates a flow based on your description.

1. Sign in to the Quick console.
2. In the navigation pane, choose **Flows**.
3. Choose **Create Flow**. You see a page where you can enter a natural language prompt or use a sample prompt.
4. In the prompt field, describe the flow you want to create. Be as specific as possible about:
 - The purpose of the flow

- The inputs it should accept
- The processing it should perform
- The outputs it should produce
- The actions it should take

5. Choose **Generate Flow**.

6. Review the generated flow and make any necessary adjustments.

7. Switch to **Run mode** to test your flow. If the flow is ready for use, you can share or publish it.

 Note

The quality of the generated flow depends on the clarity and specificity of your prompt. You may need to refine your prompt or make manual adjustments to achieve your desired outcome.

Creating a flow from scratch (blank flow)

Creating a flow from scratch gives you complete control over the design and functionality of your flow.

1. Sign in to the Quick web experience.
2. In the navigation pane, choose **Flows**.
3. Choose **Create Flow**.
4. Create a blank flow.
5. Enter a name and optional description for your flow.
6. In the Flow builder, add and configure the steps you need:
 - Add user input steps to collect text or files from users.
 - Add AI response steps to generate content from chat agents, web search, general knowledge, or image generation.
 - Add data insight steps to get responses from Quick data or dashboards and topics.
 - Add reasoning groups to control how steps run with conditions, loops, or validation.
 - Add action steps to read or write to connected applications.
7. Choose **Save** to save your flow.

For more information about the different components you can use in a flow, see [the section called "Key concepts"](#).

Creating a flow by duplicating an existing flow

Duplicating a flow creates a copy that you can modify for your own purposes.

1. Sign in to the Quick console.
2. In the navigation pane, choose **Flows**.
3. Find the flow you want to duplicate.
4. Choose the ellipsis (:) next to the flow name, then choose **Duplicate**.
5. Modify the name and optionally the description for your purposes.
6. Make any necessary modifications to the flow.
7. Choose **Save** to save your flow.

Note

When you duplicate a flow, all components, connections, and configurations are copied. However, you may need to reconfigure certain settings, such as authentication for connectors.

Creating a flow from an agent conversation

You can create a flow from a conversation with a chat agent. For example, if you have been working through a task like reading an email, augmenting it with internal or web knowledge, and drafting a response, you can convert that conversation into a reusable flow.

1. Sign in to the Quick console.
2. Start a conversation with a chat agent.
3. Work through the task you want to automate.
4. Choose the Quick Flows icon in the chat bar.
5. Choose **Create Flow from conversation**. Amazon Quick Flows interprets the interactions in your conversation and brings you to the Create flow screen with a generated natural language prompt, name, and description.
6. Review and edit the prompt, name, and description as needed.

7. Choose **Generate Flow**.
8. Review the generated flow and make any necessary adjustments.
9. Choose **Save** to save your flow.

Flow creation requirements

When creating a flow, keep the following requirements in mind:

Flow name

Flow names must be unique within your Quick account and can contain up to 128 characters.

Flow components

A valid flow must have at least one output step or action step.

Reasoning groups

Each reasoning group must have at least one instruction that defines what the AI model should do with the inputs.

Action steps

Action steps require proper authentication and configuration before they can be used in a flow.

Next steps

After creating a flow, you can:

- Test your flow to ensure it works as expected.
- Publish your flow to make it available to users. See [the section called "Publishing changes"](#).
- Share your flow with specific users or groups. See [the section called "Sharing flows"](#).
- Monitor your flow's usage and performance. See [the section called "Progress tracker"](#).

Editing flows

After creating a flow, you can edit and configure it in the Flow editor.

Accessing the Flow editor

1. Sign in to the Amazon Quick console.

2. In the navigation pane, choose **Flows**.
3. Find the flow you want to edit.
4. Choose the flow tile, or choose the ellipsis (:) and select **Open**.

Configuring step types

Most steps with a prompt field support @ references to include data from previous steps. See each step's configuration for specific limitations.

Configuring text input steps

In Editor mode, add or select a text input step. In the configuration panel, set the following:

- **Title:** A name for the step.
- **Placeholder:** Optional text that appears inside the input field when it is empty. This text is not used for the flow run.
- **Default Value:** Optional. The value provided if the user doesn't enter an input.
- **Allow override of default value:** Toggle to let users replace the default value at runtime.

Configuring file upload steps

In Editor mode, add or select a file upload step. In the configuration panel, set the following:

- **Title:** A name for the step.
- **Default file:** Optional. Upload a document, image, or video to use if the user doesn't provide one. You can upload one file per step.
- **Allow override of default value:** Toggle to let users replace the default file at runtime.

Configuring general knowledge steps

In Editor mode, add or select a general knowledge step. In the configuration panel, set the following:

- **Output preference:** Choose one:
 - **Fast responses** — Across image, video, and text inputs.
 - **Versatility and performance** — Balanced capabilities for diverse tasks.

- **Prompt:** Write the prompt that instructs the model what to generate.
- **Creativity Level:** Optional. Adjust the slider from low to high to control the randomness of the response.

For more information, see [the section called “General knowledge”](#).

Configuring Quick data steps

In Editor mode, add or select a Quick data step. In the configuration panel, set the following:

- **Prompt:** Write the prompt that instructs what content to retrieve.
- **Link specific resources:** Select spaces and knowledge bases to get insights from. By default, responses are generated from all knowledge sources the user has access to.

Configuring web search steps

In Editor mode, add or select a web search step. In the configuration panel, set the following:

- **Prompt:** Write the prompt that instructs what content to search for on the web.

Configuring research steps

In Editor mode, add or select a research step. In the configuration panel, set the following:

- **Title:** A name for the step.
- **Research objective:** Describe what you want to research.
- **File uploads:** Optional. Upload default files to help guide your research.
- **Research materials:**
 - **Preferred websites:** Optional. Specify websites or types of websites the agent should prioritize (for example, government websites, academic journals).
 - **Websites to avoid:** Optional. Specify websites or types of websites to exclude (for example, social media, blogs).
- **Data and apps:** Select all data and apps, or choose specific ones.

Configuring chat agent steps

In Editor mode, add or select a chat agent step. In the configuration panel, set the following:

- **Title:** A name for the step.
- **Chat agent:** Select the agent to use.
- **Prompt instruction:** Write the prompt that instructs the agent.
- **Data and apps:** Optionally narrow down the selected data and apps to refine your use case.
- **Web search:** Toggle to enable or disable web search for the agent.

Configuring UI Agent steps

In Editor mode, add or select a UI Agent step. In the configuration panel, set the following:

- **Title:** A name for the step.
- **UI Agent Instructions:** Write the instructions for the UI agent. Use single, complete URLs for faster, more accurate results.

Configuring Create Image steps

In Editor mode, add or select a Create Image step. In the configuration panel, set the following:

- **Prompt:** Describe the image to generate.
- **Advanced settings:** Configure creativity level, exclude terms, and image seed.

Configuring Dashboards and topics steps

In Editor mode, add or select a Dashboards and topics step. In the configuration panel, set the following:

- **Quick Sight source:** Choose from Dashboard or Topic.
- **Prompt:** Describe the insights you want from your dashboard or topic.

For more information, see [the section called “Dashboards and topics”](#).

Configuring action steps

In Editor mode, add or select an action step. In the configuration panel, set the following:

- **Connector:** Select the connector to use (for example, Salesforce, Jira, Slack).
- **Action:** Select the specific action to perform.

- **Prompt:** Write prompt instructions to execute your actions.

For more information, see [the section called "Actions"](#).

Configuring reasoning groups

In Editor mode, add or select a reasoning group. In the configuration panel, set the following:

- **Instructions:** Write instructions that tell the model what to do, such as conditions, loops, or validation logic. You can reference the output of a previous step as the input to a loop or conditional statement.

Prompt writing for steps

When writing prompts for steps, consider the following best practices:

- Be clear and specific about what you want the model to generate.
- Provide context to help the model understand the task.
- Specify the desired format, tone, and style of the output.
- Use specific language to control the output — for example, "respond in bullet points", "limit the response to three sentences", or "use a formal tone".
- Use examples to illustrate the expected output when appropriate.

Adding and removing steps

Adding steps

1. In the Flow editor, choose **Add step** from the toolbar.
2. Select the type of step you want to add.
3. Drag the step to the desired position in your flow.
4. Configure the step as needed.

Removing steps

1. Select the step you want to remove.
2. Choose **Delete** from the context menu.
3. Confirm the deletion when prompted.

 Note

When you remove a step, any @ references to that step in other steps are also removed. You may need to update other steps to maintain your flow.

Publishing changes

After making changes to your flow, publish them to make them available to users.

1. In the Flow editor, choose **Save** to save your changes.
2. Choose **Publish**.
3. Choose **Publish** to confirm.

When you publish, the changes become immediately available to all users who have access to the flow.

Updating Flow details

Updating title and description

1. In the Flow editor, directly edit the title and description in-line.
2. Choose **Save**.
3. Choose **Publish**.

Viewing the original prompt

If your flow was created using a natural language prompt, you can view the original prompt:

1. In the Flow editor, select the kebab menu in the header.
2. Choose **View prompt**.

 Note

The original prompt is read-only. To create a new flow based on a modified prompt, use the natural language prompt method.

Best practices for editing flows

- Test your changes thoroughly before publishing them to ensure they work as expected.
- Use clear and descriptive names for steps to make your flow easier to understand and maintain.
- Write detailed prompts and instructions to get the best results from AI models.
- Use @ references to create dynamic flows that adapt to user inputs.
- Consider the user experience when designing the flow of steps.
- Document your changes in the publication description to maintain a clear history of updates.

Step configurations and available features may change over time. For the latest information, see the [the section called “Key concepts”](#) and the [Amazon Quick Flows product page](#).

Versioning

Amazon Quick Flows uses versioning to let you edit a flow without affecting the version that others are using. You can have up to three versions of a flow at any time.

How versioning works

Your organization's setup determines which version types you see.

If your organization uses approval review

You work with three version types:

- **Draft** — Your working copy. You can edit and test your flow without affecting the published version. As you edit, your flow is saved automatically. You can have one draft at a time.
- **Pending Approval** — A version submitted for review. You can view it and check the approval status, but you cannot edit it. If changes are requested, update your draft and resubmit.
- **Published** — The approved version that other users can access and run.

For more information about approval reviews, see [the section called “Approval review”](#).

If your organization doesn't use approval review

You work with two version types:

- **Draft** — Your working copy. You can edit and test your flow without affecting the published version. As you edit, your flow is saved automatically. You can have one draft at a time.

- **Published** — The version that other users can access and run. You can publish directly when your flow is ready.

Version Type	Can Edit?	Visible to Users?	Next Step
Draft	Yes	No	Publish (or submit for approval)
Pending Approval*	No	No	Wait for approval
Published	No	Yes	Create new draft for changes

*Pending Approval only applies if your organization uses approval review.

Publishing changes

Any changes to a flow's title, description, steps, logic, or sharing permissions require publishing. When you publish, the new version replaces the current published version for all users. End users always see only the latest published version.

If your organization uses approval review, publishing submits your flow for review. Once approved, it becomes the new published version. Without approval review, publishing makes changes available immediately.

Unpublishing flows

You can unpublish a shared flow to remove it from general availability while keeping it accessible to co-owners. Viewers lose access, and the flow returns to draft state. Unpublishing does not require approval review.

Sharing flows

When you share a flow, you give others permission to view and run it, or to collaborate on it as co-owners.

Sharing options

You can share a flow in three ways:

- **With individuals** — Share with specific people using their email addresses.
- **With groups** — Share with pre-defined groups in your organization (for example, departments or project teams).
- **With everyone** — Make the flow available to all users in your Amazon Quick Flows instance.

Depending on your organization's settings, sharing may require approval review. For more information, see [the section called "Approval review"](#).

How to share a flow

1. Open your flow.
2. Choose **Share**.
3. Select how you want to share: with individuals, groups, or everyone.
4. For individuals, enter email addresses. For groups, search for and select the group.
5. Choose the permission level: **Viewer** or **Co-owner**.
6. Choose **Share**.

Permission levels

Viewer

Viewers can run the flow and view results, but cannot edit, share, or delete it. Viewers only see the published version.

Co-owner

Co-owners can edit the flow, share it with others, manage permissions, publish changes, and access draft versions. Co-owners cannot remove the original owner. Only one person can edit at a time.

Permission reference

Permission	Can run?	Can edit?	Can share?	Can delete?
Viewer	Yes	No	No	No
Co-owner	Yes	Yes	Yes	Yes

Approval review

When approval review is enabled, users must submit their flows for review before they can be shared. This gives administrators oversight of what flows are available in the organization.

How approvals work

When approval review is enabled, sharing a flow follows a three-stage cycle:

- **Submitted** — The flow is waiting for review. You can view it and check the status, but cannot edit it. You can withdraw the request if needed.
- **Rejected** — The flow was not approved. You can view the reviewer's feedback, update your draft, and resubmit.
- **Approved** — The flow is shared with your intended audience. Any future changes require a new approval cycle.

Who can review flows

Users with Amazon Quick Enterprise subscriptions (Author Pro or Admin Pro roles) can review and approve flows. Users with Amazon Quick Professional subscriptions cannot review flows.

Reviewers can:

- View all submitted flows in the **Pending approval** tab
- Approve or reject flows individually or in bulk
- Provide feedback when rejecting a flow

Submitting a flow for approval

1. Complete and test your flow.
2. Choose **Share** and specify who should have access.
3. Choose **Submit for review**.
4. Monitor the approval status in the **Pending approval** tab.

If your flow is rejected, review the feedback, update your draft, and resubmit.

Enabling and disabling approval review

Administrators control approval review through the Custom Permissions page.

When enabled:

- All future flow sharing requires approval.
- Existing shared flows remain accessible.
- Users can still create and edit flows in draft mode.

When disabled:

- All pending approval requests are automatically rejected.
- Users can share flows immediately without approval.
- Previously approved flows remain shared.

Approval states reference

State	Can edit?	Visible to users?	Available actions
Draft	Yes	No	Submit for approval
Submitted	No	No	View status, withdraw request
Rejected	Yes	No	Update and resubmit
Approved	No	Yes	Create new draft for changes

Running flows

These topics cover how to run flows in different runtime modes, download outputs, and schedule recurring runs.

Interacting with flows in runtime mode

When you open a flow, you select **Run mode** to execute it. There are three ways to start a flow.

Starting a flow with structured input

If the flow has input steps, enter the required information and choose **Start**. The flow runs through each step in sequence and displays the results.

Starting a flow with conversational runtime

You can supply the flow input (optional) and ask the agent to start the flow through the chat panel. The agent collects any additional inputs, runs the steps, and presents results within the conversation. You can ask follow-up questions or refine outputs as the flow runs.

Starting a flow from a chat agent

You can run a flow directly from a chat agent conversation:

1. Choose the Flows menu in the chat footer.
2. Select the flow you want to run.
3. Follow the prompts to execute it.
4. When finished, choose **End** to return to your chat agent conversation.

Details from your conversation can automatically populate the text input to your flow. When the flow completes, the output is shared with the calling agent.

Progress tracker

The progress tracker shows the status of each step as the flow runs.

Resuming runs from history

You can view and resume previous flow runs from the flow's history. Open the flow and choose the history icon to view previous runs.

Downloading output in Amazon Quick Flows

After a flow run completes, you can download one or more step outputs as a Word (.docx) or PDF document. You can save files locally or to a shared Quick space for team collaboration. Downloaded files maintain the original formatting, including markdown structure, visual elements, and data tables.

Download flow outputs

1. In Run mode, choose the download icon (downward arrow) in the top right.

2. Choose **Download as**.
3. Select which outputs to include:
 - Choose **Select All** to include all steps in chronological order.
 - Use checkboxes to select specific steps.

 Note

User input and file upload steps cannot be downloaded.

4. Select your preferred file format:
 - **Word (docx)** — Editable document format
 - **PDF** — Fixed-layout document format
5. Choose your download destination:
 - **Download** to save the file locally.
 - **Save to a space** to save to a shared space (requires edit access).

Scheduling your Amazon Quick Flows

Schedules let you automate recurring flow runs without manual intervention. You can schedule flows you have created or flows that have been shared with you. All schedules are private to you and cannot be shared with other users.

Common uses include generating recurring reports, summarizing open items from external services, or preparing daily meeting briefings.

Creating a schedule

1. Open your flow in Run mode.
2. Choose the scheduling icon.
3. Choose **Create schedule**.
4. Configure your schedule:
 - **Schedule name** — A unique name for the schedule.
 - **Description** — Optional. Details about the schedule's purpose.
 - **Repeat configuration** — Choose from suggestions or configure custom recurrence (daily, weekly, or monthly) with start date, optional end date, and time zone.

5. Choose **Next**.
6. Provide default inputs for each scheduled run.
7. Choose **Next**.
8. Configure action permissions:
 - Turn on **Run with no confirmation** to automatically submit action forms during scheduled runs.
 - Turn off to review and confirm each action manually.
9. Choose **Save**.

Note

Action permissions only appear if the flow contains action steps. Automatic form submission is enabled by default for write actions. User confirmation is recommended to help avoid AI prediction errors.

Managing schedules

You can manage schedules from two places:

- **From the flow** — Open the flow, choose the scheduling icon, and edit, pause, duplicate, view runs, or delete a schedule.
- **From the Flows library** — Choose the **My schedules** tab to see all your schedules across all flows with their status, frequency, last run, and associated flow name.

Schedule history

All manual and scheduled runs appear in the flow run history. You can filter by all runs, scheduled runs, or failed runs. History is retained for 30 days.

Visual indicators help distinguish run types:

- Schedule run tag for scheduled runs
- Orange dot for un-viewed completed runs
- Running tag for in-progress runs
- Failed tag for failed runs

Note

You cannot view an ongoing scheduled run until it completes.

Notifications

You receive email notifications when:

- A scheduled run completes successfully (with a link to the results)
- A run requires your input to continue
- A run requires authentication for a third-party application
- A flow with your schedules is unshared from you (schedules are archived)
- A flow with your schedules is deleted
- A flow with your schedules is updated with a new version (schedules continue with the updated version)

Authentication for connectors

Ensure your authentication for connectors is current before scheduling. If authentication expires before a scheduled run, you receive an email notification. To verify, run the flow manually or visit the connector page in Quick to sign in.

Managing Quick Flows

As an administrator, you can manage how Amazon Quick Flows operates within your organization, including governance policies, user permissions, and feature availability.

Administrative access requirements

To manage Quick Flows settings, you must have administrator privileges in your Amazon Quick instance. Administrative controls are available through the Amazon Quick console's management interface, where you can configure permissions and manage assets.

Governance capabilities overview

Quick Flows administrative controls provide multiple layers of governance:

- **Feature enablement** - Control whether flows are available to users in your account

- **Approval workflows** - Require administrative approval before flows can be shared with users
- **Asset management** - Oversee Flow sharing, ownership, and visibility across your organization

Managing Quick Flows permissions and assets

Administrators manage Quick Flows permissions and assets through two interfaces in the Quick console: the Custom Permissions page and the Asset Management page.

Custom Permissions page

The Custom Permissions page controls which Quick Flows capabilities and features are available to users.

Restrict capabilities

- **Enable or disable flows** — Control whether Quick Flows is available to users in your account. When disabled, all Quick Flows functionality is unavailable, but existing flows are preserved. Quick Flows is enabled by default for new Quick instances.

Restrict features

- **Allow creators to share without approval** — When enabled, creators can share flows without review. When disabled, all eligible users can review and approve flow sharing requests.
- **Enable bedrock model usage in General knowledge step for output refinement** — Controls whether Bedrock models are available for General knowledge steps. Enabled by default.
- **Enable UI agent to perform browser tasks (Preview)** — Controls whether UI agent steps can be used in flows.

Asset Management page

The Asset Management page provides oversight of all flows in your organization.

- **Share flows** — Share flows on behalf of creators, redistribute flows to different groups, or manage sharing permissions across the organization.
- **Transfer ownership** — Transfer flow ownership between users, such as when a creator leaves the organization.
- **Unlist flows** — Remove flows from the shared library, making them unavailable to viewers while preserving them for the creator to edit. Unlisted flows can be re-shared once issues are resolved.

Quick Flows limits

Flow limits

The following limits apply to flow creation and management in your Quick instance:

- **Maximum flows per instance:** 10,000 flows
- **Maximum flows per user:** 100 flows
- **Maximum steps per flow:** 35 steps

Input limits

Input limits vary depending on whether you are using General knowledge or Quick data as your data source.

Text input limits

- **General knowledge:** 40,000 characters
- **Quick data:** 15,000 characters

File upload limits

File upload limits depend on your knowledge source and file type:

File size limits:

- **General knowledge:**
 - Document files: Up to 50 MB (supported file types depend on output preference)
 - Video files: Up to 1 GB
 - Image files: Up to 4.5 MB
- **Quick data:**
 - Document files: Up to 50 MB (.pdf, .txt, .rtf, .doc, .docx, .ppt, .pptx, .csv, .xls, .xlsx)
 - Image files: Up to 10 MB (.png, .jpg, .jpeg)

Maximum number of files:

- **General knowledge:** Up to 5 files

- **Quick data:** Up to 20 files

Character limits for file content:

- **General knowledge:**
 - Faster responses: Up to 1M characters total context limit
 - Versatility and Performance: Up to 1M characters total context limit

The total context limit includes characters from output prompts defined at build time and characters from input steps and file upload steps at runtime.

- **Quick data:** 665,000 characters

Output limits

Output limits control the size of prompts and generated responses:

- **Maximum input prompt size:**
 - General knowledge: 5,000 characters
 - Quick data: 5,000 characters
- **Maximum output characters rendered:**
 - General knowledge: Up to 40,000 characters
 - Quick data: 8,000 characters

Reasoning group limits

- **Maximum iterations per reasoning group:** 50 iterations

When referencing the output of a reasoning group, especially looped content, the output is bound by the input character limits of the receiving step. For larger outputs, consider staging the results and querying them in a later step.

Schedule limits

- **Region availability:** Schedules in flows are currently supported in US East (N. Virginia), US West (Oregon), and Europe (Ireland)

- **Maximum schedules per user:** 20 schedules per user
- **Maximum schedules per instance:** 10,000 schedules

Regional availability

Certain features have regional limitations:

- **Image generation:** Currently supported in US East (N. Virginia), US West (Oregon), and Europe (Ireland)

Using Amazon Quick Automate

Overview

Amazon Quick Automate is an AI-powered application that creates sophisticated automations using natural language or documentation. Amazon Quick Automate revolutionizes enterprise workflow by transforming complex processes into intelligent, adaptive automations.

Note

Amazon Quick Automate is available only for Amazon Quick accounts provisioned through the AWS Management Console. It is not available for Free or Plus accounts created at aws.com/quick.

Enterprises struggle to automate end-to-end business processes due to the growing complexity of their application ecosystems and the limitations of traditional automation tools. Amazon Quick Automate provides the easiest way for businesses to build, deploy, and continuously maintain workflow automations with the set of capabilities needed to support complex use cases that span multiple applications, data sources, and departments.

Customers can simply provide their process requirements by uploading process documents or simply describing their business process in a natural language. From the documents or description, Amazon Quick Automate creates a plan with steps and actions for your automation. You can expand upon the plan by adding additional steps or actions or modify the existing steps or actions. You can add additional steps by dragging actions or steps from an extensive Actions library.

Amazon Quick Automate's intelligent agents can seamlessly navigate and interact with web applications, make contextual decisions based on real-time data, execute API calls, and even generate custom code to handle complex scenarios. When human oversight is required, the system can create human-in-the-loop tasks for manual review or approval.

Key concepts

Automation groups

Automation groups create logical groupings for automations, allowing organizations to manage permissions and resources efficiently across different departments or projects. These groups provide a way to organize your automations and setup permissions based on business units, functional areas, or project teams.

By organizing automations into groups, you can apply consistent access controls, resource restrictions, and governance policies. This organizational structure supports scalable automation management as your organization's automation needs grow and evolve.

Project

A *project* is the primary container that encapsulates all metadata, assets, and contextual information related to an automation initiative. It serves as the foundational unit for organizing, authoring, testing, deploying, and maintaining automations across their lifecycle.

Lifecycle of a project

- **Create a project:** Define the automation's scope including its name, purpose, business case, and attach process documentation.
- **Build automation:** Within the project, build and test and automation.
- **Version and deploy:** Publish automation versions for testing or production. Projects maintain version history and deployment status.
- **Monitor and iterate:** Review logs, metrics, for each run and iterate on the automation. Each iteration creates traceable project-level change history.

Automations

An *automation* is a visual artifact that represents the executable logic of a process. It is created using the *Visual Designer* within , where you define the sequence of actions, decisions, and agent interactions needed to complete a business process. Each automation serves as the operational blueprint for how work is performed, combining AI-powered agents, system actions, and human inputs in a unified flow.

Actions

Actions are the building blocks for your automations. Each action performs a specific task, from reading data to interacting with external systems.

Agents

An *agent* is an AI-powered action that can understand natural language input, reason through scenarios, and perform complex tasks on your behalf. Agents bring intelligence and adaptability to automations by interpreting intent, handling variability, and executing actions dynamically.

- **UI agent** is a native agent that understands natural language instructions to perform complex browser actions. It can autonomously navigate websites, click, type, read data, and produce structured outputs optimized for downstream automation steps.
- **Custom agent** is an AI-powered action that processes natural language inputs to automate complex steps using integrated tool-calling capabilities. It primarily uses integrations as its tool interface, while offering extensibility to use Code as tool, and other native actions like human-in-the-loop task. The agent delivers structured, predictable outputs optimized for seamless integration into downstream automation steps.

Getting started

Amazon Quick Automate is a browser-based solution that requires no installation, has minimal IT dependencies, and is always up to date. Amazon Quick Automate is designed for **technical teams and power users** who build, test, and maintain intelligent automations across enterprise systems. These users typically have a strong understanding of business processes, system integrations, but may not necessarily be software developers. Amazon Quick Automate equips advanced users and technical teams with the flexibility, control, and depth needed to design and scale enterprise-grade automations. To get started with Amazon Quick Automate, simply access it through your Amazon Quick and begin exploring the automation capabilities that best fit your needs.

Key capabilities

- Multi-agent architecture
 - Planning Agent designs automations from natural language inputs
 - UI Agent handles interface interactions
 - Specialized agents for process-specific tasks
 - Integration with

- Enterprise controls and governance
 - Granular access control management
 - Comprehensive activity logging
 - Built-in version control
 - Governance features for compliance
- Human-in-the-loop capabilities
- Case management
- Exception handling support
- Real-time monitoring
- Built in scalability

Setup tasks

Complete these setup tasks to prepare your Amazon Quick Automate environment for creating automations.

Sign up

Before you can use Amazon Quick Automate, you need to sign up for and create your account. The sign-up process establishes your initial workspace and provides access to Amazon Quick Automate.

Set up automation groups

Automation groups create logical groupings for automations, allowing organizations to manage permissions and resources efficiently across different departments or projects. These groups provide a way to organize your automations and setup permissions based on business units, functional areas, or project teams. By organizing automations into groups, you can apply consistent access controls, resource restrictions, and governance policies. This organizational structure supports scalable automation management as your organization's automation needs grow and evolve. After signing up, configure automation groups and permissions to organize your automations and control access across your organization. This step ensures that different departments and teams can work with automations appropriate to their roles and responsibilities.

Setting up proper automation groups and permissions from the beginning helps maintain security and compliance as your automation environment grows. You'll establish the organizational structure that supports efficient workflow management across multiple departments or projects.

Setup user roles

Amazon Quick Automate provides granular role based access: Viewer, Contributor, and Owner. Viewers can submit new project ideas, interact with human in the loop tasks, and access monitoring dashboards. Contributors can build, test, and deploy automations. Owners can control automation access to systems through integrations and secure credentials as well as user access.

Configure integrations

- After setting up AWS service integrations, you can begin using them in Quick Automate. See [the section called “Connectors”](#) for setup details.
- First, add the integration to an Automation Group. This allows you to control access for which automations can use this integration. To add an integration to your Automation Group:
 - Go to the **Projects** page
 - Click **Manage groups** and select the group you want to add an integration to
 - In the **Assets** sections, click **Add**, and then **Actions**
 - Select the Integration you created earlier and click **Add** to link it to your Automation Group
- Now when users create projects in that Automation Group, they will find the actions associated with this Integration and be able to select this Integration for authentication

Set up Virtual Private Cloud (VPC) connections

Amazon Quick Automate can access publicly hosted internet endpoints by default. For more complex setups, including accessing privately hosted websites, Amazon Quick Automate automation jobs can optionally be associated with your VPC. For more information, see [the section called “Setting up a VPC to use with Amazon Quick”](#).

With this configuration in place, all outbound network traffic from the managed browser is routed through an ENI in your configured VPC. From there, you can send that traffic to privately hosted resources or use it to obtain a persistent IP for IP allow listing.

The VPC-connected Amazon Quick Automate setup provides:

- **Direct access** to privately hosted resources in the connected VPC
- **Extended access** to other privately hosted resources in peered, PrivateLinked, etc. VPCs
- **Internet access** through your managed Internet Gateway

Setup instructions

Step 1: Choose your VPC

Select an existing VPC or create a new one that includes private and public subnets in one or more Availability Zones, NAT and Internet Gateways.

Note

If creating a new VPC, the default selections in AWS VPC creation wizards are sufficient.

Step 2: Setup connectivity to target resources

Bot traffic will egress through an ENI in your connected VPC. Choose the appropriate connectivity method:

For resources in the same VPC:

- No additional setup required

For resources in different VPCs, use one of these AWS constructs:

- AWS VPC Endpoint Services (PrivateLink) - Exposing individual service endpoints from one VPC to another
- AWS Transit Gateway - Centralized management of a cluster of peered networks
- AWS VPC Peering - Direct connection between a pair of VPCs

Step 3: Create Quick VPC Connection

Use Quick Admin tools to create a VPC Connection. This step creates two ENIs in the private subnet within your chosen VPC.

Step 4: Associate VPC Connection with Automation Group

Once the VPC Connection is created, associate it with your automation group from the VPC connection section in the automation group page. After this association is configured, all subsequent automations run within the specified group will use the VPC Connection for network access.

Create project

This section walks you through the process of creating a new automation project in Amazon Quick Automate.

To create a new project

1. Click the **Create Project** button to begin.
2. Fill in the project details in the Provide project details section:
 - **Name:** Enter a descriptive name for your automation project.
 - **Group:** Select the appropriate group for your automation.
 - **Description** (optional): Provide additional context about the project's purpose.
 - **Upload Documents** (optional): Attach existing documentation to jumpstart your automation.
3. Click **Next: Business case** to proceed to the business case section.

Defining the business case (Section is optional)

This section is optional but recommended for tracking ROI and prioritization. Complete the following fields:

- **Hours saved per case:** Estimate time savings per instance.
- **Cases per year:** Enter the expected annual volume.
- **Hours saved per year:** This may calculate automatically based on previous entries.
- **Project priority:** Set the relative importance of this automation.
- **Target launch date:** Define the target implementation date.

Click **Create** to finalize and generate your new automation project.

Note

Required fields are marked accordingly in the interface. Optional fields provide additional context but can be completed later if needed.

After creating your project, you can access a summary page with Overview, launch goals and document section will open for review. This comprehensive layout allows you to quickly grasp the essential information about your project or resource. You will have Summary (default selected), Versions and Deployments tabs.

In Summary, the Overview section provides a high-level description and launch Goals. The Documents section contains relevant document uploaded. On the right-hand side of the page, you'll notice a Status panel. This panel offers real-time updates on the current state of your project. It may include information such as deployment status, health checks, or any ongoing processes.

Building automations

Amazon Quick Automate provides multiple methods for creating automations to suit different needs and skill levels. This section describes the available creation methods and tools.

Prerequisites

Before creating an automation, you need to create a project within a specific automation group. The automation group will control what integrations and credentials are available to you when building that automation. Ensure the required integrations and credentials are set up for any external systems you plan to interact with in your automation.

Once you have created a project, click the **Start building** button to get started.

Note

You must have owner permissions to manage integrations and credentials for an automation group.

Creation methods

Choose from three approaches to build your automation. If you're new to Amazon Quick Automate, we recommend:

- Start by exploring sample automations
- Try creating a simple automation using natural language
- Experiment with manual editing once you're familiar with the basics

Using sample automations

Get started quickly by exploring pre-built samples that demonstrate common automation patterns. These samples provide hands-on examples of different automation capabilities and serve as learning resources to help you become familiar with the capabilities of Amazon Quick Automate. To use a sample automation:

- Search to explore different samples by industry.
- Click on the sample to view an overview of the automation.
 - If any integrations are required, they will be listed as prerequisites.
- Click **Start with sample** to open the automation in the canvas.
- You will now be able to view the automation, edit it, and test it.

Creating with natural language

The Automation Assistant provides an AI-powered approach to creating automations through:

- Chat interface - Describe your process conversationally in natural language
- Document upload - Import any documentation that describes your process steps and requirements

When you provide input through either method, the Automation Assistant will generate your automation through a two-step guided experience:

- **High-level plan**
 - First, the Assistant analyzes your requirements and generates a high-level automation plan. The plan consists of **process steps** that logically group the related actions as part of the automation. Each process step initially contains natural language instructions.
 - Review and edit the instructions for each process step and then click **Generate** to create the low-level actions for that step.
- **Low-level actions**
 - Next, the Assistant will build the low-level actions and process logic based on the step instructions.
 - Review and edit the generated actions. Click **Run** or **Debug** to begin testing.

Best practices for providing natural language inputs:

- Specify the step by step process as if you were training a new hire
- Include exact details needed to perform each step:
 - Email address if sending a message
 - File name and location if uploading/downloading a document
 - URL if navigating to a website

Creating from scratch (blank automation)

Build automations manually using the visual designer interface:

- Navigate to your project summary
- Click **Start building**
- Select **Skip** to access the canvas

The designer interface provides several key components:

- **Canvas** - Visualizes the automation. You can zoom in and out, expand and collapse process steps, and reorder actions on the canvas.
- **Actions panel** - The actions panel has a comprehensive list of all the automation actions made available within your automation group. You can search and filter to find actions organized by category (Agents, Process flow, Web browser, etc.). Drag-and-drop actions onto the canvas to build your automation. You can also click the plus sign found when hovering between actions to add a new action directly in place on the canvas.
- **Properties panel** - Once you add an action or click on an existing one in your process, the properties panel allows you to configure the input and output parameters that control how that action will behave.
- **Settings panel** - Allows you to create and edit runtime configurations and explore the credentials available to your automation.
- **Variables panel** - Displays all the variables used within your automation. Creating a variable is seamless by adding a new reference directly in your automation.

Runtime configurations and variables

Runtime configurations allow you to create easily editable settings that are used by your automation. Examples of runtime configurations include:

- Website URLs
- File names and locations
- Email configurations like subjects and sender lists

Variables are used to store and pass information between the actions in your automation when it runs. Add a new variable to your automation by simply providing a new reference name in an output property. Common variable types include:

- String - Plain text (e.g., name, description)
- Number - Numeric value (e.g., quantity, score)
- Boolean - True/False value
- Array - Collection or list of items
- Object - Key-value pairs
- File - Documents and media (e.g., PDFs, images)
- Data table - Spreadsheet-like data with rows and columns

Editing automations

Once you've created your automation, you can modify it using either the Automation Assistant or by directly editing on the canvas.

Using Automation Assistant

The Automation Assistant helps you make changes through natural language. You can:

- Ask for updates to the entire automation, specific steps or specific actions
 - Focus the chat on specific steps by selecting them first
- Ask questions and get in-product help and suggestions based on your actual automation
- Ask for help writing expressions and code based on your needs

To edit with the Assistant:

- Click **Build with Assistant** in the toolbar
- Describe the changes you want to make
- Review and confirm the suggested modifications
 - The chat includes a summary of changes. Click **Reject changes** to revert to the previous version.
- Test the updated automation

Editing on canvas

Make changes directly in the visual designer:

- Select the step or action to modify
- Use the properties panel to adjust settings
- Rearrange steps using drag-and-drop

Note

Every action has a menu of options with common actions like duplicating the action or deleting it.

Best practices for editing:

- Make incremental changes
- Test after each significant modification

Note

Changes are saved automatically to the live version. If you want to deploy those changes, commit and deploy the updated version.

Tip

If you encounter issues while building:

- Use the Automation Assistant to get help
- Check the action documentation for specific requirements

Automation inputs and outputs

Define input and output schemas to create reusable, parameterized automations in Amazon Quick Automate. By defining input and output schemas using the Start and End nodes, you can transform static automations into reusable workflows that accept different data each time they run. Instead of hardcoding values, you define typed input parameters that are provided at runtime and structured output values that are captured when the automation completes. Inputs and outputs work across all invocation methods: manual runs, API calls, and scheduled triggers.

Key benefits of using inputs and outputs:

- **Reusability** – Run the same automation with different data without modifying the automation itself.
- **Type safety** – Amazon Quick Automate validates input data against the schema before execution starts, which prevents invalid data from running.
- **API integration** – Auto-generated schemas enable programmatic discovery and integration with external systems.
- **Observability** – Structured outputs are captured as execution artifacts for audit and review.

Supported data types

The following data types are supported for input and output fields:

- **Text** – Plain text values (e.g., text1, text2)
- **Number** – Numeric values including decimals (e.g., 3.14, 100)
- **Boolean** – True or false values
- **File** – File objects with a maximum size of 5 MB

Start and End nodes

Every automation includes a Start node and an End node, which are blank by default. You can edit these nodes to create a schema, use the inputs in the automation, and update the output data

to return from the automation. The Start node receives input data at runtime, while End nodes (including End Process nodes) collect output data during execution and return it as structured artifacts when the automation completes.

Start

The Start node is the entry point that accepts input parameters when the automation is triggered. It is blank by default.

Properties:

- **Input format** – Defines the schema for input parameters that the automation accepts. Edit using the Input schema editor described in Defining input and output schemas.
- **Input variable** – Variable that stores the input values for the automation as defined in the input format and supplied by the user.

End

The End node is the termination point that collects and returns output values when the automation completes successfully. You can set the output values from variables in the automation using the properties of the End node. Your automation can have multiple End nodes (End process) based on the structure of the automation.

Properties:

- **Output format** – Defines the schema for output parameters that the automation returns. Choose **Edit** and add or modify the schema using the Output schema editor described in Defining input and output schemas.
- **Output data** – Maps values from variables in your automation to the output fields that you defined. For each output variable that you create in the End node (Output schema), specify which automation variable contains the data that you want to return. Use the **Edit output data** editor to configure these mappings in the **Output Value** field.

Defining input and output schemas

Schemas define the structure of data that your automation accepts as input and produces as output. The authoring studio provides a visual form builder for defining input and output schemas directly on the automation canvas.

To define an input schema:

- Open your automation in Amazon Quick Automate.
- Choose the **Start** node on the canvas to open the schema editor. You can also open the schema editor from the properties pane. To do this, choose the **Start** node, and then choose **Edit in Input format** in the properties pane.
- Choose **+Add field** to add an input field.
- For each input field, configure the following properties:
 - **Name** – A unique identifier for the field.
 - **Type** – The type of data the field accepts. For more information, see Supported data types.
 - **Required** – Whether the field must be provided when running the automation.
 - **Default value** (Optional) – This option is active only if the **Required** field is cleared. Default values appear pre-populated in the input form when you run a test or trigger the automation.
 - **Description** – A description of what the field represents.
- Choose **Save** to store the schema with your automation.

To define an output schema:

- Choose an **End** node on the canvas to open the Output schema editor. You can also open the schema editor from the properties pane. To do this, choose the **End** node, and then choose **Edit in Output format** in the properties pane.
- Choose **+Add field** to add an output field.
- For each output field, configure the following properties:
 - **Name** – A unique identifier for the field.
 - **Type** – The type of data for the output.
 - **Description** – A description of what the output represents.
- Choose **Save**.

Note

You can define inputs from the Start node and outputs from any End node. If your automation has multiple End nodes, adding or modifying the schema of one End node modifies all End node schemas.

Using input values from the start node

When your automation has an input schema defined at the Start node, you can access those input values throughout your workflow using the `inputs` dictionary. The runtime automatically validates and populates this dictionary with the values provided when the automation runs.

```
# Access required input fields
value = inputs["field_name"]

# Example usage
customer_id = inputs["customer_id"] # Retrieves a required string input
```

Setting output values in the End node

The End node defines which values from your automation are returned as outputs. You configure this using the **Output Data** property, which provides two interaction modes for setting output values in the editor. Toggle between the modes by choosing the code icon (`</>`) next to the **Output value** field.

Two modes for setting outputs:

- **Variable Selection Mode (Dropdown)** – The default interface displays a dropdown list of all available variables in your automation. Select the variable that you want to assign to each output field.
- **Expression Mode (Code)** – Choose the code icon (`</>`) next to any output value field to switch to expression mode. This mode allows you to enter custom expressions, perform calculations, access nested data, or set literal values.

Defining schemas with the Build with Assistant

Build with Assistant can create or modify input and output schemas directly. Describe your input and output requirements in natural language, and the assistant generates the schema definition for you. Any changes that the assistant makes automatically sync with the Studio visual form builder.

Considerations

Keep the following in mind when you use automation inputs and outputs:

- Input and output schemas are optional. Existing automations without schemas continue to work unchanged.
- File inputs have a maximum size of 5 MB. For larger files, pass the file location (such as an Amazon S3 path) as a text input instead.
- Input and output values are stored with each execution run for observability and audit purposes.
- When you update a schema, you must redeploy the automation for the changes to take effect on deployed runs. Test runs always use the latest draft schema.

You can use the input and output values in the following ways:

- Testing and running the automation from the canvas. For more information, see [Testing automations](#).
- Manually triggering deployed automations. For more information, see [Deploying automations](#).
- Scheduled triggers for deployed automations. For more information, see [Deploying automations](#).

Managing automation versions

Amazon Quick Automate provides version control capabilities to help you track and maintain the history of updates to your automations and easily restore previous versions.

Key concepts

- **Live version** - The current working copy of your automation that you can edit in the canvas. Changes are auto-saved to the live version as you edit.
- **Committed versions** - Read-only snapshots of your automation which can be deployed. Commit a new version of your automation to keep track of significant updates and be able to revert back if needed.
- **Deployed versions** - Committed versions can be deployed and activated to run on a schedule.

Note

Each version maintains its own runtime configuration values. Changes to the Live version's runtime settings don't affect previously committed or deployed versions.

Committing versions

To commit a version:

- Click **Commit** in the canvas toolbar
- Add a descriptive note explaining your changes
- Choose how to increment the version number:
 - Minor version (e.g., 1.05 → 1.06) for smaller updates (default)
 - Major version (e.g., 1.0 → 2.0) for significant changes
- Click **Commit**

Important

You cannot commit a version if the automation has any validation errors. Resolve all errors before attempting to commit.

When you commit a version:

- The committed version becomes a read-only snapshot
- The current runtime configuration is saved with the committed version
- A new Live version is created based on that snapshot to continue editing

Important

Only committed versions can be deployed. The Live version must be committed first before it can be made deployed.

Viewing versions

View versions in two places:

- **Version dropdown in canvas** - Defaulted to the Live version. Choose any previous version from the dropdown to view in read-only mode on the canvas.

- **Versions tab** - Found within Project details. Shows a complete version history including version number, when the version was committed, the user that committed the version, and any version notes. Click on the actions menu to view version details or deploy the version.

Restoring previous versions

To restore a previous version and continue editing it as the Live version:

- Select the version from the version dropdown above canvas
- Choose **Restore live version**
- The selected version replaces your current Live version
- Continue editing the Live version to make any needed adjustments
- Commit as a new version to take a snapshot or deploy the updates

Note

Restoring a version creates a new working copy but doesn't delete any version history.

Best practices

- Add clear version notes to track the purpose of changes
- Commit versions after significant updates
- Test changes before committing
- Review runtime configuration before committing

Automation actions

Actions are the building blocks for your automations. Each action performs a specific task, from reading data to interacting with external systems. This section describes all available actions and how to use them effectively.

Action Categories

- **Agents** - AI-powered actions that use natural language to perform complex tasks like web automation and multi-tool orchestration

- **Quick** - Use native integrations with Amazon Quick features and services directly in your automations
- **Process flow** - Control the flow of your automation with steps, loops, and conditions
- **General** - Common utility actions
- **Web browser** - Interact with websites through clicking, typing, and extracting data
- **Microsoft Excel** - Read, write, and manipulate Excel spreadsheets
- **Data tables** - Work with structured data in memory for processing and analysis
- **Orchestration** - Manage work items through cases and coordinate human-in-the-loop tasks
- **Exception handling** - Define how your automation responds to different types of errors
- **Files** - Manage files used within your automation
- **PDF** - Create, modify, and extract content from PDF documents
- **Code** - Write custom Python code to extend automation capabilities
- **Integrations** - Connect with AWS services and external applications like Salesforce, ServiceNow, and Microsoft 365

Agents

Actions that use AI to understand instructions and perform complex tasks.

- **UI agent** - AI agent for web browser tasks. Used for dynamic and intelligent web automation. Simply write instructions to have it navigate websites, extract data, and generate structured outputs.
- **Custom agent** - AI agent for complex tasks. Create an agent that can understand instructions in natural language and take actions using available tools. Used for tasks that require reasoning, judgement, and dynamic planning.

UI agents

UI agent is a native agent that understands natural language instructions to perform complex browser actions. It can autonomously navigate websites, click, type, read data, and produce structured outputs optimized for downstream automation steps. Example use cases include summarizing products on a webpage or fetching data by navigating websites.

Properties

Title

Name of the step/UI agent

Instructions

In this field you write the prompt for the agent in natural language. Best practices while writing the prompt:

- Be clear and explicit about what you want.
- Structure the prompt. Start with mentioning the 'Task' or 'Role' first and then 'Instructions' to achieve the task with numbered steps
- Add constraints (e.g., only review the products section) and specify when to stop/end (e.g., stop when you find the relevant info)
- Provide positive and negative (don't do this) examples
- Specify length requirements (e.g., less than 100 words) or output format (e.g., date in MM/DD/YY format) clearly

Wrap the text in triple quotes (""") to write multiline prompts. For example:

```
"""Task: Locate the company's latest annual report.  
* Visit the provided URL.  
* Look for the annual report. The report may be titled 'Annual Report', 'Financial  
Report', 'Year in Review', or similar variations..."""
```

Structured Output (optional)

Agent Response: Name of the variable to assign the output of this operation

How to configure structured output fields

Adding fields

- Click Add field to create a new output field
- Enter the Output name - this becomes the JSON property name
- Select the Type from the dropdown
- Check Required if the field must always be present
- Add a Description to guide the AI agent

Field types

- *String* - Text values (Names, descriptions, summaries)
- *Number* - Numeric values (Counts, scores, percentages)
- *Boolean* - True/false values (Status flags, yes/no questions)
- *Object* - Nested structure (Complex data groupings)
- *Array* - List of items (Tags, categories, multiple values)
- *File* - File references (Document attachments, images)
- *Data table* - Tabular data (Structured datasets, reports)

Working with complex types

Objects and Arrays can contain nested fields:

- Click the expand arrow (►) next to Object or Array fields
- Use Add field within the nested structure
- Keep nesting to 2-3 levels maximum for optimal performance

Example configuration

Here's a simple configuration for summarizing customer feedback:

```
{
  "orderId": "12345",
  "numberOfOrders": 3,
  "hasShipped": true,
  "orderDetails": {
    "quantity": 2,
    "productName": "ABC",
  },
  "tags": ["electronics", "urgent"]
}
```

This structure would be configured as:

- orderId (String, required)
- numberOfOrders (Number, required)
- hasShipped (Boolean, required)

- **orderDetails** (Object, required)
 - **quantity** (Number, required)
 - **productName** (String, required)
- **tags** (Array of Strings, Optional)

Best practices

- Use descriptive field names - Help the AI understand what data to extract
- Add clear descriptions - Provide context for complex fields
- Mark critical fields as required - Ensure essential data is always present
- Limit nesting depth - Keep structures simple for better performance
- Test your configuration - Verify the output matches your expectations by running the agent step and verifying the response.

Important notes

- **JSON Knowledge:** Unfamiliar with JSON? Learn the basics at json.org
- **No validation:** Currently, the system doesn't validate output structure - ensure your automation handles missing or malformed data

Custom agents

Custom agent is an intelligent action that processes natural language inputs to automate complex steps. It uses integrated tool-calling capabilities with integrations as its primary tool interface. It also offers extensibility to use Code as a tool and other native actions like human-in-the-loop task. The agent delivers structured, predictable outputs optimized for downstream automation steps.

Properties

- **Title:** Name of the step/custom agent
- **Mode:** A mode defines how the agent operates based on your use case. The three available modes are Fast, Pro, and Custom. Fast is best for simple tasks like summarization, classification, and high-volume automations. Pro is ideal for complex tasks that involve reasoning and orchestration of multiple tools or actions. Fast and Pro are fully managed modes that require no pre-setup in advance. Custom Mode requires a Bedrock runtime connector and lets you select

the model you want to use. For more information, see [Using Custom Models in Custom Agent \(Bring your own bedrock model\)](#). Custom Mode is ideal when you have a prompt fine-tuned for a particular Bedrock model, need a specific Bedrock model for the Agent, or want to use your own custom or fine-tuned model hosted on Bedrock. In Custom Mode, you bring your own model from Bedrock through an integration. Model inference is billed separately to the account associated with that Bedrock integration.

- **Instructions:** In this field you write the prompt for the agent in natural language. Best practices while writing the prompt:
 - Be clear and explicit about what you want.
 - Structure the prompt. Start with mentioning the 'Task' or 'Role' first and then 'Instructions' to achieve the task with numbered steps
 - To improve tool-call accuracy and guide the Agent, clearly specify in the prompt which tool to use at each step, if applicable.
 - Specify length requirements (e.g., less than 100 words) or output format (e.g., date in MM/DD/YY format) clearly
 - Wrap the text in triple quotes (""") to write multiline prompts. For example:

```
"""You are content summarization agent.  
Summarize the last two paragraphs of the provided text, focusing only on the main  
conclusion."""
```

- **Actions:** Action is a tool that enables the AI agent to interact with external systems or perform specific tasks. This is optional. You can run the custom agent without any actions. The following actions can be used in the custom agent.
 - **General Actions**
 - **Create user task** - If enabled, this tool allows the Agent to trigger a Human-in-the-Loop (HITL) task when it gets stuck during execution. The Agent pauses and waits for human input. The HITL task is visible in the task center. For best results, specify in the prompt exactly when the Agent should invoke HITL. This action is selected by default. The automation runs until the task is finished.
 - **Code** - The Code action generates and executes Python code within a restricted Python environment, same as code actions. It solves tasks involving calculations, data manipulation, and file processing. Unlike code generators, it actively creates and runs scripts to accomplish objectives. It works with Excel, PDF files, various data formats, and available integrations.
 - **Key Capabilities:**

- **File Operations:** Process multi-tab Excel files, extract content, perform date calculations, apply conditional formatting, and upload results to S3
- **Data Transformation:** Convert between JSON and table formats, transpose data, rename columns, and join tables
- **Advanced Computations:** Generate numerical sequences and perform automated validation
- **Integrations:** If you have added specific integration actions — such as Salesforce, MS Exchange, or Bedrock—to your automation group, their corresponding actions appear here to be use in the custom agent. The author can then select the relevant actions to use as tools for the agent.

List of integrations which can be used as tools/actions in the custom agent

- Amazon S3
- Amazon Bedrock Data automation
- Amazon Comprehend
- Amazon Textract
- Custom REST API
- Custom MCP connector
- Microsoft Outlook
- Salesforce
- **Structured Output (optional)**

Configure your AI agent to return structured JSON output that downstream steps can process. This feature is ideal for text summarization, report generation, data transformation, and extracting statistics from unstructured content. This is an optional field. If you do not define structured output, the agent returns output in natural language by default. Use structured output when your output has a defined structure, such as a list, data table, or JSON.

 Note

The structured output configuration for Custom agents follows the same format as UI agents. Refer to the UI agent structured output section for detailed configuration instructions.

- **Agent response:** Name of the variable to assign the output of the agent. The response follows your structured output format in a JSON schema if defined, otherwise is a free-form text.

Using Custom Models in Custom Agent (Bring your own bedrock model)

Integrate your desired or custom fine-tuned models hosted in AWS Bedrock with Quick Suite automation workflows.

Before you begin, ensure you have the following:

- A fine-tuned model deployed and accessible in AWS Bedrock
- Quick Suite Admin access for creating connectors
- An IAM role with Bedrock permissions for invoking models
- Your model ID (for example, `us.anthropic.claude-3-5-sonnet-20241022-v2:0`)

Step 1: Create a Bedrock Runtime Action integration by following the detailed instructions in [AWS service connectors](#)

Step 2: Set Up Your Automation Group

Create an automation group and connect the integration:

- **Create an automation group** - Follow the detailed instructions in [Setup tasks](#)
- **Configure integrations** - Follow the detailed instructions in [Setup tasks](#)
- Once configured, the connector appears in your available assets list

Step 3: Configure a Custom Agent

Add and configure a custom agent to use your fine-tuned model:

- Within your automation workflow, add a custom agent
- Configure the following agent settings:
 - **Agent Title:** Enter a descriptive name for your agent
 - **Instructions:** Enter custom prompts tailored to your use case
 - **Mode:** Select Custom
 - **Connector:** Choose your Bedrock Runtime connector (required when Custom mode is selected)

- **Custom Model:** Enter your model ID (for example, `us.anthropic.claude-3-5-sonnet-20241022-v2:0`) - required when Custom mode is selected

Next Steps

Once configured, your custom agent uses the fine-tuned model to process requests according to the instructions you provided. You can now incorporate this agent into your Quick Automate workflows.

Note

Ensure your model ID is correctly formatted and matches the model deployed in your AWS Bedrock account. You can find your model ID in the AWS Bedrock console under your provisioned models.

Custom agent testing

Custom agent testing enables you to test individual agents independently from the complete automation workflow. This capability helps you validate agent behavior, debug prompts, and iterate more efficiently without executing the entire workflow.

Prerequisites

- An automation workflow with at least one configured custom agent
- Appropriate permissions to run automations in your workspace

Start a test

- In the workflow canvas, hover over the agent card you want to test
- Choose the **Unit test** button that appears at the top of the card
- In the variable collection window that opens, review the automatically detected variables from your agent's prompt
 - The prompt preview displays all detected variables with highlighting
- Enter a value for each variable
 - Values must use valid expression syntax
 - If a value contains invalid syntax, an error message appears and prevents test execution

Monitor test execution

During test execution, you can monitor progress in the audit panel. The test skips all preceding workflow steps and executes only the selected agent. You get the same logging experience as a full workflow run.

Review test results

After the test completes, review the following information in the Test panel:

- Metrics Card (Monitor Tab in the Test panel)
 - Total execution time
 - Number of tools used
 - Number of tasks created
- Logs in between
- Watch Variables Tab (Variables accordion in the Test panel)
 - Input - View input variables and their values
 - Output - Examine output results from the agent execution
 - For structured outputs, choose **View Details** to open the View Output dialog box:
 - Fields Tab - Navigate data using the tree structure view
 - Fields - Highlight corresponding values by selecting tree nodes in Fields tab
 - Output fields - Corresponding values for the JSON keys

Using Custom agent with Build with Assistant

The current tenet for custom agent is it has to be specifically mentioned to consistently get it invoked, here are the things needed in the prompt to make it appear:

```
- Function names: `use_inline_agent`  
- Representation names: "Custom Agent", "Inline Agent" # use `use_inline_agent`  
- Generic terms: "agentic skills" # default to `use_inline_agent`
```

Otherwise, the model is preferred to author the workflow deterministically.

Although, in practice, when no appropriate actions are available, planner might pick custom agent as a workaround. But to consistently invoke custom agent in the workflow, the above phrases are encouraged to use in the prompt.

Examples of agent use cases

Use Case 1: Email Classification and Assignment Agent

Role: You are an Email Categorization and Assignment Agent

Instructions: Follow these steps:

- Step 1: Classify the incoming email based on the Category column of the provided reference table as knowledge
- Step 2: Use the email system to send a notification:
 - From: [system_email]
 - To: [team_distribution_email]
 - Subject: [Classification Result]
 - Body: Include a brief summary explaining the classification reasoning and key points from the original email
- Step 3: For all valid categories (except 'unknown'), create a new case in Salesforce with:
 - Subject: [Original Email Subject]
 - Description: Summarized issue from email body
 - Priority: Based on content urgency (High/Medium/Low)
 - Type: Select appropriate type (Question/Problem/Feature Request/Other)
 - Status: 'New'
 - Category: [Classification result from Step 1]
- Step 4: If classified as 'unknown':
 - Escalate to supervisor for manual review
 - Add note explaining why classification was uncertain
 - Based on the category received from the supervisor, follow step 2 and 3 and stop
 - If the category received from the supervisor is unknown or invalid, stop

Using knowledge bases with custom agents

In Amazon Quick Automate, you can connect knowledge bases to custom agents to enable AI-powered retrieval and question answering over your organization's documents. By linking a Quick space to your automation group, custom agents can search and retrieve information from the knowledge bases within that space.

Use this for automations that need to reference organizational knowledge — such as answering questions from policy documents, summarizing reports, or classifying content based on reference data.

Knowledge bases index your documents for semantic search, so the custom agent retrieves only the most relevant passages rather than processing entire files. This makes retrieval faster and more accurate, especially across large document sets.

Prerequisites

- A Quick space with one or more knowledge bases configured. For more information, see [Organize, collaborate, and share resources with spaces in Amazon Quick](#).
- An automation group where you are an owner
- Owner-level access to the space you want to link

Link a space to your automation group

Before a custom agent can access knowledge bases, you must link the space that contains those knowledge bases to your automation group. Linking a space grants the automation group permission to access the knowledge bases and files within that space.

To link a space to an automation group:

1. In the **Automations** tab, go to the **Projects** page.
2. Choose **Groups** and select the group you want to attach the space to.

Tip

You can also choose **Create group** to create a new automation group.

3. In the **Assets** section, choose **Add**, and then choose **Spaces**.
4. Select the space that contains the knowledge bases you want to use, and then choose **Add**.

The space now appears in the automation group's connections list. Custom agents in this automation group can access the knowledge bases and files within the linked space. Other resources in the space are not available to automations.

Note

If the space shows **Limited access** after being added, it means not all knowledge bases are shared with the automation group. This can happen if knowledge bases were added to the space after linking, or if not all knowledge bases were shared initially. To resolve this, refresh the space connection to share all resources with the automation group. You do not need to reconfigure the Knowledge tab on individual custom agents.

Add knowledge to a custom agent

After linking a space to your automation group, you can configure a custom agent to use the knowledge bases within that space. The workflow must be in the same automation group where you attached the space.

To add knowledge to a custom agent:

1. In the workflow builder, add a **Custom Agent** step. You can either drag and drop a Custom Agent node onto the canvas, or chat with the automation assistant to build this step.
2. In the agent properties panel, choose **Knowledge**, and then choose **Add**.
3. A picker opens showing available spaces linked to the automation group. Select one or more spaces that contain the knowledge bases you want the agent to use.
4. Choose **Save**.

The custom agent can now search and retrieve content from the knowledge bases in the selected spaces when the automation runs.

When you attach a space, all knowledge bases inside that space automatically become available to the agent. You don't need to attach each knowledge base individually. At runtime, the agent queries each knowledge base independently and combines the results in its response.

Note

If the automation group owner loses access to a specific knowledge base within the space, that knowledge base is skipped during queries and the workflow editor displays a warning badge on the space attachment.

Writing instructions for knowledge base queries

When a custom agent has knowledge bases attached, it automatically searches and retrieves relevant content based on your instructions. Write instructions that clearly describe what information the agent should find or how it should use the knowledge base content.

Best practices:

- Be specific about what information to retrieve or summarize
- Reference the type of content you expect the agent to find (for example, "Search the policy documents for..." or "Find information about...")
- Specify how the agent should use the retrieved information in its response
- Include fallback instructions for when the knowledge base doesn't contain relevant content

Example: Customer inquiry agent with knowledge base

The following example shows how to configure a custom agent that uses a knowledge base to answer customer inquiries based on company documentation.

Setup:

- A space containing a knowledge base with product documentation and FAQ content
- The space is linked to the automation group
- The space is added as knowledge to the custom agent

Instructions:

```
""""You are a customer support agent.
```

```
Task: Answer the customer inquiry using information from the knowledge base.
```

```
Instructions:
```

1. Search the knowledge base for information relevant to the customer's question.
2. Provide a clear, concise answer based on the retrieved content.
3. If the knowledge base does not contain relevant information, respond with:
 "I don't have enough information to answer this question. Please escalate to a human agent."

Constraints:

- Only use information found in the knowledge base. Do not make up answers.
- Keep responses under 200 words.
- Include the source document name when referencing specific information."

Structured output:

```
{
  "answer": "The response to the customer inquiry",
  "sourceDocument": "Name of the document used",
  "confidence": "high/medium/low",
  "escalationNeeded": false
}
```

Using datasets with custom agents

In Amazon Quick Automate, you can connect datasets to custom agents so that an agent can answer natural-language questions about your data. The underlying query returns a list of data tables and a string output from the API call. You can then convert this output into a desired data structure, either by prompting the custom agent or by using the structured output feature of the custom agent.

Dataset Q&A (querying datasets) is an agentic action that you use with the custom agent. A custom agent can query multiple datasets, but it runs one query at a time.

Use datasets for data-driven question-answering automations. For example, you can build an agent that answers questions such as "which customers have unpaid invoices over \$10,000" by querying an invoices dataset and returning the matching rows.

Prerequisites

- Owner-level access to the dataset you want to attach
- A dataset that does not use row-level security (RLS) or column-level security (CLS). Datasets with RLS or CLS are not supported.
- An automation group where you are an owner
- Datasets attached to the automation group for run-as-service mode, or datasets shared with your user ID for run-as-user mode

Attach a dataset to your automation group

Before a custom agent can query a dataset, you must attach the dataset to your automation group. You must already have access to the dataset as an owner. Attaching the dataset to the automation group does not grant you access to it.

To attach a dataset to an automation group:

1. In the **Automations** tab, go to the **Projects** page.
2. Choose **Groups** and select the group you want to attach the dataset to.

Tip

You can also choose **Create group** to create a new automation group.

3. In the **Assets** section, choose **Add**, and then choose **Datasets**. The picker opens with **Actions**, **Credentials**, **Spaces**, and **Datasets** tabs.
4. On the **Datasets** tab, select the dataset you want to use, and then choose **Add**. You can search your Quick assets. Datasets that you cannot use appear disabled, and you can hover over one to see the reason, such as needing to be an owner.

The dataset now appears in the automation group's assets and connections list. Custom agents in this automation group can query it.

Note

You must be the owner of the dataset to use it. Datasets that use row-level security (RLS) or column-level security (CLS) are not supported.

Add datasets to a custom agent

After you attach one or more datasets to your automation group, you can configure a custom agent to query them. The workflow must be in the same automation group where you attached the datasets. After you add the Custom Agent step, you add the dataset from the agent's properties panel on the **Datasets** tab.

To add datasets to a custom agent:

1. In the workflow builder, add a **Custom Agent** step. You can either chat with the automation assistant to build this step, or drag and drop a Custom Agent node onto the canvas.
2. In the agent properties panel, choose the **Datasets** tab.
3. Add one or more datasets directly on the **Datasets** tab.
4. Choose **Save**.

A custom agent can use multiple datasets, but it runs one query at a time. If you connect a Quick space that contains a dataset, the agent can query that dataset as well. For more information about spaces, see [Organize, collaborate, and share resources with spaces in Amazon Quick](#).

Query a dataset with the agent

After you add a dataset to the custom agent, you can ask the agent a question about the data. When the automation runs, or when you test the agent, the agent queries the attached dataset and returns a response based on the results.

To query a dataset:

1. In the agent **Instructions**, write a prompt that asks a question about the data. For example, ask a natural-language question about records in the dataset.
2. Run the automation, or use the agent unit test to run the agent. For more information about testing an agent, see [Custom agent testing](#).

The agent queries the dataset and returns the answer.

To return the results in a specific format that downstream steps can process, such as a JSON object or a data table, configure the Structured Output option for the agent. Structured output is optional and returns structured JSON. The structured output configuration for custom agents follows the same format as UI agents. In your prompt, instruct the agent to produce output that matches the structured output schema.

Use datasets in a space with a custom agent

Instead of attaching datasets directly on the agent's **Datasets** tab, you can add your datasets to a Quick space, attach the space to your automation group, and then attach the space to the custom agent on the **Knowledge** tab. The agent can then query the datasets in that space based on your instructions. This approach is useful when you already organize datasets, and other knowledge, in a space.

To use datasets in a space:

1. Add your dataset or datasets to a Quick space. For more information about spaces, see [Organize, collaborate, and share resources with spaces in Amazon Quick](#).
2. Attach the space to your automation group. In the **Automations** tab, on the **Projects** page, choose **Groups** and select your group. In the **Assets** section, choose **Add**, and then choose **Spaces**. Select the space and choose **Add**.
3. In the workflow builder, add a **Custom Agent** step. You can either chat with the automation assistant to build this step, or drag and drop a Custom Agent node onto the canvas.
4. In the agent properties panel, choose the **Knowledge** tab, choose **Add**, select the space that contains your datasets, and then choose **Save**.
5. In the agent **Instructions**, write a prompt that asks a question about the data in the space's datasets.

When the automation runs, the agent queries the datasets in the attached space and returns the results. The datasets must still meet the dataset requirements. You must be an owner of each dataset, and datasets that use row-level security (RLS) or column-level security (CLS) are not supported.

Writing instructions for dataset queries

When a custom agent has datasets attached, it automatically determines the relevant dataset and constructs the query based on your instructions. Write instructions that clearly describe what data the agent should retrieve and how it should present the results.

Best practices:

- Be specific about what data to retrieve, such as the columns, records, or aggregations you expect in the results.
- Include filters, calculation definitions, or metric logic in the prompt to improve query accuracy.
- Specify the output format so that downstream steps can process the results.

Example: Invoice analysis agent with a dataset

The following example shows how to configure a custom agent that queries a dataset to answer questions about outstanding invoices.

Setup:

- A dataset that contains customer invoice records, including customer name, invoice amount, and payment status
- The dataset is attached to the automation group
- The dataset is added to the custom agent on the Datasets tab

Instructions:

```
""""You are an invoice analysis agent.
```

```
Task: Answer the user's question by querying the invoices dataset.
```

```
Instructions:
```

1. Identify the relevant dataset and construct a query for the user's request.
2. For the request "Show me customers with unpaid invoices over \$10,000", filter for records where payment status is unpaid and invoice amount is greater than 10000.
3. Return the results as a data table with customer name and invoice amount.

```
Constraints:
```

- Only use data found in the dataset. Do not make up values.
- Sort the results by invoice amount in descending order."""

Output:

The agent returns a data table similar to the following:

Customer name	Invoice amount
Example Corp	24,500
AnyCompany Retail	15,200
AnyCompany Financial	11,750

Quick

With Quick actions, you can use native integrations with Amazon Quick features and services directly in your automations. These actions work within the Quick environment without requiring external authentication or complex infrastructure setup. You can interact with other Quick capabilities while using unified governance, permissions, and data management.

Shared File Actions

Shared file storage provides a centralized location for managing files used by your automations. Files uploaded by one automation are immediately available to other automations in the same automation group. This eliminates the need for external storage solutions for lightweight file management scenarios.

Key Benefits:

- Share files across multiple automations within the same automation group
- Avoid external storage setup (for example, Amazon Simple Storage Service or SharePoint)
- Upload files manually by using the built-in file management interface (Select File)

The following two actions are available for shared file operations.

- **Download shared file** – Download a shared file for use in the automation.
- **Save as shared file** – Upload a file from the automation to shared storage.

Download Shared File

Retrieves a file from shared storage for use in your automation. Use this action to retrieve files that were previously uploaded either manually or by another automation in the same automation group.

Properties:

- **File to download** (Required): The file to retrieve from shared storage. The File to download property includes a folder icon (#) next to the field. Choose this icon to open the Select File editor, which provides an interface to:
 - *View all files*: See all files currently stored in your automation group's shared storage. Files appear as a list with Name, Last modified by, and Last modified time.
 - *Actions*: Each file has an Actions menu (:) with the following options:
 - *Download*: Save the file to your local machine
 - *Delete*: Remove the file from shared storage
 - *Upload files*: Choose **Upload** to manually add new files to shared storage.
 - *Select and Save*: Choose a file from the list and choose Save to use it in your action, or choose Cancel to close without selecting.

- **Output Variable** (Required): Variable name to store the downloaded file object.

Save as shared file

Uploads a file to shared storage, making it available to other automations in the automation group. Use this action to save output files generated by your automation. Other automations can then access these files, or you can download them manually.

Properties:

- **File to save** (Required): The file object to upload to shared storage (for example, an Excel file, PDF, or other file type generated by your automation).
- **Save as filename** (Optional): The name to use when saving the file in shared storage. If not provided, the action uses the original filename.
- **Replace existing file** (Optional): When checked, the existing file with the same name is replaced by the file being uploaded

Access the files manually

You can manually access and download files in Amazon Quick Automate using either of the following methods.

From the authoring studio (Action)

- Choose the folder icon (#) next to the **File to download** property for the **Download shared file** action to open the **Select File** dialog box. This displays the list of files available for the automation group.
- Choose the three dots (:) under **Actions**, and then choose **Download** to save the file to your local machine.

From the automation group

- Open your automation group in Quick Automate.
- Choose the **Shared files** tab to view the list of available files.
- Choose the three dots (:) under **Actions**, and then choose **Download** to save the file to your local machine.

Limitations

Shared file storage has the following limits per automation group.

Limit	Value	Scope
Maximum number of files	250	Per automation group
Maximum total storage	1 GB	Per automation group
Maximum individual file size	200 MB	Per file

Note

Supported file types: HTML, TXT, JSON, CSV, PDF, XLSX, XLS, JPEG/JPG, PNG, DOCX, DOC, TIFF/TIF, and ZIP.

Best Practices

- **Use descriptive filenames:** Include dates or identifiers in filenames to avoid confusion (for example, "report_2026-03-31.xlsx").
- **Clean up old files:** Regularly delete files that are no longer needed by using the Select File editor.
- **Consider file size limits:** Individual files can be up to 200 MB, and total shared storage is limited to 1 GB per automation group. For large-scale file storage requirements, consider using Amazon S3 integration instead.
- **Use consistent naming conventions:** Establish naming patterns across your automation group for easier file management.

Notes

Keep the following considerations in mind when using shared file actions.

- Quick Automate stores files at the automation group level. This means:
 - All automations within the same automation group can access the same shared files.

- Files uploaded by one automation are immediately available to other automations in the group.
- The file count limit (250 files) and total storage limit (1 GB) apply at the automation group level. All automations in the group share these limits.

Examples

Example 1: Processing a shared configuration file

Scenario: Multiple automations need to read the same configuration file.

1. Download Shared File
 - File to download: "config.xlsx"
 - Output Variable: configFile
2. Read Excel Range
 - File: configFile
 - Sheet name: "Settings"
 - Output Variable: configData
3. Continue with automation logic using configData

Example 2: Sequential processing across automations

Scenario: Automation A processes data and saves it. Automation B retrieves and continues processing.

Automation A:

1. [Process data and create output file]
2. Save as Shared File
 - File to save: processedData
 - Save as filename: "processed_orders.csv"

Automation B (runs after Automation A):

1. Download Shared File
 - File to download: "processed_orders.csv"
 - Output Variable: ordersFile

2. Continue processing the orders data

Example 3: Manual upload and automation processing

Scenario: A user manually uploads a file that an automation will process.

Manual steps:

- The user opens the Select File editor from any Download Shared File action.
- The user chooses Upload and selects "customer_list.xlsx" from their computer.
- The user chooses Save to confirm the upload.

Automation steps:

1. Download Shared File
 - File to download: "customer_list.xlsx"
 - Output Variable: customerFile
2. Process customer data

Process flow

- **Process step** - Groups logically related actions. Used for organizing your process.
- **If decision** - Checks a true/false condition. The process is split into two branches based on the result.
- **Loop through items** - Repeats actions for each item. Used for processing multiple items like emails, files, or data rows one at a time.
- **Loop while true** - Repeats while a condition is met. The condition is checked before each loop and must be True for the loop to continue.
- **End process** - Ends the current run successfully. Optionally, provide a custom message or value as the final outcome of the process.

General

- **Save value** - Assigns a value to a variable. Used to save information that you can reference later in your automation.

- **Write log message** - Adds a message to the logs. Useful for tracking progress, troubleshooting issues, or recording important events.
- **Wait** - Pauses the automation. After the specified amount of time, the automation will continue with the next action.

Web browser

Overview

Browser actions provide a comprehensive automation toolkit for performing web interactions. Browser sessions are automatically managed — opened, maintained, and closed as needed. Quick Automate supports flexible element identification through AI-powered natural language descriptions and precise XPath selectors. Key capabilities include intelligent element targeting with fallback mechanisms, self-healing features that automatically handle popups and retry failed actions, data extraction including structured table content, and a full suite of interaction methods from basic clicks and typing to advanced AI-driven multi-step tasks.

Element identification methods

- **Description method:** Uses AI to identify elements using natural language descriptions (e.g., "Log In button"), making automations more resilient to UI changes.
- **XPath selector method:** Uses precise XPath expressions for exact element targeting (e.g., `//button[text()='Log in']`).
- **Combined approach:** When both methods are enabled, XPath is tried first before falling back to the description method, combining precision with adaptability.

Self-Healing features available for type-ins and clicks

- **HandlePopups:** Automatically detects and handles unexpected dialogs, cookie notices, and overlays, preventing blocking elements from interrupting workflows.
- **ValidateAndRetry:** Verifies action success through screenshot comparison and retries if needed, reducing false failures.

Browser Session Management

Browser instances are automatically created, maintained throughout workflows, and properly cleaned up when complete. The `restart_browser` action allows fresh sessions when needed for scenarios such as login timeouts or session expiration.

Start Browser Session

Opens a new browser session. Actions inside is scope interact with this browser. The browser closes automatically when finished.

Properties:

- **Action Title** (text-only): The title of the action displayed in the process visualization (default: Browser)

Note

1. All browser actions must be placed within a browser session scope
2. Each browser scope is a browser session. Browser automatically closes when actions inside a scope completes.

Go to Webpage

Navigates to a specific URL. Used to go to a new webpage in the current browser tab.

Properties:

- **URL** (required): The web address to navigate to (e.g., "example.com") Note: Please provide the complete URL when working with this.

Click

Clicks on a webpage element. Used to interact with buttons, links, or other clickable elements.

Properties:

- **Find Element with Description** (radio button): Use natural language description to identify the element with AI (default: ON)

- **Description Field** (conditionally required): Natural language description of the browser element to click (e.g., "Submit button"). Don't use the action in the element, just the description of the element
- **Find Element with Selector** (radio button): Use XPath expression to identify the element (default: OFF)
 - **XPath Field** (conditionally required): XPath expression (e.g., "//input[@id='xyz']")
- **Self-healing** (checkbox): Use AI to handle unexpected popups automatically (default: OFF, optional)
- **Mouse Button** (dropdown): Which mouse button to click - Left, Middle, or Right (default: Left, optional)
- **Click Type** (dropdown): Single or Double click (default: Single, optional)
- **Get File Download** (radio button): Enable if click downloads a file (default: OFF, optional)
- **Downloaded File** (output, conditionally required): Variable name storing the downloaded file (default: downloaded_file)

Element Identification:

- At least one element identification method must be enabled
- When both methods are enabled, XPath selector is tried first before falling back to description

Enter Text

Types text into an input field. Used to fill in forms, search boxes, or other text inputs on webpages.

Properties:

- **Text to Enter** (required): The text you want to type into the field (e.g., "Order #12345")
- **Find Element with Description** (radio button): Use natural language description to identify the element with AI (default: ON)
 - **Description Field** (conditionally required): Natural language description (e.g., "Order number field")
- **Find Element with Selector** (radio button): Use XPath expression to identify the element (default: OFF)
 - **XPath Field** (conditionally required): XPath expression (e.g., "//input[@id='xyz']")

- **Self-healing** (checkbox): Use AI to handle unexpected popups automatically (default: OFF, optional)
- **Replace Existing Text** (checkbox): Clear any pre-existing text in the field before typing (default: ON)

Element Identification:

- At least one element identification method must be enabled. Recommended to use element description and move to element selector only if required.

Enter Credential

Types a username or password. Used to securely sign in to a website using saved credentials.

Properties:

- **Credential** (dropdown, required): Choose which saved credential to use from automation group
- **Value to Enter** (dropdown, required): Choose whether to enter Username or Password (default: Username)
- **Find Element with Description** (radio button): Use natural language description to identify the element with AI (default: ON)
 - **Description Field** (conditionally required): Natural language description (e.g., "Username field")
- **Find Element with Selector** (radio button): Use XPath expression to identify the element (default: OFF)
 - **XPath Field** (conditionally required): XPath expression (e.g., "//input[@id='username']")
- **Self-healing** (checkbox): Use AI to handle unexpected popups automatically (default: OFF, optional)

Element Identification:

- At least one element identification method must be enabled

Select from Dropdown

Chooses a value from a dropdown. Used to make selections in forms, filters, or other dropdown menus on webpages.

Properties:

- **Value to Select** (required): The option you want to select from the dropdown field (e.g., "Complete")
- **Find Element with Description** (radio button): Use natural language description to identify the element with AI (default: ON)
 - **Description Field** (conditionally required): Natural language description (e.g., "Order status dropdown")
- **Find Element with Selector** (radio button): Use XPath expression to identify the element (default: OFF)
 - **XPath Field** (conditionally required): XPath expression (e.g., "//select[@id='xyz']")
- **Self-healing** (checkbox): Use AI to handle unexpected popups automatically (default: OFF, optional)

Element Identification:

- At least one element identification method must be enabled

Extract Text

Reads a value from a webpage. Used to capture the text from an individual field.

Properties:

- **Find Element with Description** (radio button): Use natural language description to identify the element with AI (default: ON)
 - **Description Field** (conditionally required): Natural language description (e.g., "Total amount field")
- **Find Element with Selector** (radio button): Use XPath expression to identify the element (default: OFF)
 - **XPath Field** (conditionally required): XPath expression (e.g., "//input[@id='xyz']")
- **Self-healing** (checkbox): Use AI to handle unexpected popups automatically (default: OFF, optional)
- **Extracted Text** (output): Variable name storing the extracted text (default: extracted_text)

Element Identification:

- At least one element identification method must be enabled

Extract Table

Reads data from a webpage table. Used to capture structured information found in tables.

Intelligently extracts structured data from web pages using natural language targeting or XPath selectors. Features include AI-enhanced extraction, multiple attribute extraction (text, links, etc.), automatic column generation for attributes, and data table output for programmatic manipulation.

Properties:

- **Find Element with Description** (radio button): Use natural language description to identify the element with AI (default: ON)
 - **Description Field** (conditionally required): Natural language description (e.g., "Order details table")
- **Find Element with Selector** (radio button): Use XPath expression to identify the element (default: OFF)
 - **XPath Field** (conditionally required): XPath expression (e.g., "//table[@id='xyz']")
- **Self-healing** (checkbox): Use AI to handle unexpected popups automatically (default: OFF, optional)
- **Extract Multiple Pages** (radio button): Continue extracting data from additional pages if they exist (default: OFF, optional)
- **Next Page Button Selector** (conditionally displayed): XPath expression for next page button (e.g., "//*[@id='nextButton']", optional)
- **Intelligent Data Extraction** (checkbox): Use AI to extract and structure data from complex tables (default: ON). Do not use for large table sizes of 100 rows or more. This option should be used for complex tables or table-like structures, where normal table extraction from a web browser fails
- **Data to Extract** (multi-select dropdown): Choose what to extract - Text, Links (Href), or Element selectors (XPath) (default: Text, optional)
- **Extracted Table** (output): Variable name storing the extracted data table (default: extracted_table)

Element Identification:

- At least one element identification method must be enabled

Usage Notes:

- Additional data types are saved in separate columns (e.g., columnName_Href for Links)
- Disable intelligent extraction for tables with 100+ rows for better performance

Take Screenshot

Captures an image of the webpage. The screenshot is saved to a file to be used later in your process.

Properties:

- **File Name** (optional): Name for the saved image file. Auto-generated if empty (e.g., "Screenshot image")
- **File Type** (dropdown): Choose the image format - PNG or JPEG (default: PNG, optional)
- **Screenshot File** (output): Variable name storing the screenshot file (default: screenshot_file)

Visual Q&A

Answer questions about a webpage. Uses AI to visually analyze the page and answer true/false questions about the content.

Properties:

- **Question** (required): Enter your true/false question about the webpage content (e.g., "Is the product in-stock?")
- **Self-healing** (checkbox): Use AI to handle unexpected popups automatically (default: OFF, optional)
- **Answer** (output): Variable name storing the true/false response (default: is_true)

Click and Upload Files

Uploads files to a webpage. Used to automate file pickers by clicking on a file upload button and choosing the files to upload.

Properties:

- **Files to Upload** (required): The list of files to be uploaded, typically stored in a variable (e.g., [my_file1, my_file2])
- **Find Element with Description** (radio button): Use natural language description to identify the element with AI (default: ON)
 - **Description Field** (conditionally required): Natural language description (e.g., "Upload button")
- **Find Element with Selector** (radio button): Use XPath expression to identify the element (default: OFF)
 - **XPath Field** (conditionally required): XPath expression (e.g., "//input[@id='xyz']")
- **Self-healing** (checkbox): Use AI to handle unexpected popups automatically (default: OFF, optional)
- **Mouse Button** (dropdown): Which mouse button to click - Left, Middle, or Right (default: Left, optional)
- **Click Type** (dropdown): Single or Double click (default: Single, optional)

File Requirements:

- Must be an array of media/file objects

Element Identification:

- At least one element identification method must be enabled

Enter Keystroke

Sends a key command or shortcut. Used to automate typing individual keys or key combinations on a webpage.

Properties:

- **Special Keys** (dropdown, required): Select modifiers like Ctrl, Alt, Shift or singular keystrokes like Enter, Tab, Pagedown
- **Command Key** (optional): Enter the key to be used in combination with the Special key (e.g., "c" for Ctrl+c)

- **Find Element with Description** (radio button): Use natural language description to identify the element with AI (default: ON)
 - **Description Field** (conditionally required): Natural language description (e.g., "Search bar")
- **Find Element with Selector** (radio button): Use XPath expression to identify the element (default: OFF)
 - **XPath Field** (conditionally required): XPath expression (e.g., "//input[@id='xyz']")
- **Self-healing** (checkbox): Use AI to handle unexpected popups automatically (default: OFF, optional)

Element Identification:

- Both element toggles can be OFF - keystroke is sent to the current active field if no element is defined

Wait for Element

Checks for an element to appear. Used to wait for changes or validate conditions on a webpage. Returns true if the element is found within the maximum wait time, false if not.

Properties:

- **Action Title** (text-only): Display name for the action
- **Element Selector** (required): XPath expression to define the element you want to check (e.g., "//input[@id='xyz']")
- **Max Wait Time** (optional): Maximum time to wait in seconds for the element to appear (default: 30)
- **Element Found** (output): Variable name storing whether the element was found (True/False) (default: is_found)

Validation:

- Max wait time must be an integer or decimal

Find Matching Elements

Gets elements matching a pattern. Used to get a list of similar elements on a webpage that you can process one by one.

Properties:

- **Element Selector** (required): XPath expression to define the pattern for elements you want to get (e.g., "//div[@class='abc']")
- **List of Elements** (output): Variable name storing the list of found elements (default: `element_list`)

Usage Notes:

- The list is empty if no matching elements are found
- Use for processing multiple similar elements like search results or hyperlinks

Wait for New Window

Checks for a new window to open. Used after clicking a link or button that opens a new child window in the current browser session.

Properties:

- **Max Wait Time** (optional): Maximum time to wait in seconds for the new window to appear (default: 30)
- **Window Identifier** (output): Variable name storing the identifier for the new window (default: `window_id`)

Usage Notes:

- If time exceeds and window not found, an exception occurs
- Window identifier can be used to switch focus or close the window

Validation:

- Max wait time must be an integer or decimal

Switch Window

Changes browser windows. After switching focus to the specified window, subsequent browser actions interact with that window.

Properties:

- **Window Identifier** (optional): The window you want to switch to, typically stored in a variable (e.g., `window_id`). Leave empty to switch to the main window

Close Window

Closes a browser window. Once closed, the automation returns to the main window of the current browser session.

Properties:

- **Window Identifier** (required): The window you want to close, typically stored in a variable (e.g., `window_id`)

Save to Clipboard

Copies text to the clipboard. Used to save text that you can paste later on. Existing clipboard text is replaced.

Properties:

- **Text to Save** (required): The text you want to copy to the clipboard (e.g., "Order #12345")

Paste from Clipboard

Inserts text from the clipboard. Used to paste copied text into webpage fields.

Properties:

- **Find Element with Description** (radio button): Use natural language description to identify the element with AI (default: ON)
 - **Description Field** (conditionally required): Natural language description (e.g., "Order number field")

- **Find Element with Selector** (radio button): Use XPath expression to identify the element (default: OFF)
 - **XPath Field** (conditionally required): XPath expression (e.g., "//input[@id='xyz']")
- **Self-healing** (checkbox): Use AI to handle unexpected popups automatically (default: OFF, optional)
- **Replace Existing Text** (checkbox): Clear any pre-existing text in the field before pasting (default: ON)

Element Identification:

- At least one element identification method must be enabled

Refresh Webpage

Reloads the current webpage. Some pages may redirect on refresh.

Properties:

- **Action Title** (text-only): Display name for the action

Restart Browser

Closes and reopens the browser. A new session starts from a blank page.

Properties:

- **Restart All** (checkbox): Close and restart all browser windows, not just the current one (default: OFF, optional)

Limitations

Element Identification Uncertainty: If the AI cannot reliably identify UI elements, actions fail with 'LowConfidence' errors. In these cases, use more specific XPath selectors or element descriptions.

Browser Compatibility: The system operates exclusively with Chrome browser instances and utilizes Playwright as the underlying automation framework, which means compatibility is limited to Chrome-supported web technologies and may not work with browser-specific features from other vendors. **Dynamic Content Challenges:** Highly dynamic pages with frequent layout changes,

heavy JavaScript frameworks, or complex single-page applications may require additional wait times, retry logic, or specialized handling approaches. **Performance Overhead:** AI-powered features like natural language element targeting and self-healing capabilities require more processing time than direct XPath targeting.

Excel

Excel actions enable you to read, update, and create Excel files in your automations. All Excel actions support both .xlsx and .xlsm file formats. Workbook identifiers maintain references across multiple operations.

Note

While values can be read from .xlsm files, macro execution is not supported.

Create New Workbook

Creates a blank Excel file. Outputs a workbook identifier you can use to update the spreadsheet in subsequent steps.

Properties:

- **Workbook Identifier** (output): Variable name storing the workbook reference for future actions (default: `workbook_id`)

Open Existing Workbook

Loads an existing Excel file. Returns a workbook identifier you can use to update the spreadsheet in subsequent steps. Supports only Excel (.xlsx) files.

Properties:

- **Excel File** (required): The .xlsx file to open, typically stored in a variable (e.g., `my_file`)
- **Workbook Identifier** (output): Variable name storing the workbook reference (default: `workbook_id`)

File Requirements:

- Must be a valid Excel (.xlsx) file
- File must be accessible as a media file object

Save Workbook

Saves updates to an Excel file. Allows you to update the file name and file type for the saved workbook.

Properties:

- **File Name** (required): Name for the saved file without extension (e.g., "Monthly Report")
- **File Type** (dropdown): Output format - currently supports XLSX (default: XLSX)
- **Saved File** (output): Variable storing the saved file object (default: saved_file)

Read Sheet

Gets data from a range of cells. The action stores the output in a data table variable.

Properties:

- **Workbook Identifier** (required): The workbook to read from (e.g., workbook_id)
- **Sheet Name** (required): Worksheet or tab name (default: "Sheet1")
- **Cell Range** (optional): Range specification - supports multiple formats:
 - Starting cell: "A2" (reads all data from anchor point)
 - Exact range: "A1:B10"
 - Column range: "A:B"
 - Row range: "1:3"
 - Empty: reads entire sheet
- **Include Headers** (checkbox): Treats first row as column headers when enabled. When disabled, uses default naming (Column0, Column1, etc.) (default: TRUE)
- **Data Table** (output): Variable storing the extracted data (default: excel_table)

Formula Handling:

- The action automatically calculates formulas and stores results in the data table.

Read Cell

Gets the value from a cell. Used to read an individual cell value from a worksheet.

Properties:

- **Workbook Identifier** (required): The workbook to read from (e.g., `workbook_id`)
- **Sheet Name** (required): Worksheet name (default: "Sheet1")
- **Cell Reference** (required): Cell location (e.g., "A1")
- **Cell Value** (output): Variable storing the cell content (default: `cell_value`)

Write to Sheet

Outputs a data table to a sheet. Used to write a range of rows and columns to a worksheet.

Properties:

- **Data Table** (required): The data table to write (e.g., `my_table`)
- **Workbook Identifier** (required): Target workbook (e.g., `workbook_id`)
- **Sheet Name** (required): Target worksheet (default: "Sheet1")
- **Start at Cell** (optional): Starting position for data placement (default: "A1")
- **Include Headers** (checkbox): Writes column headers when enabled (default: TRUE)

Write to Cell

Outputs a value to a cell. Used to update individual cells in a worksheet.

Properties:

- **Value to Write** (required): Content for the cell (e.g., "Order #12345")
- **Workbook Identifier** (required): Target workbook (e.g., `workbook_id`)
- **Sheet Name** (required): Target worksheet (default: "Sheet1")
- **Cell Reference** (required): Target cell location (e.g., "A1")

Write New Row

Adds a row of data to the sheet. The new row is appended to the end of the existing data.

Properties:

- **Row Values** (required): Array of values for the new row, starting from first column (e.g., ["Q1", "Sales", 100])
- **Workbook Identifier** (required): Target workbook (e.g., `workbook_id`)
- **Sheet Name** (required): Target worksheet (default: "Sheet1")

Data Validation:

- Must provide values as an array format
- Values are written sequentially starting from the first column

Create New Sheet

Adds a blank worksheet. The new sheet is added to the end of the workbook.

Properties:

- **Workbook Identifier** (required): Target workbook (e.g., `workbook_id`)
- **Sheet Name** (required): Name for the new worksheet (e.g., "Sales Data")

Copy Sheet

Creates a copy of the worksheet. The new sheet is created within the same workbook.

Properties:

- **Workbook Identifier** (required): Target workbook (e.g., `workbook_id`)
- **Sheet Name to Copy** (required): Source worksheet name (e.g., "Original Sheet")
- **New Sheet Name** (required): Name for the duplicated sheet (e.g., "Original Sheet (Copy)")

Rename Sheet

Updates the name of an existing worksheet.

Properties:

- **Workbook Identifier** (required): Target workbook (e.g., `workbook_id`)

- **Current Sheet Name** (required): Existing worksheet name (e.g., "Sheet1")
- **Updated Sheet Name** (required): New name for the worksheet (e.g., "Q1 Data")

Delete Sheet

Removes a sheet from a workbook. Cannot delete the last remaining sheet of a workbook.

Properties:

- **Workbook Identifier** (required): Target workbook (e.g., `workbook_id`)
- **Sheet Name to Delete** (required): Worksheet to remove (e.g., "Sheet1")

Constraints:

- Cannot delete the last remaining sheet in a workbook

Set Cell Color

Updates cell background color. Used to highlight a specific range of cells.

Properties:

- **Cell Color** (required): RGB hex code format (e.g., "FF0000" for red)
- **Workbook Identifier** (required): Target workbook (e.g., `workbook_id`)
- **Sheet Name** (required): Target worksheet (e.g., "Sheet1")
- **Cell Range** (required): Range to format - supports:
 - Single cell: "A1"
 - Exact range: "A1:B10"
 - Column range: "A:B"
 - Row range: "1:3"

Get Cell Color

Reads the cell background color. Outputs the color in RGB hex code format (e.g., "FF0000" for red).

Properties:

- **Workbook Identifier** (required): Source workbook (e.g., `workbook_id`)
- **Sheet Name** (required): Source worksheet (e.g., "Sheet1")
- **Cell Reference** (required): Cell to read (e.g., "A1")
- **Cell Color** (output): Variable storing RGB hex code (default: `cell_color`)

Hide Rows

Makes rows hidden in the sheet. The data remains intact but is not visible.

Properties:

- **Workbook Identifier** (required): Target workbook (e.g., `workbook_id`)
- **Sheet Name** (required): Target worksheet (e.g., "Sheet1")
- **Start Row** (required): First row number to hide (Excel numbering starts at 1)
- **End Row** (optional): Last row number to hide. If empty, only the start row is hidden

Row Numbering:

- Excel row numbers start at 1 (not 0)
- Must provide integer values

Unhide Rows

Makes hidden rows visible. Used to show previously hidden rows.

Properties:

- **Workbook Identifier** (required): Target workbook (e.g., `workbook_id`)
- **Sheet Name** (required): Target worksheet (e.g., "Sheet1")
- **Start Row** (required): First row number to unhide (Excel numbering starts at 1)
- **End Row** (optional): Last row number to unhide. If empty, only the start row is made visible

Best practices and limitations

Workbook Identifier Management

- Store workbook identifiers in descriptive variables (e.g., `sales_workbook`, `report_file`)

- Reuse the same identifier across multiple actions on the same workbook
- Always create or open a workbook before performing data operations

Range Specifications

- Use exact ranges ("A1:B10") for precise data operations
- Use column ranges ("A:B") when working with entire columns
- Use row ranges ("1:3") for header or summary operations
- Leave range empty to process entire sheets

Performance Optimization

- Read entire ranges when possible instead of individual cells
- Batch write operations using data tables rather than individual cell writes
- Save workbooks only when all modifications are complete

Limitation

File compatibility is limited to modern Excel (.xlsx) format only - legacy Excel (.xls) files are not supported.

Data tables

Data table actions enable you to work with structured data in table format. These actions allow you to create, transform, and output tabular data in your automations.

Sort Table

Orders a table by a column. Used to organize your data in ascending or descending order.

Properties:

- **Data Table** (required): The table variable to sort (e.g., my_table)
- **Column Name to Sort** (required): Name of the column to sort by (e.g., "Total amount")
- **Sort Order** (dropdown): Choose "Ascending" (smallest first) or "Descending" (largest first) - default: Descending
- **Sorted Table** (output): Variable name for the new sorted table

Filter Table

Keeps rows matching a criteria. Used to extract relevant rows from a larger data set.

Properties:

- **Data Table** (required): The table variable to filter (e.g., `my_table`)
- **Filter Expression** (required): Boolean expression using column names and operators (`==`, `>`, `<`, `!=`). Combine conditions with `&` (AND) or `|` (OR). Use single quotes for column names with spaces and text values (e.g., `"Team" == 'Sales' & 'Total amount' > 100`)
- **Filtered Table** (output): Variable name for the filtered table

Example filters:

```
# Column 'amount' is greater than 25
"amount > 25"

# Column 'team' equals text 'Sales'
"team == 'Sales'"

# Multiple conditions
"amount > 25 & status == 'active'"

# Grouped conditions
"(amount > 25 & team == 'Sales') | (amount > 50 & team == 'Marketing')"
```

```
# Column 'title' contains text 'Director'
"title.str.contains('Director')"
```

```
# Column 'Customer No' equals a variable customer_id
"`Customer No` == " + str(customer_id)
```

```
# Column 'ProfitCenter' equals variable profitCenter
"`ProfitCenter` == '" + str(profitCenter) + '"
```

Lookup Value

Searches a value in a table. Used to lookup a value in one column and get the corresponding value from another column in the same row.

Properties:

- **Data Table** (required): The table to search in (e.g., `my_table`)
- **Column Name to Search** (required): Column containing the lookup value (e.g., "Employee ID")
- **Value to Search For** (required): The value to find (e.g., "12345")
- **Column Name to Output** (required): Column to retrieve the result from (e.g., "Date of hire")
- **Cell Value** (output): Variable storing the found value. Returns first match or empty if not found.

Add Columns

Creates new columns in a table. Newly added columns are appended to the end of the existing table.

Properties:

- **Data Table** (required): The table to modify (e.g., `my_table`)
- **Column Names to Add** (required): Array of new column names (e.g., ["Name", "Address"])
- **Default Value** (optional): Initial value for all cells in new columns (e.g., "N/A")
- **Updated Table** (output): Variable name for the modified table

Remove Columns

Deletes columns from a table. Outputs a table with all of the remaining columns.

Properties:

- **Data Table** (required): The table to modify (e.g., `my_table`)
- **Columns to Remove** (required): Array of column names or index numbers. Index numbers start at 0 and can be specific numbers (e.g., [0,1,2]) or ranges (e.g., `range(0,2)`)
- **Updated Table** (output): Variable name for the modified table

Keep Columns

Drops extra columns from a table. Used to select a specific subset of columns you want to keep.

Properties:

- **Data Table** (required): The table to modify (e.g., `my_table`)
- **Columns to Keep** (required): Array of column names to retain (e.g., ["Name", "Address"])

- **Updated Table** (output): Variable name for the modified table

Add New Row

Appends a new row to a table. The new row can be created with specific values or as a blank row and is added to the bottom of the table.

Properties:

- **Data Table** (required): The table to modify (e.g., `my_table`)
- **Row Values** (optional): Array of values for the new row, starting from the first column (e.g., `["Q1", "Sales", 100]`). If empty, adds a blank row. Missing values result in blank cells.
- **Updated Table** (output): Variable name for the modified table

Remove Rows

Deletes rows from a table. Outputs a table with all of the remaining rows.

Properties:

- **Data Table** (required): The table to modify (e.g., `my_table`)
- **Rows to Remove** (required): Array of row positions (0-based indexing). Index numbers start at 0 and can be specific numbers (e.g., `[0,1,2]`) or ranges (e.g., `range(0,2)`)
- **Updated Table** (output): Variable name for the modified table

Remove Duplicates

Deletes duplicate rows. Used to create a dataset of unique rows based on specific columns.

Properties:

- **Data Table** (required): The table to clean (e.g., `my_table`)
- **Columns to Check** (optional): Array of column names for duplicate detection (e.g., `["Name", "Address"]`). If empty, checks entire rows for uniqueness. Duplicates are identified by combined values across specified columns.
- **Duplicate Row to Keep** (dropdown): Choose "First" or "Last" occurrence to retain (default: First)
- **Updated Table** (output): Variable name for the modified table

Append Tables

Combines the rows of two tables. Used to add data from one table to another.

Properties:

- **Table to Append To** (required): Main table receiving additional rows (e.g., `main_table`)
- **Table to Add** (required): Source table providing rows to append (e.g., `new_data`)
- **Handle Column Differences** (dropdown):
 - "Add": Keep all columns from both tables
 - "Ignore": Only keep columns matching the primary table
 - "Error": Require exact column matches
- **Combined Table** (output): Variable name for the merged table

Create New Table

Creates an empty table. Used to set up a table with required columns to add rows to in subsequent steps. The new table has no rows.

Properties:

- **Column Names** (optional): Array of column names for the new table (e.g., `["Name", "Address"]`). If empty, creates a table with no columns.
- **New Table** (output): Variable name for the newly created table

Convert Text to Table

Transforms delimited text into a structured table.

Properties:

- **Text to Convert** (required): Delimited text containing table data (e.g., `"Year,Qty 2001,100"`)
- **Value Separator** (optional): Character separating values in rows (default: `","`)
- **Newline Separator** (optional): Character separating rows (default: `" "`)
- **Has Headers** (checkbox): Whether first row contains column names. If True, uses first row as headers; if False, generates default names (`Column0`, `Column1`, etc.)
- **New Table** (output): Variable name for the newly created table

Convert Table to HTML

Creates an HTML formatted table. Used to output your table as formatted text for a document, email, and more.

Properties:

- **Data Table** (required): The table to format (e.g., `my_table`)
- **Formatted Table Text** (output): Variable storing the HTML formatted text

Examples

Loop through rows in a table

To loop through rows in a data table, use the "Loop through items" action under "Process flow". Provide the data table variable as an input for "Collection of items". Update the "Item reference" to `row` as each item represents a single row of the table.

Use or update cell values in a row

When looping through rows in a table, refer to individual cell values using the syntax of `row["column name"]` where column name is replaced with the name of the column for the specific cell.

To update the value of a cell in a row, use the "Save value" action under "General". The "Value to save" is the value you want to update the cell with. The "Variable name" is the reference to the cell using the same syntax as above, `row["column name"]`.

Orchestration

Orchestration enables you to automate complex end-to-end processes, coordinating automated tasks with human decisions where needed. The orchestration capabilities in Amazon Quick Automate include case management for tracking work items and human-in-the-loop integration for incorporating human judgment.

Case management

Cases track individual items of work for your automation to process such as a new claim, an IT support ticket, a customer complaint, or a new invoice. Each case has:

- A unique reference name (e.g., "Order-12345")
- A case type for grouping related work (e.g., "Sales orders")
- Custom data stored as key-value pairs
- A defined lifecycle with status tracking and an audit trail
- Associated human-in-the-loop tasks if applicable

Case status lifecycle

To track the progress of work through your automation, cases follow a defined lifecycle with specific status transitions:

- **Ready** - The case has been created and is waiting to be picked up for processing. This is the initial state of all new cases.
- **In Progress** - The case is actively being processed by the automation. You can monitor real-time progress through the logs.
- **Pending Resolution** - The case is waiting for a human-in-the-loop task to be completed before processing can continue. Cases automatically move back to Ready status after tasks are resolved.
- **Successful** - The case has completed all processing steps without any exceptions.
- **Failed** - The case encountered one of the following exception types:
 - **Business Exception** - The case encountered a handled business rule violation and stopped processing. Detailed exception information is available in the logs.
 - **System Exception** - The case experienced a technical error and stopped processing. Detailed error information is available in the logs.

Actions

Amazon Quick Automate provides the following actions to create, process, and manage cases throughout their lifecycle.

Create new case

Creates a single case to track work. Each case has a reference name (e.g., "Order-12345") and stores custom data as key-value pairs. Cases are grouped by type (e.g., "Sales orders") for organization and reporting. Properties:

- **Title (optional)** - Action name shown in the process visualization (e.g., "Create sales order case")
- **Reference name (required)** - Business identifier used for searching and tracking cases in monitoring dashboards (e.g., "Order-12345")
- **Case type (required)** - Label that groups related cases by business purpose. Provides organization and metric tracking (e.g., "Sales orders", "Support tickets")
- **Custom data (required)** - Additional case information stored as key-value pairs. This data is visible to users and can be retrieved, updated, or appended to during case processing (e.g., {"Product": "ABC-12345", "Qty": "100", "Priority": "High"})

Create multiple cases

Bulk creates cases from a data table. Each row becomes a new case, inheriting the specified case type and using a designated column for reference names. All other columns become custom data fields. Properties:

- **Title (optional)** - Action name shown in the process visualization (e.g., "Create cases from invoice batch")
- **Case type (required)** - Label that groups related cases by business purpose (e.g., "Invoice processing")
- **Cases data table (required)** - Data table where each row creates a new case. All columns are stored as custom data (e.g., cases_table)
- **Reference column name (required)** - Name of the column containing the reference name identifier for each case (e.g., "Invoice number")

Process cases

Loops through cases in 'Ready' status. Automatically manages case status by moving cases to 'In Progress' during processing and marking them as successful or failed based on completion. When adding actions inside the Process cases loop, uncaught exceptions are handled for you, marking the case as failed with the associated error details and moving to the next case. The action also provides access to case data during processing. Properties:

- **Title (optional)** - Action name shown in the process visualization (e.g., "Process pending invoices")
- **Case type (required)** - Type of cases to process (e.g., "Invoice processing")
- **Current case (output)** - Variable containing the case being processed in each loop. Access case data using `current_case["custom_data"]["key_name"]`

Update case data

Saves changes to case information during processing. Can add new fields or modify existing data. Only available while a case is 'In Progress'. Used to track processing results and manage case lifecycle. Properties:

- `Title` (optional) - Action name shown in the process visualization (e.g., "Update case status")
- `Case ID` (required) - Unique identifier of the case to update (e.g., `current_case["case_id"]`)
- `Data to update` (required) - New or modified information to store as key-value pairs (e.g., `{"Status": "Approved", "ProcessedDate": "2024-01-20"}`)
- `Updated case` (output) - Variable containing the modified case. Access updated data using `updated_case["custom_data"]["key_name"]`

Search cases

Retrieves cases for reporting and analysis. Filter by case type, status, or reference name. Returns results as a data table containing case information and custom data. Properties:

- `Title` (optional) - Action name shown in the process visualization (e.g., "Find overdue cases")
- `Case type` (required) - Type of cases to search (e.g., "Support tickets")
- `Filter by status` (optional) - Filter for cases based on their current status (e.g., "Pending Resolution")
- `Filter by reference name` (optional) - Filter for cases with a specific reference name (e.g., "Ticket-12345")
- `Maximum results` (optional) - Limits the number of cases to return. Leave empty to return all cases up to 10,000 (e.g., 100)
- `Search results` (output) - Variable name that will store the data table of cases retrieved by the search (e.g., `cases_table`)

Human-in-the-Loop (HITL)

While many decisions can be automated, some scenarios require human judgment. Amazon Quick Automate's HITL capabilities allow you to seamlessly incorporate human decision-making into your automated processes. There are two ways to create HITL tasks:

- Using the Create user task action
- Using HITL chat through a Custom agent

Create user task

Creates a task for human input. Tasks appear in a list for users to review, make decisions, or provide information. Tasks can only be created when in a case processing loop while the case is in progress. Creating a task moves the case to 'Pending task' status and the automation continues with the next case. Once the task is resolved, the case returns to 'Ready' status for further processing. Properties:

- **Title (required)** - Subject line that appears in the user's task list. Should clearly describe what needs to be done (e.g., "Review loan application", "Approve expense report")
- **Description (required)** - Detailed instructions and context provided to users completing the task (e.g., "Please review the attached application details and either approve or reject based on the following criteria...")
- **Form (required)** - Interface for collecting structured input from users
- **Severity (required)** - Priority level to help users triage tasks:
 - **Critical** - Urgent attention required, highest priority
 - **Moderate** - Normal priority (default)
 - **Low** - Non-urgent task
- **Due in (required):**
 - **Number** - Quantity of time units (e.g., 24)
 - **Unit** - Hours or Days
- **Case ID (required)** - Unique identifier of the case this task is for (e.g., `current_case["case_id"]`)

Important

When creating a HITL task:

- The Process cases loop automatically updates the case status to Pending Resolution and moves on to the next case
- Do not add actions after creating a task inside the Process cases loop as they won't execute for the current case

Building forms

When creating a HITL task, you can build custom forms to collect exactly the information needed from human reviewers. The following components are available for form design:

- Text field - Single or multi-line text input for collecting user inputs (e.g., "Please provide reason for rejection in detail")
- Dropdown - Selection from predefined options (e.g., ["Approve", "Reject", "Escalate"])
- Date/time picker - Calendar-based input
- Media - Display images or documents for review
- Display text - Read-only information to provide context (e.g., case details, policy references)

HITL chat

For scenarios requiring more dynamic interaction, Amazon Quick Automate also supports HITL chat through Custom agents. This enables natural language conversation between the agent and human reviewer. The agent can create a HITL task when it needs human input. The case will remain In progress while the agent chats with the human reviewer. Once sufficient input is provided, the agent will continue.

```
# Example agent prompt for HITL chat
"""
Review the data and if any values are outside normal ranges,
create a HITL task for human review. Include the specific
values and acceptable ranges in the task description.
"""
```

Note

HITL chat tasks will be given a default severity (Moderate) and due in (24 hours).

Task resolution and case re-entry

After a human completes a HITL task, your automation needs to handle the case's return to processing. Understanding how to work with task resolution data is key to implementing effective human-in-the-loop workflows. When a task is resolved:

- The associated case automatically returns to Ready status
- The case becomes available for processing again through Process cases
- The `latest_task_resolution` field contains all form inputs and decisions

Example checking for HITL resolution and handling the case accordingly:

```
# Example handling HITL resolution
if current_case["latest_task_resolution"]:
    # Handle case returning from HITL
    resolution_data = current_case["latest_task_resolution"]["form_data"]
    if resolution_data["decision"] == "Approve":
        # Process approved case
    else:
        # Handle rejected case
else:
    # First time processing this case
```

Best practices for handling HITL resolution:

- Always check latest_task_resolution when processing cases
- Structure your logic to handle both new cases and those returning from HITL
- Consider implementing different processing paths based on human decisions
- Include error handling for missing or invalid resolution data

Exception handling

Exception handling allows you to manage errors and unexpected conditions in your automations. Amazon Quick Automate provides capabilities for creating, raising, and handling exceptions appropriately to ensure robust error management and process continuity.

Types of exceptions

Amazon Quick Automate supports two types of exceptions:

- Business exceptions - Used for expected errors from business rule violations such as:
 - Missing required data
 - Invalid input values
 - Policy violations
- System exceptions - Used for technical or infrastructure errors such as:
 - Connection failures
 - Service timeouts
 - Authentication errors

Actions

Raise exception

Interrupts the process flow with an exception. Used to trigger or throw an exception to either end the process or to take specific actions to handle the exception scenario. If you do not want to end the process immediately, add an Exception flow to your Process step to handle the exception. Properties:

- **Title** (optional) - Action name shown in the process visualization (e.g., "Raise validation error")
- **Create custom exception** (required) - When selected on, create a new exception with custom details. When off, raise or re-raise an existing exception stored in a variable
- **Exception type** (required) - Category of the exception (e.g., "Business exception", "System exception")
- **Exception reason** (required) - Short identifier used to categorize similar exceptions for reporting (e.g., "REQUIRED_FIELD_MISSING", "INVALID_FORMAT")
- **Exception message** (required) - Detailed description that will help with troubleshooting (e.g., "Customer email is required but not provided")
- **Exception to raise** (required when Create custom exception is off) - The exception you want to raise or re-raise, typically stored as a variable (e.g., new_exception)

Create custom exception

Creates an exception without raising it. Used to prepare an exception variable that can be raised later in subsequent steps. Properties:

- **Title** (optional) - Action name shown in the process visualization (e.g., "Create validation exception")
- **Exception type** (required) - Category of the exception (e.g., "Business exception", "System exception")
- **Exception reason** (required) - Short identifier used to categorize similar exceptions for reporting (e.g., "REQUIRED_FIELD_MISSING")
- **Exception message** (required) - Detailed description that will help with troubleshooting (e.g., "Customer email is required but not provided")
- **Error code** (optional) - Numerical code used to distinguish different types of errors (e.g., 404 for not found, 503 for service unavailable)
- **Caused by** (optional) - Reference to another exception that triggered this one, typically stored as a variable (e.g., original_exception)

- **New exception** (output) - Variable that will store the newly created exception (e.g., `new_exception`)

Exception flow

Defines how to handle exceptions that occur within a Process step. Used to create an alternative path to follow when exceptions occur in your process. After an exception is handled, the process continues with the next Step. Raise the exception again if you want to end the process. Add an Exception flow by clicking the **Exception flow** plus button found in the Process step. Properties:

- **Title** (optional) - Action name shown in the process visualization (e.g., "Handle validation errors")
- **Exception reference** (required) - Variable name to refer to the exception within the Exception flow. Access exception details using `variable["property"]` where property can be: type, reason, message, code, or `caused_by` (e.g., `error`)

Note

Exception flows can only be added to Process steps. They are not found otherwise in the Actions panel.

Working with exceptions

Exception properties

When handling exceptions, you can access these properties:

- `type` - Category of the exception ("Business exception" or "System exception")
- `reason` - Short identifier for the exception
- `message` - Detailed description of the error
- `code` - Numerical error code if provided
- `caused_by` - Original exception that triggered this one if applicable

Best practices

- Use descriptive exception reasons for easy categorization and reporting
- Include detailed messages for troubleshooting
- Implement retry logic for temporary system exceptions

- Consider human intervention for business exceptions
- Consider the impact on case status when handling exceptions
- Ensure critical cleanup operations occur even after exceptions such as restarting a browser
- Monitor exception frequencies and patterns
- Review exception logs regularly
- Re-raise exceptions once handled if you do not want to proceed with the remaining steps

Files

- **Duplicate file** - Creates a copy of a file. Used to create a new version of the same file.
- **Zip files** - Creates a compressed zip file. Used to combine multiple related files into a single package.
- **Unzip file** - Extracts files from a zip. Used to unpack individual files from a single zip file.

PDF

- **Create PDF file** - Generates a PDF file from text. Used to create a new PDF document with formatted contents.
- **Read PDF text** - Extracts text from a PDF file. Used to get the content of text-based PDF documents. Does not extract text from scanned documents or preserve the structure of the extracted text.
- **Split PDF file** - Extracts pages from a PDF. Used to create a new PDF from selected pages of an original file.
- **Merge PDF files** - Combines multiple PDF files. Used to create a single PDF from several documents by appending their pages.
- **Get page count** - Gets the count of pages in a PDF. The number of pages can be used in subsequent steps to extract text from specific pages or split the PDF.

Code

Code actions in Quick Automate let you implement custom logic using Python code blocks, going beyond what standard automation actions support. They are well-suited for complex data transformations and calculations, and run within a restricted Python environment to maintain security.

Two Types of Code Actions:

- **Single Line Expressions:** Quick, one-line operations that modify variables without returning values
- **Custom Code Blocks:** Multi-line Python functions for complex logic with parameters and return values

When to use code actions:

Use code blocks when you need to:

- Perform complex data transformations not available in standard actions
- Implement custom business logic or calculations
- Process or manipulate data structures (lists, dictionaries, JSON)
- Work with dates, times, and time zones in custom ways
- Parse or format strings with complex patterns
- Optimize automation performance by consolidating multiple actions into one code block

When not to use code actions:

Avoid code blocks when:

- A standard automation action already exists for your use case
- The operation is simple enough for built-in actions
- You need to interact with external APIs (use REST API integration instead)
- You need to access file systems or databases (use appropriate integrations)

How to Access code actions:

Code blocks are available through multiple interfaces:

- **Actions Panel (Recommended):**
 - Open your automation in the automation builder
 - Click on the Actions Panel on the right side
 - Locate "Custom Code Block" under the Code Actions section
 - Drag and drop the code block into your automation workflow

- **Build with Assistant:**

- Available during plan generation when the assistant determines custom code is needed
- The assistant automatically suggests code blocks for complex operations
- You can request code blocks by describing your custom logic needs

Actions available:

Single Line Expressions

Single Line Expressions execute one-line Python statements that perform operations without returning a value. They are ideal for quick modifications to existing variables like appending to lists, updating dictionaries, or performing simple calculations that modify state.

Properties:

- **Expression (required):** The Python expression to execute (e.g., "my_list.append('new item')")

Examples:

- **Appending to list**

```
my_list.append("1")
my_list.append(new_item)
```

- **Removing List Items**

```
task_list.remove(completed_task)
```

Custom Code Block

Custom Code Blocks are multi-line Python functions that execute complex logic, accept parameters, and return values. They are the fallback option when standard automation actions and Single Line Expressions are not sufficient for your needs.

Properties:

- **Function Title (required):** Name identifier for the code block (e.g., "Calculate_Total")
- **Function (required):** Python code block that contains your custom logic.

- **Step 1: Define Parameters**
 - Click the "Edit" button to open the code editor
 - In the Parameter panel, click "Add" to create new parameters
 - Enter parameter names that match your automation variables
 - Parameters are available as function arguments
- **Step 2: Write Your Python Code**
- **Return Value (optional):** Variable name to store the function's output
 - Follow the required code block structure (see below)
 - Implement your custom logic within the function
 - Use only approved libraries and built-in functions
 - Include a return statement if you need to output data

Code Block Structure

All code blocks must follow this specific format:

```
@code_block()
def your_function_name(parameter1, parameter2, parameter3):
    -----
    """
    Optional: Add a docstring describing what your function does
    """
    # Your custom logic here
    result = parameter1 + parameter2 + parameter3

    return result
```

Built-in Python Functions and Imports

All standard Python built-in functions are available without imports (len, str, int, etc.)

Approved Standard Libraries (Security Restricted)

Code blocks can ONLY import these standard libraries:

- `base64` - Base64 encoding/decoding
- `datetime` - Date and time operations

- `json` - JSON parsing and generation
- `math` - Mathematical functions
- `re` - Regular expressions
- `zoneinfo` - Time zone handling

Note

- Cannot import standard libraries other than the ones listed above.
- Cannot install or import third-party libraries. `pip install` is not supported in code blocks.

Limitations

- Restricted Python environment with limited library access. The execution environment is based on RestrictedPython, a subset of Python 3.10.
- Code blocks cannot invoke other code blocks or actions

Best Practices

- Keep code blocks simple and focused
- Use descriptive function names
- Always prefer pre-built actions when available
- Test your code blocks thoroughly as focused debugging options are limited)

Example Use Cases

- Mathematical operations (Calculate circle properties - radius as parameter)

```
def function
(radius):

    return {
        "radius": radius,
        "diameter": 2 * radius,
        "circumference": round(2 * math.pi * radius, 2),
```

```
"area": round(math.pi * radius ** 2, 2)
}
```

- Getting current date/time

```
def function
():

    now = datetime.datetime.now()

    return {
        "current_date": now.strftime("%Y-%m-%d"),
        "current_time": now.strftime("%H:%M:%S"),
        "formatted": now.strftime("%B %d, %Y at %I:%M %p"),
        "iso_format": now.isoformat(),
        "timestamp": now.timestamp()
    }
```

- Calculating date differences - Start date and end date as parameters

```
def function
_(start_date_str, end_date_str):

    # Parse date strings (format: YYYY-MM-DD)_
    start = datetime.datetime.strptime(start_date_str, "%Y-%m-%d")
    end = datetime.datetime.strptime(end_date_str, "%Y-%m-%d")

    _# Calculate difference_
    difference = end - start
    return {
        "days": difference.days,
        "weeks": difference.days // 7,
        "start": start_date_str,
        "end": end_date_str    }
```

- Pattern matching and text manipulation using regular expressions (Validating email addresses, phone numbers, etc.)

```
def function
(email, phone, zip_code):

    email_pattern = r'^[a-zA-Z0-9._%+-]+@[a-zA-Z0-9.-]+\.[a-zA-Z]{2,}$'
    phone_pattern = r'^\d{3}-\d{3}-\d{4}$'
```

```
zip_pattern = r'^\d{5}(-\d{4})?$'

return {
    "email_valid": bool(re.match(email_pattern, email)),
    "phone_valid": bool(re.match(phone_pattern, phone)),
    "zip_valid": bool(re.match(zip_pattern, zip_code))
}
```

- **List Operations (Filter and Transform List)**

```
def function
(numbers, threshold):

    # Filter numbers above threshold and calculate statistics
    filtered = [n for n in numbers if n > threshold]

    if filtered:
        return {
            "filtered_numbers": filtered,
            "count": len(filtered),
            "sum": sum(filtered),
            "average": sum(filtered) / len(filtered),
            "min": min(filtered),
            "max": max(filtered)
        }
    else:
        return {
            "filtered_numbers": [],
            "count": 0,
            "message": "No numbers above threshold"
        }
```

Integrations

AWS Services

Amazon S3

Amazon S3 actions allow you to store and retrieve files and data.

Available Actions

- **Download File** - Downloads a file from Amazon S3 and returns a file object handle.

- **Upload File** - Uploads a file object handle to Amazon S3.
- **Copy Object** - Creates a copy of an object that is already stored in Amazon S3 from one source file to a destination location.
- **Delete Object** - Deletes a specified object from an S3 bucket.
- **List Objects** - Lists all of the objects in the given bucket. Can be filtered using a prefix.

Amazon Bedrock

Amazon Bedrock actions allow you to connect to foundation models (FMs) from leading AI companies through a single API.

- **Basic model converse** - Sends a prompt to an AI model. Use natural language to generate text, analyze content, and get AI-powered responses.
- **Advanced model converse** - Prompts model with more options. Advanced options include custom message formats, tool integrations, and granular control over model behavior.

Amazon Bedrock Agents

Amazon Bedrock Agent actions allows you to invoke AI assistants that can connect to your data sources, APIs, and backend systems.

- **Basic agent invoke** - Sends a request to an AI agent. Use for simple interactions that don't require file attachments, user input, or custom configurations.
- **Advanced agent invoke** - Calls an agent with more options. Used for advanced interactions that require file attachments, user input, or custom configurations.

Amazon Bedrock Data Automation

Bedrock Data Automation (BDA) simplifies the process of extracting valuable insights from unstructured content using generative AI.

Available Actions

- **Invoke Data Automation Async** - Process data with a data automation project or blueprints. Starts asynchronous data processing and returns an invocation ID.
- **Get Data Automation Status** - Gets details about a data automation invocation status and output location.

Amazon Textract

Amazon Textract helps you add document text detection and analysis to your automations.

- **Basic document query** - Extracts data based on questions. Each query contains the question you want to ask and the alias you want to associate. Textract provides the text answer to each question and a confidence score.
- **Basic document analysis** - Extracts data from documents. Automatically detects and extracts forms (key-value pairs), tables (structured data), and text while preserving document layout and data relationships.

Amazon Comprehend

Amazon Comprehend is a natural language processing (NLP) service for gaining insight into document content. It helps analyze text to extract key phrases, identify sentiment, and classify documents.

Available Actions

- **Classify Document** - Creates a classification request to analyze a single document in real-time using a custom model endpoint. Supports text input or document files (PDF, Word, or image).
- **Detect Key Phrases** - Detects the key noun phrases found in the text, identifying important concepts and topics within the content.

External Applications

Microsoft Outlook

The Microsoft Outlook actions allow your automations to manage emails and calendars.

- **Email**
 - **Send User Email** - Send an email message on behalf of a specific user.
 - **Reply to Email** - Reply to the sender of a message.
 - **List Folder Messages** - Get the messages in a specific folder of the signed-in user's mailbox.
 - **List User Mails** - Get the messages in the signed-in user's mailbox (including Deleted Items and Clutter folders).
 - **View Email** - Retrieve the properties and relationships of a specific message object.
 - **Update Email** - Update the properties of a message object.

- **Delete Email** - Delete a message in the specified user's mailbox.
- **List Email Attachments** - Retrieve a list of attachment objects attached to a message.
- **Get Attachment** - Read the properties, relationships, or raw contents of an attachment.
- **Folders**
 - **List Mail Folders** - Get the mail folder collection directly under the root folder of the signed-in user.
 - **Move Email to Folder** - Move a message to another folder within the specified user's mailbox.
 - **Get Mailbox Settings** - Get the user's mailbox settings, such as automatic replies, date format, and time zone.
- **Calendar**
 - **List Calendar Events** - Fetch a list of calendar events for the specified user or resource from Microsoft Outlook.
 - **Create Calendar Event** - Create an event in the user's default calendar or specified calendar.
 - **Update Calendar Event** - Update the properties of an existing event object.
- **Other**
 - **List Places** - Get a collection of place objects (rooms or room lists) defined in the tenant.
 - **List Users** - Retrieve a list of users in the organization from Microsoft Outlook with their basic information.
 - **List Contacts** - Get a contact collection from the default contacts folder of the signed-in user.

Microsoft Teams

The Microsoft Teams actions allow your automations to communicate with team members through channels and chat messages, as well as manage meetings.

- **Messages**
 - **List Chats** - View all chat conversations
 - **Create Chat** - Start a new chat conversation
 - **Get Individual Chat** - View details of a specific chat
 - **List All Chat Messages** - View messages in a chat conversation
 - **Send Chat Message** - Send a new message in a chat
- **Teams**
 - **List Teams** - View all teams accessible to the authenticated user

- **Get Team** - View detailed information about a specific team
- **List All Team Members** - View members of a team
- **Invite User To Team** - Add a new member to a team
- **Channels**
 - **List All Channels** - View all channels within a specific team
 - **Create Channel** - Create a new channel within a team
 - **Get Channel** - View detailed information about a specific channel
 - **List All Channel Messages** - View messages posted in a channel
 - **Send Channel Message** - Post a new message to a channel
 - **Reply To Channel Message** - Add a reply to an existing channel message
 - **Invite Channel Member** - Add a member to a specific channel
- **Meetings**
 - **Create Online Teams Meeting** - Schedule a new online meeting
 - **Get Online Teams Meeting** - View details of a specific meeting
 - **List All Recordings** - View recordings from a meeting
 - **List All Transcripts** - View transcripts from a meeting
- **Users**
 - **List Users** - View list of users in the organization

Microsoft SharePoint

The Microsoft SharePoint allows you to centrally store, manage, and share documents and information through your automations.

- **Lists and items**
 - **Get List** - Get a list of operations associated with a list
 - **Create Item** - Create a new list Item in a list
 - **Update Item** - Update the properties on a listItem
 - **Delete Item** - Removes an item from a list
 - **Get Item** - Returns the metadata for an item in a list
 - **List Item** - Get the collection of items in a list
- **Sheets and files**

- **Add Sheet** - Add a new worksheet to the workbook
- **Delete Sheet** - Remove worksheet from workbook
- **Update Sheet** - Edit worksheet properties (rename, visibility)
- **List Sheets** - Retrieve a list of worksheet objects
- **Read Sheet** - Retrieve properties of a worksheet
- **Upload File** - Creates or updates a workbook file
- **Ranges and cells**
 - **Read Range** - Retrieves values from a specified range
 - **Delete Range** - Deletes cells in a specified range
 - **Write Range** - Updates values in a specified range
 - **Get Used Range** - Returns the used range of the given worksheet
 - **Clear Range** - Clear range values including format, fill, and border
 - **Read Cell** - Gets the value from a specific cell
 - **Write Cell** - Sets the value of a specific cell

Microsoft OneDrive

Microsoft OneDrive actions allow you to store, sync, and share files. You can interact directly with Microsoft Excel files saved to OneDrive for spreadsheet actions.

- **File management**
 - **Get Item** - View details of a specific file or folder
 - **Get Drive** - View OneDrive account details and storage information
 - **List Items** - View all files and folders in a drive
 - **Create Item / Create Folder** - Create a new folder or item in OneDrive
 - **List Children** - View items contained within a specific folder
 - **Delete Item** - Remove a file or folder
 - **Update Item / Move Item** - Update metadata or move files between folders
 - **Copy Item** - Create a copy of a file or folder in a different location
 - **Add Permissions** - Configure sharing and access permissions for files
 - **Upload File** - Add new files to OneDrive

- **Add Sheet** - Create a new worksheet in an Excel workbook
- **Clear Range** - Remove content and formatting from a range of cells
- **Delete Range** - Remove cells, rows, or columns from a worksheet
- **Delete Sheet** - Remove a worksheet from a workbook
- **List Sheets** - View all worksheets in a workbook
- **Read Cell** - Get the value of a specific cell
- **Read Range** - Get values from a range of cells
- **Read Sheet** - View contents of an entire worksheet
- **Read Used Range** - Get the range of cells that contain data
- **Update Sheet** - Modify worksheet properties
- **Write Cell** - Set the value of a specific cell
- **Write Range** - Set values for a range of cells

Salesforce

Salesforce actions allow you to automate the process of managing customer relationships across cases, opportunities, leads, campaigns, contacts and more.

- **Cases**
 - **Get Case List** - Gets a list of customer support cases from Salesforce, including their metadata and recent items.
 - **Get Case** - View details of a specific case
 - **Create Case** - Create a new support case
 - **Delete Case** - Remove an existing case
 - **Update Case** - Edit case details and information
- **Opportunities**
 - **Get Opportunities** - View list of sales opportunities
 - **Get Specific Opportunity** - View details of a specific opportunity
 - **Create Opportunity** - Create a new sales opportunity
 - **Update Opportunity** - Edit opportunity details
 - **Delete Opportunity** - Remove an existing opportunity

- **Update Lead** - Edit lead details and information
- **Campaigns**
 - **Update Campaign** - Edit campaign details and information
- **Feed Items**
 - **Update Feed Item** - Edit feed item content and properties
- **Contacts**
 - **Get Contact List** - View all contacts in the system
 - **Get Contact** - Fetch details of a specific contact
 - **Update Contact** - Edit contact information
- **Users**
 - **Get User List** - Retrieve list of Salesforce users
- **System**
 - **Describe SObject** - Get object metadata and field details for any Salesforce object type

Jira

Jira actions allow you to automate managing issues, projects, sprints and more.

- **Issues**
 - **Create Issue** - Create an issue in a project.
 - **Edit Issue** - Modify an existing issue in a project.
 - **Update Issue Status (Do Transition)** - Change task status of an issue.
 - **Delete Issue** - Delete an issue in a project.
 - **Get Issue** - View details of an issue in a project.
 - **Search Issues** - Searches for issues using JQL
 - **Search Statuses** - Search issue statuses.
 - **Download Issue Attachment** - View the contents of an attachment.
 - **Add Attachment** - Add an attachment to an issue.
 - **Get All Labels** - View all labels.
- **Comments**
 - **Add Comment** - Add new comment to an issue.
 - **Delete Comment** - Remove comment from an issue.

- **Update Comment** - Edit an existing comment on an issue.
- **Get Comments** - View issue comments.
- **Projects**
 - **Create Project** - Create new project in Jira.
 - **Update Project** - Modify project details.
 - **Delete Project** - Remove project from Jira.
 - **Get Project** - View project details.
 - **Get Issue Types For Project** - View project issue types.
 - **Search Projects** - Find visible projects.
- **Sprints**
 - **Create Sprint** - Create a sprint in a project.
 - **Update Sprint** - Update sprint details.
 - **Delete Sprint** - Delete a sprint in a project.
 - **Get Sprint** - View details of a sprint in a project.
 - **Move Issues to Sprint and Rank** - Assign an issue to a sprint.
 - **Move Issues to Backlog** - Move issues to backlog.
- **Users**
 - **Find Users** - Search for a Jira user.
 - **Find Assignable Users** - Returns a list of users that can be assigned to an issue.
 - **Get All Users** - List all Jira users.

ServiceNow

ServiceNow actions allow you to automate IT service management of incidents, change requests, and more.

- **Incidents**
 - **Create Incident** - Creates a new incident record.
 - **Read Incident** - Retrieves details of a specific incident.
 - **Update Incident** - Modifies an existing incident record.
 - **Delete Incident** - Removes a specific incident record.
- **Change Requests**

- **Create Change Request** - Creates a new change request record.
- **Read Change Request** - Retrieves details of a specific change request.
- **Update Change Request** - Modifies an existing change request record.
- **Delete Change Request** - Removes a specific change request record.
- **Knowledge Base Articles**
 - **Update Knowledge Base Article** - Modifies an existing knowledge base article.
- **Problem Records**
 - **Update Problem Record** - Modifies an existing problem record.
- **Attachments**
 - **Upload Binary Attachment** - Uploads a file as an attachment to a specified record.
 - **Upload Multipart Form Attachment** - Uploads a form attachment to a record.
 - **Retrieve Attachment Content** - Gets the binary content of a specific attachment.
 - **Retrieve Attachment Metadata** - Gets metadata for a specific attachment.
 - **Delete Attachment** - Removes an attachment from the system.
 - **Retrieve Metadata for Attachments** - Gets metadata for multiple attachments.
- **System**
 - **List Users** - Retrieves all existing records from system user table.
 - **List Choices** - Retrieves choice list values from the system.

SAP

SAP actions allow you to automate processes involving business partner data, material stocks, bills of material, product masters, and physical inventory.

- **SAP Business Partners**
 - **Get Business Partner** - Retrieves general data for business partners, providing a comprehensive view of partner information.
 - **Get Business Partner By ID** - Retrieves detailed business partner data using a specific business partner number as identifier.
 - **Get Business Partner Address** - Retrieves address details associated with business partners, including postal addresses and contact information.
 - **Get Business Partner Role** - Retrieves role information for business partners, showing their relationships and functions within the system.

- **Get Business Partner Role By ID** - Retrieves specific role data for a business partner using key identifier fields.
- **SAP Material Stock**
 - **Get Material Stock In Account Model Collection** - Gets material stock levels with details like batch, storage location, and special stock indicators.
- **SAP Bill Of Material**
 - **Get Material BOM Item** - Retrieves details of materials used in bills of materials including quantities, categories, and relationships.
- **SAP Product Master**
 - **Get Product Master Records** - View product master general details. Returns complete product master records with options to filter, sort and select specific data.
 - **Get Plant Data Of Product Master Record** - View plant details of the product. Access detailed plant-specific information for a given product including manufacturing, storage, and logistics data.
 - **Get Supply Planning Data By Product Number And Plant** - View supply planning details by product number and plant. Retrieves detailed planning parameters including lot sizes, safety stock levels, and procurement data.
- **SAP Physical Inventory**
 - **Get Phys Inventory Doc Item** - Retrieves physical inventory document items including counting results and inventory differences.

REST API Integration

The REST API Connection integration enables Quick Automate to interact with custom REST APIs and web services, allowing you to extend automation capabilities to external systems. This integration supports action execution for GET, POST, DELETE, PATCH and PUT HTTP methods.

Common Use Cases:

- Sending notifications to external systems
- Retrieving data from third-party services
- Updating records in external databases
- Triggering workflows in connected applications

Prerequisites

Before creating automations with REST API integration, ensure you have:

- **Configured REST API Integration**
 - Access Quick Suite console
 - Navigate to Integrations > REST API Connection
 - Configure your REST API endpoint with base URL
 - Complete authentication setup (see Authentication section below)
 - Full details: [REST API Connection integration](#)
- **Connected Integration to Automation Group**
 - Link your configured REST API integration to your automation group
 - Verify integration appears in available actions
 - Step-by-step guide: [AWS service connectors](#)
- **Authentication Configured**
 - OAuth 2.0 credentials obtained from your API provider

Authentication

For Quick Automate, this integration supports **OAuth 2.0** authentication. You must configure OAuth credentials before creating automations.

OAuth 2.0 Setup Steps:

- Obtain OAuth credentials (Client ID and Client Secret) from your identity provider
- In the Quick Suite console, navigate to your REST API integration settings
- Select OAuth 2.0 as the authentication method
- Enter your Client ID and Client Secret
- Configure the authorization URL and token URL provided by your API provider
- Complete the OAuth flow to authorize Quick Suite
- Test the connection to verify authentication

Important Notes:

- Quick Automate does not support bearer token authentication in request headers. Use OAuth configuration instead.
- Configure authentication at the integration level, not per automation action

Configuration

Setting Up Your REST API Integration

Step 1: Create Base URL Configuration

Step 2: Connect to Automation Group

Step 3: Access REST API Actions

- Open the Actions Panel in your automation
- Locate REST API action
- Drag and drop actions into your automation workflow

Note

REST API actions must be added through the Actions Panel; they are not available in the Build with Assistant interface

Properties Reference

- **Q Action Connector ID (Required)**
 - **Description:** Unique identifier that links the REST API action to your configured integration, including base URL and authentication settings.
 - **Format:** Auto-populated from your connected integration
 - **Example:** rest-api-connector-abc123
- **URI (Optional)**
 - **Description:** Additional path appended to the base URL to specify the exact API endpoint.
 - **Format:** Path string with or without leading slash (depends on the base url format)
 - **How It Works:**
 - Base URL: https://api.example.com
 - URI: /users/123

- Final URL: `https://api.example.com/users/123`

- **Examples:**

```
/users/123
prod/send-email
/v2/orders
customers/search
```

- **Additional Headers (Optional)**

- **Description:** Custom HTTP headers to include in the API request as key-value pairs.

- **Format:**

```
Key: Value
```

- **Common Examples:**

```
Content-Type: application/json
Accept: application/json
X-Custom-Header: custom-value
X-API-Version: 2.0
```

- **Important Limitations:**

- Do not include Authorization headers; authentication is handled via OAuth configuration
- Each header must be on a separate line
- Headers are case-sensitive

- **Request (Required)**

- **Description:** JSON-formatted data to send with POST or PUT requests.
- **Format:** Valid JSON object. {} for blank requests
- **POST Request Example (Creating a resource):**

```
{
  "title": "My New Post",
  "body": "This is the content of my new post.",
  "userId": 1,
  "tags": ["automation", "api"],
  "published": true
}
```

- **PUT Request Example (Updating a resource):**

```
{
  "status": "completed",
  "completedDate": "2026-01-27",
  "notes": "Task finished successfully"
}
```

- **Output Variable (Optional)**

- **Description:** Variable name to store the JSON response from the API call for use in subsequent automation actions.
- **Format:** Alphanumeric variable name (no spaces)
- **Example:** apiResponse, userData, orderDetails

Example of API usage

Example 1: GET Request - Retrieve Ticket Details

Scenario: Retrieve details of an existing support ticket from an external ticketing system

Configuration:

- **Q Action Connector ID:** rest-api-connector-tickets
- **HTTP Method:** GET
- **URI:** /tickets/ticketId
- **Additional Headers:**

```
Accept: application/json
```

- **Request Body:** {} (empty for GET requests)
- **Output Variable:** ticketDetails

Example 2: POST Request - Create New Record

Scenario: Submit a new support ticket to an external ticketing system

Configuration:

- **Q Action Connector ID:** rest-api-connector-tickets

- **HTTP Method:** POST
- **URI:** /tickets
- **Additional Headers:**

```
Content-Type: application/json
Accept: application/json
```

- **Request Body:**

```
{
  "title": "{{ticketTitle}}",
  "description": "{{ticketDescription}}",
  "priority": "{{ticketPriority}}",
  "requestedBy": "{{userEmail}}",
  "category": "technical_support"
}
```

- **Output Variable:** ticketResponse

Testing automations

Amazon Quick Automate provides comprehensive capabilities for testing your automations. This section describes the tools and features available for validating your automation behavior.

Test modes

Choose from two modes to test your automation:

- **Run mode** - Executes the automation from start to finish without stopping. Any breakpoints in the automation will be ignored. This mode is best for testing the complete flow of your automation.
- **Debug mode** - Executes the automation and pauses at any breakpoints you've set or if an exception occurs. This allows you to inspect the automation state, monitor variables, and validate behavior at specific points in your process.

Test pane

The Test pane includes includes two main tabs that help you monitor and control your automation test:

Setup tab

The Setup tab provides tools for managing your test configuration:

- Breakpoint manager - Lists all breakpoints currently set in your automation. Remove breakpoints directly from this view without returning to the canvas.
- Test navigation - Quick access links to view:
 - View runs - See all automation runs from testing
 - View cases - View cases created during testing
 - View tasks - Review any human-in-the-loop tasks generated

Monitor tab

The Monitor tab displays real-time information about your running automation:

- UI streaming - Watch browser automation actions execute in real-time
- Variable watcher - Monitor and modify variable values
- Logs - Track detailed automation progress

Test statuses

During testing, your automation will be in one of these statuses:

- Running - The automation is actively executing actions
- Paused (breakpoint) - Execution has stopped at a user-defined breakpoint
- Paused (exception) - Execution has stopped due to an error condition
- Completed - The automation has finished all steps successfully
- Failed - The automation encountered an unrecoverable error and stopped

Running and debugging

Test automations with inputs and outputs

When you test an automation that has input and output fields defined, Amazon Quick Automate validates the input values and displays both inputs and outputs as expandable cards in the **Monitor** pane alongside the execution logs.

Running an automation with inputs from the authoring studio

When you choose **Run** or **Debug** to test an automation with inputs and outputs, the authoring studio (Studio) displays a dynamic input form titled **Provide input values**. Amazon Quick Automate automatically generates this form based on the schema you defined.

The form includes:

- Field names from your schema.
- Input controls appropriate for each data type (text fields for strings, number inputs for integers, and file upload buttons for files).
- Required field indicators (marked with an asterisk).
- Default values pre-populated where you defined them.
- Client-side validation for data types, required fields, and file size limits (maximum 5 MB for files).

To run an automation with inputs:

- Open your automation in Studio and choose **Run** or **Debug**.
- In the **Provide input values** form, enter values for each field:
 - For text and number fields, type the values directly
 - For file fields, choose **Browse** to select a file from your local machine
 - Optional fields can be left blank unless you want to override default values
- Choose **Start** to begin the automation with your provided inputs.

Amazon Quick Automate performs two layers of validation:

- **Client-side validation** – Checks for blank required fields, correct data types, and file size limits before execution starts
- **Runtime validation** – Validates the complete input payload against your JSON schema during execution

Viewing inputs and outputs

After the automation runs, input and output values appear as collapsible cards in the **Monitor** pane:

- **Input card** – Displays at the beginning of the run logs, showing all values you provided when starting the automation
- **Output card** – Displays at the end of the run logs after execution completes, showing all values your automation produced

Both cards are collapsed by default. When you expand them, you can:

- View the complete schema definition and actual values
- Download any file objects included in the inputs or outputs
- Copy the structured data as JSON
- Download the complete payload as a JSON file

Note

If the automation terminates with an error, the output card won't be available.

Setting breakpoints

Breakpoints allow you to pause your automation at specific points:

To add a breakpoint:

- Hover over an action or step on the canvas
- Click **Add breakpoint**
- The breakpoint icon appears on the action or step

To remove a breakpoint:

- Click **Remove breakpoint** on the action
- Or use the breakpoint manager in the Setup tab

Note

Set up breakpoints before starting debug mode.

Debug controls

When your automation is paused, you have several control options:

- Next - Run the next action in your automation and pause again
- Continue - Resume the run until the next breakpoint is reached
- Stop - End the current test run
- Ignore - If paused on an exception, this will clear the exception and continue as if that action was successful. This is useful if the exception is not blocking the rest of your test and you want to continue.
- Retry - If paused on an exception, this will attempt to run the current action again. This is useful if the issue is temporary or if you want to change the value of a variable and retry with the new value

Deactivating steps

To temporarily disable any actions or steps without removing them, you can deactivate them before starting your test. Deactivated actions or steps will be skipped during testing.

- Select the step to deactivate
- Click the **Menu options**
- Choose **Deactivate**
- The step appears grayed out

To reactivate:

- Select the deactivated step
- Click the **Menu options**
- Choose **Activate**

Variable watcher

The Variable watcher in the Monitor tab provides visibility to inspect data being used by your automation during the test. To inspect a variable:

- Open the Variable watcher in the Monitor tab while the test is paused

- Click **Add** to search and select variables to inspect
- View the current value for the variable
- Modify values to test different scenarios:
 - Click the **pencil icon** next to any variable
 - Enter a new value to test
 - Continue the run to proceed with the new value

This feature is particularly useful for:

- Testing different data conditions
- Validating error handling
- Simulating edge cases

Troubleshooting

Fix with Assistant

When your automation encounters an exception, the Automation Assistant can help identify and resolve issues:

- Click **Fix with Assistant** when paused at an error
- The Assistant will:
 - Analyze the error message
 - Review the run logs
 - Check its troubleshooting knowledge base
 - Provide a clear explanation of the issue
 - Suggest potential solutions
- Chat with the Assistant to:
 - Ask questions about the error
 - Update the automation based on any of the recommended changes

Test metrics

After your test completes, Amazon Quick Automate provides comprehensive test metrics to help understand automation performance and validate test coverage. View key metrics about your test run:

- **Total running time** - How long the test took from start to finish
- **Number of completed cases** - Count of cases that finished processing (excluding those created or pending)
- **Average time per case** - The processing average time for each completed case
- **Case success rate** - Percentage of cases that completed without exceptions
- **Count of tasks created** - Number of human-in-the-loop tasks generated during the test
- **Action coverage** - Percentage of actions in your automation that executed during the test, helping identify untested paths

Deploying automations

After you create and test your automations in Amazon Quick Automate, the next step is to **deploy** them so they can run regularly on a trigger. Deployment makes the automation operational and ready for execution. You can add a trigger to a deployed automation to run it at a predefined schedule. Deployment involves configuring runtime settings, assigning users for human-in-the-loop tasks, verifying credentials and integrations.

This section explains each step of the deployment process and how to configure your automation for reliability, security, and optimal performance.

Prerequisites

Before deploying your automation, ensure that the following steps are complete:

- **Automation is tested thoroughly** - Validate your automation through end-to-end testing to confirm that all logic, actions, and agent interactions work as expected.
- **Version committed for deployment** - Only committed automation versions can be deployed. Review your changes, finalize the version, and commit it before proceeding.
- **Integrations configured** - If your automation interacts with external applications such as Salesforce or Jira via APIs, make sure all necessary integrations are configured.
 - Navigate to **Connections** → **Integrations** in the left panel to create new integrations.

- Currently, only integrations available under the **Actions** tab are supported in Amazon Quick Automate.
- Once an integration action is created, associate it with the **Automation Group** where it will be used.
- The associated actions will then appear in the canvas. During deployment, you can select the appropriate connection to be used by the deployed automation.
- **Credentials configured** - Verify that all credentials required by your automation are correctly set up.

Deploying an automation

You can deploy an automation directly from the Canvas by clicking Deploy, or by navigating to the Deployment tab on the automation's landing page. Once you initiate deployment, the system guides you through a series of steps to complete the configuration and release process.

Release details

On the **Release Details** page, select the version of the automation you want to deploy. Only **committed versions** are available for deployment and will appear in the dropdown list.

Additional settings

Additional settings include:

- **Runtime configuration**
- **Tasks (for HITL assignments)**
- **Access**

Runtime configuration

Runtime configurations are parameters that may differ between environments such as development, testing, and production.

For example, an automation step that sends an email may use your personal email address during testing but should switch to a shared team address in production. Such environment-dependent values can be defined as **runtime configurations** when authoring the automation.

At deployment time, you can review and override these configurations to ensure the automation runs correctly in the intended environment. Runtime parameters can include:

- Email addresses or notification recipients
- File paths or URLs specific to the environment

This flexibility helps maintain a single automation definition across environments while adapting key parameters as needed.

Tasks

Select the resolver users or user groups for each of the tasks that require human-in-the-loop.

Access (Credentials and Connections)

Automations often need to connect to external systems, databases, or services. Amazon Quick Automate provides secure methods for managing credentials and connections without embedding sensitive information within your automation logic.

Connection and credential data are securely stored and encrypted, and made available to workflows at runtime without exposing them to authors or end users. This design ensures strong separation of secrets from automation definitions, improving both security and maintainability.

You can store and use two primary types of credentials:

- **Website credentials** - Used for UI automation steps that require website logins (username and password).
- **Action credentials (Integrations)** - Used for connecting AWS services (e.g. S3) or external systems through configured integrations (e.g., Salesforce, Jira).

At deployment, ensure that the correct credentials and connections are selected so the automation can access all required systems securely and successfully.

Setting up triggers

Triggers determine when and how your automations run. You can configure automations to start based on a predefined schedule or invoke them programmatically through the Amazon QuickSight API.

Schedules

You can configure automations to start based on a predefined schedule. To setup a trigger:

- On the Deployment page, click "Create Trigger" and configure the rules.
- Select the frequency
- Select the start date and time (Note that the actual execution will initiate within 15 minutes of the start time selected)
- Select the end date and time
- Select the timezone
- Amazon Quick Automate provided built-in scalability. Select the number of parallel executions of the automation (you can select a maximum of 10 parallel executions per trigger and 50 across all automations within an account. Please reach out to AWS)
- For complex scheduling needs, you can use cron expressions to define precise running patterns. For example, to run an automation at 2:30 AM every Monday, Wednesday, and Friday, you would use the cron expression: `30 2 * * 1,3,5`.

API triggers

The Automation Job APIs enable you to programmatically start and monitor automation jobs from external applications. You can use these APIs to invoke deployed automations with custom input payloads and retrieve execution results through the AWS SDK and AWS CLI.

The Automation Job APIs include two operations:

- **StartAutomationJob** – Starts a new job for a deployed automation with an optional input payload.
- **DescribeAutomationJob** – Retrieves the status, timestamps, and optional input and output payloads for a specified job.

These APIs are part of the Amazon QuickSight service namespace. You access them through the `quicksight` namespace in the AWS SDK and AWS CLI.

For more information about AWS SDKs and toolkits, see the [AWS Getting Started Resource Center](#).

Prerequisites

Before you call the Automation Job APIs, complete the following setup steps.

Find your automation identifiers

To call the Automation Job APIs, you need the following identifiers:

- **AWS account ID** – Your 12-digit AWS account ID.
- **Automation group ID** – The unique ID of the automation group that contains your automation.
- **Automation ID** – The unique ID of the automation you want to invoke.

You can find the automation group ID and automation ID in the Deployments section when you open any automation and have a deployed version.

To find your identifiers

- Sign in to Amazon Quick Automate.
- In the left navigation pane, choose **Automations**.
- Choose the automation group that contains your automation.
- Choose the automation name to open the automation editor.
- Choose the **Deployments** tab.
- Choose the **Actions** (:) and **View deployment details** to get the **Automation ID** and **Group ID** at the top just below the heading Deployment Details.

Configure IAM permissions

The Automation Job APIs require IAM permissions attached to your IAM identity (user, role, or group). Each operation requires a separate permission.

Permission for StartAutomationJob

Attach a policy that grants the `quicksight:StartAutomationJob` action. Scope the resource ARN to the specific automation that you want to allow.

```
{
  "Version": "2012-10-17"
  ,
  "Statement": [
    {
      "Sid": "AllowStartAutomationJob",
      "Effect": "Allow",
      "Action": [
        "quicksight:StartAutomationJob"
      ],
      "Resource": [
```

```

        "arn:aws:quicksight:us-west-2:111122223333:automation-group/EXAMPLE-
        GROUP-ID/automation/EXAMPLE-AUTOMATION-ID"
    ]
}
]
}

```

Permission for DescribeAutomationJob

Attach a policy that grants the `quicksight:DescribeAutomationJob` action. The resource ARN for this operation includes the job ID segment. To allow describing any job under an automation, use a wildcard (*) for the job segment.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowDescribeAutomationJob",
      "Effect": "Allow",
      "Action": [
        "quicksight:DescribeAutomationJob"
      ],
      "Resource": [
        "arn:aws:quicksight:us-west-2:111122223333:automation-group/EXAMPLE-
        GROUP-ID/automation/EXAMPLE-AUTOMATION-ID"
      ]
    }
  ]
}

```

AWS recommends scoping each permission to the most specific resource ARN possible to follow the principle of least privilege. For more information, see the following:

- [IAM policy examples for Amazon QuickSight](#)
- [Actions, resources, and condition keys](#)
- [IAM JSON policy elements](#)

Deploy your automation

The `StartAutomationJob` API targets deployed automations only. You must commit and deploy your automation in the Amazon Quick Automate console before you can invoke it through the API.

StartAutomationJob

Starts a new job for a deployed automation. The operation is asynchronous — Amazon Quick Automate accepts the request, queues the job, and returns a **JobId** immediately. The automation runs in the background. If the automation has an input schema defined, Amazon Quick Automate validates the **InputPayload** against the schema before accepting the job. An invalid payload results in an **InvalidParameterValueException**.

Request syntax

```
POST /accounts/AwsAccountId/automation-groups/AutomationGroupId/
automations/AutomationId/jobs HTTP/1.1
Content-type: application/json

{
  "InputPayload": "string"
}
```

Request parameters

- **AwsAccountId** (String, required) – Your AWS account ID (12 digits).
- **AutomationGroupId** (String, required) – The ID of the automation group (UUID).
- **AutomationId** (String, required) – The ID of the automation to run (UUID).
- **InputPayload** (String, optional) – Input for the job as a JSON string.

Response elements

- **Arn** (String) – ARN of the automation job.
- **JobId** (String) – ID of the started job. Use this with `DescribeAutomationJob` to track status.
- **Status** (Integer) – HTTP status code of the response.
- **RequestId** (String) – AWS request ID.

Errors

- **AccessDeniedException** – Insufficient permissions or invalid credentials.
- **InvalidParameterValueException** – One or more parameters has a value that isn't valid.
- **ResourceNotFoundException** – Automation group or automation not found.

- **LimitExceededException** – A limit is exceeded.
- **ThrottlingException** – Request was throttled.
- **InternalFailureException** – Internal service error.

For more details, see the [API reference guide for StartAutomationJob](#).

DescribeAutomationJob

Retrieves the status and details of a specified automation job, including execution timestamps and optional input and output payloads. Use this operation to poll for job completion after calling **StartAutomationJob**.

The response does not include input and output payloads by default. Set the **IncludeInputPayload** and **IncludeOutputPayload** query parameters to `true` to request them. Amazon Quick Automate returns the output payload only when all of the following conditions are met:

- **IncludeOutputPayload** is `true`.
- **JobStatus** is `SUCCEEDED`.
- The automation produced output values.

Request syntax

```
GET /accounts/AwsAccountId/automation-groups/AutomationGroupId/
automations/AutomationId/jobs/JobId?
IncludeInputPayload=boolean&IncludeOutputPayload=boolean HTTP/1.1
```

Request parameters

- **AwsAccountId** (String, required) – Your AWS account ID (12 digits).
- **AutomationGroupId** (String, required) – The ID of the automation group (UUID).
- **AutomationId** (String, required) – The ID of the automation (UUID).
- **JobId** (String, required) – The ID of the job returned by **StartAutomationJob** (UUID).
- **IncludeInputPayload** (Boolean, optional) – Include the input payload in the response. Default: `false`.
- **IncludeOutputPayload** (Boolean, optional) – Include the output payload in the response. Default: `false`.

Response fields

- **Arn** (String) – ARN of the automation job.
- **CreatedAt** (Timestamp) – When the job was created (epoch seconds).
- **StartedAt** (Timestamp) – When the job started running (epoch seconds).
- **EndedAt** (Timestamp) – When the job finished (epoch seconds).
- **JobStatus** (String) – QUEUED, RUNNING, SUCCEEDED, FAILED, or STOPPED.
- **InputPayload** (String) – The input payload. Omitted from response unless `IncludeInputPayload` is true.
- **OutputPayload** (String) – The output payload. Omitted from response unless `IncludeOutputPayload` is true.
- **RequestId** (String) – AWS request ID.

Errors

- **AccessDeniedException** – Insufficient permissions or invalid credentials.
- **InvalidParameterValueException** – One or more parameters has a value that isn't valid.
- **ResourceNotFoundException** – Job, automation, or automation group not found.
- **ThrottlingException** – Request was throttled.
- **InternalFailureException** – Internal service error.

For more details, see the [API reference guide for DescribeAutomationJob](#).

Run automations with API triggers using input and output

You can include input values as a JSON payload when you start an automation job through the API. Amazon Quick Automate validates the payload against the automation's input schema before execution begins, and returns structured output values when the job completes.

Prerequisites

Before you run an automation with API triggers, make sure the following are in place:

- The automation is deployed.
- The automation has an input schema defined in the Start node.
- You have the automation group ID and automation ID.

Sending input values through the API

To include input values, pass a JSON payload in the **StartAutomationJob** request using the **InputPayload** parameter.

Sample Request

```
POST /accounts/123456789012/automation-groups/a1b2c3d4-e5f6-7890-abcd-ef1234567890/
automations/11111111-2222-3333-4444-555555555555/jobs
{
  "InputPayload": "{\"customer_id\":\"C-98765\",\"threshold\":100,\"region\":\"us-
east-1\"}"
}
```

Sample Response

```
{
  "Arn": "arn:aws:quicksight:us-west-2:123456789012:automation-group/a1b2c3d4-
e5f6-7890-abcd-ef1234567890/automation/11111111-2222-3333-4444-555555555555/job/
aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee",
  "JobId": "aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee",
  "Status": 200,
  "RequestId": "req-12345678-abcd-efgh-ijkl-123456789012"
}
```

Note

The **InputPayload** value must be a JSON-serialized string that contains the input field values matching your automation's input schema.

Retrieving output values through the API

You can retrieve output values by calling the **DescribeAutomationJob** API. To include input and output payloads in the response, set the **includeInputPayload** and **includeOutputPayload** query parameters to **true**.

The response includes the **OutputPayload** field only when the automation completes successfully.

Sample Request

```
GET /accounts/123456789012/automation-groups/a1b2c3d4-e5f6-7890-abcd-ef1234567890/
automations/11111111-2222-3333-4444-555555555555/jobs/aaaaaaaa-bbbb-cccc-dddd-
eeeeeeeeeeee?includeInputPayload=true&includeOutputPayload=true
```

Sample Response

```
{
  "Arn": "arn:aws:quicksight:us-west-2:123456789012:automation-group/a1b2c3d4-
e5f6-7890-abcd-ef1234567890/automation/11111111-2222-3333-4444-555555555555/job/
aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee",
  "JobStatus": "SUCCEEDED",
  "CreatedAt": "2026-03-11T09:59:50Z",
  "StartedAt": "2026-03-11T10:00:00Z",
  "EndedAt": "2026-03-11T10:05:00Z",
  "InputPayload": "{\"customer_id\":\"C-98765\",\"threshold\":100,\"region\":\"us-
east-1\"}",
  "OutputPayload": "{\"result\":\"success\",\"records_processed\":42,\"summary\":
{\"passed\":40,\"failed\":2}}",
  "RequestId": "req-12345678-abcd-efgh-ijkl-123456789012"
}
```

Note

The **OutputPayload** field is available only after the automation completes successfully (when **JobStatus** is SUCCEEDED). If the automation fails or is still running, the response does not include the **OutputPayload** field.

Deploy and run automations with inputs and outputs

This section describes how to deploy automations that use input and output schemas, run them manually or on a schedule, and view run results.

View schema information before deployment

Before deploying an automation, you must commit it to create a version. For more information, see [maintaining automation versions](#).

After you commit an automation with input or output schemas, you can view the schema details in the **Data model** section of the version details page. This section displays the complete field definitions for both inputs and outputs.

Deploy automations with input and output schemas

When you deploy an automation that has input or output schemas defined, the deployment dialog box displays schema information in the **Data model** section, including:

- Input and output field definitions (name, data type, description, required or optional status, and default values).
- Copyable JSON schemas for inputs and outputs that API callers can use for integration.

Important

The schema is frozen at deployment time along with the automation code. If you update the schema after deployment, you must redeploy the automation for the changes to take effect.

To complete the deployment, review the schema information and choose **Deploy**.

Run deployed automations manually

To start a deployed automation with inputs, complete the following steps:

- On the deployment page, choose the **Actions** menu (:).
- Choose **Run now**.
- In the **Provide input values** dialog box, enter values for each input field.
- Choose **Start** to start the automation run.

The input form is identical to the one you use when you test in Studio.

Run automations with scheduled triggers

For scheduled triggers, you provide input values when you create or edit the trigger. The stored values are passed to the automation each time the trigger fires.

You can do the following:

- Create multiple triggers with different input values for the same automation
- Edit input values for a trigger without redeploying the automation

To configure inputs for a scheduled trigger, complete the following steps:

- Navigate to the deployment page for your automation.
- Choose **Create Trigger**.
- In **Step 1: Set Trigger**, configure the schedule.
- In **Step 2: Define Run**, enter values for each input field in the auto-generated form.
- Choose **Next**, review your configuration, and choose **Create Trigger**.

 Note

If you create a trigger with a specific schema version and later deploy the automation with an updated schema, you must modify the trigger. The trigger becomes incompatible when the schema version changes and the automation runs will fail.

Viewing inputs and outputs for deployed runs

After an automation run completes (whether started manually or by a scheduled trigger), input and output values are available as structured artifacts in the logs panel on the **Runs** page.

The artifacts appear as dedicated cards:

- **Input artifact** – Displays at the top of the logs panel
- **Output artifact** – Displays at the bottom of the logs panel (only available if the automation completes successfully)

Both cards are collapsed by default. When you expand them, you can:

- View the complete schema and actual values
- Download any file objects included in the inputs or outputs
- Copy the structured data as JSON
- Download the complete payload as a JSON file

Export and import automations

You can use the import and export feature in Amazon Quick Automate to share and migrate automation versions across automation groups, AWS accounts, and AWS Regions. Use this feature to promote automations from development to production environments, create backups, or share automations with other teams.

When you export an automation version, Amazon Quick Automate packages it into a secure, encrypted link that you can use to transfer the automation between environments. The export bundle contains the following:

- The automation workflow
- Runtime configuration settings
- Process step descriptions and metadata

Note

Dependencies such as connectors, credentials, and task queue configurations are not included in the export bundle. You must configure these separately in the destination environment.

Use cases

The import and export feature supports the following use cases:

- Move tested automations from development to production accounts.
- Deploy automations across different AWS Regions.
- Create point-in-time snapshots of automation versions for disaster recovery.
- Share automation versions across different automation groups within the same account.

Prerequisites

Before you import or export automations, make sure that you have the following:

- Access to Amazon Quick Automate.

- Appropriate permissions to create and manage automations in both the source and destination environments.
- Amazon Quick Automate enabled in both the source and destination AWS accounts (for cross-account transfers).

Export an automation

To export an automation version, complete the following steps.

- Navigate to your automation in **Amazon Quick Automate**.
- Choose the actions menu (:) next to **Edit automation**.
- Choose **Export version**.
- Choose the version from the dropdown list and wait for the link to be generated.
- Choose **Copy link** or copy the link manually.

Amazon Quick Automate generates a secure, pre-signed download link for your automation. Amazon Quick Automate encrypts the bundle by using AWS KMS with envelope encryption to protect your automation content.

Export link validity

Export links are valid for 12 hours from the time of creation. After this period, the link expires and you must generate a new export link. You can reuse the same export link multiple times within the 12-hour window without creating a new export.

Import an automation

To import an automation version, complete the following steps.

- Navigate to the destination automation group and create a blank automation.
- Choose the actions menu (:) next to **Edit automation**.
- Choose **Import version**.
- Paste the exported link (the pre-signed URL that you received during export).
- Choose **Start**.

Considerations

- You can export one automation version per operation.
- Connectors, credentials, and other dependencies are not included in the export. You must configure these separately in the destination environment.
- For cross-account transfers, both the source and destination accounts must have Amazon Quick Automate enabled.

Monitoring performance

Amazon Quick Automate provides comprehensive monitoring capabilities that help you track performance, audit and troubleshoot your automations. This section describes how to use the performance monitoring features in Amazon Quick Automate.

Prerequisites

Before using the Performance dashboard, you need:

- **Active automations** - At least one automation must be run to see metrics
- **Automation group access** - Permission to view the automation groups you want to monitor

Automation summary dashboard

The Automations tab provides high-level metrics and key performance indicators across your automation portfolio.

Automation summary charts

The dashboard includes three main performance visualizations:

- **Automation Distribution** - Shows the number of deployed automations organized by automation group, helping you understand your automation footprint across the organization
- **Success Rate** - Displays the percentage of cases that completed successfully versus those that encountered exceptions, providing insight into automation reliability
- **Time Savings** - Calculates total hours saved based on successful case completions multiplied by the estimated time savings configured for each automation project

Automation details table

Each automation is listed with key metrics and status information:

- **Automation name** - Name and version of the deployed automation
- **Latest run** - Most recent execution status and timestamp
- **Case metrics** - Count of cases processed, broken down by:
 - Successfully completed cases
 - Cases with business exceptions
 - Cases with system exceptions
- **Tasks** - Number of human-in-the-loop tasks created by the automation

Runs dashboard

The Runs tab provides detailed visibility into individual automation executions and their outcomes.

Run statuses

Automations can be in one of these run statuses:

- **Waiting** - The automation is queued and awaiting available system resources to begin execution. This is typically a brief transitional state.
- **In Progress** - The automation is actively executing its configured steps. You can monitor real-time progress through the logs.
- **Completed** - The automation has finished all steps successfully.
- **Failed** - The automation encountered an error it could not recover from and stopped execution. Detailed error information is available in the logs.
- **Stopped** - A user manually interrupted the automation execution using either the Exit or Terminate action.

Note

Count of incomplete runs includes Waiting and In Progress.

Run details table

Each run provides comprehensive execution information through the following columns:

- **Status** - Current run status (as defined in Run Status Types)
- **Automation** - Name of the automation being run
- **Version** - Specific version number of the automation which ran
- **Start time** - When the automation run began
- **End time** - When the automation completed or stopped
- **Duration** - Total running time of the automation
- **Case metrics** - Count of cases processed, broken down by:
 - Successfully completed cases
 - Cases with business exceptions
 - Cases with system exceptions
- **Tasks** - Number of human-in-the-loop tasks created in the run

Note

Data is refreshed when first navigating to the page. Click the refresh button to pull the latest data at any point.

Cases dashboard

The Cases tab enables tracking of individual case records through their lifecycle.

Case charts

The dashboard includes two main performance visualizations:

- **Total cases created** - Shows the number of cases created over time, helping you understand your automation volumes.
- **Top exceptions** - Displays the top 5 exception reasons and the relative count of each, helping you prioritize your optimization efforts to improve success rates.

Case statuses

Cases can be in one of these processing statuses:

- **Ready** - The case has been created and is waiting to be picked up for processing. This is the initial state of all new cases.
- **In Progress** - The case is actively being processed by the automation. You can monitor real-time progress through the logs.
- **Pending Resolution** - The case is waiting for a human-in-the-loop task to be completed before processing can continue. Cases move back to Ready status after tasks are resolved.
- **Successful** - The case has completed without any exceptions.
- **Failed** - The case encountered one of the following exception types:
 - **Business Exception** - The case encountered a handled business rule violation and stopped processing. Detailed exception information is available in the logs.
 - **System Exception** - The case experienced a technical error and stopped processing. Detailed error information is available in the logs.

For detailed information about case handling and orchestration patterns, see [Orchestration actions](#).

Search and filtering

The Performance dashboard includes search and filtering capabilities available across all monitoring views to help you find specific information. Filter by:

- Time range
- Status
- Automation group
- Automation

Note

You can also search on the cases page by reference name or exception reason.

Environment selection

Switch between viewing metrics from:

- Test - Data from automation testing in development environment
- Deployed - Data from deployed automations

Note

Your selected environment applies across all dashboard tabs until changed.

CloudWatch

Amazon CloudWatch provides monitoring and observability capabilities for your automations in Amazon Quick Automate. This section explains the metrics available in CloudWatch, how to view the metrics, and how to set up alarms for these metrics.

Prerequisites

IAM roles and permissions

To grant CloudWatch access following least-privilege principles:

- Create an IAM role or group, preferably using AWS IAM Identity Center.
- Attach the AWS managed policy CloudWatchFullAccess for full monitoring and alarm capabilities.
- Optionally, add CloudWatchLogsReadOnlyAccess for log querying without deletion permissions.
- Assign users to this role or group to enable CloudWatch operations without broader administrative access.

For detailed step-by-step instructions, see [Getting setup in CloudWatch](#) and [CloudWatch permissions guide](#).

Accessing CloudWatch

- Navigate to the AWS Management Console.
- Enter CloudWatch in the services search bar.

- Choose CloudWatch from the results to open the CloudWatch console.

Accessing CloudWatch metrics for Amazon Quick Automate

- Open the CloudWatch console.
- In the left navigation pane, choose **Metrics, All metrics**.
- Choose the service namespace **QuickSight**.
- Choose the relevant dimensions, **AutomationGroupId** or **AutomationId**, to view the metrics.
- Use the search bar to search or filter by metric name or dimension.

For more detailed information, see the [CloudWatch metrics documentation](#).

Available metrics

Amazon Quick Automate publishes metrics to CloudWatch under the **QuickSight** namespace. Metrics are grouped by either **AutomationId** or **AutomationGroupId** dimensions.

Note

CloudWatch is a Regional service. To view metrics, ensure that you are in the same AWS Region where your automations run.

AutomationId metrics

These metrics track individual automation performance:

- **FailedAutomationRunCount** - The total number of automation runs that failed during execution. Use this metric to identify problematic automations that require attention or debugging.
- **SuccessfulAutomationRunCount** - The total number of automation runs that completed successfully. Use this metric to track automation reliability and success rates.
- **AutomationRunDuration** - The time taken for each automation run to complete. Use this metric to identify performance bottlenecks and optimize automation efficiency.
- **StoppedAutomationRunCount** - The number of automation runs that were manually stopped or terminated before completion. This can indicate user intervention or system-initiated stops.

- **TotalAutomationRunCount** - The aggregate count of all automation runs, regardless of status. Use this metric to monitor overall automation activity and usage patterns.

AutomationGroupId metrics

These metrics provide a broader view across all cases:

- **TotalCaseCount** - The total number of cases processed by the automation system. Use this metric to track overall workload volume.
- **CompletedCaseCount** - The number of cases that were successfully processed and completed. Use this metric to measure throughput and productivity.
- **FailedCaseCount** - The number of cases that failed during processing. Use this metric to identify systemic issues or patterns in failures.
- **CaseDuration** - The time taken to process cases from start to completion. Use this metric to assess overall system performance and identify opportunities for optimization.

Finding AutomationId and AutomationGroupId

To find the AutomationId and AutomationGroupId for your automation:

- Sign in to Amazon Quick Automate.
- In the left navigation pane, choose **Automations**.
- Choose the automation group that contains your automation.
- Choose the automation name to open the automation.
- Choose the **Deployments** tab.
- Choose the **Actions** (:) and **View deployment details** to get the **Automation ID** and **Group ID** at the top just below the heading Deployment Details.

Setting up CloudWatch alarms

Use these metrics to monitor the health of your automations or set up alarms in CloudWatch. For example, you can create alarms for the following conditions:

- More than five automation runs fail within a specified period.
- More than 10 cases fail within a specified period.
- Case duration exceeds 30 minutes.

For more information about creating alarms, see [CloudWatch alarms](#).

Human-in-the-loop task center

Human-in-the-loop (HITL) tasks enable you to incorporate human judgment at critical points in your automated processes. The Task Center provides a centralized interface for managing HITL tasks. Users can review, resolve, and track tasks that require human intervention.

Overview

The Task center displays tasks requiring human attention and provides metrics on task processing.

Task metrics

The dashboard shows key performance indicators:

- **Open tasks** - Total number of tasks awaiting completion
- **Critical tasks** - Count of high-priority tasks requiring attention
- **Overdue tasks** - Number of tasks past their due date

Task details table

Each task provides comprehensive information through the following columns:

- **Title** - Brief description of what needs to be done
- **Status** - Current task state (Open, Completed, Archived)
- **Due date** - When the task should be completed (includes overdue warning)
- **Severity** - Task priority (Low, Moderate, Critical)
- **Assignee** - User or group responsible for the task
- **Creation time** - When the task was created
- **Completion time** - When the task resolution was submitted by a user

Prerequisites

Before working with tasks, you need:

- Task permissions - Access granted through automation deployment settings
- Active automations - At least one automation with HITL tasks must be run

Types of tasks

Chat tasks

Interactive conversations where AI agents gather input through natural language. To participate in a chat task:

- Select the task
- Review the conversation history
- Respond to agent questions in the chat interface
- The agent will close the task once it has sufficient information

Note

Chat tasks are closed automatically by the AI agent. You can archive unresolvable tasks, which the agent will treat as exceptions.

Form tasks

Tasks requiring structured input through form fields. To complete a form task:

- Select the task
- Fill in the required form fields
- Click Submit when finished

Note

Enable "Automatically open next task" to streamline processing multiple tasks. Use "Save as Draft" to preserve partial progress.

Managing tasks

Task statuses

Tasks can be in one of these states:

- Open - Awaiting human input
- Completed - Successfully submitted
- Archived - Removed from active view

Task actions

Manage tasks through these available actions:

- Submit - Complete a form task
- Save as Draft - Preserve partial form progress
- Archive - Remove task from active view
- Unarchive - Restore archived task

Note

Only Open tasks can be archived.

Task assignment

Distribute work by assigning tasks:

- Select a task
- Click the assignee field
- Search for and select users or groups
- Click Remove assignee to clear assignment

Note

Users must have appropriate permissions to be assigned tasks.

Related information

Access connected resources through the Sources menu:

- Case - View related case details (if applicable)
- Automation - See the automation that created the task

Note

Source access requires appropriate permissions.

Search and filtering

Locate specific tasks using:

- Search - Find tasks by title
- Filters:
 - Status
 - Due date
 - Severity
 - Assignee
 - Creation date

Note

Click refresh to update task data at any time.

Environment selection

Switch between viewing tasks from:

- Test - Tasks from automation testing
- Deployed - Tasks from deployed automations

Build web applications with apps in Amazon Quick

You can use apps in Amazon Quick to build interactive web applications by describing what you need in natural language. You tell the apps in Quick agent what your app should do, who it is for, and what data it needs. The agent builds a working app in real time while you watch. You refine it through ongoing conversation. You can then publish and share the app for daily use across your organization.

With Apps in Quick you can bridge the gap between data visualization and custom application development. Whether you need a dashboard, an internal tool, a data entry interface, or a document viewer, you can create it conversationally and publish it for your team in minutes.

Key capabilities

With Apps in Quick, you get the following capabilities:

- **Conversational authoring** — Describe what you want, and the AI builds it.
- **Live dashboard embeds** — Embed interactive Amazon Quick Sight visuals directly in your app.
- **Connectors** — Call external APIs and services from your app. For more information, see [Work with integrations in Amazon Quick](#).
- **Built-in AI inference** — Add AI-powered features such as text summarization, classification, and content generation using foundation models.
- **Spaces integration** — Read and manage documents and resources from Amazon Quick spaces. For more information, see [Organize, collaborate, and share resources with spaces in Amazon Quick](#).
- **Persistent data storage** — Save and retrieve data across sessions with built-in key-value storage.
- **Enterprise authentication** — Inherits Quick's security model with single sign-on support.
- **One-click publishing** — Share apps with your team instantly.

How apps in Quick works

Building an app follows this workflow:

1. **Describe** — Tell the AI what you want to build.
2. **Generate** — The AI writes the code in real time.

3. **Preview** — See a live preview instantly and test the app.
4. **Iterate** — Refine with follow-up requests.
5. **Publish** — Share with your team in one click.

Getting started with apps in Quick

You can create your first app in apps in Amazon Quick in minutes. This section walks you through each step.

Prerequisites

Before you begin, confirm the following:

- You have an active Amazon Quick account.
- Your subscription includes Author, Professional, Author Pro, Enterprise, or Admin Pro access.

Open the apps in Quick landing page

To open the apps in Quick landing page:

1. Sign in to Amazon Quick.
2. In the navigation pane, choose **Apps**.

The apps in Quick landing page provides a prompt area where you describe the app you want to build. Rotating example prompts suggest ideas you can use or customize.

Below the prompt area, you can browse your existing apps in two views: **Library** (all apps you have access to, including apps shared with you) and **My apps** (apps you created). You can search for apps by name or owner and sort results by last visited, last updated, or name.

Create an app

To create an app:

1. In the prompt area, enter a description of the app you want to build. Alternatively, choose one of the example prompts to start with a pre-written description, then edit it before proceeding.
2. Choose **Generate**.

3. Review the live preview in the apps in Quick editor as the agent builds your app. Use the chat panel to provide follow-up instructions.

Write your description as if you were explaining the app to a colleague. Include the purpose, the audience, and the data it needs. A detailed description produces a better first version and reduces iteration.

Edit an app

The apps in Quick editor is a two-panel workspace. The preview panel shows a live, interactive rendering of your app. The chat panel is where you converse with the apps in Quick agent to build, modify, and debug the app.

To edit an app:

1. Enter an instruction in the chat panel.
2. Wait for the agent to update the preview with your changes.
3. Interact with the preview to test buttons, forms, navigation, and other features.

The chat conversation persists across sessions. If you close the editor and return later, your previous messages are still there. Choose **Load older messages** to see the full history.

Manage versions

Apps in Quick automatically creates a new version each time the agent changes your app. You do not need to save manually. A version selector in the editor lets you browse all previous versions and preview any of them.

To restore a previous version:

1. Select the version you want to review from the version selector.
2. Confirm the preview shows the state you want.
3. Choose **Restore to this version**.

Restoring a version does not affect the published version. You must publish again for end users to see the change. For more information about recovering from a broken app, see [Recovering from a broken app](#).

Review app settings

The app settings panel provides two views:

- **Overview** — Shows the app name (editable), a unique app ID, creation date, last published date, the published URL, the public URL (if published publicly), and an editable description. You can also delete the app from this view.
- **Assets** — Lists all integrations and services registered on the app. Each asset shows its name, type (Action or AI), and permission level (Read or Write).

Publish an app

To publish an app:

1. When your app is ready for others to use, choose **Publish**.
2. Copy the shareable URL from the confirmation dialog.

You can continue editing after publishing. Changes do not affect the published version until you publish again.

Share an app

To share an app:

1. Choose **Share** to open the sharing controls.
2. Search for users by name, alias, or email.
3. Assign each person a role and choose **Share**.

Each shared user has a role that you can change at any time:

- **Co-owner** — Can edit, publish, and share the app.
- **Viewer** — Can view and interact with the published app.

Apps in Quick supports three access levels:

Access level	Description
Limited	Only users you explicitly share the app with can access it.
Account	Everyone in your Amazon Quick account can access the app.
Public	Anyone on the internet can access the app without signing in. Available on Free and Plus accounts only.

You can also toggle **Share with all** to make the app accessible to everyone in your Amazon Quick account, or choose **Copy link** to copy the published URL.

Publish an app to the public internet

To publish an app publicly (Free and Plus accounts):

1. Choose **Share** to open the sharing controls.
2. Set the access level to **Public**.
3. Choose **Publish**.

After publishing, the app receives a public URL that you can share with anyone. Anonymous viewers can use the app without creating an account.

Important

Public apps cannot use connectors, embedded visuals, embedded chat experiences, or Amazon Quick spaces. If your app uses any of these integrations, remove them before publishing publicly.

Manage public app usage

When your app is published publicly, AI inference usage counts against your subscription quota. Monitor your usage in the Amazon Quick account settings.

To manage or revoke public access:

1. Choose **Share** to open the sharing controls.

2. Change the access level from **Public** to **Limited** or **Account**.

Revoking public access takes effect immediately. The public URL stops working and anonymous viewers can no longer access the app.

What you can build with apps in Quick

You can build complete web applications with apps in Quick, not just static documents or simple forms. Your apps run in the browser, respond to user interaction, and connect to live data.

User interfaces

The agent generates responsive layouts using standard web components: navigation menus, tabs, cards, tables, charts, forms, modals, and buttons. You can describe the layout you want in natural language, or let the agent choose a layout based on the purpose you describe. Applications can include multiple views or sections, and the agent can implement navigation between them.

Role-based views are possible. If you tell the agent which users should see which content (for example, by alias or role), it can build conditional visibility into the interface using the user identity API available in the sandbox.

Data storage

Every app has access to built-in app storage, a key-value system that requires no external setup. There are two modes: private storage (scoped to the individual user, invisible to others) and shared storage (visible to everyone who accesses the app). Built-in storage scales to support large numbers of records.

You can also store and retrieve data through external systems using connectors or through Amazon Quick spaces. For more information, see [Working with data in apps in Quick](#).

AI inference

With apps in Quick, you can apply AI reasoning to features within your app. Common use cases include summarizing submitted text, classifying data into categories, generating recommendations, and answering natural language questions based on connected data.

AI inference supports two modes:

- **Free-form text** — Generate summaries, creative writing, chat responses, and any unstructured text output.
- **Structured output** — Extract structured data, classify inputs, and parse information into JSON. Uses tool-use patterns to guarantee valid, typed responses.

Available models range from fast (for simple tasks), to balanced (general purpose), to most capable (for complex reasoning). For more information about AI inference, see [Handling write approvals when AI inference is active](#).

Embedded visuals

With apps in Quick, you can embed live, interactive visuals from your Amazon Quick Sight dashboards directly in the app. Charts, tables, KPIs, and graphs update in real time with your data.

Each embedded visual must represent a unique dashboard, sheet, and visual combination. You can embed up to 8 visuals per app, with a minimum size of 100×100 pixels per visual. Embedded visuals are fully interactive and support filters, tooltips, and drill-downs. Viewers see visuals based on their Quick access permissions.

Embedded chat experiences

You can add a conversational chat interface to your app by connecting a Amazon Quick space as a knowledge base. The app creates its own agent instance that answers questions based on the documents and data in that space. This is useful for building knowledge portals, FAQ tools, or help desks within an app.

Important

You cannot currently embed a standalone chat agent that was created separately in Amazon Quick. The app's embedded agent is a new instance backed by the space you connect.

Public-facing applications

You can publish apps to the public internet so that anyone with the link can use them—no Amazon Quick account required. Public apps are available on Free and Plus accounts.

Public apps support the following capabilities:

- **Shared storage** — Anonymous viewers can read from and write to shared app storage. Private storage is not available to anonymous viewers.
- **AI inference** — You can enable AI inference for public apps. Usage counts against the app owner's subscription quota.
- **Custom domains** — Public apps are served from a unique URL on the Quick domain. Custom domains are not supported.

Public apps do not support connectors, embedded visuals, embedded chat experiences, or Amazon Quick spaces. For the full security model, see [Public app security](#).

File handling

With apps in Quick, you can generate files for download through the secure bridge API. Supported file types include CSV, JSON, plain text, HTML, XML, and Markdown. Apps can also read files from Amazon Quick spaces and display their contents. For more information about bridge API restrictions, see [Sandbox restrictions](#).

Important

Direct browser APIs for file creation are blocked by the sandbox. All downloads must go through the secure download utility provided by the platform.

Connecting to integrations in apps in Quick

You can connect your apps in Quick apps to external services and data sources through the integration framework in Amazon Quick. The same integration model used elsewhere in Quick applies in apps in Quick. The agent registers integrations on your app, and you and your users authorize them. For more information about integrations, see [Work with integrations in Amazon Quick](#).

Prerequisites

Before you connect integrations, confirm the following:

- You have an active Amazon Quick account with Author Pro or higher access.
- Your administrator has enabled the connectors you plan to use.

Integration types

Quick organizes integrations into two categories:

- **Knowledge integrations** — Connect to data sources that the system can search and reason over. In apps in Quick, this is most commonly a Amazon Quick space used as a knowledge base for an embedded chat experience.
- **Action integrations** — Connect to external applications and services where your app can read data, write data, or perform operations. Examples include Microsoft Outlook, SharePoint, OneDrive, Slack, Jira, and Asana. Quick provides over 100 pre-built action connectors. You can also create custom connectors using REST API, OpenAPI, or MCP specifications.

Authentication models

Action integrations support two authentication models:

- **User authentication** — The integration uses the credentials of the individual end user. Every user must have their own access to the connected resource.
- **Service authentication** — The integration uses a service-level credential configured by an administrator. All users of the app share that access. Not all connectors support service authentication.

Adding an integration to your app

You do not need to set up integrations manually. To add an integration:

1. Ask the agent to use a specific service in your instructions. For example: "Connect to my Outlook calendar and display my meetings for this week."
2. Authorize the integration when the agent prompts you.
3. Verify that the integration appears in the Assets view.

When other users open the published app, they authorize their own credentials for each registered integration on first use.

How apps in Quick works with other Quick capabilities

Apps in Quick connects to several other capabilities within Amazon Quick:

- **Amazon Quick spaces** — An app can read files from a space, write new files to it, and use a space as the knowledge base for an embedded chat experience. For more information, see [Organize, collaborate, and share resources with spaces in Amazon Quick](#).
- **Amazon Quick Flows** — There is no direct integration between apps in Quick and Quick Flows. Use a space as a shared data layer instead. A flow processes data and saves its output to a space. The app reads from that space and displays the results. For more information, see [Using Amazon Quick automations](#).

Integration tips

- **Outlook and OneDrive** — These connectors do not reliably resolve the me alias in API calls. Instruct the agent to use the user identity API to retrieve the current user's information instead.
- **Slack** — The Slack connector's API schema does not include all available Slack API operations. Provide specific details about the Slack API operations you need, such as the channel ID and message format.
- **Integration removal** — You cannot currently remove a registered integration from an app through the settings UI. As a workaround, ask the agent to remove references to the integration in the app code.

Tip

Limited integrations in public apps — Public apps do not support connectors, embedded visuals, embedded chat experiences, or Amazon Quick spaces. If you plan to publish your app publicly, design it to use only shared storage and AI inference.

Working with data in apps in Quick

You can persist and manage data within your apps in Quick apps in multiple ways.

Built-in app storage

The simplest way to persist data is with built-in app storage. It is a key-value system that requires no external setup and scales to support large numbers of records.

Storage scopes

- **Private storage** — Data visible only to the current user. Use for personal settings, preferences, saved filters, bookmarks, and per-user state.
- **Shared storage** — Data visible to anyone with app access. Use for collaborative lists, comments, votes, shared configuration, and team data.

Storage operations

Operation	Private	Shared	Description
Put Item	Yes	Yes	Store or update a key-value item.
Get Item	Yes	Yes	Retrieve an item by key.
List Items	Yes	Yes	List items with optional key prefix filter.
Delete Item	Yes	Yes	Remove an item by key.
List by Tag	No	Yes	Query shared items by tag (secondary index).

Key concepts

- **Tables** — Logical groupings for your data. You define table names; no setup is required.
- **Keys** — Each item has a unique key within its table. Keys can be up to 255 characters.
- **Values** — String values up to 350 KB. Use JSON serialization for structured data.
- **Tags (shared only)** — Optional categorization strings on shared items. Tags enable efficient querying by category.
- **Write modes** — UPSERT (default) overwrites existing items. INSERT fails if the key already exists, which is useful for preventing duplicates.

Note

Each app has completely separate storage. Data persists across user sessions and app reloads.

Note

In public apps, anonymous viewers can read from and write to shared storage but cannot access private storage. Design your data model accordingly if you plan to publish your app publicly.

Exporting data

You can ask the agent to add export functionality. Apps in Quick supports exporting data as CSV, JSON, PDF, and Excel files through the bridge API. You can also have your app write data snapshots to a connected space. This serves as a backup and makes the data available to other Quick capabilities.

Handling write approvals when AI inference is active

When an app uses AI inference and writes data (to shared storage or through an action connector), you must review and approve each write payload. This security measure ensures that you review AI-generated content before the app persists it.

Three strategies can reduce the frequency of approval prompts:

1. **Batch writes** — Collect all items and save them under a single storage key in one operation.
2. **Separate AI from writes** — Design the app so that AI processing and data persistence happen in distinct user actions.
3. **Remove AI inference when not needed** — If your app does not use AI-generated content, ensure the AI inference integration is not registered. Without AI inference, you can choose "Allow on this app" for write operations. The permission persists across sessions.

Accessing user information

With apps in Quick, you can access the current user's identity at runtime. This lets you personalize the app experience, display the user's name, or implement per-user logic.

Available user information includes email, first name, last name, and identity name.

Tip

Combine user identity with private storage to build personalized experiences such as greetings, saved preferences, bookmarks, and custom dashboards per user.

Security and sandbox in apps in Quick

Apps in Quick inherits the enterprise-grade authentication and authorization of Amazon Quick. Users access apps through their existing Quick identity, and every app runs inside a secure sandboxed iframe.

Authentication

- **Single sign-on** — Users authenticate through their organization's identity provider (SSO, Active Directory, IAM) via Quick. No additional credentials are needed.
- **Session security** — All app interactions run within an authenticated Quick session. Tokens are managed automatically by the platform.

Authorization layers

Layer	What it controls
App access	Who can view or edit the app (set by the app owner when sharing)
Integration approval	Which connectors, spaces, and dashboards the app can access (set by the author during authoring)
Runtime permissions	What data and actions are available to the viewer based on their own Quick permissions
Connector auth	How the connector authenticates with the external API (configured by admin)
Public access	Whether anonymous viewers can access the app without signing in (set by the app owner when sharing; Free and Plus accounts only)

Important

App viewers can only access data they are already authorized to see in Quick. Embedding a dashboard visual does not bypass row-level security or column-level permissions.

Integration consent model

When the apps in Quick agent adds an integration to your app (connector, space, dashboard visual, or AI inference), it prompts you for approval. This consent model ensures:

- You know exactly what external calls your app makes.
- You control READ vs WRITE permissions.
- The published app never includes unapproved integrations.
- App viewers inherit the approved integration scope, not broader access.

Sandbox restrictions

Every apps in Quick app runs inside a sandboxed iframe with strict security policies. The sandbox only permits script execution. All other capabilities (navigation, popups, direct network access) are restricted.

- **Link navigation** — Apps cannot open external URLs directly. Users can follow links by pressing Cmd+Click (macOS) or Ctrl+Click (Windows).
- **External resources** — The Content Security Policy blocks loading images, scripts, fonts, and other assets from external servers. Use inline SVG graphics, Base64-encoded image data, or image files loaded from a Amazon Quick space.
- **Network requests** — App code cannot make direct HTTP requests to external servers. All communication with external systems goes through the secure bridge API or a registered action connector.
- **File downloads** — File downloads must use the `downloadFile` function from the apps in Quick runtime library.
- **Public app isolation** — Public apps run in the same sandbox as private apps but cannot access connectors, embedded visuals, embedded chat experiences, or Amazon Quick spaces. Only shared storage and AI inference are available to anonymous viewers.

Public app security

Public apps allow anonymous access without authentication. The following security measures apply:

- **No identity** — Anonymous viewers have no user identity. The user identity API returns null values for public viewers.
- **No private storage** — Anonymous viewers cannot access private storage. Only shared storage is available.
- **No integrations** — Public apps cannot use connectors, embedded visuals, embedded chat experiences, or Amazon Quick spaces.
- **Rate limiting** — AI inference requests from public apps are rate-limited to prevent abuse. Usage counts against the app owner's subscription quota.
- **Same sandbox** — Public apps run in the same sandboxed iframe with the same Content Security Policy as private apps.

Tips for building effective apps

These tips come from patterns observed in successful app-building sessions.

- **Start with a detailed first prompt** — The first prompt sets the foundation. Including the purpose, audience, data model, and integration needs in your initial description gives the agent a clear starting point and reduces rework.
- **Make changes one at a time** — The agent produces more reliable results with focused, single-purpose instructions than with broad requests that modify many things at once.
- **Provide context about your goals** — When you explain why you want a change, not just what you want, the agent can make better implementation choices.
- **Investigate before changing** — The agent executes code changes with every instruction. If you want to explore options without modifying the app, explicitly say so: "Investigate the current data flow but do not write any code yet."
- **Note stable version numbers** — After completing a working feature, note the current version. If subsequent changes cause problems, you can restore the stable version immediately using the version selector.

- **Add a debug panel for complex apps** — For apps with significant logic, a debug panel that logs storage operations, integration calls, and state changes makes it easier to track down problems. You can make the panel visible only to yourself based on your user alias.
- **Specify roles when your app has different user types** — If different people should see different things, include that in your instructions.
- **Use structured AI output** — When you need data in a specific format (JSON, categories), use structured output mode instead of asking for free-form text. It guarantees valid, parseable responses.
- **Scope storage thoughtfully** — Use private storage for user-specific data and shared storage for collaborative features. Keep table names descriptive.
- **Approve integrations deliberately** — Review each integration approval carefully. Only approve connectors and spaces your app actually needs.
- **Design for anonymous viewers for public apps** — If you plan to publish your app publicly, remember that anonymous viewers have no user identity and cannot access private storage. Use shared storage for all data that public viewers need, and avoid features that depend on user identity.

Limitations of apps in Quick

The following limitations apply to apps in Amazon Quick in its current release.

Regional availability

Apps in Amazon Quick is available in a subset of the AWS Regions that Amazon Quick supports: US East (N. Virginia), US West (Oregon), Europe (Ireland), and Asia Pacific (Sydney). Support for additional Regions is being added.

Limits

Limits

Resource	Limit
Dashboard visuals per app	8
Visual minimum size	100 × 100 pixels

Resource	Limit
Storage value size	350 KB per item
Storage key length	255 characters
Table name length	255 characters

Building experience

- **Content policy violations** — Prompts occasionally trigger security guardrails as false positives. When this happens, the agent cannot process further prompts in the current session. Close the editor and wait 15 to 20 minutes for the session to time out, then reopen the app.
- **Agent memory in long conversations** — The agent's accuracy decreases as the conversation grows longer. For complex applications, consider building in phases.
- **No image upload from agent chat** — You cannot upload screenshots or reference images to the agent.
- **No investigation-only mode** — The agent executes code changes with every instruction. To have the agent investigate without making changes, explicitly say "Investigate but do not write code yet."
- **Network sensitivity** — The editor uses a WebSocket for real-time streaming. Unstable connections can cause prompts to fail silently.

Sharing and access

- **Subscription requirement** — Only users with Author, Professional, Author Pro, Enterprise, or Admin Pro subscriptions can view apps.
- **External access** — Users must have a Amazon Quick account to view an app, unless the app is published publicly. Public access is available on Free and Plus accounts only. Public apps cannot use connectors, embedded visuals, embedded chat, or spaces.

Portability

- **No code export** — You cannot download the source code of an app.

- **Duplication** — You can duplicate an app to create a copy.

Integration limitations

- **No direct Quick Flows integration** — Use a space as an intermediary.
- **No standalone agent embedding** — You can create a new agent instance backed by a space.
- **No integration removal** — You cannot remove a registered integration from an app through the settings UI.

Sandbox restrictions

For detailed information about sandbox restrictions, see [Sandbox restrictions](#). Key restrictions include:

- **No direct link navigation** — Users must use Cmd+Click or Ctrl+Click.
- **No external images** — CSP blocks loading images from external URLs.
- **No built-in app analytics** — As a workaround, you can ask the agent to implement a view counter using shared app storage.

Troubleshooting apps in Quick

This section describes common issues and how to resolve them.

Recovering from content policy violations

If you receive the error "This request could not be processed due to content policy violations":

1. Close the apps in Quick editor.
2. Wait 15 to 20 minutes for the session to reset.
3. Reopen the app.
4. Try a simpler, more focused prompt.

All prompts in the same session after a violation continue to fail until the session resets.

Recovering from a broken app

If an app stops loading or displays errors after an edit:

1. Use the version selector to restore a previous working version.
2. If the editor is not accessible, close the browser tab, wait 15 to 20 minutes, and reopen.
3. In a fresh session, try: "Review all app code. Check the existing code against the actual types and interfaces exported by the runtime library. Fix any issues."
4. If an integration change caused the issue, try: "The prior issue impacting integrations has been resolved. Please try again."

Fixing connector authentication issues

If you see a "Sign in to connectors" dialog with no sign-in option, one or more integrations were not properly registered during app creation. In the editor, ask the agent to retry registering each affected connector individually. After successful re-registration, publish the updated app.

Debugging complex apps

You can ask the agent to add a debug panel that logs storage operations, integration calls, and state changes. Make the panel visible only to yourself (based on your user alias) to keep it hidden from end users.

File export not working

If an export feature does not work, ask the agent: "Use the `downloadFile` function from the runtime library to handle the file export." The sandbox blocks direct browser APIs for file creation. For more information, see [Sandbox restrictions](#).

Work with integrations in Amazon Quick

Integrations in Amazon Quick connect you to external applications and services for AI-powered analysis and automation. With integrations, you can perform actions in external applications and bring data from external applications to enhance your AI agents and chat experiences.

You can create three types of integrations:

Connectors

Initiate real-time calls to perform actions in external services. Use action connectors to address user natural language chat requests, automate workflows, send notifications, and/or trigger processes in connected applications.

Data access integrations

Connect Quick with external applications to access data. Data access integrations serve as the foundation for creating knowledge bases. You cannot use these integrations directly for analysis.

Knowledge bases

Connect to data access integrations to make specific content accessible for AI analysis. Choose which data or knowledge to include from external applications. Add knowledge bases to spaces or use them directly with chat agents.

Use the Integrations tab in the Amazon Quick console to create these connections. You can connect to Model Context Protocol (MCP) servers, Google Drive, Amazon S3, web crawlers, OneDrive, and other supported applications.

Note

Not all applications support all integration types. Available options depend on each application's capabilities.

Note

Not all applications support all integration types. The available options depend on the capabilities of each specific application and your user role.

Integration capability definitions

Actions

Call APIs and perform actions in external applications directly from Amazon Quick. You can share connectors with other users and use them in automated workflows.

Knowledge base

Create searchable repositories of information from external sources. Knowledge bases are children of data access integrations. Add them to spaces or use them directly in chat agents.

Authentication method definitions

User auth

Custom user-based OAuth authentication requiring base URL, client ID, client secret, token URL, auth URL, and redirect URL.

Service auth

Service-to-service authentication using either API key (with base URL and email) or service-to-service OAuth (with base URL, client ID, client secret, and token URL).

Managed OAuth 2.0

Managed OAuth 2.0 authentication flow with provider-specific sign-in interface.

AWS credentials

AWS-specific authentication using AWS access keys and permissions.

Basic auth

Username and password authentication.

Form/SAML auth

Form-based or SAML authentication with configurable field selectors.

JSON schema

Schema-based authentication for OpenAPI specifications.

Set up integrations in the console

The console organizes integrations into separate categories based on their purpose. Use **Knowledge** to connect data sources for Q&A and insights. Use **Connectors** to set up connectors that perform operations in external applications. The setup process adapts based on the integration you select, your subscription, and existing integrations.

Choose integration options

When you set up an integration, the console guides you based on several factors:

- **Integration capabilities** – Each application supports different combinations of actions and knowledge base creation. For example, Google Drive supports both actions and knowledge base creation. Web Crawler supports knowledge base creation only.
- **Subscription** – Configuring integrations requires an Enterprise subscription. This includes creating connectors, setting up knowledge bases, and managing integration settings. Users with a Professional subscription can use integrations that have been shared with them.
- **Existing integrations** – When you choose a connector that already exists, the console shows your existing connectors before offering to create new ones.

View setup process examples

The following examples show how different integrations guide you through different console setup processes.

Google Drive – Set up a knowledge base

Google Drive supports knowledge base creation through user-managed or admin-managed authentication.

1. In the console, choose **Knowledge**.
2. Find **Google Drive** and choose the **Add (+)** icon.
3. Choose your authentication method and complete the sign-in flow.
4. Enter a name and description for your knowledge base.
5. Select the files and folders you want to index, then choose **Create**.

Google Drive – Set up an action connector

Google Drive also supports connectors for performing file operations directly from .

1. In the console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Google Drive**.
4. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
5. Choose your **Connection type** and **OAuth Configuration**, then complete the authentication setup.

6. Review the available actions and choose **Publish**.

Available connectors tab

The **Available** tab on the Connectors page shows connectors that use managed OAuth and are ready to use without additional configuration. Users can connect directly by choosing **Connect** on the connector card.

1. In the console, choose **Connectors**.
2. On the **Available** tab, find the connector you want to use.
3. Choose **Connect**.
4. Complete the sign-in flow for the application.

Working with existing connectors

When you choose a connector on the **Create for your team** tab that already exists, the console displays your existing connectors before offering to create a new one.

1. In the console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Choose a connector that you've configured before.
4. A dialog appears showing your existing connectors. To use an existing connector, choose it. To create a new one, choose **No, create new**.

Integration management options

After creating integrations, you can manage them through several console options:

- **Edit integration** – Modify integration settings, authentication details, and configuration options.
- **Delete integration** – Remove integrations with confirmation dialogs to prevent accidental deletion.
- **Knowledge base management** – Separate flows for creating, editing, and deleting knowledge bases associated with your integrations.

Integration workflows

The following procedures describe the general workflows for creating and managing different types of integrations in Amazon Quick.

Creating a knowledge base

Knowledge bases connect external data sources to Amazon Quick so you can ask questions about and get insights from your content.

1. In the Amazon Quick console, choose **Knowledge**.
2. Find the application you want to connect to (for example, **Google Drive**, **Microsoft OneDrive**, or **Amazon S3**) and choose the **Add (+)** icon.
3. Complete the authentication process for your chosen application.
4. Enter a **Name** and optional description for your knowledge base.
5. Select the files and folders you want to include in your knowledge base using the file picker or sync options.
6. Choose **Create**.

After you choose **Create**, the data sync starts automatically.

Creating a connector

Connectors enable you to perform actions in external applications directly from Amazon Quick.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose the application you want to connect to (for example, **Google Drive**, **Atlassian Confluence Cloud**, or **Slack**).
4. Enter a **Name** for your connector. Optionally, add a description.
5. Configure the connection type and authentication method. For more information about authentication options, see [the section called "Authentication methods"](#).
6. Review the available actions and choose **Publish**.

After successful creation, your connector is available for use in Amazon Quick chat, workflows, and Amazon Q Apps.

Managing existing integrations

You can edit, delete, share, and manage existing integrations from the Amazon Quick console.

To edit an integration

For knowledge bases:

1. In the Amazon Quick console, choose **Knowledge**.
2. Choose the knowledge base you want to edit.
3. Choose the menu icon (:) and select **Edit**.
4. Modify the settings as needed and choose **Save changes**.

For connectors:

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the connector you want to edit.
3. Choose the menu icon (:) and select **Edit**.
4. Modify the connector settings as needed and choose **Save changes**.

To delete an integration

For knowledge bases:

1. In the Amazon Quick console, choose **Knowledge**.
2. Choose the knowledge base you want to delete.
3. Choose the menu icon (:) and select **Delete**.
4. In the confirmation dialog, choose **Delete** to confirm.

For connectors:

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the connector you want to delete.
3. Choose the menu icon (:) and select **Delete**.
4. In the confirmation dialog, choose **Delete** to confirm.

The integration is permanently removed from your account. Any dependent resources (such as knowledge bases) that rely on this integration will be impacted.

To share an integration

From the connector or knowledge base details page, choose the menu icon (⋮) and select **Share**.

Managing connectors

Connectors have additional management options available from the connector details page.

Sign in or re-connect

For connectors that use Default OAuth app or Custom OAuth app authentication, you must sign in to the service before you can use its actions. If you have not yet signed in, a **Sign in** button appears on the details page. After you sign in, you can use **Re-Connect** to re-authenticate if your session expires or the connection is interrupted.

Test action APIs

Choose **Test action APIs** in the Actions section of the details page to test individual actions provided by the connector. This lets you verify that the connection is working correctly and that the service responds as expected.

Note

The **Test action APIs** option is available for connectors only. Knowledge bases do not support action testing.

Knowledge bases

A knowledge base is an organized, indexed collection of documents or content from data sources optimized for generative AI-powered retrieval and question answering. Whether your team stores documentation in Confluence, collaborates through SharePoint, or manages files in cloud storage, you can bring all this information into one unified search experience by creating knowledge bases.

The built-in integrations can be set up with just a few clicks to sync your data in Quick and make it effortless to tap into your organization's knowledge across Google Drive, OneDrive,

Confluence, SharePoint, S3, and Web Crawler. Whether your team stores documentation in Confluence, collaborates through SharePoint, or manages files in cloud storage, you can bring all this information into one unified search experience with the help of knowledge bases.

How knowledge bases work

Knowledge base is an indexed collection of documents or content from data sources such as Google Drive, optimized for generative AI-powered retrieval and question answering. Multiple knowledge bases can be created from the same source, and all can reside within a shared Quick Index. For example, if you sync two folders from Google Drive and create two knowledge bases — one for “Policy Documents” to answer queries such as *“What’s our refund policy”* and one for “Customer feedback” to answer queries such as *“What are the common customer complaints”* — both can be part of the same index. Quick distinguishes between them using the knowledge base id, so queries can be filtered to retrieve only the relevant documents from the desired knowledge base. This allows users to organize, secure, and retrieve information relevant to different domains or use cases, even though the underlying data is indexed together.

Your knowledge bases can be used individually or shared with team members through Amazon Quick spaces. Our coarse-grained access control enables security at the knowledge base level, ensuring that users only receive information from knowledge bases they're authorized to access.

Creation process

You can create knowledge bases while setting up a new data access integration and use existing integrations to create additional knowledge bases:

1. **Data access integration setup** - Connect to your external data source
2. **Content selection** - Choose which content to include through filters and scope settings
3. **Indexing** - Amazon Quick processes and indexes the selected content
4. **Availability** - The knowledge base becomes available for use in spaces and by AI agents

Capabilities

Each knowledge base provides the following capabilities:

- **Content indexing** - Processes text, documents, and structured data from external sources
- **Semantic search** - Enables AI-powered search across indexed content

- **Automatic synchronization** - Keeps content up-to-date with configurable sync schedules
- **Coarse-grained access control** - Ensures that users only receive information from knowledge bases they're authorized to access.
- **Multi-space usage** - Can be used across multiple spaces and by different AI agents

General workflow

The typical workflow for working with knowledge bases follows these steps:

1. **Set up data source integration** - Connect to your external application (such as SharePoint, Google Drive, or Confluence) with appropriate authentication. For more information, see [the section called "Integration-specific guides"](#).
2. **Create a knowledge base** - You can create a knowledge base while configuring your new integration. Configure your content filters by setting up include filters, file type restrictions, and folder selections to focus on relevant content.
3. **Set sync schedule** - Data refresh frequency is set to daily by default. You can edit the sync frequency to configure how often the knowledge base should be updated with new content from the source.
4. **Monitor and manage** - Review sync status, manage access permissions.

Common configuration settings

Knowledge bases share common configuration patterns across different data source integrations. Understanding these settings helps you optimize content indexing and manage sync behavior effectively.

Note

While these configuration options are available across most integrations, specific settings and available options may vary depending on your chosen data source integration.

Service principal for knowledge base operations

If you use a customer-managed key (CMK) as your default CMK and Q data key (see [the section called "Managing AWS KMS keys"](#)), Amazon Quick accesses your AWS KMS key using the

`qbusiness.amazonaws.com` and `quicksight.amazonaws.com` service principals during knowledge base sync operations.

Note

Ensure that any policies governing access to your CMK permit both the `qbusiness.amazonaws.com` and `quicksight.amazonaws.com` service principals.

File size and content limits

Configure file size limits to optimize processing performance and manage storage costs. The specific limits vary by content type and are displayed in the console when you configure your knowledge base.

Standard text documents

Applies to documents like PDFs, Word files, and text files. File size limit is 500 MB.

Video files

Available when video processing is enabled. Supported formats include `.mp4`, `.mov`, `.m4v`. File size limit is 10 GB (10240 MB). Quick Index supports up to **10 video files per GB of storage**. If your use case requires higher video volumes, please open a ticket with AWS support to extend this limit.

Audio files

Available when audio processing is enabled. Supported formats include `.mp3`, `.wav`, `.m4a`, `.flac`, and `.ogg`. Limit is 2 GB (2048 MB) for audio files.

Note

Files with extracted text that exceeds the 30 MB system limit are not indexed, regardless of the original file size. The maximum amount of text that can be extracted from a single document is 30 MB.

Images

Quick Index applies the following limits for images:

- **Per-document limit:** 500 images per document
- **Per-GB limit:** 10K images per GB of index storage
- **Per-index limit:** 2M images per index

If your use case requires higher image volumes, please open a ticket with AWS support to extend these limits.

Sync schedule and safeguards

Configure how often your knowledge base updates and protect against unintended content deletion:

Sync frequency

Data refresh frequency is set to daily by default. You can edit the sync frequency to configure how often the knowledge base should update with new content from the source

Document deletion safeguard

Protect your indexed content from accidental mass deletion by setting a maximum deletion percentage threshold. If a sync job would delete more documents than your threshold allows, the deletion phase is skipped, preserving your existing indexed content.

This safeguard protects against temporary network issues, permission changes, or source system problems that might make content temporarily unavailable.

Maximum sync duration

Each sync run has a maximum runtime of 14 days. If a sync run is still in progress after 14 days, Amazon Quick ends the run with a status of **FAILED** and the following error message:

Maximum sync time exceeded: Please edit your sync configuration to reduce the number of files to be crawled and ingested. For web crawler data sources, we recommend using Web Search feature if you want to chat with public websites like wikipedia.org.

If your sync run reaches this limit, edit your knowledge base to narrow the sync scope. For example, apply include or exclude filters, restrict the file types or folders being crawled, or split the content

across multiple knowledge bases. For web crawler data sources, consider using the Web Search feature instead when your goal is to chat with large public websites.

Best practices for managing ACLs in knowledge bases

With document-level access control lists (ACLs), Amazon Quick enforces source-document permissions for an ACL-aware knowledge base. Each authorized user retrieves only the indexed documents they have permission to access. Use ACLs when different users need access to different documents in the same knowledge base.

You're responsible for keeping source identities, groups, and document permissions accurate. Quick enforces the synchronized document permissions on every retrieval. For supported integrations, it also verifies document access against the source in real time when returning results. If Quick can't evaluate document permissions for a query, it returns no documents rather than unfiltered results.

Quick synchronizes identity and document-permission changes on the knowledge base refresh schedule, which is every 24 hours by default. Configure a different schedule when your access-change requirements demand it.

Sharing and document access are separate controls

Sharing a knowledge base and granting document access are separate controls. Knowledge-base sharing determines who can use the knowledge base. For ACL-aware knowledge bases, source-document ACLs further limit which indexed documents each authorized user can retrieve. Review both controls before granting access.

For more information about configuring ACLs for a specific data source, see [Amazon S3](#), [Google Drive](#), or [Microsoft SharePoint](#). For [Atlassian Confluence Cloud](#) and [Microsoft OneDrive](#), configure document-level ACLs in the console where available.

To verify document-level access controls and troubleshoot permission issues, see [the section called "Check document access \(ACL verification\)"](#).

Note

Quick treats all email addresses as case-insensitive. `JohnDoe@example.com`, `johndoe@example.com`, and `JOHNDOE@example.com` are all considered the same user.

Plan ACL-aware knowledge bases before creation

Before you create an ACL-aware knowledge base, complete the following steps:

1. Confirm that your integration supports document-level ACLs.
2. Confirm the identity attribute that Quick uses to resolve users and groups.

Quick resolves ACLs within the namespace of the knowledge base creator. For details, see [Limitations](#).

3. Remove shared or recycled identities from source ACLs before you assign them to another person.
4. Select a refresh schedule that meets your access-change requirements. For Amazon S3, permission changes take effect at the next sync, so plan the schedule accordingly.
5. Test document access with representative users before you share the knowledge base broadly. To check document access, see [the section called "Check document access \(ACL verification\)"](#).
6. Confirm that the knowledge base isn't required for Quick Research.
7. Assign at least one additional owner to an admin-managed knowledge base so that it remains manageable when its original creator leaves.

Important user management scenarios

Understanding email binding

Email addresses are bound to Quick users dynamically when users initiate chat interactions. This binding follows a first-come-first-serve approach. The first user to chat with a given email address establishes the binding for that identity within the namespace.

When an employee leaves your organization

When an employee leaves, clean up their access promptly:

1. Update the ACL configuration files to remove references to their email address. For example, in Amazon S3, update the global ACL file or metadata files.
2. Refresh the knowledge bases to apply the changes.

This prevents potential security issues if the email is later reassigned to someone else.

Updating knowledge base ACLs is separate from removing the user from Quick. For the full model of how user removal affects a user's assets and data, see [User lifecycle and data handling in Amazon Quick](#).

Share admin-managed knowledge bases with co-owners

Admin-managed knowledge bases (service credentials) are often used across teams and organizations. If the original creator leaves the company and no co-owners exist, the knowledge base becomes unmanageable — no one can edit settings, trigger syncs, or update permissions. To avoid this, share admin-managed knowledge bases with at least one additional owner. For more information, see [the section called "Sharing knowledge bases and data sources"](#).

When an email address is reassigned to a new employee

- ACL-aware knowledge base access is automatically locked for the reassigned email address to protect data security.
- Contact Quick support to clean up the previous user's access before the new employee can access documents associated with that email.

Limitations

When configuring document-level ACLs for your knowledge bases, be aware of these limitations:

- **Document-level ACL configuration is permanent** – You cannot turn on ACLs for a knowledge base created without ACL support. You also cannot turn them off after you turn them on. To change ACL configuration, create a new knowledge base with your desired setting from the start.
- **Shared email addresses within a namespace** – If multiple Quick users share the same email address within a namespace, the system denies access to everyone using that shared email. This safeguard prevents accidentally granting document access to the wrong person.
- **ACL resolution scope** – Quick resolves all ACLs within the namespace of the knowledge base creator. This applies whether you specify ACLs by email address or group name. Quick looks up identities in the creator's organizational context to ensure consistent identity resolution.
- **Email address recycling timing** – If your organization reassigns an email address from one employee to another, there's an important timing consideration. If the previous employee never used Quick for chat or AI interactions, and the email is reassigned before the next ACL refresh, the new employee may temporarily access documents intended for the previous employee.

To avoid this, complete the following steps in order:

1. Update your ACLs (if applicable, such as in Amazon S3) to remove the old user and add the new user.
2. Manually refresh your knowledge base, or wait for the automatic daily refresh.
3. Assign the email address to the new employee.

This ensures access permissions are properly synchronized before the new user begins using Quick.

Research compatibility

Knowledge bases with document-level ACLs enabled aren't currently compatible with Quick Research. If you need to use documents from an ACL-enabled knowledge base for research, create a separate knowledge base without ACLs for those documents.

Sharing knowledge bases and data sources

Amazon Quick enables you to share knowledge bases and data source connections with other users in your account. You can collaborate with multiple users on knowledge bases or reuse existing data source connections without re-entering credentials.

Note

All knowledge bases can be shared with the Viewer role, which allows users to query the knowledge base. The Owner role (co-owner sharing) is available only for admin-managed Microsoft SharePoint Online and Google Drive knowledge bases. Data source sharing is also limited to admin-managed SharePoint and Google Drive connections.

Sharing knowledge bases

Knowledge base owners can share their knowledge bases with other users and assign one of two roles:

Knowledge base sharing roles

Role	Permissions
Owner	View all tabs (Summary, Sync History, Settings, Permissions). Edit knowledge base details. Trigger manual syncs. Update the sync schedule. Share the knowledge base with others. Delete the knowledge base. Owners cannot edit the underlying data source connection unless they are also an Owner of the data source.
Viewer	View the knowledge base in the list and access the Summary tab only. Viewers cannot edit, share, delete, or trigger syncs.

Before you share, note the following:

- All knowledge bases support sharing with the Viewer role. Viewers can query the knowledge base.
- Any owner of the knowledge base can share it, not only the original creator.
- Co-owner sharing (the Owner role) is available only for admin-managed SharePoint and Google Drive knowledge bases. All other knowledge base types can be shared only with the Viewer role.
- The original creator of a knowledge base always retains the Owner role and cannot be removed.

Sharing a knowledge base

You can access the sharing permissions from either of the following locations:

- From the knowledge base list, choose the actions menu (:) next to the knowledge base and choose **Share knowledge base**.
- From within a knowledge base, choose the **Permissions** tab.

To add a user:

1. Choose **Add users & groups**.
2. In the search field, enter the user's name or email. Choose the user from the results, and then choose **Add**.

3. The user appears in the permissions list with a default role of **Viewer**. To change the role, open the **Permissions** dropdown next to the user's name and choose **Owner** or **Viewer**.

Changing or revoking knowledge base access

To change or remove a user's access to a knowledge base, complete the following steps.

1. Open the knowledge base and choose the **Permissions** tab.
2. Locate the user in the permissions list.
3. To change their role, open the **Permissions** dropdown and choose **Owner** or **Viewer**.
4. To remove access, choose **Revoke access** in the **Actions** column.

Sharing data source connections

Amazon Quick administrators can share data source connections with other users in their account. This enables multiple users to create knowledge bases using the same connection without re-entering credentials.

Before you share, note the following:

- Only users with Amazon Quick administrator privileges can share data source connections.
- Data source sharing is available only for admin-managed (service credentials) connections. User-managed connections that are created through single sign-on cannot be shared.
- If you revoke a user's access to a data source, the user's existing knowledge bases continue to sync. Knowledge bases that were previously created with the shared data source continue to sync normally.
- If an administrator deletes a data source, then existing knowledge bases that are linked to it remain visible. However, syncs fail with an error that indicates the underlying data source was deleted.
- Unlike knowledge bases, the original creator of a data source can be removed or have their role changed.

Data source sharing roles

Role	Permissions
Owner	Use the shared data source to create knowledge bases and edit the connection details (such as App ID or App Secret).
Viewer	Use the shared data source to create knowledge bases but cannot edit the connection details.

Sharing a data source connection

To share a data source connection with other users, complete the following steps.

1. In Amazon Quick, choose **Manage account** from the left navigation pane.
2. Choose **Manage assets**.
3. Under **Browse assets**, choose **Data sources**.
4. Select the checkbox next to the data source that you want to share.
5. Choose **Share**.
6. In the **Share assets** dialog, choose a **Permissions** level (**Owner** or **Viewer**).
7. In the **User or Group** field, enter the user's name or email and choose the user from the results.
8. Choose **Share**.

The user now sees the shared data source in the **Connected account** dropdown when the user creates a new knowledge base.

Editing a data source connection

Data source Owners can edit the connection details from the knowledge base list:

1. In the knowledge base list, choose the actions menu (:) next to a knowledge base that uses the data source.
2. Choose **Edit integration**.
3. Update the connection details and choose **Save**.

Important

If you edit a shared data source connection, then all knowledge bases that use it are updated. Review the impact before you save changes.

Changing or revoking data source access

To view or manage permissions for a data source, complete the following steps.

1. Choose **Manage account**, then choose **Manage assets**, and then choose **Data sources**.
2. Choose the data source name to open its details page.
3. Under **User & Groups Permissions**, locate the user and change their role or remove their access.

Sync reports and observability

With Amazon Quick, you can view sync schedules, sync activity logs, and detailed sync reports for every knowledge base. If your knowledge base has document-level access control (ACL) enabled, you can also verify individual document permissions.

Sync schedules and activity

To view sync schedules and activity, open a knowledge base and choose the **Sync schedules** tab.

Sync schedule

Displays the configured sync frequency and timing. The table shows the occurrence (for example, Daily), the start time for the next scheduled sync, and the email notification status. You can add or modify sync schedules. To receive email notifications for sync failures, turn on **Email on sync failure**.

Sync activity

Displays a historical log of all past syncs. You can filter by time frame (for example, Last 90 days) and sync status (for example, All, Completed, Failed).

The following table describes the sync activity columns:

Sync activity columns

Column	Description
Start time	The date and time the sync began.
Sync status	The outcome of the sync: Queued (waiting to run), Completed (all items processed), Completed with issues (some items were skipped or failed), or Failed.
Duration	How long the sync took to complete.
Total items scanned	The number of items processed during the sync.
Type	Whether the sync was Scheduled (automatic) or Manual (initiated by choosing the Sync now button).
Sync report	A View report link that opens the detailed sync report for that run.

Tip

To start a sync on demand, choose **Sync now** on the knowledge base detail page.

Review sync reports

To view detailed results for a specific sync, open a knowledge base and choose the **Sync reports** tab.

Use the **Select sync** dropdown to choose the sync run you want to inspect.

Overview

The overview section provides a summary of the selected sync. The following table describes the overview fields:

Sync report overview fields

Field	Description
Sync status	The overall outcome (for example, Completed, Completed with issues).
Sync type	Whether the sync was Scheduled or Manual.
Sync duration	Total time elapsed for the sync.
Sync start time	When the sync began.
Sync end time	When the sync finished.

Sync items

The sync items section shows all items that were processed during the sync, organized into the following categories:

Available items

Items that are present and indexed in the knowledge base after the sync:

- **Unmodified** – Items already indexed that have not changed since the last sync.
- **Modified** – Previously indexed items that were updated and re-indexed.
- **Added** – New items indexed for the first time.

Unavailable items

Items that are not available in the knowledge base after the sync:

- **Skipped** – Items filtered out (for example, empty files, unsupported formats, or items outside the date filter range).
- **Failed** – Items that could not be processed because of an error.
- **Deleted** – Items previously indexed that have been removed from the source.

Filter and inspect individual items

The **All items** tab displays the complete list of items that were processed during the sync. You can narrow the results by using the following filters:

Sync item filters

Filter	Description
Filter by status	Filter items by their sync status (for example, Added, Modified, Unmodified, Skipped, Failed, Deleted).
Filter by error type	Filter failed or skipped items by their specific error type.
Filter by item title	Search for a specific item by name.

After you set your filters, choose **Apply filters** to update the results.

The following table describes the sync item columns:

Sync item columns

Column	Description
Item Title	The name of the file, page, or item.
Item Status	The sync status for this item.
Error type	The category of error, if applicable.
Error message	A detailed description of why the item failed or was skipped.

Download report

To export the full sync results for offline analysis, choose **Download detailed report (.csv)** in the Sync items section. The CSV file includes all items with their status, error type, and error message.

Check document access (ACL verification)

If your knowledge base has document-level access control (ACL) enabled, you can verify whether a specific user has access to a particular document. Use this feature to troubleshoot when users cannot see documents that you expect them to access, or to confirm that sensitive documents are properly restricted.

 Note

ACL verification is available for admin-managed SharePoint and Google Drive knowledge bases with ACL management enabled. Amazon S3 knowledge bases with document-level ACLs are not included in this feature. Because the ACL configuration files are customer-managed, you can verify them directly in Amazon S3.

1. Open the knowledge base and choose the **Sync reports** tab.
2. In the sync items list, choose the actions menu (:) for an item.
3. Choose **View Access Details**.

The **Access Details** panel shows:

- The document name, status, and last synced timestamp.
- **Permission Checker** – Enter a user's email address and choose **Check Access** to verify whether that user can access the document.
- **Users and group membership** – Lists all users and groups with access to the document.

The following table describes the permission checker results:

Permission checker results

Result	Meaning
User has access	The user's identity matches the document's ACL. They see this document in Quick responses.
[user] does not have access to this document	The user is not in the document's ACL. Quick does not surface this document for them.
No access control list found	The ACL was not crawled for this document. Either ACL management is not enabled, or the required permissions are not configured correctly.

If you see "No access control list found", take the following steps:

- Verify that ACL management is enabled in the knowledge base settings.
- Confirm the app registration has the required ACL permissions for your data source.
- Run a full sync after you fix the permissions.

Monitor index storage usage

Index usage logs provide visibility into how your Amazon Quick index storage is consumed across knowledge bases and Spaces, including file uploads. You can use these logs to track growth trends, identify the largest sources, detect unexpected spikes, and plan capacity.

Before you query index usage data, you must configure INDEX_USAGE_LOGS delivery. For instructions on setting up delivery, see [the section called “Monitoring using CloudWatch Logs”](#).

Log schema

Each index usage log event includes the common fields that are shared across all Amazon Quick log types, such as `resource_arn`, `event_timestamp`, `log_type`, `account_id`, and `user_arn`. The event also includes the following index-specific fields:

Index usage log fields

Field	Type	Description
<code>consumed_index_size</code>	Integer	Total size (in bytes) consumed by the entire index. This is the authoritative total.
<code>source_type</code>	String	SPACE or KB.
<code>source_name</code>	String	Display name of the Space or knowledge base.
<code>source_arn</code>	String	Full ARN of the source.
<code>consumed_source_size</code>	Integer	Size (in bytes) consumed by this individual source.
<code>consumed_source_documents_count</code>	Integer	Number of documents in this source.

Note

Events are published per source on change. Not all sources emit events every day. To reconstruct the current state, use the most recent event per `source_arn`.

CloudWatch Logs Insights queries

The following CloudWatch Logs Insights queries help you analyze index usage data. All queries use the pattern `stats latest(field) by source_arn` to get the most recent state per source. The queries then aggregate as needed. Replace *YOUR_LOG_GROUP* with your log group name.

Size by source type (knowledge bases compared to Spaces)

Shows the total size split between knowledge bases and Spaces.

```
fields @timestamp, source_type, source_arn, consumed_source_size
| stats latest(consumed_source_size) as latest_size, latest(source_type) as type by
  source_arn
| stats sum(latest_size) as total_size by type
```

Total index size over time

Shows the index size trend by using the `consumed_index_size` field.

```
fields @timestamp, consumed_index_size
| stats latest(consumed_index_size) as total_index_size by bin(1d) as day
| sort day asc
```

Top knowledge bases by size

Shows the top 20 knowledge bases ranked by size.

```
fields @timestamp, source_type, source_arn, source_name, consumed_source_size
| filter source_type = "KB"
| stats latest(consumed_source_size) as latest_size, latest(source_name) as name by
  source_arn
| sort latest_size desc
| limit 20
```

Top Spaces by size

Shows the top 20 Spaces ranked by size.

```
fields @timestamp, source_type, source_arn, source_name, consumed_source_size
| filter source_type = "SPACE"
| stats latest(consumed_source_size) as latest_size, latest(source_name) as name by
  source_arn
| sort latest_size desc
| limit 20
```

All sources detail

Shows the latest state of every source with size, type, name, document count, and last update time.

```
fields @timestamp, source_type, source_name, consumed_source_size,
  consumed_source_doc_count, source_arn
| stats latest(consumed_source_size) as latest_size, latest(source_type) as type,
  latest(source_name) as name, latest(consumed_source_doc_count) as doc_count,
  latest(@timestamp) as last_updated by source_arn
| sort latest_size desc
| limit 100
```

Top users by total size

Shows the top 20 users ranked by total source size across all their sources.

```
fields @timestamp, user_arn, source_arn, consumed_source_size
| parse user_arn "*:user/*/*" as @prefix, @namespace, @username
| stats latest(consumed_source_size) as latest_size, latest(@username) as user by
  source_arn
| stats sum(latest_size) as total_size by user
| sort total_size desc
| limit 20
```

Create a CloudWatch dashboard

You can create a CloudWatch dashboard to visualize index usage metrics. Use the CloudWatch console to create a dashboard and add Logs Insights widgets by using the queries from the preceding section.

1. Open the [CloudWatch console](#).
2. In the navigation pane, choose **Dashboards**.
3. Choose **Create dashboard** and enter a name (for example, IndexUsageMetrics).
4. Add widgets by using the **Logs** widget type. Select your index usage log group and paste the queries from the preceding section.

i Tip

Use the pie chart visualization for the source type breakdown. Use the line chart for size over time. Use the bar chart for top sources. The table visualization works well for the all-sources detail query.

Troubleshooting knowledge bases

When you encounter issues with your Quick knowledge base, you can use this troubleshooting guide to identify and resolve common problems. Knowledge base issues typically involve document synchronization, refresh job failures, or access permissions.

Documents don't appear in your knowledge base

When documents you expect to see don't appear in your knowledge base, several factors might cause this issue.

Common causes:

- **Sync in progress** – Documents might still be processing. Check the refresh status to confirm the refresh is complete.
- **Unsupported file format** – Verify your documents are in a supported format. For supported formats and size limits, see [the section called “File size and content limits”](#).
- **File size too large** – Verify the file is within the size limits. For details, see [the section called “File size and content limits”](#).
- **Insufficient access permissions** – Confirm the knowledge base has proper permissions to access the document source.
- **Document filtering** – Check if filters or exclusion rules prevent certain documents from being indexed.

To troubleshoot:

1. Review the refresh history for error messages related to specific documents that failed to sync.
2. Verify your document formats and file sizes meet requirements.
3. Check your access permissions and connection settings.

Refresh job fails

A refresh job typically fails when there's a configuration error in the knowledge base or data source connection.

Common causes:

- **Permission issues** – The integration lacks sufficient permissions to access the data source.
- **Configuration errors** – Incorrect URLs or data source connection settings.
- **Resource limitations** – Rate limiting from the source system.

To resolve:

1. Check the refresh history details for specific error messages.
2. Verify all connection settings and permissions are correctly configured.
3. Take the recommended action based on the error message.

Refresh job completes with issues

When a refresh job completes with issues, the job processed successfully but encountered problems with some documents.

What this means:

- **Partial success** – Some documents synced successfully while others failed.
- **Document-level errors** – Individual files might have formatting issues, corruption, or access problems.
- **Metadata issues** – Problems with document metadata or associated information.
- **Size or format violations** – Some files might exceed size limits or be in unsupported formats.

To resolve:

1. Review the detailed refresh reports to identify which documents encountered issues.
2. Address the individual document problems.
3. Run another refresh after resolving the issues.

Refresh job succeeds but no documents appear

If a refresh job shows as successful but no documents appear in your knowledge base, check these potential causes.

Common causes:

- **Empty source** – The configured data source location contains no documents.
- **Incorrect path configuration** – The source path or connection settings don't point to the correct location.
- **Document filters** – Inclusion or exclusion criteria might filter out all documents.
- **Read permissions missing** – The job connected successfully but lacked permissions to read the actual documents.

To resolve:

1. Verify your data source configuration points to the correct location.
2. Confirm documents are present in the specified location.
3. Check that appropriate access permissions are configured.
4. Review any document filters that might exclude content.

File format issues during refresh

Quick knowledge bases support specific file formats. Files must meet format, size, and character limit requirements. For the full list of supported formats and limits, see [the section called “File size and content limits”](#).

To resolve format issues:

1. Verify your files meet the format and size requirements.

2. Convert unsupported formats to supported ones.
3. Remove password protection from files.
4. Check that files aren't corrupted.

Access denied errors

Access denied errors typically occur due to authentication or authorization issues.

Common causes:

- **Invalid credentials** – Authentication tokens or passwords might have expired.
- **Insufficient permissions** – The account used in the integration lacks read access to the data source.
- **Network restrictions** – Firewall or security policies block access.
- **SSL/TLS issues** – Certificate problems with secure connections.

To resolve:

1. **Verify authentication credentials** – Confirm that authentication credentials are current and valid. Edit the integration to re-authenticate and generate a new token.
2. **For web crawler data sources** – Verify that secure connections are properly configured and SSL certificates are properly configured and trusted.
3. **Contact your system administrator** – If you continue experiencing access issues, contact your system administrator. They might need to adjust permissions or security settings.

ACL validation errors

If your sync report shows items with status **SKIPPED** and error type **VALIDATION_ERROR** with the message "File has no ACL while crawlACL is true, skipping ingestion," the app registration used by your knowledge base connector is missing the required ACL permissions.

To resolve:

1. Verify the app registration has the correct API permissions for ACL crawling. The required permissions vary by connector. See the permissions section in your connector's setup documentation.

2. Confirm that admin consent has been granted for all required permissions.
3. Re-run a full sync after fixing permissions.

Sync run exceeds maximum runtime

If a sync run takes longer than 14 days, Amazon Quick ends the run with a status of **FAILED** and the message *Maximum sync time exceeded*. This typically happens when a knowledge base is configured to crawl more content than can be processed in a single run.

To resolve:

1. Edit your knowledge base to reduce the volume of content per sync. Apply include or exclude filters, restrict the file types or folders being crawled, or split the content across multiple knowledge bases.
2. For web crawler data sources, consider using the Web Search feature instead if your goal is to chat with large public websites such as `wikipedia.org`.
3. Run the sync again after narrowing the scope.

For more information about this limit, see [the section called "Maximum sync duration"](#).

Connectors

Connectors use secure connections to external services and execute actions based on your authentication level and permissions.

How connectors work

Connectors in Amazon Quick create secure connections between Amazon Quick and external services. When you configure these integrations, you can perform actions based on your authentication level and permissions.

Core components

Connectors

The foundational resources that integrate with external services. For a list of supported connectors, see [Supported integrations](#). For information about setting up AWS built-in service connectors, see [AWS service connectors](#).

Authentication methods

Connectors support multiple authentication methods including Default OAuth app, Custom OAuth app, Service-to-Service OAuth, and API key. For detailed information about each authentication method, see [the section called "Authentication methods"](#).

Implementation types

- **On-demand actions for immediate, user-triggered operations** - Real-time operations that execute immediately when you trigger them. You can initiate actions through chat interfaces, dashboards, or Amazon Q Apps. Examples include creating tickets, sending messages, or querying data.
- **Automated workflows for scheduled or system-triggered tasks** - System-managed operations that execute based on schedules or triggers. They run in the background without user intervention. Examples include data synchronization, report generation, or system maintenance.

Permission models

- **Personal access permissions through 3LO** - You can grant specific permissions to Amazon Quick through Three-Legged OAuth, maintaining control over your service access. Permissions are tied to your identity and credentials in the target service.
- **Service-level permissions for automated workflows** - Applied to automated workflows, these permissions support system-to-system interactions without user involvement. They're configured at the service level and typically use API keys or service account credentials.
- **Entity-level access controls** - Govern access to actions within Amazon Quick, determining which users or groups can execute specific actions. These controls integrate with Amazon Quick's broader permission system for consistent access management across the platform.

Types of actions

Amazon Quick supports two methods of invoking actions, each serving different use cases and authentication models.

On-demand actions

On-demand actions execute immediately when you trigger them. These actions support interactive operations that require real-time response.

Key characteristics:

- User-initiated execution - You trigger actions through natural language in the chat interface.
- Interactive form completion - You fill out forms with required parameters before the action executes.
- Immediate response - Actions execute in real-time and provide instant feedback on success or failure.
- Personal authentication (3LO) - Uses your individual credentials and permissions from the target service.

Common use cases:

- Creating tickets in Jira.
- Sending messages in Slack.
- Updating Salesforce records.
- Retrieving information from SharePoint.

Automated workflows

Automated workflows execute actions on a schedule or in response to specific triggers. These are useful for background and system-level operations.

Key characteristics:

- System-level execution - Actions run automatically without user intervention based on predefined triggers.
- Scheduled or event-triggered - Execute on time-based schedules or in response to specific system events.
- Non-interactive operation - Run in the background without requiring user input or form completion.
- Service-level authentication - Use system credentials rather than individual user authentication.

Common use cases:

- Regular data synchronization.
- Scheduled report generation.
- Automated ticket updates.

- System health checks.

Prerequisites

Before using actions in Amazon Quick, ensure you have the following:

Subscription requirements

For information about subscription requirements for configuring and using connectors, see [Set up integrations in the console](#).

Service requirements

For third-party services (such as Jira or Salesforce), ensure that you have:

- Appropriate permissions in the target services.
- Authentication credentials for each service.

For AWS connectors, you need admin access to the relevant services.

AWS account requirements

- Active AWS account - A valid AWS account with billing enabled and in good standing.
- Appropriate IAM permissions - IAM roles and policies that allow Amazon Quick to access the required AWS services.
- Required service quotas - Sufficient service limits for the AWS services you plan to integrate with your actions.

Tool permissions

Connector owners and administrators can enable or disable individual tools within a connector to control which tools are available to users. Tool permission settings also let connector owners decide which tools require user consent before running, and which tools users can configure for themselves.

Tool permission settings

Connector authors configure tool permissions at the individual action level. The permission setting determines whether you see a confirmation prompt before an action runs. These settings apply across all Amazon Quick clients, including Chat, Agents, Pages, and Flows.

Always Ask

When a connector author sets an action to **Always Ask**, every invocation presents you with a confirmation prompt. You cannot override this behavior through your user-level preferences. The prompt always appears.

Let Users Choose (default)

Let Users Choose is the default setting for all actions. When a connector author sets an action to **Let Users Choose**, your user-level preference determines the initial behavior.

- For write actions, the user-level default is **Always Ask**, so you see a confirmation prompt on every invocation until you change your preference.
- For read actions, the user-level default is **Always Allow**, so you do not see a confirmation prompt unless you change your preference.

When you see a confirmation prompt, you can choose one of the following options.

- **Allow**. The action runs this time. The prompt reappears on the next invocation.
- **Trust**. The action runs and the prompt does not appear for future invocations.
- **Deny**. The action does not run.

Connector-level settings

Connector owners configure tool behavior for all users of a connector.

Connector-level settings

Setting	Behavior
Let Users Choose	You can individually configure how each action runs through your user-level preferences.
Always Ask	You always see a confirmation prompt before the action runs.

Setting	Behavior
Disable	No user can run the action.

User-level settings

You can configure tool behavior for your own connector. These settings apply only to your connection and do not affect other users.

User-level settings

Setting	Behavior
Always Ask	You see a confirmation prompt before the action runs.
Always Allow	The action runs without a confirmation prompt.
Disable	You cannot run the action from your connection.

Default behavior

The following table shows the default settings that Amazon Quick applies to each action type.

Default behavior by action type

Action type	Connector-level default	User-level default	User-changeable
Write actions	Let Users Choose	Always Ask	Yes
Read actions	Let Users Choose	Always Allow	Yes

Supported connector types and available actions

Amazon Quick supports multiple connector types, each with specific actions available:

External service connectors

- **Adobe Marketing Agent** - Work with Adobe Experience Platform marketing data and AI-powered marketing capabilities.
- **Airtable** - Create and update records, manage bases and tables, filter views, and perform relational data operations.
- **Asana** - Manage tasks, workspace operations, and project handling.
- **Atlassian Confluence Cloud** - Create, update, and manage pages, spaces, and other Confluence objects.
- **Atlassian Jira Cloud** - Create issues, update tickets, search projects, manage workflows.
- **BambooHR** - Access employee data, manage time-off requests.
- **Box** - Manage files, folders, and collaborate on documents.
- **Canva** - Create and edit designs, manage templates and assets.
- **Cisco Webex Meetings** - Schedule meetings, retrieve recordings, and manage participants.
- **Cisco Webex Video Messaging** - Manage video updates, retrieve transcripts, and access video metadata in Cisco Webex (Vidcast).
- **Dropbox** - Upload files, manage folder structures, generate sharing links, and control access permissions.
- **Dun & Bradstreet** - Look up company profiles, credit risk data, and business intelligence.
- **GitHub** - Manage repositories, issues, pull requests, and code collaboration.
- **Gmail** - Read emails, search inbox, draft messages, manage labels, and organize threads.
- **Google Analytics** - Query traffic reports, retrieve audience data, monitor conversion events, and access performance metrics.
- **Google Calendar** - Create and update events, check availability, manage invites, and retrieve schedules.
- **Google Chat** - Send messages, manage spaces, and interact with chat threads.
- **Google Docs** - Create and edit documents, read content, and collaborate on text-based files.
- **Google Drive** - Upload files, manage folders, search content, and perform file operations.
- **Google Meet** - Schedule video meetings, list hosted meetings, retrieve transcripts, and update access settings.
- **Google Sheets** - Create and edit spreadsheets, read and write cell ranges, and perform data operations.

- **Google Slides** - Create presentations, edit slides, manage layouts, and add speaker notes.
- **HG Insights** - Access technographic data, query company technology profiles, and retrieve market intelligence.
- **HubSpot** - Manage contacts, deals, marketing campaigns, and CRM data.
- **HuggingFace** - Access AI models, datasets, and machine learning workflows.
- **Intercom** - Manage customer conversations, support tickets, and messaging.
- **Linear** - Create and manage issues, projects, and development workflows.
- **Microsoft OneDrive** - Create, update, delete, and manage OneDrive files and folders.
- **Microsoft OneNote** - Create and edit notebooks, manage sections, and organize notes.
- **Microsoft Outlook** - Send emails, manage calendar events, access contacts.
- **Microsoft SharePoint** - Perform actions on SharePoint lists, items, files, and Excel workbooks.
- **Microsoft Teams** - Send messages, manage channels, schedule meetings, and manage team collaboration.
- **Monday.com** - Manage projects, tasks, and team collaboration workflows.
- **Moody's GenAI Ready Data** - Access Moody's credit ratings, financial research, and risk analytics data.
- **New Relic** - Access observability data, query metrics, and manage monitoring workflows.
- **Notion** - Create and manage pages, databases, and collaborative workspaces.
- **PagerDuty** - Create incidents, manage escalations, update on-call schedules.
- **QuickBooks** - Manage invoices, track expenses, generate financial reports, and handle vendor records.
- **Salesforce** - Create records, update opportunities, search accounts, manage leads.
- **SAP** - Access SAP S/4HANA systems to perform read operations on enterprise data.
- **ServiceNow** - Create incidents, update requests, manage workflows.
- **Shopify** - Manage products, orders, customers, and store operations.
- **Slack** - Send messages, create channels, manage notifications.
- **Smartsheet** - Update sheets, manage project data.
- **Snowflake Cortex Agent** - Query Snowflake data and run AI-powered analytics through Cortex Agent.
- **Visier Agent** - Access workforce analytics, query people data, and generate HR insights.
- **WhatsApp** - Send and manage messages through WhatsApp Business.

- **Zapier** - Trigger workflows across thousands of connected applications.
- **Zendesk** - Create tickets, update cases, search knowledge base.
- **Zoom** - Schedule meetings, add webinar registrants, summarize recorded meetings, and list participants.
- **ZoomInfo** - Look up company and contact data, and query firmographic and intent data.

AWS service connectors

- **Amazon S3** - Upload files, manage buckets, retrieve objects.
- **Amazon Bedrock** - Generate content, analyze data, process requests.
- **Amazon Textract** - Extract text and data from documents.
- **Amazon Comprehend** - Natural language processing and sentiment analysis.
- **Amazon Comprehend Medical** - Medical text analysis and entity extraction.

Connector compatibility matrix

The following table shows which Amazon Quick features each connector type supports:

Connector feature compatibility

Connector	Chat Agents	Flows	Dashboard Visuals	Dashboard Alerts	Automations	Companions
AWS Built-in Services						
AWS Bedrock Agent Runtime	—	—	—	—	✓	—
AWS Bedrock Data Automation Runtime	—	—	—	—	✓	—

Custom Connector Types

Model Context Protocol (MCP)	✓	✓	—	—	✓	—
OpenAPI	✓	✓	—	—	—	—
REST API	—	—	—	—	✓	—

Authentication Support:

- **Chat Agents and Companions** - Support user authentication (Default OAuth app, Custom OAuth app, Basic)
- **Dashboard Visuals** - Support user authentication (Default OAuth app, Custom OAuth app)
- **Dashboard Alerts** - Support system authentication (Service-to-Service OAuth or API Key)
- **Automations** - Support system authentication (Service-to-Service OAuth)

Connector APIs

Connector APIs let you programmatically create and manage connections between Amazon Quick and external services. These APIs support the action integration functionality that allows users to perform actions in third-party applications directly from Amazon Quick chat interfaces and automated workflows.

What are connector APIs?

Connectors serve as the foundational resources that enable integration with first and third party applications. Through these APIs, you can authenticate to applications, manage permissions, and control which actions are available to users within your Amazon Quick applications.

How connector APIs support action integrations

Connector APIs provide the backend infrastructure for Amazon Quick action integrations. When you create a connector through the API, you establish a secure connection that lets you:

- Execute actions in external services through chat interfaces.
- Perform automated workflows in background processes.
- Integrate third-party services with Amazon Quick applications.
- Manage authentication and permissions for service access.

The APIs handle the complex authentication flows, credential management, and permission controls needed to securely connect Amazon Quick with external services.

Authentication methods

Connector APIs support multiple authentication methods to accommodate different use cases and security requirements:

Managed authentication (3LO)

Three-Legged OAuth provides the simplest setup for personal access to third-party services:

- No initial configuration required.
- User-specific authentication through service provider login.
- Automatic token refresh with 90-day lifecycle.
- Secure credential storage managed by Amazon Quick.

Service-to-service authentication (2LO)

For complex enterprise integrations:

- Supports client credentials OAuth flow.
- Enables system-to-system interactions.
- Requires client ID, client secret, and token URL configuration.
- Suitable for automated workflows requiring sophisticated security.
- OAuth - Dynamic Client Registration (DCR - applicable only for select MCP servers).

API key authentication

Simplified authentication for automated workflows:

- Single token-based authentication.
- Service-level permissions.
- Ideal for background processes and scheduled actions.
- Requires valid API key from target service.

Basic Auth

Basic authentication provides a simple username/password authentication method:

- Uses standard HTTP Basic Authentication headers.
- Credentials are base64 encoded.
- Suitable for services that don't support OAuth or API keys.
- Requires secure HTTPS connection.
- Not recommended for public-facing services.

None

No authentication required:

- Used for public APIs and services.
- No credentials or tokens needed.
- Limited to read-only or public operations.
- Typically used for public data feeds and documentation.
- Should not be used for sensitive operations.

Permissions and access control

Connector APIs implement comprehensive permission controls through Access Control Lists (ACLs):

Resource-level permissions

- **Owner** - Full control including delete and permission management.
- **Contributor** - Can use and modify connector settings.

- **Viewer** - Can view connector details and use enabled actions.

API operations for permission management

- `DescribeActionConnectorPermissions` - Retrieve current permission settings.
- `UpdateActionConnectorPermissions` - Grant or revoke user permissions.

Supported connector categories

Dual-purpose connectors

These connectors support both action integrations and knowledge base creation:

- **Amazon S3** - Use the Admin Console to create Actions for file operations, use the webapp to create knowledge bases from S3 content.
- **Microsoft SharePoint** - Document management actions, content indexing.
- **OneDrive** - File operations, document search capabilities.
- **Confluence** - Content creation actions, knowledge base integration.

Action-only connectors

Specialized for action execution without knowledge base capabilities:

- **Salesforce** - Enterprise CRM integration supporting account and contact operations, custom object CRUD operations, Sales process automation.
- **JIRA** - Issue tracking and project management.
- **Microsoft Outlook** - Send emails, manage calendar events, access contacts.
- **Slack** - Communication and notification workflows.
- **ServiceNow** - IT service management operations.
- **Zendesk** - Create tickets, update cases, search knowledge base.
- **PagerDuty** - Create incidents, manage escalations, update on-call schedules.
- **Asana** - Create actions, update projects, manage team workflows.
- **BambooHR** - Access employee data, manage time-off requests.
- **Smartsheet** - Update sheets, manage project data.
- **FactSet** - Access financial data, generate reports.

- **SAP** - Access SAP systems, execute business functions, and manage enterprise data.

Knowledge base-only connectors

Focused on knowledge base integration without action capabilities:

- **Google Drive** - Document indexing and search.
- **Web Crawler** - Content discovery and indexing.

API lifecycle management

Credential management

- Automatic refresh token handling for OAuth connectors.
- Secure storage of authentication credentials using AWS KMS.
- Support for credential rotation and updates.
- Cross-account access for Amazon S3 connectors.

Connection updates

Use the `UpdateActionConnector` API to:

- Modify authentication credentials.
- Update service configuration parameters.
- Change connector metadata.

Monitoring and troubleshooting

- Track API usage through CloudWatch metrics.
- Monitor connection health and authentication status.
- Implement error handling for common failure scenarios.
- Use validation APIs to diagnose configuration issues.

Rate limiting and quotas

Connector APIs implement standard AWS API rate limiting:

- Standard AWS API throttling applies to all operations.
- Connection validation may have additional limits.
- Action execution rates depend on target service capabilities.
- Implement exponential backoff for retry logic.

Cross-account support

For Amazon S3 connectors, the APIs support cross-account access:

- Specify different AWS account IDs during connector creation.
- Configure appropriate IAM permissions for cross-account access.
- Use AWS KMS for secure credential management across accounts.
- Validate permissions before enabling cross-account connections.

Error handling and troubleshooting

Connector APIs return standard AWS error responses:

Common error types

- `AccessDeniedException` - Insufficient permissions for the operation.
- `InvalidParameterValueException` - One or more parameter values are invalid for the operation.
- Invalid configuration parameters - Service-specific configuration values are incorrect or missing.
- `ResourceNotFoundException` - Connector or resource not found.
- `ThrottlingException` - Rate limit exceeded.
- `ConflictException` - Resource conflict or duplicate names.
- `InternalFailureException` - Internal service error occurred during request processing.
- `ResourceExistsException` - Attempt to create a resource that already exists.
- `InvalidNextTokenException` - The pagination token provided is invalid or expired.
- `AccessTokenNotFoundException` - User needs to authorize the connection (that is, sign-button). This exception is used by UX to ask users for authorization.
- `TokenResponseException` - Action setup is not valid.

Implement proper error handling in your applications to manage these scenarios gracefully and provide meaningful feedback to users.

Using connector APIs with AWS CLI

You can use the AWS CLI to manage connectors programmatically. The following examples demonstrate common operations using generic placeholder values.

Creating a connector

Use the `create-action-connector` command to create a new connector for integrating with external services.

```
aws quicksight create-action-connector \  
  --aws-account-id "123456789012" \  
  --name "MyS3Connector" \  
  --action-connector-id "my-s3-connector-id" \  
  --type "AMAZON_S3" \  
  --authentication-config '{  
    "AuthenticationType": "IAM",  
    "AuthenticationMetadata": {  
      "IamConnectionMetadata": {  
        "RoleArn": "arn:aws:iam::123456789012:role/MyConnectorRole"  
      }  
    }  
  }' \  
  --enabled-actions "CreateBucket" "ListBuckets" \  
  --description "S3 connector for automation workflows" \  
  --region "us-east-1"
```

Listing connectors

Use the `list-action-connectors` command to retrieve all connectors in your account.

```
aws quicksight list-action-connectors \  
  --aws-account-id "123456789012" \  
  --max-results 10 \  
  --region "us-east-1"
```

Describing a connector

Use the `describe-action-connector` command to get detailed information about a specific connector.

```
aws quicksight describe-action-connector \  
  --aws-account-id "123456789012" \  
  --action-connector-id "my-s3-connector-id" \  
  --region "us-east-1"
```

Updating a connector

Use the `update-action-connector` command to modify an existing connector's configuration.

```
aws quicksight update-action-connector \  
  --aws-account-id "123456789012" \  
  --action-connector-id "my-s3-connector-id" \  
  --name "UpdatedS3Connector" \  
  --authentication-config '{  
    "AuthenticationType": "IAM",  
    "AuthenticationMetadata": {  
      "IamConnectionMetadata": {  
        "RoleArn": "arn:aws:iam::123456789012:role/UpdatedConnectorRole"  
      }  
    }  
  }' \  
  --enabled-actions "CreateBucket" "ListBuckets" "DeleteBucket" \  
  --region "us-east-1"
```

Searching connectors

Use the `search-action-connectors` command to find connectors based on specific criteria.

```
aws quicksight search-action-connectors \  
  --aws-account-id "123456789012" \  
  --max-results 5 \  
  --filters '[{
```

```
"Name": "ACTION_CONNECTOR_NAME",
"Operator": "StringLike",
"Value": "S3"
}]' \
--region "us-east-1"
```

Managing connector permissions

Use the `update-action-connector-permissions` command to grant or revoke permissions for a connector.

```
aws quicksight update-action-connector-permissions \
--aws-account-id "123456789012" \
--action-connector-id "my-s3-connector-id" \
--grant-permissions '[{
  "Actions": [
    "quicksight:DescribeActionConnector",
    "quicksight:UpdateActionConnector",
    "quicksight:DeleteActionConnector"
  ],
  "Principal": "arn:aws:quicksight:us-east-1:123456789012:user/default/myuser"
}]' \
--region "us-east-1"
```

Viewing connector permissions

Use the `describe-action-connector-permissions` command to view current permissions for a connector.

```
aws quicksight describe-action-connector-permissions \
--aws-account-id "123456789012" \
--action-connector-id "my-s3-connector-id" \
--region "us-east-1"
```

Deleting a connector

Use the `delete-action-connector` command to remove a connector from your account.

```
aws quicksight delete-action-connector \  
  --aws-account-id "123456789012" \  
  --action-connector-id "my-s3-connector-id" \  
  --region "us-east-1"
```

Next steps

After understanding connector APIs, you can:

- Review the complete API reference documentation for detailed parameter specifications.
- Explore specific connector setup guides for your target services.
- Implement authentication flows appropriate for your use case.
- Set up monitoring and error handling for production deployments.
- Configure permissions and access controls for your organization.

Authentication methods

Amazon Quick supports multiple authentication methods for connectors. The available methods depend on the specific connector. During setup, you choose your authentication method from the **OAuth Configuration** options or from the connector-specific authentication settings.

Default OAuth app

Default OAuth app (also known as managed authentication or 3LO) is the recommended authentication method for personal access to third-party services. With this method, Amazon Quick manages the OAuth flow and no additional credentials are required from your organization.

Key features:

- No additional credentials or configuration required.
- User-specific authentication through provider sign-in.
- Secure credential storage managed by Amazon Quick.
- Automatic token refresh.
- 90-day refresh token lifecycle.

Setup process:

1. Choose **Default OAuth app** as your OAuth configuration.
2. Complete the service provider sign-in flow.
3. Grant the requested permissions.
4. Confirm the connection.

Note

Not all connectors support Default OAuth app. Check the connector-specific documentation for available authentication methods.

Custom OAuth app

Custom OAuth app authentication is for organizations that require specific control over the OAuth application configuration. Like Default OAuth app, this method uses a three-legged OAuth (3LO) flow where users sign in directly with the service provider. The difference is that you provide your own OAuth credentials instead of using the Amazon Quick managed application.

Required information:

- Client ID
- Client Secret
- Domain URL
- Authorization URL
- Token URL
- Redirect URL

Setup process:

1. Create an OAuth application in your service provider's developer console.
2. Choose **Custom OAuth app** as your OAuth configuration.
3. Enter the credentials from your OAuth application.
4. Complete the sign-in flow and validate the connection.

Service-to-Service OAuth

Service-to-Service OAuth uses client credentials for server-to-server authentication without user interaction. This method is suitable for automated workflows and shared connectors where actions run under a service account.

Required information:

- Client ID
- Client Secret
- Domain URL
- Token URL
- Service-specific parameters (varies by connector)

API key authentication

Some connectors support API key authentication for service-level access. This method uses a single token for authentication and is common for connectors that don't support OAuth.

Required information:

- Valid API key from the service provider
- Base URL or domain
- Service-specific parameters (such as email or account ID)

Action execution methods

Amazon Quick provides multiple ways to execute actions, accommodating different use cases and interaction preferences.

Chat interface

You can execute implicit actions in the Amazon Quick chat.

Implicit actions

Amazon Quick also supports implicit action execution through natural conversation with agents. Using advanced natural language processing, the system can identify when your conversation

indicates the need for specific actions. Conversations are analyzed to determine which actions are required to fulfill your request.

A single request might require multiple actions to complete. When this happens, the system handles these actions sequentially, guiding you through each step. For each identified action, the system presents the appropriate form for you to complete. After each action completes, you receive a confirmation before moving on to the next action in the sequence.

For example, if you ask "Create a Jira ticket for this issue and notify the team in Slack," the system would:

1. First present the Jira ticket creation form.
2. After completing the ticket creation, show the Slack message form.
3. Complete both actions in sequence.

Throughout the process, you can track your progress through multiple actions. When all actions complete, the system provides a comprehensive summary showing all executed actions and their outcomes. You can access related documentation if needed and review any error states that may have occurred during the process.

Monitoring and maintenance

Monitoring your connectors helps ensure reliable performance and identify issues before they impact users. Regular monitoring allows you to track usage patterns, optimize performance, and maintain healthy connections to external services.

Performance monitoring

You can assess connector performance using the following metrics and analytics.

CloudWatch metrics

- Action execution success rates - Track the percentage of successful action executions to identify reliability issues.
- Response times - Monitor how long actions take to complete and identify performance bottlenecks.
- Error frequencies - Track error patterns to identify common failure points and areas for improvement.

- API quota usage - Monitor usage against service limits to prevent throttling and plan for capacity.

Usage analytics

The following usage analytics are collected for connectors:

- Active users - Track how many users are actively using connectors to understand adoption and usage patterns.
- Popular actions - Identify which actions are used most frequently to prioritize optimization efforts.
- Execution patterns - Analyze when and how often actions are executed to optimize resource allocation.
- Error trends - Monitor error patterns over time to identify systemic issues and improvement opportunities.

Connection health

You can assess connector health using the following connection health tools:

Status monitoring

- Connection state - Monitor whether connectors are actively connected and functioning properly.
- Authentication validity - Track the status of authentication tokens and credentials to prevent access failures.
- Token expiration tracking - Monitor when authentication tokens will expire and need renewal.
- Service availability - Track the availability and response status of connected external services.

Automated maintenance

- Token refresh handling.
- Connection recovery.
- Error retry logic.
- Performance optimization.

CloudWatch metrics reference

Available CloudWatch metrics

Metric	Description	Unit
ActionSuccess	Successful executions	Count
ActionLatency	Execution time	Milliseconds
AuthFailures	Failed authentications	Count
APIThrottling	API throttling events	Count

Best practices

Following best practices for connectors helps ensure secure, reliable, and efficient operations. These practices help you maintain optimal performance, protect sensitive data, and minimize operational issues.

Security

Authentication management

- Regular credential rotation - Update API keys and OAuth tokens on a scheduled basis to maintain security.
- Periodic permission reviews - Audit user and service permissions quarterly to ensure least-privilege access.
- Token lifecycle monitoring - Track token expiration dates and set up alerts before credentials expire.
- Access audit logging - Enable comprehensive logging to track who accessed which services and when.

Access control

- Implement least-privilege access - Grant only the minimum permissions necessary for each action to function properly.

- Regular permission audits - Review and validate that current permissions align with actual usage patterns and business needs.
- Document access patterns - Maintain clear documentation of who has access to which connectors and why.
- Monitor usage anomalies - Set up alerts for unusual access patterns that might indicate security issues.

Performance

Action configuration

- Optimize form defaults - Pre-populate commonly used values to reduce user input time and errors.
- Configure appropriate timeouts - Set realistic timeout values based on typical response times for each service.
- Set up error handling - Implement robust error handling with clear user messages and retry logic where appropriate.
- Document dependencies - Clearly document any prerequisites or dependencies between different actions.

Resource management

- Monitor API quotas.
- Track usage patterns.
- Optimize refresh schedules.
- Regular cleanup of unused connectors.

Maintenance

Regular actions

- Review connector status.
- Update configurations.
- Validate connections.

- Document changes.

Troubleshooting

- Monitor error patterns.
- Review CloudWatch logs.
- Track resolution times.
- Document solutions.

Troubleshooting

When connectors encounter issues, systematic troubleshooting helps you quickly identify and resolve problems. This guidance covers common issues and their solutions to minimize downtime and restore functionality.

Common issues and solutions

Authentication problems

Token expiration

Symptom: "Authentication token expired" error
Resolution:

1. Choose "Reconnect" in console.
2. Complete authentication flow.
3. Retry action.

Permission errors

Symptom: "Insufficient permissions" message
Resolution:

1. Verify service permissions.
2. Check connector configuration.
3. Review action requirements.

Connection failures

Symptom: "Unable to connect to service" error

Resolution:

1. Verify service availability.
2. Check network connectivity.
3. Validate credentials.
4. Review service quotas.

Action-specific issues

Form submission failures

Validation errors

- Check required fields.
- Verify data formats.
- Review field limitations.
- Check for special characters.

Timeout issues

- Reduce form complexity.
- Check network latency.
- Review service response times.
- Consider breaking into multiple actions.

Sync and performance issues

Slow response times

Resolution:

1. Check API rate limits.
2. Review concurrent executions.

- 3. Monitor service health.
- 4. Optimize action configuration.

Failed executions

Resolution:

- 1. Review CloudWatch logs.
- 2. Check error messages.
- 3. Verify service status.
- 4. Test connection health.

Common error messages

Error codes and resolutions

Error code	Description	Resolution
AUTH_001	Authentication failed	Verify credentials and retry
CONN_002	Connection timeout	Check network and service status
PERM_003	Insufficient permissions	Review required permissions
TOKEN_004	Token expired	Reinitiate authentication

Integration-specific guides

Use these guides to configure integrations with specific applications. Each guide includes setup instructions for both action and data ingestion capabilities when the integration supports them.

Adobe Marketing Agent integration

With the Adobe Marketing Agent connector, you can work with Adobe Experience Platform marketing data and AI-powered marketing capabilities directly in Amazon Quick through natural language.

Amazon Quick supports multiple authentication methods for Adobe Marketing Agent. Choose the method that best fits your organization's security requirements.

- **Default OAuth app** – Uses an AWS-managed OAuth application. No additional credentials are needed. Users authenticate directly with their Adobe account.
- **Custom OAuth app** – Uses a customer-managed application registered in Adobe Developer Console. This option gives your organization full control over the OAuth configuration.
- **Service-to-Service OAuth** – Uses client credentials for server-to-server authentication without user interaction. Suitable for automated workflows.
- **API Key** – Uses an API key for authentication. Suitable for service-account access patterns.

For more information about the authentication methods that Amazon Quick supports, see [the section called “Authentication methods”](#).

Before you begin

Make sure that you have the following before you set up the integration.

- An active Adobe account with access to Adobe Marketing Agent.
- For **Custom OAuth app** or **Service-to-Service OAuth**: Access to [Adobe Developer Console](#) on the Adobe website to create an app and obtain client credentials.
- For **API Key**: An Adobe-issued API key with the required marketing data access scopes.
- For Amazon Quick subscription requirements, see [the section called “Set up integrations in the console”](#).

Configuring Adobe

If you are using **Default OAuth app** authentication, skip this section and proceed to [the section called “Setting up the connector in Amazon Quick”](#).

For Custom OAuth app or Service-to-Service OAuth authentication, register an app in [Adobe Developer Console](#) on the Adobe website and add the Amazon Quick callback URL `https://{region}.quicksight.aws.amazon.com/sn/oauthcallback` as a redirect URI. Replace `{region}` with your AWS Region (for example, `us-east-1`). Record the Client ID and Client Secret — you need them when you configure Amazon Quick. For API Key authentication, generate an API key from your Adobe account.

Setting up the connector in Amazon Quick

Connect from the Available tab

If you want to use Default OAuth app authentication, you can connect directly from the **Available** tab without additional configuration.

1. In the Amazon Quick console, choose **Connectors**.
2. On the **Available** tab, find **Adobe Marketing Agent** and choose **Connect**.
3. Complete the Adobe sign-in flow and grant the requested permissions.

To configure a connector with one of the other authentication methods, use the **Create for your team** tab as described below.

Create from the Create for your team tab

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Adobe Marketing Agent**.
4. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
5. For **Connection type**, choose **Public network**.
6. For **OAuth Configuration**, choose one of the following authentication methods and configure the required fields.
 - a. For **Default OAuth app**:

No additional credentials are needed. Choose **Next** to continue.

- b. For **Custom OAuth app**, configure the following fields:
 - **Client ID** – The client ID from your Adobe Developer Console app.
 - **Public OAuth client** (Optional) – Select this option if your Adobe Developer Console app is configured as a public client (no client secret).
 - **Client secret** – The client secret from your Adobe Developer Console app.
 - **Token URL** – The token endpoint. Default: `https://aep-ai-ama.adobe.io/token`
 - **Authorization URL** – The authorization endpoint. Default: `https://aep-ai-ama.adobe.io/authorize`

- **Redirect URL** – Pre-filled with the Amazon Quick callback URL.
- c. For **Service-to-Service OAuth**, configure the following fields:
 - **Client ID** – The client ID from your Adobe Developer Console Server-to-Server credential.
 - **Client secret** – The client secret from your Adobe Developer Console Server-to-Server credential.
 - **Token URL** – The token endpoint. Default: `https://aep-ai-ama.adobe.io/token`
 - d. For **API Key**, configure the following fields:
 - **API Key** – The Adobe API key.
 - **Email (Optional)** – The email address associated with the API key.
7. Choose **Next**.
 8. If you chose **Default OAuth app** or **Custom OAuth app**, an Adobe authorization window opens. Review the requested permissions and choose **Allow**.
 9. On the **Review** page, review the available actions for the connector. Choose **Next**.
 10. On the **Publish** page, choose who can access the connector. You can enable access for everyone in your organization or search for specific teams or groups.
 11. Choose **Publish**.

Available actions

After you set up the connector, the actions exposed by Adobe Marketing Agent are available. To see the current set of actions for your connector, go to the connector's **Available actions** view in the Amazon Quick console.

Managing and troubleshooting

To edit, share, or delete your connector, see [the section called “Managing existing integrations”](#).

Authentication issues

- **Sign-in fails (Default OAuth app or Custom OAuth app)** – Verify that your Adobe account is active and that you can sign in to Adobe directly. For Custom OAuth app, confirm that the redirect URI in your Adobe Developer Console app matches the Amazon Quick callback URL.

- **Invalid client credentials (Custom OAuth app or Service-to-Service OAuth)** – Verify that the Client ID and Client secret match the values in your Adobe Developer Console app.
- **API Key authentication fails** – Verify that the API key has not been revoked and that it has the required scopes for the operations you want to perform.

Airtable integration

With the Airtable connector, you can access the Airtable platform directly in Amazon Quick through natural language. You can create and update records, manage bases and tables, filter views, and perform relational data operations without leaving Amazon Quick.

Amazon Quick supports multiple authentication methods for Airtable. Choose the method that best fits your organization's security requirements.

- **Default OAuth app** – Uses an AWS-managed OAuth application. No additional credentials are needed. Users authenticate directly with their Airtable account.
- **Custom OAuth app** – Uses a customer-managed OAuth application registered in Airtable. This option gives your organization full control over the OAuth configuration.
- **API Key** – Uses an Airtable personal access token for authentication. Suitable for individual use or testing.

For more information about the authentication methods that Amazon Quick supports, see [the section called “Authentication methods”](#).

Before you begin

Make sure that you have the following before you set up the integration.

- An active Airtable account with access to the bases and data that you want to use.
- For **Custom OAuth app**: Access to the [Airtable Builder Hub](#) on the Airtable website to register an OAuth integration.
- For **API Key**: A personal access token from the [Airtable Builder Hub](#) on the Airtable website.
- For Amazon Quick subscription requirements, see [the section called “Set up integrations in the console”](#).

Configuring Airtable

If you are using **Default OAuth app** authentication, skip this section and proceed to [the section called "Setting up the connector in Amazon Quick"](#).

For Custom OAuth app or API Key authentication, complete the applicable steps in Airtable before configuring Amazon Quick.

Register an OAuth integration (Custom OAuth app)

Create an OAuth integration in the Airtable Builder Hub to obtain the client credentials that you need for Amazon Quick.

1. Sign in to the [Airtable Builder Hub](#) on the Airtable website and choose **OAuth integrations**.
2. Choose **Register new OAuth integration**.
3. Enter a **Name** for your integration.
4. For **OAuth redirect URLs**, enter the redirect URL from Amazon Quick:
`https://{region}.quicksight.aws.amazon.com/sn/oauthcallback`
5. Choose **Register integration**.
6. After registration, generate a client secret by choosing **Regenerate client secret**.
7. Record the following values. You need them when you configure Amazon Quick.
 - **Client ID**
 - **Client secret**
8. Under **Scopes**, select the permissions that your integration requires. For the full list of recommended scopes, see [the section called "Recommended scopes"](#).

Create a personal access token (API Key)

Create a personal access token in the Airtable Builder Hub for API Key authentication.

1. Sign in to the [Airtable Builder Hub](#) on the Airtable website and choose **Personal access tokens**.
2. Choose **Create token**.
3. Configure the token name, scopes, and base access as needed for your use case.
4. Copy and securely store the generated token. You need it when you configure Amazon Quick.

Recommended scopes

When you register an OAuth integration or create a personal access token, configure the following scopes based on the actions that you want to use.

Airtable recommended scopes

Scope	Description
<code>data.records:read</code>	Read data in records.
<code>data.records:write</code>	Create, edit, and delete records.
<code>data.recordComments:read</code>	Read comments in records.
<code>data.recordComments:write</code>	Create, edit, and delete record comments.
<code>schema.bases:read</code>	Read the structure of bases, including table names and field types.
<code>schema.bases:write</code>	Edit the structure of bases, including table names and field types.
<code>user.email:read</code>	Read the email address of the authenticated user.

Setting up the connector in Amazon Quick

Connect from the Available tab

If you want to use Default OAuth app authentication, you can connect directly from the **Available** tab without additional configuration.

1. In the Amazon Quick console, choose **Connectors**.
2. On the **Available** tab, find **Airtable** and choose **Connect**.
3. Complete the Airtable sign-in flow and grant the requested permissions.

To configure a connector with Custom OAuth app or API Key instead, use the **Create for your team** tab as described below.

Create from the Create for your team tab

After you complete any required Airtable configuration, create the connector in Amazon Quick.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Airtable**.

Note

If an Airtable connector already exists, a dialog appears with your existing connectors. To use an existing connector, choose it. To create a new one, choose **No, create new**.

4. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
5. For **Connection type**, choose **Public network**.
6. For **OAuth Configuration**, choose one of the following authentication methods and configure the required fields.

a. For **Default OAuth app**:

No additional credentials are needed. Choose **Next** to continue.

b. For **Custom OAuth app**, configure the following fields:

- **Base URL** (Optional) – The Airtable API base URL. Example: `https://api.airtable.com`
- **Client ID** – The client ID from your Airtable OAuth integration.
- **Client secret** – The client secret from your Airtable OAuth integration.
- **Token URL** – The token endpoint. Example: `https://airtable.com/oauth2/v1/token`
- **Authorization URL** – The authorization endpoint. Example: `https://airtable.com/oauth2/v1/authorize`
- **Redirect URL** – Pre-filled with the Amazon Quick callback URL.

c. For **API Key**, configure the following fields:

- **Base URL** (Optional) – The Airtable API base URL. Example: `https://api.airtable.com`
- **API Key** – Your Airtable personal access token.

- **Email (Optional)** – The email address associated with your Airtable account.

7. Choose **Next**.
8. If you chose **Default OAuth app** or **Custom OAuth app**, an Airtable authorization window opens. Review the requested permissions, choose the bases and workspaces to grant access to, and choose **Grant access**.
9. On the **Review** page, review the available actions for the connector. Choose **Next**.
10. On the **Publish** page, choose who can access the connector. You can enable access for everyone in your organization or search for specific teams or groups.
11. Choose **Publish**.

Available actions

After you set up the connector, the following actions are available.

Airtable available actions

Category	Action	Description
Records	List Records	Lists records in a table with optional filtering and sorting.
Records	Get Record	Retrieves a specific record by ID.
Records	Batch Create Record	Creates one or more new records in a table.
Records	Update Record	Updates fields on an existing record.
Records	Batch Update Record	Updates multiple records in a single operation using PATCH.
Records	Batch Put Record	Upserts multiple records in a single operation using PUT.
Comments	List Comments	Lists comments on a record.
Comments	Create Comment	Adds a comment to a record.
Comments	Update Comment	Edits an existing comment on a record.

Category	Action	Description
Schema	List Bases	Lists all bases accessible to the authenticated user.
Schema	Get Base Schema	Retrieves the schema of a base, including tables and field definitions.
Schema	Create Table	Creates a new table in a base.
Schema	Update Table	Updates table properties such as name or description.
Schema	Create Field	Adds a new field to a table.
Schema	Update Field	Updates field properties such as name or type.
Attachments	Create Attachment	Uploads an attachment to a record.
Users	Get User Info	Retrieves information about the authenticated user.

Note

The actions that you can use depend on the bases and workspaces accessible to the authenticated user.

Managing and troubleshooting

To edit, share, or delete your connector, see [the section called “Managing existing integrations”](#).

Authentication issues

- **Sign-in fails (Default OAuth app or Custom OAuth app)** – Verify that your Airtable account is active and that you can sign in to airtable.com on the Airtable website directly. For Custom OAuth app, confirm that the redirect URL in your Airtable OAuth integration matches the Amazon Quick callback URL.

- **Invalid client credentials (Custom OAuth app)** – Verify that the Client ID and Client secret match the values in your Airtable OAuth integration. If you regenerated the client secret, update the value in Amazon Quick.
- **API Key rejected** – Verify that your personal access token is active and has the required scopes. Tokens can be revoked or expired in the Airtable Builder Hub.
- **Insufficient permissions** – Verify that the scopes configured for your authentication method include the permissions required for the actions that you want to use. See [the section called “Recommended scopes”](#).

Amazon S3 integration

With Amazon S3 integration in Amazon Quick, you can create knowledge bases from documents stored in S3 buckets. This integration supports data ingestion capabilities for indexing and searching S3 content.

Note

This guide covers Amazon S3 data ingestion integration for knowledge base creation. For Amazon S3 connectors that perform Amazon S3 operations such as uploading, downloading, and deleting files, see [the section called “AWS service connectors”](#). Amazon S3 actions are only supported for Quick Automate.

What you can do

Amazon S3 users can ask questions about content stored in their Amazon S3 buckets. For example, users can inquire about key findings from documents, search for specific information across multiple file types, or analyze data patterns.

The integration enables users to quickly access and understand information from their Amazon S3 content, regardless of file location or type. It also provides contextual details such as modification dates and file metadata, contributing to more efficient information discovery and better-informed decision making.

Before you begin

Before you set up Amazon S3 integration, make sure you have the following:

- AWS account with Amazon S3 access.
- Amazon S3 bucket with documents to index.
- Amazon Quick Enterprise subscription.
- Necessary permissions to create Amazon S3 integrations.
- Your administrator must grant Amazon Quick access to the Amazon S3 buckets you want to use. For more information, see [the section called “Grant Amazon Quick access to Amazon S3 buckets”](#).

Note

Cross-account Amazon S3 access is only supported within the same AWS region.

Administrator setup

Before users can create Amazon S3 integrations and knowledge bases, an Amazon Quick administrator must complete the following setup tasks.

Grant Amazon Quick access to Amazon S3 buckets

Grant Amazon Quick access to the Amazon S3 buckets your organization needs. This applies whether the buckets are in the same AWS account or a different account.

1. In the Amazon Quick admin console, under **Permissions**, choose **AWS resources**.
2. Under **Allow access and autodiscovery for these resources**, select the **Amazon S3** checkbox.
3. Choose **Select S3 buckets**.
4. In the **Select Amazon S3 buckets** dialog, choose the tab that matches your bucket location:
 - **S3 Buckets Linked To Quick Account** – Select the buckets from the list that you want Amazon Quick to access. Selected buckets have read-only permissions by default.
 - **S3 Buckets You Can Access Across AWS** – For cross-account buckets, make sure the account owner has authorized your account. Choose **Use a different bucket**, enter the bucket name, and choose **Add S3 bucket**.
5. (Optional) For cross-account buckets, select **Restrict bucket access to knowledge base creator** to limit access so that only the user who creates the knowledge base can use the bucket.
6. Choose **Finish**.

The selected buckets are now accessible to users during knowledge base creation.

Prepare IAM role and policy setup

Amazon S3 integration uses AWS authentication to access your Amazon S3 buckets. Prepare your IAM role and policy configuration before users set up the integration.

Required IAM permissions

Make sure your AWS account has the following minimum permissions for the Amazon S3 bucket:

- `s3:GetObject` – Read objects from the bucket.
- `s3:ListBucket` – List bucket contents.
- `s3:GetBucketLocation` – Get bucket region information.
- `s3:GetObjectVersion` – Get object versions.
- `s3:ListBucketVersions` – List bucket versions.

Configure Amazon S3 bucket permissions for cross-account access

If you're accessing Amazon S3 buckets in a different AWS account, you must configure IAM policies in the source AWS account.

To configure Amazon S3 bucket permissions for cross-account access

1. Sign in to the AWS Management Console for the account that contains the Amazon S3 bucket.
2. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
3. Choose the bucket that you want to grant access to.
4. Choose **Permissions**, and then choose **Bucket Policy**.
5. Add a bucket policy with the following elements:
 - `Version` – Set to "2012-10-17"
 - `Statement` – Array containing policy statements with:
 - `Sid` – "AllowQuickSuiteS3Access"
 - `Effect` – "Allow"
 - `Principal` – AWS ARN for the Amazon Quick service role in your account.
For example, the principal should look like this: `"Principal": { "AWS":`

```
"arn:aws:iam::<quick_account_id>:role/service-role/aws-quicksight-
service-role-v0" }
```

- Action – Array of Amazon S3 permissions: s3:GetObject, s3:ListBucket, s3:GetBucketLocation, s3:GetObjectVersion, s3:ListBucketVersions
- Resource – "*" (applies to the current key), the Amazon S3 bucket path should look like the following: "Resource": ["arn:aws:s3:::bucket_name"]

6. Choose **Save changes**.

Configure KMS key permissions (if your bucket uses encryption)

If your Amazon S3 bucket uses AWS KMS encryption, complete the following steps.

To configure KMS key permissions

1. Open the AWS Key Management Service (AWS KMS) console at <https://console.aws.amazon.com/kms>.
2. Choose the KMS key that is used to encrypt your Amazon S3 bucket.
3. Choose **Key policy**, and then choose **Edit**.
4. Add a statement to the key policy with the following structural elements:
 - Sid – "AllowQuickSuiteKMSAccess"
 - Effect – "Allow"
 - Principal – AWS ARN for the Amazon Quick service role in your account.
For example, the principal should look like this: "Principal": { "AWS": "arn:aws:iam::<quick_account_id>:role/service-role/aws-quicksight-service-role-v0" }
 - Action – Array of KMS permissions: kms:Decrypt, kms:DescribeKey
 - Resource – "*" (applies to the current key), the Amazon S3 bucket path should look like the following: "Resource": ["arn:aws:s3:::bucket_name"]
5. Choose **Save changes**.
6. Wait 2-3 minutes for the policy changes to propagate.

Configure VPC access for Amazon S3 Connector in Amazon Quick

VPC permissions ensure Amazon Quick can only access your Amazon S3 bucket through secure VPC or VPC endpoint connections.

Required policy change

Add this statement to your bucket access policy to allow Amazon Quick to access your bucket through VPC endpoints:

```
{
  "Sid": "Allow-Quick-access"
  ,
  "Principal": "arn:aws:iam::Quick Account:role/service-role/aws-quicksight-service-
role-v0",
  "Action": "s3:*",
  "Effect": "Allow",
  "Resource": [
    "arn:aws:s3:::amzn-s3-demo-bucket",
    "arn:aws:s3:::amzn-s3-demo-bucket/*"
  ],
  "Condition": {
    "Null": {
      "aws:SourceVpce": "false"
    }
  }
}
```

- Replace `amzn-s3-demo-bucket` with your bucket name.
- Replace `Quick Account` with your Amazon Quick account.

The `"aws:SourceVpce": "false"` condition ensures Amazon Quick can only access your bucket through VPC endpoints, maintaining your security requirements.

Deny policies

If your bucket has a policy that restricts traffic to a specific VPC or VPC endpoint via Deny Policy, you must reverse this policy because deny policies take precedence over allow policies.

For example:

```
{
  "Version": "2012-10-17"
  ,
```

```

    "Id": "Policy1415115909152",
    "Statement": [
      {
        "Sid": "Access-to-specific-VPCE-only",
        "Principal": "*",
        "Action": "s3:*",
        "Effect": "Deny",
        "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket",
                     "arn:aws:s3:::amzn-s3-demo-bucket/*"],
        "Condition": {
          "StringNotEquals": {
            "aws:SourceVpce": "vpce-0abcdef1234567890"
          }
        }
      }
    ]
  }
}

```

Should be reversed into:

```

{
  "Version": "2012-10-17",
  "Id": "Policy1415115909152",
  "Statement": [
    {
      "Sid": "Access-to-specific-VPCE-only",
      "Principal": "*",
      "Action": "s3:*",
      "Effect": "Allow",
      "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket",
                   "arn:aws:s3:::amzn-s3-demo-bucket/*"],
      "Condition": {
        "StringEquals": {
          "aws:SourceVpce": "vpce-0abcdef1234567890"
        }
      }
    }
  ]
}

```

Best practices

Restrict access to your Amazon Quick role

Access policies should enforce that the caller is your Amazon Quick role ARN or, at minimum, your Amazon Quick account. This ensures that despite allowing VPC traffic, calls come only from expected sources.

Security recommendations

- Restrict policies to your Amazon Quick role for most secure traffic
- Review your bucket policies regularly to ensure they follow the principle of least privilege

Restrict Amazon S3 bucket access with IAM policy assignments

You can control which Amazon S3 buckets your Amazon Quick users can use to create knowledge bases by creating IAM policies and assigning them to specific users, groups, or all users through Amazon Quick IAM policy assignments. This allows you to restrict who can create knowledge bases against specific buckets, including ACL-aware knowledge bases.

Note

IAM policies assigned through Amazon Quick take precedence over AWS resource-level policies. To ensure your access requirements are met, configure your IAM policies appropriately.

For example, you can assign a restrictive policy to specific users who need access to ACL-aware buckets, while assigning a broader policy to all users for non-ACL buckets.

Step 1: Create an Amazon S3 access policy in IAM

Create an IAM policy in the AWS IAM console that defines which Amazon S3 buckets users can access for knowledge base creation. The following example policy grants access to two specific buckets:

```
{
  "Version": "2012-10-17"
,
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "s3:ListAllMyBuckets",
      "Resource": "arn:aws:s3:::*"
    }
  ],
}
```

```

{
  "Action": [
    "s3:ListBucket"
  ],
  "Effect": "Allow",
  "Resource": [
    "arn:aws:s3:::amzn-s3-demo-bucket-1",
    "arn:aws:s3:::amzn-s3-demo-bucket-2"
  ]
},
{
  "Action": [
    "s3:GetObject",
    "s3:GetObjectVersion"
  ],
  "Effect": "Allow",
  "Resource": [
    "arn:aws:s3:::amzn-s3-demo-bucket-1/*",
    "arn:aws:s3:::amzn-s3-demo-bucket-2/*"
  ]
},
{
  "Action": [
    "s3:ListBucketMultipartUploads",
    "s3:GetBucketLocation"
  ],
  "Effect": "Allow",
  "Resource": [
    "arn:aws:s3:::amzn-s3-demo-bucket-1",
    "arn:aws:s3:::amzn-s3-demo-bucket-2"
  ]
},
{
  "Action": [
    "s3:PutObject",
    "s3:AbortMultipartUpload",
    "s3:ListMultipartUploadParts"
  ],
  "Effect": "Allow",
  "Resource": [
    "arn:aws:s3:::amzn-s3-demo-bucket-1/*",
    "arn:aws:s3:::amzn-s3-demo-bucket-2/*"
  ]
}

```

```
]
}
```

Replace `amzn-s3-demo-bucket-1` and `amzn-s3-demo-bucket-2` with the names of the Amazon S3 buckets you want to grant access to.

Step 2: Assign the policy in Amazon Quick

After creating the IAM policy, assign it to Amazon Quick users or groups.

1. In the Amazon Quick admin console, under **Permissions**, choose **IAM policy assignments**.
2. Choose **Add new assignment**.
3. Enter a name for the assignment.
4. On the **Select an IAM policy** page, search for and select the IAM policy you created in Step 1. Choose **Next**.
5. On the **Assign users and groups** page, choose one of the following:
 - Select **Assign to all users and groups** to apply the policy to all current and future users.
 - Search for and select specific users or groups to assign the policy to.

Choose **Next**.

6. On the **Review and enable changes** page, verify your assignment details and choose **Save and enable**.

Users who are not explicitly granted access through an IAM policy assignment will not be able to access the restricted Amazon S3 buckets for creating integrations or knowledge bases.

Document-level ACLs

You can enable access control lists (ACLs) at the Amazon S3 knowledge base level using one of two configuration methods, each optimized for different use cases.

Important

Document-level ACL configuration is permanent. You cannot enable ACLs on knowledge bases created without ACL support, and you cannot disable ACLs once enabled. To change ACL configuration, create a new knowledge base with your desired setting from the start.

Note

For ACL-enabled knowledge bases, documents without an associated ACL entry are not ingested. Make sure every document has an ACL defined either through the global ACL file or in its metadata file.

Global ACL configuration file

Create a single centralized file that defines access permissions at the folder level. This provides a streamlined way to manage permissions across large document hierarchies. This method is ideal for organizations with stable permission structures. Any changes to the global file require reindexing the entire affected prefix, which can take hours for knowledge bases with tens of millions of documents. For the file format, see [the section called "Global ACL file structure"](#).

Document-level metadata files

Each document has its own metadata file containing specific access control information. This approach requires you to create and maintain individual metadata files for each document. It enables significantly faster index updates when permissions change because only the affected documents need to be reindexed rather than entire folder structures. For more information about configuring ACLs in metadata files, see [the section called "Document metadata"](#).

Choose the method that best fits your operational needs: centralized management with the global ACL file for simpler administration, or document-level metadata files for faster permission updates and more granular control.

Keep your document-level ACLs current by regularly updating the Amazon S3 ACL configuration to match your organization's access requirements. For more information about common best practices, see [the section called "Best practices for managing ACLs in knowledge bases"](#).

Global ACL file structure

The global file provides centralized access control management at the folder level. Each entry in the file maps an Amazon S3 key prefix to a set of ACL entries that apply to all documents under that prefix.

The global ACL json file uses the following structure:

```
[
```

```

{
  "keyPrefix": "s3://BUCKETNAME/prefix1/",
  "aclEntries": [
    {
      "Name": "user1@example.com",
      "Type": "USER",
      "Access": "ALLOW"
    },
    {
      "Name": "group1",
      "Type": "GROUP",
      "Access": "DENY"
    }
  ]
},
{
  "keyPrefix": "s3://BUCKETNAME/prefix1/document_1.txt",
  "aclEntries": [
    {
      "Name": "user1@example.com",
      "Type": "USER",
      "Access": "ALLOW"
    },
    {
      "Name": "group1",
      "Type": "GROUP",
      "Access": "DENY"
    }
  ]
},
{
  "keyPrefix": "s3://BUCKETNAME/prefix2/",
  "aclEntries": [
    {
      "Name": "user2@example.com",
      "Type": "USER",
      "Access": "ALLOW"
    },
    {
      "Name": "user1@example.com",
      "Type": "USER",
      "Access": "DENY"
    }
  ]
}

```

```
[
  {
    "Name": "group1",
    "Type": "GROUP",
    "Access": "DENY"
  }
]
```

Each entry in the array contains the following fields:

keyPrefix

The Amazon S3 path prefix that the ACL entries apply to. All documents under this prefix inherit the specified permissions.

aclEntries

An array of access control entries, each containing the following fields:

- Name – For USER type, the email address of the user in Quick. For GROUP type, the group name in Quick.
- Type – Either USER or GROUP.
- Access – Either ALLOW or DENY.

Document metadata

You can add metadata to documents in your Amazon S3 bucket to customize chat results and control document-level access. Metadata is additional information about a document, such as its title, creation date, and access permissions.

Amazon Quick supports source attribution with citations. If you specify the `_source_uri` metadata field, the source attribution links in chat results direct users to the configured URL. If you don't specify a `_source_uri`, users can still access source documents through clickable citation links that download the file at query time.

Document metadata location

In Amazon S3, each metadata file can be associated with an indexed document. Your metadata files must be stored in the same Amazon S3 bucket as your indexed files. You can specify a location within the Amazon S3 bucket for your metadata files when configuring your Amazon S3 integration in Amazon Quick.

If you don't specify an Amazon S3 prefix, your metadata files must be stored in the same location as your indexed documents. If you specify an Amazon S3 prefix for your metadata files, they must be in a directory structure parallel to your indexed documents. Amazon Quick looks only in the specified directory for your metadata. If the metadata isn't read, check that the directory location matches the location of your metadata.

The following examples show how the indexed document location maps to the metadata file location. The document's Amazon S3 key is appended to the metadata's Amazon S3 prefix and then suffixed with `.metadata.json` to form the metadata file's Amazon S3 path.

Note

The combined Amazon S3 key, the metadata's Amazon S3 prefix, and the `.metadata.json` suffix must be no more than a total of 1,024 characters. We recommend that your Amazon S3 key is less than 1,000 characters to account for additional characters when combining your key with the prefix and suffix.

Example 1: No metadata path specified

```
Bucket name:
    s3://bucketName
Document path:
    documents
Metadata path:
    none
File mapping
    s3://bucketName/documents/file.txt ->
    s3://bucketName/documents/file.txt.metadata.json
```

Example 2: Metadata path specified

```
Bucket name:
    s3://bucketName
Document path:
    documents/legal
Metadata path:
```

```

    metadata
File mapping
    s3://bucketName/documents/legal/file.txt ->
        s3://bucketName/metadata/documents/legal/file.txt.metadata.json

```

Document metadata structure

You define your document metadata itself in a JSON file. The file must be a UTF-8 text file without a BOM marker. The file name of the JSON file must be `<document>.<extension>.metadata.json`. In this example, `document` is the name of the document that the metadata applies to and `extension` is the file extension for the document. The document ID must be unique in `<document>.<extension>.metadata.json`.

The content of the JSON file uses the following template:

```

{
  "DocumentId": "document ID",
  "Attributes": {
    "_authors": ["author of the document"],
    "_category": "document category",
    "_created_at": "ISO 8601 encoded string",
    "_last_updated_at": "ISO 8601 encoded string",
    "_source_uri": "document URI",
    "_version": "file version",
    "_view_count": number of times document has been viewed
  },
  "AccessControlList": [
    {
      "Name": "user1@example.com",
      "Type": "GROUP | USER",
      "Access": "ALLOW | DENY"
    }
  ],
  "Title": "document title",
  "ContentType": "PDF | HTML | MS_WORD | PLAIN_TEXT | PPT | RTF | XML | XSLT |
MS_EXCEL | CSV | JSON | MD"
}

```

If you provide a metadata path, make sure that directory structure inside the metadata directory exactly matches the directory structure of data file.

For example, if the data file location is at `s3://bucketName/documents/legal/file.txt`, the metadata file location should be at `s3://bucketName/metadata/documents/legal/file.txt.metadata.json`.

All of the attributes and fields are optional, so it's not necessary to include all attributes. However, you must provide a value for each attribute that you want to include; the value can't be empty.

The `_created_at` and `_last_updated_at` metadata fields are ISO 8601 encoded dates. For example, `2012-03-25T12:30:10+01:00` is the ISO 8601 date-time format for March 25, 2012, at 12:30PM (plus 10 seconds) in the Central European Time time zone.

The `AccessControlList` field is an optional array that defines document-level access control. Each entry in the array contains the following fields:

- **Name** – For **USER** type, the email address of the user in Quick. For **GROUP** type, the group name in Quick.
- **Type** – Either **USER** or **GROUP**.
- **Access** – Either **ALLOW** or **DENY**.

Note

To use the `AccessControlList` field, you must enable document-level ACLs when creating the knowledge base. For more information, see [the section called “Document-level ACLs”](#).

Set up and manage Amazon S3 integration

Set up Amazon S3 integration

After your administrator has completed the setup tasks, follow these steps to create your Amazon S3 knowledge base.

1. In the Amazon Quick console, choose **Knowledge**.
2. Under **Amazon S3**, choose **Add** (the plus + button).
3. On the **Connect S3 bucket** page, choose your data source:
 - To reuse an existing Amazon S3 data source, select it from the dropdown. Then choose **Next** to skip to the knowledge base details step.

- To connect a new Amazon S3 bucket, choose **+ Add account** from the dropdown.
4. If you are connecting a new bucket, fill in the connection details:
 - **Name** – A descriptive name for your Amazon S3 integration.
 - **S3 bucket location** – Choose **Quick Suite instance account** to access Amazon S3 buckets in the same AWS account where Amazon Quick is enabled, or choose **Other AWS account** to access buckets in a different account.
 - **S3 bucket URL** – The Amazon S3 bucket path containing your documents. Your Amazon S3 bucket must be in the same region as your Amazon Quick region.

Choose **Next**. The system validates your configuration. If errors occur, review the error message for specific remediation steps.

 Note

If you receive an access error, contact your administrator to verify that your user has the required permissions for the Amazon S3 bucket.

5. On the **Create knowledge base** page, complete the following:
 - **Name** – Enter a descriptive name for your knowledge base.
 - **Description** – Describe the purpose of this knowledge base (optional).
 - **Content** – Choose **Add all content** to sync everything from the bucket, or choose **Add specific content** to specify S3 prefixes for the folders and files you want to include. Filters are case-sensitive.
6. Choose **Next: Additional settings** to configure ACL and metadata options, or choose **Create** to create the knowledge base with default settings.
7. On the **Additional settings** page, configure ACL management and metadata:

 Important

The decision to enable or disable ACLs must be made during knowledge base creation. You cannot change this option after this step. For more information about ACLs, see [the section called “Document-level ACLs”](#).

- To enable document-level ACLs, select **Control document access with ACLs**. When enabled, the following options appear:
 - **Global ACL file location** – Enter the Amazon S3 path to your global ACL file (e.g. acl.json) if you are using a global ACL configuration file for centralized access control management at the folder level.
 - **Metadata files folder location** – Enter the Amazon S3 path to your metadata folder if you are using document-level metadata files that include ACL entries.
 - If your metadata files use the sidecar method (stored in the same folder as the original documents), you can leave both fields blank.
- You can optionally specify a **Metadata files folder location** even without ACLs enabled.

8. Choose **Create**.

After you choose create, the data sync starts automatically.

Manage knowledge bases

After setting up your Amazon S3 integration, you can create and manage knowledge bases from your Amazon S3 content.

Edit existing knowledge bases

You can modify your existing Amazon S3 knowledge bases:

1. In the Amazon Quick console, choose **Knowledge bases**.
2. Select your Amazon S3 knowledge base from the list.
3. Choose the three-dot icon under **Actions**, then choose **Edit knowledge base**.
4. Update your configuration settings as needed and choose **Save**.

Create additional knowledge bases

You can create multiple knowledge bases from the same Amazon S3 integration:

1. In the Amazon Quick console, choose **Knowledge**.
2. Choose your existing Amazon S3 integration from the list.
3. Choose the three-dot icon under **Actions**, then choose **Create knowledge base**.

4. Configure your knowledge base settings and choose **Create**.

For detailed information about knowledge base configuration options, see [the section called "Common configuration settings"](#).

Note

When you create a knowledge base in Amazon Quick, by default only you can get insights from the knowledge base. For shared content, you can provide access to different users and groups by updating the knowledge base permissions. To control document-level access within a knowledge base, see [the section called "Document-level ACLs"](#).

Troubleshooting Amazon S3 integration issues

If you encounter issues connecting to your Amazon S3 bucket, review the following common causes and solutions.

Documents not appearing in ACL-enabled knowledge base

Issue: Documents are not ingested into an ACL-enabled knowledge base.

Solution: For ACL-enabled knowledge bases, documents without an associated ACL entry are not ingested. Verify that every document has an ACL defined either through the global ACL file or in its metadata file. For more information, see [the section called "Document-level ACLs"](#).

Cross-account access not configured

Issue: Your administrator hasn't granted access to use Amazon S3 buckets from other AWS accounts in Amazon Quick.

Solution: Ask your administrator to grant cross-account Amazon S3 access. For more information, see [the section called "Grant Amazon Quick access to Amazon S3 buckets"](#).

Bucket not in approved list

Issue: The bucket you're trying to access hasn't been authorized by your administrator.

Solution:

- Confirm the bucket name is spelled correctly.

- Verify with your administrator that the bucket is included in the approved list.
- Request your administrator to add the bucket to the authorized buckets list if needed.

Insufficient IAM permissions

Issue: Your IAM role or user lacks the necessary permissions to access the Amazon S3 bucket.

Solution:

- Verify your IAM policy includes the required Amazon S3 permissions:
 - `s3:GetObject`
 - `s3:ListBucket`
 - `s3:GetBucketLocation`
 - `s3:GetObjectVersion`
 - `s3:ListBucketVersions`
- Check your own buckets for any explicit Deny statements that might be blocking access.

 Note

The ARN `arn:aws:iam::account-id:role/service-role/aws-quicksight-service-role-v0` is the default service role used when no custom role has been created. If a custom service role exists, contact your administrator to obtain the custom service role ARN and use it instead of the default.

Cross-region restrictions

Issue: The Amazon S3 bucket is located in a different AWS region than your Amazon Quick account or service.

Solution:

- Verify the bucket region matches your Amazon Quick service region.
- Check bucket region using AWS CLI: `aws s3api get-bucket-location --bucket bucket-name`
- Use a bucket in the same region as your service.

Additional troubleshooting steps

- **Test bucket accessibility** using AWS CLI:

```
aws s3 ls s3://bucket-name --profile your-profile
```

- **Review CloudTrail logs** for AccessDenied errors to identify the specific permission issue.
- **Check Amazon S3 Block Public Access settings** - while these typically don't affect authenticated access, verify they're not interfering with your specific use case.
- **Verify bucket ownership** - ensure the bucket exists and you have the correct bucket name.

Limitations

When using Amazon S3 integrations in Amazon Quick, be aware of the following limitations:

- The Amazon S3 bucket must be in the same AWS Region as your Amazon Quick application.
- Each document can have a maximum of 2,500 individual user or group ACL entries.
- Global ACL configuration file maximum size: 100 MB.
- Document metadata file maximum size: 5 MB.

For more information about document-level ACL limitations, see [the section called “Limitations”](#).

Asana integration

Connect Amazon Quick to your Asana workspace to manage projects, tasks, and team collaboration. The Asana connector uses the Asana V2 Model Context Protocol (MCP) server. You can create, update, and manage Asana content without leaving your Amazon Quick environment. Every action runs as the authenticated user, and the connector limits access to what that user can do in Asana. For Amazon Quick subscription requirements, see [the section called “Set up integrations in the console”](#).

Supported authentication methods

The Asana connector supports a single authentication method: **Custom OAuth app**. This method uses user-based Open Authorization (OAuth) to connect to the Asana V2 MCP server.

Note the following behavior when you authenticate with the Asana MCP server:

- The Asana MCP server does not support Dynamic Client Registration. You must pre-register an OAuth app in the Asana developer console before you set up the connector.
- MCP apps do not use scopes. Remove the scope parameter entirely from your authorization URL.
- Tokens issued for MCP apps work only with the MCP server, not with the standard Asana API.
- Access tokens expire after 1 hour. The connector uses refresh tokens to maintain access.

Before you begin

Before you set up the Asana connector, make sure you have the following:

- An Asana account with access to the Asana developer console.
- Permission to create and distribute apps in the Asana workspaces you want to connect.
- A Amazon Quick subscription that meets the integration requirements. For more information, see [the section called “Set up integrations in the console”](#).

Configuring the Asana OAuth MCP app

Create an OAuth MCP app in the Asana developer console, configure its OAuth settings, and configure workspace access before you set up the connector in Amazon Quick.

Create an OAuth MCP app

1. Go to the Asana developer console and sign in.
2. Choose **Create new app**.
3. Enter the app name.
4. For app type, choose **MCP app**.
5. Choose **Create app**.
6. Record the **Client ID** and **Client Secret**. You enter these values when you set up the connector in Amazon Quick.

Configure OAuth settings

1. In the sidebar, choose **OAuth**.
2. Add the Amazon Quick callback URL as the redirect URL. You can copy this value from the connector setup page in Amazon Quick.

Configure workspace access

1. In the sidebar, choose **Manage distribution**.
2. Choose how the app can be used:

Specific workspaces

Choose the individual workspaces where the app can be used.

Any workspace

Allow the app to be used in any workspace.

Important

If you choose **Specific workspaces** but do not choose any workspaces, users receive an error when they try to authenticate.

Setting up the connector in Amazon Quick

After you configure your Asana OAuth MCP app, set up the connector in Amazon Quick.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Asana**.
4. Fill in the following details:
 - **Name** - Enter a descriptive name for your Asana integration.
 - **Description** - Describe the purpose of this integration.
5. Choose the connection type and configure the network type settings.
6. Configure the authentication settings. Use the values from your Asana OAuth MCP app.

Auth Type

Choose **Custom OAuth app**.

Client ID

Enter the client ID from the Asana developer console.

Client Secret

Enter the client secret from the Asana developer console.

Authorization URL

Enter `https://app.asana.com/-/oauth_authorize`. Do not include a scope parameter.

Token URL

Enter `https://app.asana.com/-/oauth_token`.

Redirect URL

This field is pre-filled with the Amazon Quick callback URL. Use this value as the redirect URL in your Asana OAuth app.

7. Choose **Create and continue**.
8. Add users to share the integration with.
9. Choose **Next**.

Managing and troubleshooting

You can edit, share, and delete your Asana integrations after you create them. For more information, see [the section called "Managing existing integrations"](#).

If you run into problems with your Asana integration, use the following guidance to resolve common issues.

This app is not available to your workspace

The user's workspace is not included in the app's distribution settings. In the Asana developer console, choose **Manage distribution** and add the workspace, or choose **Any workspace**.

Invalid scope(s) requested

Remove the scope parameter from the authorization URL. MCP apps do not use scopes.

Authentication failures

Verify that the redirect URL matches the Amazon Quick callback URL, that the client ID and client secret are correct, and that the app is properly configured in **Manage distribution**.

Connection issues

Verify that the access token is included in your requests and has not expired. Access tokens have a 1-hour lifetime. If the token has expired, the connector uses refresh tokens to obtain a new one automatically.

Atlassian Confluence Cloud integration

Use the Atlassian Confluence Cloud integration to perform actions on Confluence content, or to create knowledge bases from Confluence spaces, pages, and blog posts for AI-powered search and Q&A.

Integration capabilities

Connector

Create and update Confluence pages, and search Confluence content through Atlassian API calls.

Knowledge base

Index Confluence pages, blog posts, and space content. Amazon Quick agents can then search and answer questions about the content. Optionally enable document-level access controls to ensure users only see answers from content they are authorized to access in Confluence.

Atlassian Confluence Cloud action integration

Use the Atlassian Confluence Cloud connector to create, update, and manage Confluence pages and spaces directly in Amazon Quick through natural language.

To set up this integration, you first create an OAuth 2.0 (3LO) app in the Atlassian Developer Console and configure its permissions. Then, you create the integration in Amazon Quick and connect it to your Atlassian app. For information about the authentication methods that Amazon Quick supports, see [the section called "Authentication methods"](#).

Before you begin

Make sure you have the following before you set up the integration.

- Atlassian Confluence Cloud.
- Access to the [Atlassian Developer Console](#) to create or manage an OAuth app.

- For subscription requirements, see [the section called “Set up integrations in the console”](#).

Configure the Atlassian Developer Console

If you plan to use user authentication (3LO), create an OAuth 2.0 app in the Atlassian Developer Console before you configure Amazon Quick. Complete all of the following steps before moving to the Amazon Quick console.

If you plan to use service authentication (API Key) only, you can skip this section and proceed to [the section called “Prepare authentication”](#).

For more information about OAuth 2.0 (3LO) apps, see [OAuth 2.0 \(3LO\) apps](#) in the Atlassian developer documentation.

Create an OAuth 2.0 (3LO) app

Amazon Quick uses an Atlassian OAuth 2.0 (3LO) app to authenticate with your Atlassian Cloud product on behalf of your users. Create this app in the Atlassian Developer Console before you configure Amazon Quick.

1. Open the [Atlassian Developer Console](#) and sign in with your Atlassian account.
2. Choose **Create**, then choose **OAuth 2.0 integration**.
3. For **Name**, enter a descriptive name for your integration, for example *your-app-name* connector.
4. Review and accept the Atlassian developer terms.
5. Choose **Create**.

Configure permissions

After you create the OAuth 2.0 app, add the API permissions that Amazon Quick needs to interact with your Atlassian product.

1. From your app in the Atlassian Developer Console, choose **Permissions** in the left navigation.
2. Find the API for your Atlassian product (for example, **Jira API** or **Confluence API**) and choose **Add**. The button changes to **Configure** after the API is added.
3. Choose **Configure**. The scopes page opens with **Classic scopes** and **Granular scopes** tabs.
4. On the **Classic scopes** tab, choose **Edit Scopes**. Select the required classic scopes and choose **Save**.

5. Choose the **Granular scopes** tab, then choose **Edit Scopes**. Select the required granular scopes and choose **Save**.

For the specific scopes required for your integration, see the scopes section that follows.

Required scopes for Confluence

Add the following scopes to your OAuth 2.0 app for the Confluence Cloud action integration.

Classic scope

On the **Classic scopes** tab, choose **Edit Scopes** and select the following scope.

Confluence action integration – classic scope

Scope	Description
search:confluence	Search Confluence content and space summaries.

Granular scopes

Choose the **Granular scopes** tab, then choose **Edit Scopes**. Select the following scopes.

Confluence action integration – granular scopes

Scope	Description
read:page:confluence	View page content.
write:page:confluence	Create and update pages.
read:space:confluence	Access space information.

Configure authorization

Set the callback URL so that Atlassian can redirect users back to Amazon Quick after they authorize the app.

1. From your app in the Atlassian Developer Console, choose **Authorization** in the left navigation.

2. Next to **OAuth 2.0 (3LO)**, choose **Add**.
3. For **Callback URLs**, enter `https://region.quicksight.aws.amazon.com/sn/oauthcallback`. Replace *region* with the AWS Region where your Amazon Quick instance is deployed, for example `us-east-1`.
4. Choose **Save changes**.

Record your credentials

Before you leave the Atlassian Developer Console, confirm that you have the following values. You need them for the Amazon Quick configuration.

1. From your app in the Atlassian Developer Console, choose **Settings** in the left navigation.
2. Under **Authentication details**, copy the **Client ID** and **Secret** values.

Required credentials from Atlassian Developer Console

Value	Where to find it
Client ID	Settings page, under Authentication details
Secret	Settings page, under Authentication details

Prepare authentication

Confluence Cloud connectors support two authentication methods. Gather the required credentials before configuring Amazon Quick.

User authentication (3LO)

If you completed the Atlassian Developer Console setup in the previous section, you should have the following values ready. Enter these when you configure the integration in Amazon Quick.

- **Base URL** – Your Confluence instance URL for API calls. This is not the same URL that users log into. It resembles the following: `https://api.atlassian.com/ex/confluence/yourInstanceId`. To find your instance ID, navigate to `https://your-domain.atlassian.net/_edge/tenant_info`.
- **Client ID** – From the Settings page of your Atlassian OAuth app.

- **Client secret** – From the Settings page of your Atlassian OAuth app.
- **Token URL** – <https://auth.atlassian.com/oauth/token>
- **Authorization URL** – <https://auth.atlassian.com/authorize>
- **Redirect URL** – [https://*region*.quicksight.aws.amazon.com/sn/oauthcallback](https://region.quicksight.aws.amazon.com/sn/oauthcallback)

Service authentication (API Key)

Gather the following information from your Confluence Cloud administrator:

- **API Key** – Confluence API token.
- **Base URL** – Your Confluence instance URL for API calls.
- **Email** – Associated user account email.

Set up the integration in Amazon Quick

After you prepare your authentication credentials, create the integration in Amazon Quick.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Atlassian Confluence Cloud**.
4. On the **Integration type** page, select **Perform actions in Atlassian Confluence Cloud** and choose **Next**.
5. In the **Create integration** form, fill in the following fields:
 - **Name** – Descriptive name for your Confluence integration.
 - **Description** (Optional) – Notes about how this connection will be used.
 - **Connection type** – Choose **Public network**.
6. Under **Authentication settings**, choose your authentication method and fill in the required fields:
 - a. For **User authentication**, configure the following fields:
 - **Base URL** – Your Confluence instance URL for API calls, in the format [https://api.atlassian.com/ex/confluence/*yourInstanceId*](https://api.atlassian.com/ex/confluence/yourInstanceId). To find your instance ID, navigate to [https://*your-domain*.atlassian.net/_edge/tenant_info](https://your-domain.atlassian.net/_edge/tenant_info).
 - **Client ID** – Client ID from the Settings page of your Atlassian OAuth app.
 - **Client secret** – Secret from the Settings page of your Atlassian OAuth app.

- **Token URL** – `https://auth.atlassian.com/oauth/token`
 - **Authorization URL** – `https://auth.atlassian.com/authorize`
 - **Redirect URL** – This field is pre-populated with your Amazon Quick callback URL.
- b. For **Service authentication**, configure the following fields:
- **API Key** – Confluence API token.
 - **Base URL** – Your Confluence instance URL for API calls.
 - **Email** – Associated user account email.
7. Choose **Create and continue**.
8. (Optional) On the **Share integration** page, choose users to share the integration with.

Available actions

After you set up the integration, the following actions are available.

Confluence Cloud available actions

Action	Description
Create Page	Create a new page.
Get Pages	View all pages.
Search	Search content using CQL.
Update Page	Update page content.

Manage and troubleshoot

To edit, share, or delete your integration, see [the section called “Managing existing integrations”](#).

Authentication issues

- **Incorrect app configuration** – Verify the OAuth app in the Atlassian Developer Console includes the required scopes and that the redirect URI matches your Amazon Quick configuration.
- **Expired API token** – If using service authentication, check that the API token has not expired and generate a new one if needed.

- **Incorrect Base URL** – The Base URL for API calls is not the same as the Confluence Cloud login URL. Verify you are using the API URL format: `https://api.atlassian.com/ex/confluence/yourInstanceId`. To find your instance ID, navigate to `https://your-domain.atlassian.net/_edge/tenant_info`.

Common error messages

- **Access denied. You do not have permission to perform this action** – The authenticated user does not have the required permissions in Confluence Cloud. Contact your Confluence Cloud administrator to verify and grant appropriate permissions.
- **OAuth 2.0 authorization failed** – Verify the client ID, client secret, and OAuth scopes are configured correctly in both the Atlassian Developer Console and Amazon Quick.

Atlassian Confluence Cloud knowledge base integration

Use the Atlassian Confluence Cloud knowledge base integration to index Confluence content so that Amazon Quick agents can search and answer questions about it. Amazon Quick supports optional document-level access controls (ACLs) for Confluence knowledge bases. When enabled, users only see answers from documents they are authorized to access in Confluence. For more information, see [the section called “Document-level access controls”](#).

Before you begin

Make sure you have the following before you set up the integration.

- An Atlassian Confluence Cloud instance.
- For Quick subscription requirements, see [the section called “Set up integrations in the console”](#).

If you plan to enable document-level access controls, you must provide Atlassian admin credentials during setup. These credentials allow Amazon Quick to access all user and group information regardless of individual email visibility settings. Without admin credentials, the ACL option is not available during knowledge base creation. To provide admin credentials, you need the following from your Atlassian organization administrator:

- **Atlassian admin API key** – An alphanumeric string generated in the Atlassian admin portal.
- **Organization ID (UUID)** – The unique identifier for your Atlassian organization. You can find this in your browser URL when signed in to the admin portal: `admin.atlassian.com/o/orgId`.

- **Directory ID (UUID)** – The unique identifier for your user directory. Retrieve this value using the Atlassian Admin Workspace API.

For detailed steps to obtain these credentials, see [the section called “Obtain Atlassian admin credentials”](#).

Set up the knowledge base integration

The setup wizard has three steps: authentication, knowledge base creation, and additional settings.

Authenticate your account

1. In the Amazon Quick console, choose **Knowledge**.
2. Under **Knowledge**, choose **Atlassian Confluence Cloud** and choose the Add (plus "+") button.
3. In the **Create Confluence knowledge base** dialog, under **Authentication method**, choose an existing connected account from the **Name** dropdown, or choose **Add account** to create a new connection.
4. If you are adding a new account, complete the following fields:
 - **Name** – A descriptive name for your connection.
 - **Description** (Optional) – Notes about the connection.
 - **Confluence URL** – The URL of your Atlassian site (for example, `https://your-site.atlassian.net`).
5. (Optional) Under **ACL Management**, select **Use Atlassian admin credentials** to provide Atlassian admin credentials. When selected, enter the following:
 - **API key** – The Atlassian admin API key.
 - **OrganizationID (UUID)** – Your Atlassian organization ID.
 - **Directory ID (UUID)** – Your Atlassian user directory ID.

Important

Atlassian admin credentials are required to enable document-level access controls (ACLs) in **Additional settings**. Without admin credentials, the ACL option is disabled. Admin credentials cannot be added after the knowledge base is created. For steps to obtain these credentials, see [the section called “Obtain Atlassian admin credentials”](#).

6. Choose **Next**.
7. Complete the Confluence Cloud authentication popup that appears. Review the requested permissions and choose **Accept** to authorize Amazon Quick to access your Confluence content.

Create the knowledge base

1. Under **Create knowledge base**, enter a **Name** for your knowledge base.
2. (Optional) Enter a **Description** with notes about how the knowledge base will be used.
3. Under **Confluence URLs**, paste the URLs of the Confluence spaces, blogs, or pages that you want to include. Choose **Add** after each URL.

Note

URLs that follow the structure `https://company.atlassian.net/wiki/spaces/space-key/overview` are treated as page URLs, not space URLs. To index an entire space, use the space URL without `/overview` (for example, `https://company.atlassian.net/wiki/spaces/space-key`).

4. Choose **Next: Additional settings** to configure access controls and indexing options, or choose **Create** to create the knowledge base with default settings.

Configure additional settings

1. To enable document-level access controls, select **Control document access with ACLs**. This option is only available if you provided Atlassian admin credentials in **Authentication method**. When enabled, Amazon Quick syncs access control lists from Confluence and verifies each user's permissions at query time. For more information about how access controls work, see [the section called "Document-level access controls"](#).

If you do not enable ACLs, access is controlled at the knowledge base level. Anyone who has access to the knowledge base can get insights from all of the content within it. When ACLs are enabled, access is controlled at the document level. Users who have access to the knowledge base only see answers from documents that they are authorized to access in Confluence.

 Important

ACL management cannot be changed after the knowledge base is created. If you need to change this setting, you must create a new knowledge base.

 Note

If you did not provide Atlassian admin credentials in **Authentication method**, this option is disabled. To enable ACLs, choose **Back** or cancel the wizard and start again with a connected account that includes admin credentials.

2. Under **Multi-media content, file size, and file patterns**, configure the following indexing options as needed:
 - **Visual content in documents** – Index visual content such as images and charts embedded in documents.
 - **Audio files** – Index audio file attachments.
 - **Video files** – Index video file attachments.
 - **Maximum single file size** – The maximum file size for individual attachments (default: 50 MB).
3. Choose **Create**.

Supported content types

- Confluence pages and blog posts
- Page and blog post attachments

When you add a Confluence space URL, Amazon Quick crawls all pages and blog posts within that space. For supported attachment file types and size limits, see [the section called “File size and content limits”](#).

Manage knowledge bases

Edit existing knowledge bases

1. In the Amazon Quick console, choose **Knowledge bases**.
2. Select your Confluence Cloud knowledge base from the list.
3. Choose the three-dot icon under **Actions**, then choose **Edit knowledge base**.
4. Update your configuration settings as needed and choose **Save**.

Troubleshoot

To edit, share, or delete your integration, see [the section called “Managing existing integrations”](#).

For general knowledge base troubleshooting, including sync issues and missing documents, see [the section called “Troubleshooting knowledge bases”](#).

Blocked OAuth app authorization

Symptoms:

- Error message: "Your site admin must authorize this app for the site *instance-name*.atlassian.net before the app can access your account."
- Choosing **Accept** in the consent dialog has no effect.

Cause:

Your Atlassian site administrator has blocked user-installed OAuth apps. When this setting is enabled, only a site or organization administrator can authorize new third-party apps.

Resolution steps:

Use one of the following options to resolve this issue.

- **Option 1 (Recommended): Admin authorizes the app directly**

1. An Atlassian site administrator navigates to Amazon Quick and starts a new knowledge base setup with Confluence Cloud.
2. Because the administrator has site-level permissions, a clean consent screen appears without the error.
3. The administrator chooses **Accept** to install the app.

After the administrator authorizes the app, all other users on the site can connect without issues.

- **Option 2: Temporarily allow user-installed apps** – An administrator goes to `admin.atlassian.com`, navigates to **Apps, Atlassian Apps**, then chooses the link for third-party and Marketplace apps. Under **Settings**, find **User Installed Apps** and toggle to allow user apps. After the user authorizes Amazon Quick, toggle the setting back to block user apps.

Important

Admin authorization applies per Atlassian site, not per organization. If your company has multiple sites (for example, `team-a.atlassian.net` and `team-b.atlassian.net`), each site requires separate authorization.

Note

While user-installed apps are unblocked (Option 2), any user on the site can authorize any OAuth app. Re-enable the block promptly after the user has connected.

Authentication popup fails

Symptoms:

- Authentication popup does not appear or closes immediately.
- Popup appears but fails to complete the OAuth flow.

Resolution steps:

1. Verify that your browser allows popups from the Amazon Quick console domain.
2. Verify that your Confluence Cloud instance is accessible from your network.
3. Try using a different browser or clearing your browser cache.

Missing content in knowledge base

Symptoms:

- Knowledge base sync completes but expected content is not indexed.
- Search results do not include content from specific spaces or pages.
- Only one document is indexed for an entire space.

Resolution steps:

1. Verify that the Confluence Cloud user who authenticated has access to the spaces and pages you selected during setup.
2. Check that the selected content types are supported (pages, blog posts, and attachments).
3. Review the content selection in your knowledge base configuration to confirm the correct spaces and pages are included.
4. Check your Confluence URLs for the /overview suffix. URLs that end with /wiki/spaces/*space-key*/overview are treated as a single page URL, not a full space. If you intended to index the entire space, use the space URL without /overview (for example, <https://company.atlassian.net/wiki/spaces/space-key>).

ACL-related issues

No results from ACL-enabled knowledge base

- Verify that the end user has signed in to Confluence when prompted during their first query. The sign-in is required for real-time permission verification.
- Verify that the end user has access to the relevant Confluence content in their Confluence instance.

Documents skipped during sync

- If sync reports show items with status SKIPPED, verify that the authenticating user has access to the Confluence spaces and pages included in the knowledge base.
- For more information about verifying document access, see [the section called “Check document access \(ACL verification\)”](#).

Document-level access controls

Confluence Cloud knowledge bases optionally support document-level access control. When enabled, Amazon Quick syncs access control lists (ACLs) from Confluence during each crawl and

verifies each user's permissions at query time. Users only see answers from documents they are authorized to access in Confluence.

How it works

When a user queries an Amazon Quick agent that uses a Confluence knowledge base with ACL management enabled, the system enforces access controls in two stages:

1. **Pre-retrieval filtering** – Amazon Quick performs a semantic search against the vector index to find the most relevant document passages. The system applies access control lists that were synced from Confluence during the last crawl. This produces a preliminary set of candidate documents.
2. **Real-time verification** – The system verifies the candidate documents in real time by checking the querying user's current access in Confluence. Only documents the user is currently authorized to access appear in the response.

This two-stage approach provides document-level access control that stays current even when Confluence permissions change between syncs.

Amazon Quick crawls the following Confluence ACL resources:

- **Spaces** – Space permissions apply to all documents in the space by default.
- **Pages** – Pages can be restricted to specific users and groups. Nested pages inherit restrictions from the parent page and can have their own restrictions.
- **Blogs** – Blog posts can be restricted to specific users and groups in the space.
- **Attachments** – Files attached to pages or blog posts inherit the access controls of their parent document.

Enable ACL management

You configure ACL management during knowledge base creation in the **Additional settings** step. Select the **Control document access with ACLs** checkbox to enable it. This option requires Atlassian admin credentials, which you provide during the **Authentication method** step. Without admin credentials, the ACL option is disabled.

⚠ Important

You cannot change ACL management after you create the knowledge base. If you need to change this setting, you must create a new knowledge base.

Atlassian admin credentials allow Amazon Quick to access all user and group information from your Confluence instance, regardless of individual email visibility settings. For steps to obtain admin credentials from your Atlassian organization, see [the section called “Obtain Atlassian admin credentials”](#). For the knowledge base setup steps, see [the section called “Authenticate your account”](#).

For more information about ACL best practices, see [the section called “Best practices for managing ACLs in knowledge bases”](#).

Real-time access verification

When a user submits a query that involves content from an ACL-enabled Confluence knowledge base, Amazon Quick verifies the user's access in real time:

1. The user asks a question in the Quick chat assistant.
2. If the answer involves Confluence content from an ACL-enabled knowledge base, Quick prompts the user to sign in to Confluence.
3. The user signs in with their Confluence email and password and accepts the authorization dialog.
4. Quick uses the user's credentials to verify access to each candidate document in real time against the Confluence API.
5. Only documents the user currently has access to in Confluence appear in the response.

The sign-in is a one-time step. After signing in, users are not prompted again until their session expires.

ℹ Note

If real-time permission verification fails (for example, if the Confluence API is temporarily unavailable), users see an error message prompting them to retry. Amazon Quick does not fall back to cached permissions — real-time verification is mandatory to ensure access control accuracy.

Obtain Atlassian admin credentials

To provide Atlassian admin credentials during Confluence knowledge base setup, your Atlassian organization administrator must complete the following steps.

Get your API key and Organization ID

1. Sign in to the [Atlassian admin portal](#) with administrator permissions.
2. Open the Administration app for your organization. The URL should look like: `https://admin.atlassian.com/o/ORGANIZATION-UUID/overview`.
3. Copy the **Organization ID** from the URL.
4. Choose **Settings**, then choose **API Keys**.
5. Choose **Create API key**.
6. Select the following scopes for the API key:
 - `read:directories:admin`
 - `read:workspaces:admin`
7. Copy and save both the **Organization ID** and **API Key**.

Note

API keys expire. Monitor the expiration date and update your data source credentials before the key expires.

Get your Directory ID

Use the Atlassian Admin Workspace API to retrieve your Directory ID.

1. Run the following command, replacing **ORGANIZATION-ID** with your Organization ID and **API-KEY** with your API key:

```
curl --request POST \  
  --url 'https://api.atlassian.com/admin/v2/orgs/ORGANIZATION-ID/workspaces' \  
  --header 'Authorization: Bearer API-KEY' \  
  --header 'Accept: application/json' \  
  --header 'Content-Type: application/json' \  
  --data '{
```

```
"query": {
  "field": {
    "name": "attributes.type",
    "values": ["confluence"]
  }
},
"limit": 20
}'
```

This query filters results to Confluence workspaces only, so you don't need to page through all workspace types.

2. In the API response, find the workspace entry that matches your Confluence Cloud instance. Verify the workspace name matches your instance.
3. Copy the `directory` value from the `attributes` section. This is your **Directory ID**.

For more information about Atlassian admin API scopes, see [Atlassian API scopes documentation](#). For API details, see [Atlassian Admin Workspace API reference](#).

Limitations

- **Atlassian admin credentials required** – Document-level access controls require Atlassian admin credentials, which must be provided during knowledge base setup. You cannot enable ACLs without admin credentials, and you cannot add admin credentials after the knowledge base is created.
- **Real-time verification is mandatory** – Amazon Quick always performs real-time permission checks at query time for ACL-enabled knowledge bases. If the Confluence API is unavailable, queries that involve ACL-protected content return an error rather than falling back to cached permissions.

For general ACL limitations and best practices, including ACL permanence, research compatibility, and email address management, see [the section called “Best practices for managing ACLs in knowledge bases”](#).

Next steps

To verify document-level access controls and troubleshoot permission issues, see [the section called “Check document access \(ACL verification\)”](#). For information about setting up the Confluence knowledge base integration, see [the section called “Set up the knowledge base integration”](#).

Atlassian Jira Cloud integration

Use the Atlassian Jira Cloud connector to create, update, search, and manage Jira issues, projects, sprints, and users directly in Amazon Quick through natural language.

Setting up this integration involves two steps. First, you create an OAuth 2.0 (3LO) app in the Atlassian Developer Console and configure its permissions. Then, you create the integration in Amazon Quick and connect it to your Atlassian app. For information about the authentication methods that Amazon Quick supports, see [the section called "Authentication methods"](#).

Before you begin

Make sure you have the following before you set up the integration.

- Atlassian Jira Cloud.
- Access to the [Atlassian Developer Console](#) to create or manage an OAuth app.
- For subscription requirements, see [the section called "Set up integrations in the console"](#).

Configure the Atlassian Developer Console

If you plan to use user authentication (3LO), create an OAuth 2.0 app in the Atlassian Developer Console before you configure Amazon Quick. Complete all of the following steps before moving to the Amazon Quick console.

If you plan to use service authentication (API Key) only, you can skip this section and proceed to [the section called "Set up the integration in Amazon Quick"](#).

For more information about OAuth 2.0 (3LO) apps, see [OAuth 2.0 \(3LO\) apps](#) in the Atlassian developer documentation.

Create an OAuth 2.0 (3LO) app

Amazon Quick uses an Atlassian OAuth 2.0 (3LO) app to authenticate with your Atlassian Cloud product on behalf of your users. Create this app in the Atlassian Developer Console before you configure Amazon Quick.

1. Open the [Atlassian Developer Console](#) and sign in with your Atlassian account.
2. Choose **Create**, then choose **OAuth 2.0 integration**.

3. For **Name**, enter a descriptive name for your integration, for example *your-app-name* connector.
4. Review and accept the Atlassian developer terms.
5. Choose **Create**.

Configure permissions

After you create the OAuth 2.0 app, add the API permissions that Amazon Quick needs to interact with your Atlassian product.

1. From your app in the Atlassian Developer Console, choose **Permissions** in the left navigation.
2. Find the API for your Atlassian product (for example, **Jira API** or **Confluence API**) and choose **Add**. The button changes to **Configure** after the API is added.
3. Choose **Configure**. The scopes page opens with **Classic scopes** and **Granular scopes** tabs.
4. On the **Classic scopes** tab, choose **Edit Scopes**. Select the required classic scopes and choose **Save**.
5. Choose the **Granular scopes** tab, then choose **Edit Scopes**. Select the required granular scopes and choose **Save**.

For the specific scopes required for your integration, see the scopes section that follows.

Configure API permissions

Add the following scopes to your OAuth 2.0 app for the Jira Cloud action integration.

Classic scopes

On the **Classic scopes** tab, choose **Edit Scopes** and select the following scopes.

Jira action integration – classic scopes

Scope	Description
read:jira-work	Read Jira project and issue data, search for issues, and objects associated with issues like attachments and worklogs.
manage:jira-project	Create and edit project settings and create new project-level objects (for example, versions and components).

Scope	Description
manage:jira-configuration	Take Jira administration actions (for example, create projects and custom fields, view workflows, manage issue link types).
read:jira-user	View user information in Jira that the user has access to, including usernames, email addresses, and avatars.
write:jira-work	Create and edit issues in Jira, post comments as the user, create worklogs, and delete issues.
manage:jira-webhook	Fetch, register, refresh, and delete dynamically declared Jira webhooks.

Granular scopes

Choose the **Granular scopes** tab, then choose **Edit Scopes**. Use the search bar to find the scopes below. For example, search for `sprint:jira-software` to find sprint-related scopes.

Jira action integration – granular scopes

Scope	Description
read:board-scope:jira-software	Read board configurations.
read:sprint:jira-software	Read sprint information.
write:sprint:jira-software	Create and modify sprints.
delete:sprint:jira-software	Delete sprints.
write:board-scope:jira-software	Manage board configurations.
read:project:jira	Read project details.

Configure authorization

Set the callback URL so that Atlassian can redirect users back to Amazon Quick after they authorize the app.

1. From your app in the Atlassian Developer Console, choose **Authorization** in the left navigation.
2. Next to **OAuth 2.0 (3LO)**, choose **Add**.
3. For **Callback URLs**, enter `https://region.quicksight.aws.amazon.com/sn/oauthcallback`. Replace *region* with the AWS Region where your Amazon Quick instance is deployed, for example `us-east-1`.
4. Choose **Save changes**.

Record your credentials

Before you leave the Atlassian Developer Console, confirm that you have the following values. You need them for the Amazon Quick configuration.

1. From your app in the Atlassian Developer Console, choose **Settings** in the left navigation.
2. Under **Authentication details**, copy the **Client ID** and **Secret** values.

Required credentials from Atlassian Developer Console

Value	Where to find it
Client ID	Settings page, under Authentication details
Secret	Settings page, under Authentication details

Set up the integration in Amazon Quick

After you prepare your authentication credentials, create the integration in Amazon Quick.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Atlassian Jira Cloud**.
4. In the **Create integration** wizard, fill in the following fields:

- **Name** – Descriptive name for your Jira integration.
 - **Description** (Optional) – Notes about how this connection will be used.
 - **Connection type** – Choose **Public network**.
5. Under **Authentication settings**, choose your authentication method and fill in the required fields:
- a. For **User authentication**, configure the following fields:
 - **Base URL** – Your Jira instance URL for API calls. This is not the same URL that users log into. It resembles the following: `https://api.atlassian.com/ex/jira/yourInstanceId`. To find your instance ID, navigate to `https://your-domain.atlassian.net/_edge/tenant_info`.
 - **Client ID** – Client ID from the Settings page of your Atlassian OAuth app.
 - **Client secret** – Secret from the Settings page of your Atlassian OAuth app.
 - **Token URL** – `https://auth.atlassian.com/oauth/token`
 - **Authorization URL** – `https://auth.atlassian.com/authorize`
 - **Redirect URL** – This field is pre-populated with your Amazon Quick callback URL.
 - b. For **Service authentication**, configure the following fields:
 - **API Key** – Jira API token.
 - **Base URL** – Your Jira instance URL for API calls.
 - **Email** – Associated user account email.
6. Choose **Create and continue**.
7. (Optional) On the **Share integration** page, choose users to share the integration with.

Important

Jira Cloud may return HTTP 200 success responses even when API tokens are revoked or improperly configured. For more information, see [JRACLOUD-82932](#). If your integration appears to connect successfully but actions fail unexpectedly, verify that your API token is valid and has not been revoked.

Available actions

After you set up the integration, the following actions are available.

Jira Cloud available actions

Action	Description
Add Attachment	Add an attachment to an issue.
Add Comment	Add new comment.
Change Issue Status	Change task status of an issue.
Create Issue	Create new issue or subtask.
Create Project	Create new project.
Create Sprint	Create a sprint in a project.
Delete Comment	Remove comment.
Delete Issue	Delete an issue in a project.
Delete Project	Remove project.
Delete Sprint	Delete a sprint in a project.
Edit Issue	Modify issue.
Find Users	Search for a Jira user.
Get All Labels	View all labels.
Get All Users	List all Jira users.
Get Attachment Content	View the contents of an attachment.
Get Comments	View issue comments.
Get Issue	View details of an issue in a project.
Get Issue Types For Project	View project issue types.

Action	Description
Get Priorities	View issue priorities.
Get Project	View project details.
Get Sprint	View details of a sprint in a project.
Move Issues to Backlog	Move issues to backlog.
Move Issues To Sprint And Rank	Assign an issue to a sprint.
Search Issues	Search for issues.
Search Projects	Find visible projects.
Search Statuses	Search issue statuses.
Update Comment	Edit comment.
Update Project	Modify project.
Update Sprint	Update sprint details.

Note

The actions you can use depend on the permissions configured in your Jira Cloud instance and your authentication method.

Manage and troubleshoot

To edit, share, or delete your integration, see [the section called “Managing existing integrations”](#).

Authentication issues

- **Incorrect app configuration** – Verify the OAuth app in the Atlassian Developer Console includes the required scopes and that the redirect URI matches your Amazon Quick configuration.

- **Expired or revoked API token** – If using service authentication, check that the API token has not expired or been revoked. Due to a known Jira Cloud behavior ([JRACLOUD-82932](#)), the integration may appear to connect successfully even with invalid tokens.
- **Incorrect Base URL** – The Base URL for API calls is not the same as the Jira Cloud login URL. Verify you are using the API URL format: `https://api.atlassian.com/ex/jira/yourInstanceId`. To find your instance ID, navigate to `https://your-domain.atlassian.net/_edge/tenant_info`.

Common error messages

- **Access denied. You do not have permission to perform this action** – The authenticated user does not have the required permissions in Jira Cloud. Contact your Jira Cloud administrator to verify and grant appropriate permissions.
- **OAuth 2.0 authorization failed** – Verify the client ID, client secret, and OAuth scopes are configured correctly in both the Atlassian Developer Console and Amazon Quick.

AWS Agent Registry integration

With Amazon Quick, you can connect to the [AWS Agent Registry](#). Use this integration to surface the remote Model Context Protocol (MCP) servers registered in your Agent Registry as native Quick connectors. Your organization can maintain a single source of truth for its MCP servers in the Agent Registry while giving Quick users governed access to them.

As an account administrator, you link one Agent Registry to your Quick account from the Quick administration console. After the registry is linked, you see the registry's remote MCP records as pre-configured connector cards on the **Connectors** page. You can then create a connector from one. The connector works like any other Quick connector across Quick Chat, agents, apps, Amazon Quick Flows, and Amazon Quick Research.

Everything happens through the Quick administration console and the **Connectors** page. There is no separate command line or SDK to install. Records are read from the Agent Registry when the **Connectors** page loads. Nothing from the Agent Registry is copied into Quick.

What is supported

The following table shows which Agent Registry records and configurations Amazon Quick supports.

AWS Agent Registry support in Amazon Quick

Supported	Not supported
MCP records that use the <code>mcpServer</code> descriptor.	Skill and custom record types.
Agent records accessed through the MCP protocol (records that use the <code>mcpServer</code> descriptor).	Agent-to-agent (A2A) descriptors.
Remote MCP servers whose record specifies a remote server URL at <code>descriptors.mcpServer.data.remotes[].url</code> .	Local MCP endpoints, such as <code>npx</code> , <code>docker</code> , and local or standard input/output (stdio) servers.

For more information about the account, Region, authorization, and status requirements that a registry must meet, see [the section called “Prerequisites”](#).

Prerequisites

Before an administrator can link a registry, make sure that all of the following are in place:

- **Registry location** – An AWS Agent Registry exists in the same AWS account and the same AWS Region as your Quick account. Cross-account and cross-Region registries are not supported.
- **Registry configuration** – The registry uses AWS IAM (AWS_IAM) authorization with Signature Version 4 (SigV4) and is in the READY status. Registries that use JSON Web Token (JWT) authorization are not supported and do not appear in the Quick administration console.
- **Registry namespace** – Only registries in the `agent-registry` namespace are supported. Older Amazon Bedrock AgentCore registries in the `bedrock-agentcore` namespace are not supported.
- **One registry for each account** – You can connect one Agent Registry for each Quick account.
- **Administrator access** – The administrator signs in to the Quick administration console with an IAM identity that has permission to list and view registries. For more information, see [the section called “IAM permissions”](#).

IAM permissions

The integration uses two distinct sets of permissions that apply to different steps. Keep them separate.

Administrator identity (to browse and select a registry)

The IAM identity that the administrator uses to sign in to the administration console needs the following permissions on the registry. Without these permissions, the **AWS Agent Registry** page cannot list your registries.

- `agent-registry:ListRegistries`

Service role (to load records on the Connectors page)

How you satisfy this requirement depends on which service role your account uses:

- **Quick-managed role** (`aws-quicksight-agent-registry-role-v0`) – Quick grants these permissions automatically when the administrator enables the registry. No action is required.
- **Customer-managed service role** – An administrator must manually add the following permissions to the role for the connected registry:
 - `agent-registry:ListDiscoverableRegistryRecords`
 - `agent-registry:SearchDiscoverableRegistryRecords`
 - `agent-registry:GetDiscoverableRegistryRecord`

If a customer-managed role is missing these permissions, the **Connectors** page cannot load registry records. Quick detects the customer-managed role and displays the role ARN and the required permissions so that the administrator knows exactly what to add. For a complete policy example, see [the section called “IAM policy reference”](#).

Link a registry (administrator)

After the prerequisites and IAM permissions are in place, you link the registry as an account administrator.

1. In the Quick administration console, go to **Manage account** -> **Permissions** -> **AWS Agent Registry**.
2. Review the list of AWS Agent Registries in your account. Only registries that meet the requirements in [the section called “Prerequisites”](#) appear.

3. Turn on the toggle for the registry that you want to connect. Only one registry can be active for each account.
4. Confirm the selection. Quick grants the account's service role the read-only Agent Registry permissions that it needs and links the registry to your Quick account.

Note

When your account uses the Quick-managed service role, linking the registry is the entire administrator action. You do not need to create a role or edit a trust policy. Quick sets up the trust relationship and permissions for you when you enable the registry.

Create a connector (user)

After an administrator links a registry, you can create a connector from it.

1. Open the **Connectors** page.
2. Choose the **Create for your team** tab. Registry-sourced connectors appear on this tab, not on the **Available** tab.
3. Find the MCP connector sourced from the registry by searching or browsing. Each connector comes pre-populated with its MCP server URL, name, and description.
4. Choose the connector to begin setup.
5. Complete the **Authenticate** step by configuring or signing in with the required credentials, such as OAuth. The Agent Registry does not store authentication credentials, so each user provides or authenticates with their own credentials.
6. On the **Manage permissions** step, choose which tools to turn on or turn off.
7. Choose **Create and continue**.
8. Share the connector with the appropriate user groups.

Note

Registry-sourced connectors are classified as **Custom MCP** connectors. This classification matters for settings such as [custom permissions](#).

After setup

After a connector is created, it is available across Quick Chat, agents, apps, Amazon Quick Flows, and Amazon Quick Research, like any other Quick connector.

The connector is an independent Quick resource. Removing the registry link in the administration console does not delete connectors that were already created from it.

Manage connectors

To edit, share, or delete a connector that you created from the Agent Registry, see [the section called “Managing existing integrations”](#).

Troubleshooting

- **Registries do not appear on the AWS Agent Registry page** – Confirm that the administrator's IAM identity has the `agent-registry:ListRegistries` permission. Also confirm that the registry uses AWS IAM authorization (registries that use JWT authorization are not listed), is in the READY status, and is in the same AWS account and Region as your Quick account.
- **The Connectors page cannot load registry records** – If your account uses a customer-managed service role, confirm that the role has the required `agent-registry` permissions for the connected registry. Quick displays the role ARN and the required permissions so that you know what to add. For the policy, see [the section called “IAM policy reference”](#).
- **A record is Approved but no connector card appears** – Quick reads the MCP server endpoint only from `descriptors.mcpServer.data.remotes[].url`. Verify that the field is populated:

```
aws agent-registry-control get-registry-record \  
  --registry-id <registry-id> --record-id <record-id> --region <region>
```

If the descriptor has no data, or data contains no `remotes[].url`, the record is not surfaced as a connector. A record can reach Approved status in this state. Populate `descriptors.mcpServer.data` with the MCP server definition, including `remotes[].url`. If you set data through the API rather than the console, you must also supply `dataSchemaVersion`, or the request fails with `ValidationException: Schema validation failed`.

Limitations

- Only remote MCP servers are supported. Local MCP endpoints, such as npx, docker, and local or stdio servers, are not supported.
- Only MCP records and agent records accessed through the MCP protocol are supported. Agent-to-agent (A2A) descriptors, skill records, and custom records are not supported.

For more information about account, Region, authorization, and registry-count requirements, see [the section called “Prerequisites”](#).

IAM policy reference

If your account uses the Quick-managed role (aws-quicksight-agent-registry-role-v0), you do not need this policy. Quick provisions the role and attaches the required Agent Registry permissions automatically when the administrator enables a registry. This policy applies only when your account uses a customer-managed service role.

If your account uses a customer-managed service role, attach a policy with the following permissions, scoped to the registry that you are connecting. Replace the example resource ARN with your registry's ARN.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "agent-registry:ListDiscoverableRegistryRecords",
        "agent-registry:SearchDiscoverableRegistryRecords",
        "agent-registry:GetDiscoverableRegistryRecord"
      ],
      "Resource": [
        "arn:aws:agent-registry:us-west-2:111122223333:registry/AbCdEf012345",
        "arn:aws:agent-registry:*:111122223333:registry/AbCdEf012345/record/*"
      ]
    }
  ]
}
```

BambooHR integration

Connect Amazon Quick to your BambooHR system to manage employee data, time-off requests, and HR processes. You can create, update, and manage HR content without leaving your Amazon Quick environment. For Amazon Quick subscription requirements, see [the section called “Set up integrations in the console”](#).

What you can do

With BambooHR integration, you can perform actions within your BambooHR systems through the BambooHR API.

Connector

Create, update, and manage employee records, time-off requests, and other HR processes through the BambooHR API.

Set up BambooHR integration

Follow these steps to connect Amazon Quick to your BambooHR system.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **BambooHR**.
4. Complete the integration details:
 - **Name** - Enter a descriptive name for your BambooHR integration.
 - **Description** (Optional) - Describe the purpose of this integration.
5. Choose connection type (user or service authentication).
6. Complete the connection settings based on authentication method:
 - **For User authentication (OAuth):**
 - **Base URL** - Your BambooHR instance URL.
 - **Client ID** - OAuth client identifier.
 - **Client Secret** - OAuth client secret.
 - **Token URL** - OAuth token endpoint.
 - **Auth URL** - OAuth authorization endpoint.

- **Redirect URL** - OAuth callback URL.

Required OAuth scopes: When you create your BambooHR OAuth application, configure the scopes you need for your use case. Common scopes include:

- `employee` - Access employee information.
- `employee.write` - Write employee information.
- `time_off` - Access time off information.
- `time_off.write` - Write time off information.
- `company:info` - Access company information.
- `payroll` - Access payroll data.

 Note

Additional scopes may be required depending on the specific BambooHR actions you plan to use. Consult your BambooHR administrator for the complete list of available scopes.

- **For Service authentication (API Key):**
 - **Base URL** - Your BambooHR instance URL.
 - **API Key** - Your BambooHR API key.
 - **Email** - Email address associated with the API key.

7. Select **Create and continue**.
8. Select users to share the integration with.
9. Click **Next**.

Manage BambooHR integration

You can perform these management tasks for your BambooHR integration:

Edit integration settings

To modify your BambooHR integration settings:

1. In the Amazon Quick console, choose **Connectors**.
2. Choose **BambooHR** from the connector list.

3. Select your integration from the list and choose **Edit**.
4. Modify your integration settings as needed.
5. Choose **Save changes**.

Share integration

You can share your BambooHR connector with other users in your organization.

1. From the BambooHR integration details page, choose **Share**.
2. Configure your sharing options and permission levels.
3. Choose **Share integration**.

Delete integration

To permanently remove your BambooHR integration:

1. From the BambooHR integration details page, choose **Delete**.
2. Review the deletion impact, including any workflows or automations using this integration.
3. Type the integration name to confirm deletion.
4. Choose **Delete integration**.

What happens next

After you complete the setup, your BambooHR integration appears in the integrations list. You can use it in Amazon Quick workflows, automations, and AI agents to perform HR-related tasks.

Troubleshoot BambooHR integration

If you encounter issues with your BambooHR integration, try these solutions:

Authentication failures

Verify that your BambooHR credentials are correct and that the API key or OAuth application has the necessary permissions.

Connection timeouts

Check that your BambooHR instance URL is correct and accessible from Amazon Quick.

Permission errors

Ensure that the authenticated user or API key has the required permissions to perform the requested HR operations in BambooHR.

Action execution failures

Review the action parameters and ensure they match the expected format for BambooHR API calls.

Box integration

Use the Box integration to perform actions on Box content, or to create knowledge bases from Box files and folders for AI-powered search and Q&A.

Integration capabilities

The Box integration offers two connector types.

Connector

Access Box AI features, manage files and folders, and organize content in hubs directly in Amazon Quick through natural language.

Knowledge base

Index Box files and folders. Amazon Quick agents can then search and answer questions about the content.

Box action integration

With the Box connector, you can access Box AI features, manage files and folders, and organize content in hubs directly in Amazon Quick through natural language.

Amazon Quick supports the following authentication methods for Box Agent.

- **Default OAuth app** – Uses an AWS-managed OAuth application. No additional credentials are needed. You authenticate directly with your Box account.
- **Custom OAuth app** – Uses a customer-managed OAuth 2.0 application registered in the Box Developer Console. This option gives your organization full control over the OAuth configuration.

For more information about the authentication methods that Amazon Quick supports, see [the section called "Authentication methods"](#).

Before you begin

Make sure that you have the following before you set up the integration.

- A Box account with access to files and folders.
- For **Custom OAuth app**: Access to the Box Developer Console to create a custom app. For more information, see [OAuth 2.0 setup](#) in the Box documentation.
- For Amazon Quick subscription requirements, see [the section called "Set up integrations in the console"](#).

Setting up the connector in Amazon Quick

Connect from the Available tab

If you want to use Default OAuth app authentication, you can connect directly from the **Available** tab without additional configuration.

1. In the Amazon Quick console, choose **Connectors**.
2. On the **Available** tab, find **Box Agent** and choose **Connect**.
3. Complete the Box sign-in flow and grant the requested permissions.

To configure a connector with Custom OAuth app instead, use the **Create for your team** tab as described below.

Create from the Create for your team tab

If you use Custom OAuth app authentication, create a custom app in the Box Developer Console before configuring Amazon Quick. For setup instructions, see [OAuth 2.0 setup](#) in the Box documentation.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Box Agent**.

 **Note**

If a Box Agent connector already exists, a dialog appears with your existing connectors. To use an existing connector, choose it. To create a new one, choose **No, create new**.

4. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
5. For **Connection type**, choose **Public network**.
6. For **OAuth Configuration**, choose one of the following:

a. For **Default OAuth app**:

No additional credentials are needed. Choose **Next** to continue.

b. For **Custom OAuth app**, configure the following fields:
 - **Base URL** (Optional) – The Box API base URL. Example: `https://mcp.box.com`
 - **Client ID** – The client ID from your Box app.
 - **Client secret** – The client secret from your Box app.
7. Choose **Next**.
8. A Box authorization window opens. Review the requested permissions and choose **Grant access to Box**.
9. On the **Review** page, review the available actions for the connector. Choose **Next**.
10. On the **Publish** page, choose who can access the connector. You can enable access for everyone in your organization or search for specific teams or groups.
11. Choose **Publish**.

Available actions

After you set up the connector, the following actions are available.

Box Agent available actions

Category	Action	Description
AI	AI Q&A (Hub)	Ask a question to a Box Hub using Box AI.
AI	AI Q&A (Single File)	Ask a question to a single file using Box AI.

Category	Action	Description
AI	AI Q&A (Multiple Files)	Ask a question to multiple files using Box AI.
AI	AI Extract (Freeform)	Extract metadata from files using Box AI in freeform format.
AI	AI Extract (Structured)	Extract structured metadata from files using Box AI based on custom fields or a metadata template.
Files	Get File Content	Extract and return file content in text format for files under 50 MB.
Files	Get File Details	Get comprehensive file information including metadata, permissions, and version details.
Files	Update File Properties	Update file metadata including name, description, tags, and collections.
Files	Upload File	Upload a new file to Box.
Files	Upload File Version	Upload a new version of an existing file.
Files	Search Files	Search for files using keywords with support for metadata filters and file extension filtering.
Folders	Create Folder	Create a new folder in Box.
Folders	Get Folder Details	Retrieve comprehensive folder information including metadata and collaboration settings.
Folders	List Folder Content	List files, folders, and web links in a folder.
Folders	Update Folder Properties	Update folder metadata including name, description, tags, and collections.
Folders	Search Folders	Search for folders by name using keyword matching.

Category	Action	Description
Hubs	Create Hub	Create a new hub for organizing content.
Hubs	Get Hub Details	Retrieve information about a specific hub.
Hubs	Get Hub Items	Retrieve items within a hub including files, folders, and web links.
Hubs	List Hubs	List all hubs accessible to the current user.
Hubs	Update Hub	Update the title or description of a hub.
Hubs	Add Items to Hub	Add files, folders, or web links to a hub.
Comments and tasks	Create File Comment	Create a new comment on a file.
Comments and tasks	List File Comments	List all comments on a file.
Comments and tasks	List Tasks	List all tasks associated with a file.
Users	Who Am I	Return information about the currently authenticated user.

Manage and troubleshoot

For instructions on editing, sharing, or deleting your connector, see [the section called “Managing existing integrations”](#).

- **Authentication popup fails** – Verify that your browser allows popups from the Amazon Quick console domain.
- **Invalid client credentials (Custom OAuth app)** – Verify that the Client ID and Client secret match the values in your Box Developer Console app.
- **Insufficient permissions** – Verify that your Box account has access to the files, folders, or hubs you are trying to access.

Box knowledge base integration

Use the Box knowledge base integration to index Box content so that Amazon Quick agents can search and answer questions about it. You can sync all of the Box content that you have access to, or choose specific Box folders and files. You can also configure advanced indexing settings when needed.

Access control limitation

This user-managed setup does not support document-level access controls (ACLs). ACLs are mechanisms that control which users can access specific documents.

Before you begin

Make sure you have the following before you set up the integration.

- A Box account with access to the files and folders that you want to include in the knowledge base.
- For Quick subscription requirements, see [the section called “Set up integrations in the console”](#).

Setting up the knowledge base integration

The setup wizard has two steps: create the knowledge base, and configure optional additional settings.

Creating the knowledge base

1. Sign in to the Amazon Quick console, and then choose **Knowledge**.
2. Under **Knowledge bases**, find **Box**, and then choose the **Add (+)** icon.
3. In the **Create Box knowledge base** dialog, under **Connected account**, choose **Sign in to Box**. Complete the Box sign-in flow and grant the requested permissions.

Note

The Box knowledge base integration uses Default OAuth app authentication. You authenticate directly with your Box account, and no additional credentials are needed.

4. Under **Create knowledge base**, enter a **Name** for your knowledge base.
5. (Optional) Enter a **Description** with notes about how the knowledge base will be used.
6. Under **Content**, choose which Box content to include:
 - **Add all content** – Includes all of the Box content that you have access to.
 - **Add specific content** – Includes only the Box folders and files that you specify. In the **Box file or folder URLs** field, enter a Box file or folder URL (for example, `https://app.box.com/file/987654321`) and choose **Add**. Repeat for each URL that you want to include.
7. Choose **Next: Additional settings** to configure indexing options, or choose **Create** to create the knowledge base with default settings.

Configuring additional settings

In the **Additional settings (optional)** step, you can configure indexing options under **Multi-media content, file size, and file patterns**.

Under **Advanced indexing**, configure the following options as needed:

- **Visual content in documents** – Extracts and indexes visual content such as images and charts embedded in documents. This option is enabled by default.
- **Audio files** – Transcribes and indexes audio files.
- **Video files** – Transcribes and indexes video files.
- **Maximum single file size** – The maximum file size for individual files, in MB (default: 500 MB).

Choose **Create** to create the knowledge base. After you choose **Create**, the data sync starts automatically.

Managing knowledge bases

Editing existing knowledge bases

1. Sign in to the Amazon Quick console, and then choose **Knowledge bases**.
2. Select your Box knowledge base from the list.
3. Choose the **More options** icon (:) under **Actions**, then choose **Edit knowledge base**.
4. Update your configuration settings as needed and choose **Save**.

Troubleshoot the Box knowledge base integration

To edit, share, or delete your integration, see [the section called “Managing existing integrations”](#).

For general knowledge base troubleshooting, including sync issues and missing documents, see [the section called “Troubleshooting knowledge bases”](#).

Canva integration

With Canva integration in Amazon Quick, you can create, edit, and manage designs and visual content through MCP server connectivity. This integration provides action capabilities for design operations and content creation.

What you can do

Canva integration provides connector capabilities through MCP server connectivity:

- Create new designs from templates
- Edit existing designs and presentations
- Manage design assets and media
- Export designs in various formats
- Share designs and collaborate with team members

Available tools

The Canva MCP server typically provides these tools:

- `comment-on-design` - Add a comment on a Canva design. You need to provide the design ID and the message text. The comment will be added to the design and visible to all users with access to the design.
- `create-design-from-candidate` - Create a new Canva design from a generation job candidate ID. This converts an AI-generated design candidate into an editable Canva design. If successful, returns a design summary containing a design ID that can be used with the `editing_transaction_tools`. To make changes to the design, first call this tool with the `candidate_id` from generate-design results, then use the returned `design_id` with `start-editing-transaction` and subsequent editing tools.
- `create-folder` - Create a new folder in Canva. You can create it at the root level or inside another folder.

- `export-design` - Export a Canva design, doc, presentation, whiteboard, videos and other Canva content types to various formats (PDF, JPG, PNG, PPTX, GIF, MP4). You should use the `get-export-formats` tool first to check which export formats are supported for the design. This tool provides a download URL for the exported file that you can share with users. Always display this download URL to users so they can access their exported content.
- `generate-design` - Generate designs with AI. Use the 'query' parameter to tell AI what you want to create.
- `get-design` - Get detailed information about a Canva design, such as a doc, presentation, whiteboard, video, or sheet. This includes design owner information, title, URLs for editing and viewing, thumbnail, created/updated time, and page count. This tool doesn't work on folders or images. You must provide the design ID, which you can find by using the `search-designs` or `list-folder-items` tools.
- `get-design-content` - Get the text content of a doc, presentation, whiteboard, social media post, sheet, and other designs in Canva. Use this when you only need to read text content without making changes. IMPORTANT: If the user wants to edit, update, change, translate, or fix content, use `start-editing-transaction` instead as it shows content AND enables editing. You must provide the design ID, which you can find with the `search-designs` tool. When given a URL to a Canva design, you can extract the design ID from the URL. Do not use web search to get the content of a design as the content is not accessible to the public. Example URL: `https://www.canva.com/design/{design_id}`.
- `get-design-pages` - Get a list of pages in a Canva design, such as a presentation. Each page includes its index and thumbnail. This tool doesn't work on designs that don't have pages (e.g. Canva docs). You must provide the design ID, which you can find using tools like `search-designs` or `list-folder-items`. You can use 'offset' and 'limit' to paginate through the pages. Use `get-design` to find out the total number of pages, if needed.
- `get-export-formats` - Get the available export formats for a Canva design. This tool lists the formats (PDF, JPG, PNG, PPTX, GIF, MP4) that are supported for exporting the design. Use this tool before calling `export-design` to ensure the format you want is supported.
- `import-design-from-url` - Import a file from a URL as a new Canva design
- `list-comments` - Get a list of comments for a particular Canva design. Comments are discussions attached to designs that help teams collaborate. Each comment can contain replies, mentions, and can be marked as resolved or unresolved. You need to provide the design ID, which you can find using the `search-designs` tool. Use the continuation token to get the next page of results, if needed. You can filter comments by their resolution status (resolved or unresolved) using the `comment_resolution` parameter.

- `list-folder-items` - List items in a Canva folder. An item can be a design, folder, or image. You can filter by item type and sort the results. Use the continuation token to get the next page of results if needed.
- `list-replies` - Get a list of replies for a specific comment on a Canva design. Comments can contain multiple replies from different users. These replies help teams collaborate by allowing discussion on a specific comment. You need to provide the design ID and comment ID. You can find the design ID using the `search-designs` tool and the comment ID using the `list-comments` tool. Use the continuation token to get the next page of results, if needed.
- `move-item-to-folder` - Move items (designs, folders, images) to a specified Canva folder
- `reply-to-comment` - Reply to an existing comment on a Canva design. You need to provide the design ID, comment ID, and your reply message. The reply will be added to the specified comment and visible to all users with access to the design.
- `resize-design` - Resize a Canva design to a preset or custom size. The tool will provide a summary of the new resized design, including its metadata.
- `search-designs` - Search docs, presentations, videos, whiteboards, sheets, and other designs in Canva. Use 'query' parameter to search by title or content. If 'query' is used, 'sortBy' must be set to 'relevance'. Filter by 'any' ownership unless specified. Sort by relevance unless specified. Use the continuation token to get the next page of results, if needed.
- `search-folders` - Search the user's folders and folders shared with the user based on folder names and tags. Returns a list of matching folders with pagination support.
- `upload-asset-from-url` - Upload an asset (e.g. an image, a video) from a URL into Canva. If the API call returns "Missing scopes: [asset:write]", you should ask the user to disconnect and reconnect their connector. This will generate a new access token with the required scope for this tool.

Setting up Canva integration

Canva integration uses MCP server connectivity to provide action capabilities. For detailed setup instructions, see [the section called "MCP integration"](#).

You'll need:

- Canva account with appropriate permissions

Compatibility

Canva integration supports:

- **Chat Agents:** Yes
- **Flows:** Yes
- **Knowledge Base:** No

Cisco Webex Meetings integration

With the Cisco Webex Meetings connector, you can schedule and manage meetings, retrieve recordings, and access participant information directly in Amazon Quick through natural language.

Amazon Quick supports multiple authentication methods for Cisco Webex Meetings. Choose the method that best fits your organization's security requirements.

- **Custom OAuth app** – Uses a customer-managed application registered in the Webex Developer portal. This option gives your organization full control over the OAuth configuration.
- **Service-to-Service OAuth** – Uses client credentials for server-to-server authentication without user interaction. Suitable for automated workflows.
- **API Key** – Uses an API key for authentication.

For more information about the authentication methods that Amazon Quick supports, see [the section called “Authentication methods”](#).

Before you begin

Make sure that you have the following before you set up the integration.

- An active Cisco Webex account with access to Webex Meetings.
- For **Custom OAuth app** or **Service-to-Service OAuth**: Access to the [Webex Developer portal](#) on the Cisco website to create an integration and obtain client credentials.
- For **API Key**: A Webex personal access token or API key with the required scopes.
- For Amazon Quick subscription requirements, see [the section called “Set up integrations in the console”](#).

Configuring Cisco Webex

For Custom OAuth app or Service-to-Service OAuth authentication, create an integration in the [Webex Developer portal](#) on the Cisco website and add the Amazon Quick callback URL `https://{region}.quicksight.aws.amazon.com/sn/oauthcallback` as a redirect URI. Replace `{region}` with your AWS Region (for example, `us-east-1`). For step-by-step instructions, see [Webex Meetings MCP Server](#) in the Webex developer documentation. Record the Client ID and Client Secret — you need them when you configure Amazon Quick. For API Key authentication, generate a Webex personal access token or API key with the required scopes.

Setting up the connector in Amazon Quick

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Cisco Webex Meetings**.
4. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
5. For **Connection type**, choose **Public network**.
6. For **OAuth Configuration**, choose one of the following authentication methods and configure the required fields.
 - a. For **Custom OAuth app**, configure the following fields:
 - **Base URL** – The Webex Meetings MCP base URL. Default: `https://mcp.webexapis.com/mcp/webex-meeting`
 - **Client ID** – The client ID from your Webex Developer portal integration.
 - **Public OAuth client** (Optional) – Select this option if your Webex integration is configured as a public client (no client secret).
 - **Client secret** – The client secret from your Webex Developer portal integration.
 - **Token URL** – The token endpoint. Default: `https://webexapis.com/v1/access_token`
 - **Authorization URL** – The authorization endpoint. Default: `https://webexapis.com/v1/authorize`
 - **Redirect URL** – Pre-filled with the Amazon Quick callback URL.
 - b. For **Service-to-Service OAuth**, configure the following fields:

- **Base URL** – The Webex Meetings MCP base URL. Default: `https://mcp.webexapis.com/mcp/webex-meeting`
 - **Client ID** – The client ID from your Webex Service App.
 - **Client secret** – The client secret from your Webex Service App.
 - **Token URL** – The token endpoint. Default: `https://webexapis.com/v1/access_token`
- c. For **API Key**, configure the following fields:
- **Base URL** – The Webex Meetings MCP base URL. Default: `https://mcp.webexapis.com/mcp/webex-meeting`
 - **API Key** – The Webex API key or personal access token.
 - **Email (Optional)** – The email address associated with the API key.
7. Choose **Next**.
8. If you chose **Custom OAuth app**, a Webex authorization window opens. Review the requested permissions and choose **Accept**.
9. On the **Review** page, review the available actions for the connector. Choose **Next**.
10. On the **Publish** page, choose who can access the connector. You can enable access for everyone in your organization or search for specific teams or groups.
11. Choose **Publish**.

Available actions

After you set up the connector, the actions exposed by Cisco Webex Meetings are available. To see the current set of actions for your connector, go to the connector's **Available actions** view in the Amazon Quick console.

Managing and troubleshooting

To edit, share, or delete your connector, see [the section called “Managing existing integrations”](#).

Authentication issues

- **Sign-in fails (Custom OAuth app)** – Verify that your Cisco Webex account is active and that you can sign in to Webex directly. Confirm that the redirect URI in your Webex Developer portal integration matches the Amazon Quick callback URL.

- **Invalid client credentials** – Verify that the Client ID and Client secret match the values in your Webex Developer portal integration or Service App.
- **API Key authentication fails** – Verify that the API key has not been revoked and that it has the required scopes for Webex Meetings operations.

Coding agents

In addition to cloud connectors, you can add a coding agent, an external AI coding tool such as Kiro or Claude Code, that Amazon Quick can hand development work to. Amazon Quick communicates with the coding agent by using the Agent Client Protocol (ACP). Like other local connectors, a coding agent runs on your own machine, so it is available only when that machine is on and connected. For an overview of cloud connectors, see [Connectors](#). For information about local connectors, see [Local connectors](#).

To add a coding agent

1. Open the Desktop App, go to **Customize**, and choose the **Connectors** tab.
2. Choose **Create**, and then choose **Coding agent**.
3. Configure the connection settings, and choose **Save**.

Each coding agent shows its name, a description, and a toggle to enable or disable it. After you configure a coding agent, you can delegate tasks to it from chat. For example, you can ask Amazon Quick to use Kiro to refactor a module, or ask Claude Code to write tests for a function. Amazon Quick dispatches the work to the coding agent and reports the results to you.

Cisco Webex Video Messaging integration

With the Cisco Webex Video Messaging connector, you can manage video updates, retrieve transcripts, and access video metadata from Cisco Webex (formerly known as Vidcast) directly in Amazon Quick through natural language.

Amazon Quick supports multiple authentication methods for Cisco Webex Video Messaging. Choose the method that best fits your organization's security requirements.

- **Custom OAuth app** – Uses a customer-managed application registered in the Webex Developer portal. This option gives your organization full control over the OAuth configuration.

- **Service-to-Service OAuth** – Uses client credentials for server-to-server authentication without user interaction. Suitable for automated workflows.
- **API Key** – Uses an API key for authentication.

For more information about the authentication methods that Amazon Quick supports, see [the section called “Authentication methods”](#).

Before you begin

Make sure that you have the following before you set up the integration.

- An active Cisco Webex account with access to Webex Video Messaging (Vidcast).
- For **Custom OAuth app** or **Service-to-Service OAuth**: Access to the [Webex Developer portal](#) on the Cisco website to create an integration and obtain client credentials.
- For **API Key**: A Webex personal access token or API key with the required scopes.
- For Amazon Quick subscription requirements, see [the section called “Set up integrations in the console”](#).

Configuring Cisco Webex

For Custom OAuth app or Service-to-Service OAuth authentication, create an integration in the [Webex Developer portal](#) on the Cisco website and add the Amazon Quick callback URL `https://{region}.quicksight.aws.amazon.com/sn/oauthcallback` as a redirect URI. Replace `{region}` with your AWS Region (for example, `us-east-1`). For step-by-step instructions, see [Vidcast MCP Server](#) in the Webex developer documentation. Record the Client ID and Client Secret — you need them when you configure Amazon Quick. For API Key authentication, generate a Webex personal access token or API key with the required scopes.

Setting up the connector in Amazon Quick

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Cisco Webex Video Messaging**.
4. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
5. For **Connection type**, choose **Public network**.

6. For **OAuth Configuration**, choose one of the following authentication methods and configure the required fields.
 - a. For **Custom OAuth app**, configure the following fields:
 - **Base URL** – The Webex Video Messaging MCP base URL. Default: `https://mcp.webexapis.com/mcp/vidcast`
 - **Client ID** – The client ID from your Webex Developer portal integration.
 - **Public OAuth client** (Optional) – Select this option if your Webex integration is configured as a public client (no client secret).
 - **Client secret** – The client secret from your Webex Developer portal integration.
 - **Token URL** – The token endpoint. Default: `https://webexapis.com/v1/access_token`
 - **Authorization URL** – The authorization endpoint. Default: `https://webexapis.com/v1/authorize`
 - **Redirect URL** – Pre-filled with the Amazon Quick callback URL.
 - b. For **Service-to-Service OAuth**, configure the following fields:
 - **Base URL** – The Webex Video Messaging MCP base URL. Default: `https://mcp.webexapis.com/mcp/vidcast`
 - **Client ID** – The client ID from your Webex Service App.
 - **Client secret** – The client secret from your Webex Service App.
 - **Token URL** – The token endpoint. Default: `https://webexapis.com/v1/access_token`
 - c. For **API Key**, configure the following fields:
 - **Base URL** – The Webex Video Messaging MCP base URL. Default: `https://mcp.webexapis.com/mcp/vidcast`
 - **API Key** – The Webex API key or personal access token.
 - **Email** (Optional) – The email address associated with the API key.
7. Choose **Next**.
8. If you chose **Custom OAuth app**, a Webex authorization window opens. Review the requested permissions and choose **Accept**.
9. On the **Review** page, review the available actions for the connector. Choose **Next**.

10. On the **Publish** page, choose who can access the connector. You can enable access for everyone in your organization or search for specific teams or groups.
11. Choose **Publish**.

Available actions

After you set up the connector, the actions exposed by Cisco Webex Video Messaging are available. To see the current set of actions for your connector, go to the connector's **Available actions** view in the Amazon Quick console.

Managing and troubleshooting

To edit, share, or delete your connector, see [the section called “Managing existing integrations”](#).

Authentication issues

- **Sign-in fails (Custom OAuth app)** – Verify that your Cisco Webex account is active and that you can sign in to Webex directly. Confirm that the redirect URI in your Webex Developer portal integration matches the Amazon Quick callback URL.
- **Invalid client credentials** – Verify that the Client ID and Client secret match the values in your Webex Developer portal integration or Service App.
- **API Key authentication fails** – Verify that the API key has not been revoked and that it has the required scopes for Webex Video Messaging operations.

Dropbox integration

With the Dropbox connector, you can access the Dropbox platform directly in Amazon Quick through natural language. You can upload files, manage folder structures, generate sharing links, and search for content without leaving Amazon Quick.

Amazon Quick supports multiple authentication methods for Dropbox. Choose the method that best fits your organization's security requirements.

- **Default OAuth app** – Uses an AWS-managed OAuth application. No additional credentials are needed. You authenticate directly with your Dropbox account.
- **Custom OAuth app** – Uses a customer-managed OAuth application that is registered in Dropbox. This option gives your organization full control over the OAuth configuration.

- **API Key** – Uses a Dropbox access token for authentication. This method is suitable for individual use or testing.

For more information about the authentication methods that Amazon Quick supports, see [the section called “Authentication methods”](#).

Before you begin

Make sure that you have the following before you set up the integration.

- An active Dropbox account with access to the files and folders that you want to use.
- For **Custom OAuth app**: Access to the [Dropbox App Console](#) on the Dropbox website to create an app.
- For **API Key**: An access token that is generated from the [Dropbox App Console](#) on the Dropbox website.
- For Amazon Quick subscription requirements, see [the section called “Set up integrations in the console”](#).

Configuring Dropbox

If you are using **Default OAuth app** authentication, skip this section and go to [the section called “Setting up the connector in Amazon Quick”](#).

For Custom OAuth app or API Key authentication, complete the applicable steps in Dropbox before you configure Amazon Quick.

Create a Dropbox app for Custom OAuth app

Create an app in the Dropbox App Console to get the client credentials that you need for Amazon Quick.

1. Sign in to your Dropbox account and go to the [Dropbox App Console](#) on the Dropbox website.
2. Choose **Create app**.
3. For **Choose an API**, select **Scoped access**.
4. Choose the type of access that you need:
 - **App folder** – Provides access only to a specific folder.
 - **Full Dropbox** – Provides access to all files and folders.

5. Enter an app name and choose **Create app**.
6. On the app settings page, record the following values. You need them when you configure Amazon Quick.
 - **App key** – This is your Client ID.
 - **App secret** – This is your Client secret.
7. Under **OAuth 2**, in the **Redirect URIs** section, add the Amazon Quick callback URL:
`https://{region}.quicksight.aws.amazon.com/sn/oauthcallback`
8. Choose the **Permissions** tab and select the scopes that your integration requires. For the recommended scopes, see [the section called “Recommended scopes”](#).

Generate an access token for API Key

Generate an access token from the Dropbox App Console for API Key authentication.

1. Sign in to your Dropbox account and go to the [Dropbox App Console](#) on the Dropbox website.
2. Choose your app, or create a new one if needed.
3. Under **OAuth 2**, choose **Generate** to create an access token.
4. Copy and securely store the generated token. You need it when you configure Amazon Quick.

Recommended scopes

When you create a Dropbox app, configure the following scopes on the **Permissions** tab based on the actions that you want to use.

Dropbox recommended scopes

Scope	Description
account_info.read	Reads account information.
account_info.write	Updates account information.
contacts.read	Reads contact information.
contacts.write	Updates contact information.
events.read	Reads event log entries.

Scope	Description
<code>events.write</code>	Creates event log entries.
<code>file_requests.read</code>	Reads file requests.
<code>file_requests.write</code>	Creates and manages file requests.
<code>files.content.read</code>	Reads file content.
<code>files.content.write</code>	Creates, modifies, and deletes files.
<code>files.metadata.read</code>	Reads file and folder metadata.
<code>files.metadata.write</code>	Edits file and folder metadata.
<code>files.permanent_delete</code>	Permanently deletes files.
<code>files.team_metadata.read</code>	Reads team file metadata.
<code>files.team_metadata.write</code>	Edits team file metadata.
<code>groups.read</code>	Reads group information.
<code>groups.write</code>	Manages groups.
<code>members.delete</code>	Removes team members.
<code>members.read</code>	Reads team member information.
<code>members.write</code>	Manages team members.
<code>sessions.list</code>	Lists active sessions.
<code>sessions.modify</code>	Modifies active sessions.
<code>sharing.read</code>	Reads sharing settings and shared links.
<code>sharing.write</code>	Creates and manages shared links and folder sharing.
<code>team_data.content.read</code>	Reads team content.

Scope	Description
team_data.content.write	Manages team content.
team_data.governance.read	Reads team data governance settings.
team_data.governance.write	Manages team data governance settings.
team_data.team_space	Accesses team space data.
team_info.read	Reads team information.
team_info.write	Updates team information.

Setting up the connector in Amazon Quick

Connect from the Available tab

If you want to use Default OAuth app authentication, you can connect directly from the **Available** tab without additional configuration.

1. In the Amazon Quick console, choose **Connectors**.
2. On the **Available** tab, find **Dropbox** and choose **Connect**.
3. Complete the Dropbox sign-in flow and grant the requested permissions.

To configure a connector with Custom OAuth app or API Key instead, use the **Create for your team** tab as described below.

Create from the Create for your team tab

After you complete any required Dropbox configuration, create the connector in Amazon Quick.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Dropbox**.

 Note

If a Dropbox connector already exists, a dialog appears with your existing connectors. To use an existing connector, choose it. To create a new one, choose **No, create new**.

4. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
5. For **Connection type**, choose **Public network**.
6. For **OAuth Configuration**, choose one of the following authentication methods and configure the required fields.

- a. For **Default OAuth app**:

No additional credentials are needed. Choose **Next** to continue.

- b. For **Custom OAuth app**, configure the following fields:

- **Base URL** (Optional) – The Dropbox API base URL. Example: `https://api.dropboxapi.com`
- **Client ID** – The app key from your Dropbox app.
- **Client secret** – The app secret from your Dropbox app.
- **Token URL** – The token endpoint. Example: `https://api.dropboxapi.com/oauth2/token`
- **Authorization URL** – The authorization endpoint. Example: `https://www.dropbox.com/oauth2/authorize`
- **Redirect URL** – Pre-filled with the Amazon Quick callback URL.

- c. For **API Key**, configure the following fields:

- **Base URL** (Optional) – The Dropbox API base URL. Example: `https://api.dropboxapi.com`
- **API Key** – Your Dropbox access token.
- **Email** (Optional) – The email address that is associated with your Dropbox account.

7. Choose **Next**.
8. If you chose **Default OAuth app** or **Custom OAuth app**, a Dropbox authorization window opens. Review the requested permissions and choose **Allow**.
9. On the **Review** page, review the available actions for the connector. Choose **Next**.

10. On the **Publish** page, choose who can access the connector. You can turn on access for everyone in your organization or search for specific teams or groups.
11. Choose **Publish**.

Available actions

After you set up the connector, the following actions are available.

Dropbox available actions

Category	Action	Description
Files	List Files	Lists files in a folder.
Files	Get File	Reads the content of a file.
Files	Import File	Uploads a file to Dropbox.
Files	Search Files	Searches for files or folders by name or content.
Files	Update File Location	Moves a file or folder to a different location.
Files	Get Temporary Link	Generates a temporary download link for a file.
Files	Get Metadata	Retrieves metadata for a file or folder.
Files	Save File From URL	Saves a file to Dropbox from a URL.
Folders	Create Folder	Creates a new folder.
Folders	List Folders	List of folders user has access to.
Batch operations	Get Batch Move Status	Checks the status of a batch move operation.
Sharing	Create Shared Link	Creates a shared link for a file or folder.
Sharing	List Shared Links	Lists shared links for a file or folder.
Sharing	Update Folder Sharing	Shares a folder with other users.

Category	Action	Description
Sharing	List Received Files	Lists files that other users have shared with you.
File requests	Create File Request	Creates a file request for others to upload files to.
Account	Get User	Retrieves information about the authenticated user.
Account	Get Space Usage	Retrieves storage space usage for the account.

 Note

The actions that you can use depend on the files and folders that are accessible to the authenticated user.

Managing and troubleshooting

To edit, share, or delete your connector, see [the section called “Managing existing integrations”](#).

Authentication issues

- **Sign-in fails (Default OAuth app or Custom OAuth app)** – Verify that your Dropbox account is active and that you can sign in to [the Dropbox website](#) directly. For Custom OAuth app, confirm that the redirect URL in your Dropbox app matches the Amazon Quick callback URL.
- **Invalid client credentials (Custom OAuth app)** – Verify that the Client ID and Client secret match the app key and app secret values in your Dropbox app. If you regenerated the app secret, update the value in Amazon Quick.
- **API Key rejected** – Verify that your access token is active. Tokens can expire or be revoked in the Dropbox App Console.
- **Insufficient permissions** – Verify that your Dropbox app has the required permission scopes for the actions that you want to use.

Dun & Bradstreet integration

With the Dun & Bradstreet connector, you can look up company profiles, credit risk data, and business intelligence directly in Amazon Quick through natural language.

Amazon Quick supports multiple authentication methods for Dun & Bradstreet. Choose the method that best fits your organization's security requirements.

- **Custom OAuth app** – Uses a customer-managed OAuth application registered in the Dun & Bradstreet developer portal. This option gives your organization full control over the OAuth configuration.
- **Service-to-Service OAuth** – Uses client credentials for server-to-server authentication without user interaction. Suitable for automated workflows.

For more information about the authentication methods that Amazon Quick supports, see [the section called “Authentication methods”](#).

Before you begin

Make sure that you have the following before you set up the integration.

- An active Dun & Bradstreet D&B Direct+ account with access to the data products you want to query.
- For **Custom OAuth app** or **Service-to-Service OAuth**: OAuth credentials from your Dun & Bradstreet developer portal.
- For Amazon Quick subscription requirements, see [the section called “Set up integrations in the console”](#).

Configuring Dun & Bradstreet

For Custom OAuth app or Service-to-Service OAuth authentication, register an OAuth app in the Dun & Bradstreet developer portal and add the Amazon Quick callback URL `https://{region}.quicksight.aws.amazon.com/sn/oauthcallback` as a redirect URI. Replace `{region}` with your AWS Region (for example, `us-east-1`). For authentication details, see [Authentication](#) in the [D&B Direct+ documentation](#). Record the Client ID and Client Secret — you need them when you configure Amazon Quick.

Setting up the connector in Amazon Quick

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Dun & Bradstreet**.
4. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
5. For **Connection type**, choose **Public network**.
6. For **OAuth Configuration**, choose one of the following authentication methods and configure the required fields.
 - a. For **Custom OAuth app**, configure the following fields:
 - **Base URL** – The Dun & Bradstreet MCP base URL. Default: `https://plus.dnb.com/v2/mcp`
 - **Client ID** – The client ID from your Dun & Bradstreet OAuth app.
 - **Public OAuth client** (Optional) – Select this option if your Dun & Bradstreet OAuth app is configured as a public client (no client secret).
 - **Client secret** – The client secret from your Dun & Bradstreet OAuth app.
 - **Token URL** – The token endpoint. Default: `https://plus.dnb.com/v2/mcp/token`
 - **Authorization URL** – The authorization endpoint. Default: `https://plus.dnb.com/v2/mcp/authorize`
 - **Redirect URL** – Pre-filled with the Amazon Quick callback URL.
 - b. For **Service-to-Service OAuth**, configure the following fields:
 - **Base URL** – The Dun & Bradstreet MCP base URL. Default: `https://plus.dnb.com/v2/mcp`
 - **Client ID** – The client ID from your Dun & Bradstreet OAuth app.
 - **Client secret** – The client secret from your Dun & Bradstreet OAuth app.
 - **Token URL** – The token endpoint. Default: `https://plus.dnb.com/v2/mcp/token`
7. Choose **Next**.
8. If you chose **Custom OAuth app**, a Dun & Bradstreet authorization window opens. Review the requested permissions and choose **Allow**.
9. On the **Review** page, review the available actions for the connector. Choose **Next**.

10. On the **Publish** page, choose who can access the connector. You can enable access for everyone in your organization or search for specific teams or groups.
11. Choose **Publish**.

Available actions

After you set up the connector, the actions exposed by Dun & Bradstreet are available. To see the current set of actions for your connector, go to the connector's **Available actions** view in the Amazon Quick console.

Managing and troubleshooting

To edit, share, or delete your connector, see [the section called “Managing existing integrations”](#).

Authentication issues

- **Sign-in fails (Custom OAuth app)** – Verify that your Dun & Bradstreet account is active. Confirm that the redirect URI in your Dun & Bradstreet OAuth app matches the Amazon Quick callback URL.
- **Invalid client credentials** – Verify that the Client ID and Client secret match the values in your Dun & Bradstreet OAuth app.

GitHub integration

With GitHub integration in Amazon Quick, you can manage repositories, create and review pull requests, track issues, and collaborate on code through MCP server connectivity. This integration provides action capabilities for development workflow operations.

What you can do

GitHub integration provides connector capabilities through MCP server connectivity:

- Create and manage repositories
- Create, review, and merge pull requests
- Track and manage issues
- Manage branches and commits
- Review code and provide feedback
- Manage project boards and milestones

Available tools

The GitHub MCP server typically provides these tools:

- `create_repository` - Create new repositories
- `get_repository` - Get repository information
- `list_issues` - List repository issues
- `create_issue` - Create new issues
- `create_pull_request` - Create pull requests
- `list_pull_requests` - List pull requests
- `get_file_contents` - Read file contents
- `create_commit` - Create commits
- `search_repositories` - Search for repositories

Note

The specific tools and capabilities available through this MCP server may change over time. For the most current information about supported tools, features, and implementation details, check the official GitHub documentation and MCP server repository.

Setting up GitHub integration

GitHub integration uses MCP server connectivity to provide action capabilities. For detailed setup instructions, see [the section called “MCP integration”](#).

You'll need:

- GitHub account with appropriate repository permissions
- Personal access token or GitHub App credentials

Compatibility

GitHub integration supports:

- **Chat Agents:** Yes

- **Flows:** Yes
- **Knowledge Base:** No

Gmail integration

With the Gmail connector, you can access Gmail directly in Amazon Quick through natural language. You can read and send emails, manage labels and drafts, organize threads, and search contacts without leaving Amazon Quick.

Amazon Quick supports multiple authentication methods for Gmail. Choose the method that best fits your organization's security requirements.

- **Default OAuth app** – Uses an AWS-managed OAuth application. No additional credentials are needed. You authenticate directly with your Google account.
- **Custom OAuth app** – Uses a customer-managed OAuth client created in the Google Cloud Console. This option gives your organization full control over the OAuth configuration.

For more information about the authentication methods that Amazon Quick supports, see [the section called “Authentication methods”](#).

Before you begin

Make sure that you have the following before you set up the integration.

- A Google account with access to Gmail.
- For **Custom OAuth app**: Access to the [Google Cloud Console](#) on the Google website with permissions to create OAuth clients.
- For Amazon Quick subscription requirements, see [the section called “Set up integrations in the console”](#).

Configuring Google Cloud

If you use **Default OAuth app** authentication, skip this section and see [the section called “Setting up the connector in Amazon Quick”](#).

For Custom OAuth app authentication, complete the following steps in the Google Cloud Console before you configure Amazon Quick. When you enable the API in step 3, search for and enable the **Gmail API**.

Create an OAuth client in Google Cloud Console

Create an OAuth client in the Google Cloud Console to get the client credentials that you need for Amazon Quick. For more information, see [Using OAuth 2.0 to Access Google APIs](#) on the Google website.

1. Sign in to the [Google Cloud Console](#) on the Google website.
2. Create a new project or select an existing project.
3. In the left navigation pane, choose **APIs & Services**, then choose **Library**. Search for the API that your integration requires and choose **Enable**.
4. Choose **OAuth consent screen** and choose **Get Started**.
5. Configure the consent screen:
 - Enter an **App Name** and select a **User support email**.
 - For **Audience**, choose **Internal** (your organization only) or **External** (any Google user).
 - Add developer contact details and choose **Create**.
6. Choose **Create OAuth client**.
7. Configure the client:
 - For **Application type**, choose **Web application**.
 - Enter a **Name** for your client.
 - Under **Authorized redirect URIs**, add the Amazon Quick callback URL:
`https://{region}.quicksight.aws.amazon.com/sn/oauthcallback`
8. Choose **Create**.
9. Record the following values. You need them when you configure Amazon Quick.
 - **Client ID**
 - **Client secret**

Recommended scopes

The following scopes are requested when you connect to Gmail.

Gmail recommended scopes

Scope	Description
https://www.googleapis.com/auth/gmail.modify	Reads, sends, and manages emails and labels.
https://www.googleapis.com/auth/gmail.send	Sends emails on behalf of the user.
https://www.googleapis.com/auth/contacts.readonly	Reads contact information.
openid	Authenticates the user's identity.
email	Reads the user's email address.

Note

The `openid` and `email` scopes are automatically included in the OAuth consent flow for user authentication. They are not required for Service-to-Service OAuth.

Setting up the connector in Amazon Quick

Connect from the Available tab

If you want to use Default OAuth app authentication, you can connect directly from the **Available** tab without additional configuration.

1. In the Amazon Quick console, choose **Connectors**.
2. On the **Available** tab, find **Gmail** and choose **Connect**.
3. Complete the Google sign-in flow and grant the requested permissions.

To configure a connector with Custom OAuth app instead, use the **Create for your team** tab as described below.

Create from the Create for your team tab

After you complete any required Google Cloud configuration, create the connector in Amazon Quick.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Gmail**.

Note

If a Gmail connector already exists, a dialog appears with your existing connectors. To use an existing connector, choose it. To create a new one, choose **No, create new**.

4. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
5. For **Connection type**, choose **Public network**.
6. For **OAuth Configuration**, choose one of the following authentication methods and configure the required fields.
 - a. For **Default OAuth app**:

No additional credentials are needed. Choose **Next** to continue.
 - b. For **Custom OAuth app**, configure the following fields:
 - **Base URL** (Optional) – The Gmail API base URL. For example: `https://gmail.googleapis.com`
 - **Client ID** – The client ID from your Google Cloud OAuth client.
 - **Client secret** – The client secret from your Google Cloud OAuth client.
 - **Token URL** – The token endpoint. For example: `https://oauth2.googleapis.com/token`
 - **Authorization URL** – The authorization endpoint. For example: `https://accounts.google.com/o/oauth2/v2/auth`
 - **Redirect URL** – Pre-filled with the Amazon Quick callback URL.
7. Choose **Next**.
8. If you chose **Default OAuth app** or **Custom OAuth app**, a Google authorization window opens. Review the requested permissions and choose **Allow**.

9. On the **Review** page, review the available actions for the connector. Choose **Next**.
10. On the **Publish** page, choose who can access the connector. You can enable access for everyone in your organization or search for specific teams or groups.
11. Choose **Publish**.

Available actions

After you set up the connector, the following actions are available.

Gmail available actions

Category	Action	Description
Messages	Get Emails	Retrieves emails from the mailbox.
Messages	Get Message By Thread Id	Retrieves a message by its thread ID.
Messages	Get Message By Message Id	Retrieves a message by its message ID.
Messages	Send Email	Sends a new email message.
Messages	Send Thread Reply	Replies to an existing email thread.
Messages	Forward Message	Forwards an email to other recipients.
Messages	Get Attachment	Retrieves an email attachment.
Messages	Batch Update Message	Modifies labels on multiple messages in a single operation.
Threads	List Threads	Lists email threads in the mailbox.
Threads	Update Thread Labels	Modifies labels on a thread.
Trash	Delete Email	Moves an email to the trash.
Trash	Delete Thread	Moves a thread to the trash.
Trash	Restore Message	Restores an email from the trash.
Trash	Restore Thread	Restores a thread from the trash.

Category	Action	Description
Labels	List Labels	Lists all labels in the mailbox.
Labels	Get Label	Retrieves details for a specific label.
Labels	Create Label	Creates a new label.
Labels	Update Label	Updates a label's properties.
Labels	Tag Email	Adds a label to an email.
Drafts	List Drafts	Lists email drafts.
Drafts	Get Draft	Retrieves a specific draft.
Drafts	Create Draft	Creates a new email draft.
Drafts	Update Draft	Updates an existing draft.
Drafts	Send Draft	Sends an existing draft.
Contacts	Search Contacts	Searches for contacts by name or email.
Contacts	Get Contacts	Retrieves contact information.
History	List History	Lists mailbox change history.
Settings	Get Profile	Retrieves the authenticated user's Gmail profile.
Settings	Get Send As Alias	Retrieves a specific send-as alias configuration.
Settings	List Send As Aliases	Lists all send-as aliases for the account.

 Note

The actions that you can use depend on the data accessible to the authenticated user.

Manage and troubleshoot

To edit, share, or delete your connector, see [the section called “Managing existing integrations”](#).

Common Google authentication issues

- **Sign-in fails (Default OAuth app or Custom OAuth app)** – Verify that your Google account is active and that you can sign in to [the Google website](#) directly. For Custom OAuth app, confirm that the redirect URI in your Google Cloud OAuth client matches the Amazon Quick callback URL.
- **App blocked by administrator** – If your Google Workspace administrator restricts third-party app access, you might see an error when you attempt to sign in. Contact your Google Workspace administrator to allow the Amazon Quick app.
- **Invalid client credentials (Custom OAuth app)** – Verify that the Client ID and Client secret match the values in your Google Cloud OAuth client.
- **Authentication popup fails** – Verify that your browser allows popups from the Amazon Quick console domain. Try using a different browser or clearing your browser cache.
- **Permissions revoked** – If you previously revoked Amazon Quick access from your Google Account permissions settings, you need to re-authenticate by editing the connector and signing in again.
- **Google API rate limiting** – Google might limit requests during high usage periods. If actions fail, retry after a few minutes.

Gmail-specific issues

- **Gmail API not enabled** – Verify that the Gmail API is enabled in your Google Cloud project under **APIs & Services, Library**.

Google Analytics integration

With the Google Analytics connector, you can access Google Analytics directly in Amazon Quick through natural language. You can run reports, retrieve audience data, monitor key events, and access real-time metrics without leaving Amazon Quick.

Amazon Quick supports multiple authentication methods for Google Analytics. Choose the method that best fits your organization's security requirements.

- **Default OAuth app** – Uses an AWS-managed OAuth application. No additional credentials are needed. You authenticate directly with your Google account.
- **Custom OAuth app** – Uses a customer-managed OAuth client created in the Google Cloud Console. This option gives your organization full control over the OAuth configuration.

For more information about the authentication methods that Amazon Quick supports, see [the section called “Authentication methods”](#).

Before you begin

Make sure that you have the following before you set up the integration.

- A Google account with access to Google Analytics properties and data that you want to use.
- For **Custom OAuth app**: Access to the [Google Cloud Console](#) on the Google website with permissions to create OAuth clients.
- For Amazon Quick subscription requirements, see [the section called “Set up integrations in the console”](#).

Configuring Google Cloud

If you are using **Default OAuth app** authentication, skip this section and go to [the section called “Setting up the connector in Amazon Quick”](#).

For Custom OAuth app authentication, complete the following steps in the Google Cloud Console before you configure Amazon Quick. When you enable the API in step 3, search for and enable the **Google Analytics Data API**.

Create an OAuth client in Google Cloud Console

Create an OAuth client in the Google Cloud Console to get the client credentials that you need for Amazon Quick. For more information, see [Using OAuth 2.0 to Access Google APIs](#) on the Google website.

1. Sign in to the [Google Cloud Console](#) on the Google website.
2. Create a new project or select an existing project.
3. In the left navigation pane, choose **APIs & Services**, then choose **Library**. Search for the API that your integration requires and choose **Enable**.

4. Choose **OAuth consent screen** and choose **Get Started**.
5. Configure the consent screen:
 - Enter an **App Name** and select a **User support email**.
 - For **Audience**, choose **Internal** (your organization only) or **External** (any Google user).
 - Add developer contact details and choose **Create**.
6. Choose **Create OAuth client**.
7. Configure the client:
 - For **Application type**, choose **Web application**.
 - Enter a **Name** for your client.
 - Under **Authorized redirect URIs**, add the Amazon Quick callback URL:
`https://{region}.quicksight.aws.amazon.com/sn/oauthcallback`
8. Choose **Create**.
9. Record the following values. You need them when you configure Amazon Quick.
 - **Client ID**
 - **Client secret**

Recommended scopes

The following scopes are requested when you connect to Google Analytics.

Google Analytics recommended scopes

Scope	Description
<code>https://www.googleapis.com/auth/analytics.readonly</code>	Reads Analytics data and configuration.
<code>https://www.googleapis.com/auth/analytics.edit</code>	Edits Analytics configuration and data.
<code>openid</code>	Authenticates the user's identity.
<code>email</code>	Reads the user's email address.

 Note

The `openid` and `email` scopes are automatically included in the OAuth consent flow for user authentication. They are not required for Service-to-Service OAuth.

Setting up the connector in Amazon Quick

Connect from the Available tab

If you want to use Default OAuth app authentication, you can connect directly from the **Available** tab without additional configuration.

1. In the Amazon Quick console, choose **Connectors**.
2. On the **Available** tab, find **Google Analytics** and choose **Connect**.
3. Complete the Google sign-in flow and grant the requested permissions.

To configure a connector with Custom OAuth app instead, use the **Create for your team** tab as described below.

Create from the Create for your team tab

After you complete any required Google Cloud configuration, create the connector in Amazon Quick.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Google Analytics**.

 Note

If a Google Analytics connector already exists, a dialog appears with your existing connectors. To use an existing connector, choose it. To create a new one, choose **No, create new**.

4. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
5. For **Connection type**, choose **Public network**.

6. For **OAuth Configuration**, choose one of the following authentication methods and configure the required fields.
 - a. For **Default OAuth app**:

No additional credentials are needed. Choose **Next** to continue.
 - b. For **Custom OAuth app**, configure the following fields:
 - **Base URL** (Optional) – The Google Analytics API base URL. Example: `https://analyticsdata.googleapis.com`
 - **Client ID** – The client ID from your Google Cloud OAuth client.
 - **Client secret** – The client secret from your Google Cloud OAuth client.
 - **Token URL** – The token endpoint. Example: `https://oauth2.googleapis.com/token`
 - **Authorization URL** – The authorization endpoint. Example: `https://accounts.google.com/o/oauth2/v2/auth`
 - **Redirect URL** – Pre-filled with the Amazon Quick callback URL.
7. Choose **Next**.
8. If you chose **Default OAuth app** or **Custom OAuth app**, a Google authorization window opens. Review the requested permissions and choose **Allow**.
9. On the **Review** page, review the available actions for the connector. Choose **Next**.
10. On the **Publish** page, choose who can access the connector. You can enable access for everyone in your organization or search for specific teams or groups.
11. Choose **Publish**.

Available actions

After you set up the connector, the following actions are available.

Google Analytics available actions

Category	Action	Description
Reports	Create Report	Runs a report for a property.
Reports	Batch Create Report	Runs multiple reports in a single request.

Category	Action	Description
Reports	Create Realtime Report	Runs a real-time report for a property.
Reports	Create Funnel Report	Runs a funnel report for a property.
Audiences	List Audiences	Lists audiences for a property.
Audiences	Create Audience List	Creates an audience list for export.
Audiences	List Audience Lists	Lists audience lists for a property.
Audiences	Get Audience List	Retrieves data from an audience list.
Audiences	Create Audience Export	Creates an audience export.
Audiences	Get Audience Export	Retrieves data from an audience export.
Accounts	List Account Summaries	Lists account summaries accessible to the user.
Accounts	List Accounts	Lists all accounts accessible to the user.
Accounts	Get Account	Retrieves details for a specific account.
Properties	Get Property	Retrieves details for a specific property.
Properties	Search Properties	Searches for properties with filtering.
Properties	Get Property Quotas	Retrieves quota usage for a property.
Events	List Key Events	Lists key events (conversions) for a property.
Metadata	Get Metadata	Retrieves available dimensions and metrics for reporting.
Metadata	Get Compatibility	Checks compatibility of dimensions and metrics for a report.

Category	Action	Description
Annotations	List Annotations	Lists reporting data annotations for a property.

Note

The actions that you can use depend on the Analytics properties and accounts accessible to the authenticated user.

Managing and troubleshooting

To edit, share, or delete your connector, see [the section called “Managing existing integrations”](#).

Common Google authentication issues

- **Sign-in fails (Default OAuth app or Custom OAuth app)** – Verify that your Google account is active and that you can sign in to [the Google website](#) directly. For Custom OAuth app, confirm that the redirect URI in your Google Cloud OAuth client matches the Amazon Quick callback URL.
- **App blocked by administrator** – If your Google Workspace administrator restricts third-party app access, you might see an error when you attempt to sign in. Contact your Google Workspace administrator to allow the Amazon Quick app.
- **Invalid client credentials (Custom OAuth app)** – Verify that the Client ID and Client secret match the values in your Google Cloud OAuth client.
- **Authentication popup fails** – Verify that your browser allows popups from the Amazon Quick console domain. Try using a different browser or clearing your browser cache.
- **Permissions revoked** – If you previously revoked Amazon Quick access from your Google Account permissions settings, you need to re-authenticate by editing the connector and signing in again.
- **Google API rate limiting** – Google might limit requests during high usage periods. If actions fail, retry after a few minutes.

Google Analytics-specific issues

- **Google Analytics Data API not enabled** – Verify that the Google Analytics Data API is enabled in your Google Cloud project under **APIs & Services, Library**.
- **No properties visible** – Verify that the authenticated Google account has access to the Google Analytics properties that you want to query.

Google Calendar integration

With the Google Calendar connector, you can access Google Calendar directly in Amazon Quick through natural language. You can create and update events, check availability, manage calendars, and organize attendees without leaving Amazon Quick.

Amazon Quick supports multiple authentication methods for Google Calendar. Choose the method that best fits your organization's security requirements.

- **Default OAuth app** – Uses an AWS-managed OAuth application. No additional credentials are needed. You authenticate directly with your Google account.
- **Custom OAuth app** – Uses a customer-managed OAuth client created in the Google Cloud Console. This option gives your organization full control over the OAuth configuration.

For more information about the authentication methods that Amazon Quick supports, see [the section called “Authentication methods”](#).

Before you begin

Make sure that you have the following before you set up the integration.

- A Google account with access to Google Calendar.
- For **Custom OAuth app**: Access to the [Google Cloud Console](#) on the Google website with permissions to create OAuth clients.
- For Amazon Quick subscription requirements, see [the section called “Set up integrations in the console”](#).

Configuring Google Cloud

If you are using **Default OAuth app** authentication, skip this section and go to [the section called “Setting up the connector in Amazon Quick”](#).

For Custom OAuth app authentication, complete the following steps in the Google Cloud Console before you configure Amazon Quick. When you enable the API in step 3, search for and enable the **Google Calendar API**.

Create an OAuth client in Google Cloud Console

Create an OAuth client in the Google Cloud Console to get the client credentials that you need for Amazon Quick. For more information, see [Using OAuth 2.0 to Access Google APIs](#) on the Google website.

1. Sign in to the [Google Cloud Console](#) on the Google website.
2. Create a new project or select an existing project.
3. In the left navigation pane, choose **APIs & Services**, then choose **Library**. Search for the API that your integration requires and choose **Enable**.
4. Choose **OAuth consent screen** and choose **Get Started**.
5. Configure the consent screen:
 - Enter an **App Name** and select a **User support email**.
 - For **Audience**, choose **Internal** (your organization only) or **External** (any Google user).
 - Add developer contact details and choose **Create**.
6. Choose **Create OAuth client**.
7. Configure the client:
 - For **Application type**, choose **Web application**.
 - Enter a **Name** for your client.
 - Under **Authorized redirect URIs**, add the Amazon Quick callback URL:
`https://{region}.quicksight.aws.amazon.com/sn/oauthcallback`
8. Choose **Create**.
9. Record the following values. You need them when you configure Amazon Quick.
 - **Client ID**
 - **Client secret**

Recommended scopes

The following scopes are requested when you connect to Google Calendar.

Google Calendar recommended scopes

Scope	Description
https://www.googleapis.com/auth/calendar	Reads and writes calendar events and settings.
openid	Authenticates the user's identity.
email	Reads the user's email address.

Note

The `openid` and `email` scopes are automatically included in the OAuth consent flow for user authentication. They are not required for Service-to-Service OAuth.

Setting up the connector in Amazon Quick

Connect from the Available tab

If you want to use Default OAuth app authentication, you can connect directly from the **Available** tab without additional configuration.

1. In the Amazon Quick console, choose **Connectors**.
2. On the **Available** tab, find **Google Calendar** and choose **Connect**.
3. Complete the Google sign-in flow and grant the requested permissions.

To configure a connector with Custom OAuth app instead, use the **Create for your team** tab as described below.

Create from the Create for your team tab

After you complete any required Google Cloud configuration, create the connector in Amazon Quick.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Google Calendar**.

 Note

If a Google Calendar connector already exists, a dialog appears with your existing connectors. To use an existing connector, choose it. To create a new one, choose **No, create new**.

4. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
5. For **Connection type**, choose **Public network**.
6. For **OAuth Configuration**, choose one of the following authentication methods and configure the required fields.
 - a. For **Default OAuth app**:

No additional credentials are needed. Choose **Next** to continue.
 - b. For **Custom OAuth app**, configure the following fields:
 - **Base URL** (Optional) – The Google Calendar API base URL. Example: `https://www.googleapis.com/calendar`
 - **Client ID** – The client ID from your Google Cloud OAuth client.
 - **Client secret** – The client secret from your Google Cloud OAuth client.
 - **Token URL** – The token endpoint. Example: `https://oauth2.googleapis.com/token`
 - **Authorization URL** – The authorization endpoint. Example: `https://accounts.google.com/o/oauth2/v2/auth`
 - **Redirect URL** – Pre-filled with the Amazon Quick callback URL.
7. Choose **Next**.
8. If you chose **Default OAuth app** or **Custom OAuth app**, a Google authorization window opens. Review the requested permissions and choose **Allow**.
9. On the **Review** page, review the available actions for the connector. Choose **Next**.
10. On the **Publish** page, choose who can access the connector. You can enable access for everyone in your organization or search for specific teams or groups.

11. Choose **Publish**.

Available actions

After you set up the connector, the following actions are available.

Google Calendar available actions

Category	Action	Description
Events	List Events	Lists events on a calendar.
Events	Search Events	Searches for events by keyword or criteria.
Events	Get Event	Retrieves details for a specific event.
Events	Create Event	Creates a new calendar event.
Events	Create Quick Event	Creates an event from a text string.
Events	Update Event	Updates an existing event.
Events	Update Event Calendar	Moves an event to a different calendar.
Events	Import Events	Imports events into a calendar.
Events	List Event Instances	Lists instances of a recurring event.
Events	Delete Attendee	Removes an attendee from an event.
Availability	List Free Slots	Finds available time slots across calendars.
Calendars	List Calendars	Lists calendars for the authenticated user.
Calendars	List Calendar Events	Lists events across all calendars.
Calendars	Get Calendar	Retrieves details for a specific calendar.
Calendars	Get Calendar List	Retrieves a calendar list entry.
Calendars	Update Calendar List	Updates a calendar list entry.

Category	Action	Description
Settings	List Settings	Lists calendar settings for the user.
Utilities	Get Current Date Time	Retrieves the current date and time.

Note

The actions that you can use depend on the calendars accessible to the authenticated user.

Managing and troubleshooting

To edit, share, or delete your connector, see [the section called “Managing existing integrations”](#).

Common Google authentication issues

- **Sign-in fails (Default OAuth app or Custom OAuth app)** – Verify that your Google account is active and that you can sign in to [the Google website](#) directly. For Custom OAuth app, confirm that the redirect URI in your Google Cloud OAuth client matches the Amazon Quick callback URL.
- **App blocked by administrator** – If your Google Workspace administrator restricts third-party app access, you might see an error when you attempt to sign in. Contact your Google Workspace administrator to allow the Amazon Quick app.
- **Invalid client credentials (Custom OAuth app)** – Verify that the Client ID and Client secret match the values in your Google Cloud OAuth client.
- **Authentication popup fails** – Verify that your browser allows popups from the Amazon Quick console domain. Try using a different browser or clearing your browser cache.
- **Permissions revoked** – If you previously revoked Amazon Quick access from your Google Account permissions settings, you need to re-authenticate by editing the connector and signing in again.
- **Google API rate limiting** – Google might limit requests during high usage periods. If actions fail, retry after a few minutes.

Google Calendar-specific issues

- **Google Calendar API not enabled** – Verify that the Google Calendar API is enabled in your Google Cloud project under **APIs & Services, Library**.

Google Chat integration

With the Google Chat connector, you can send messages, manage spaces, and interact with chat threads from your Google Workspace account directly in Amazon Quick through natural language.

Google Chat uses Custom OAuth app authentication. For more information about the authentication methods that Amazon Quick supports, see [the section called “Authentication methods”](#).

Before you begin

Make sure that you have the following before you set up the integration.

- An active Google Workspace account with access to the Google Chat spaces that you want to use.
- An OAuth 2.0 client registered in the Google Cloud console for your Google Workspace project, with the Google Chat API enabled.
- A Google Chat App configured in the Google Cloud console under the Google Chat API settings. The Chat App must be configured before you can use the Chat API to send messages and interact with spaces. For more information, see [the section called “Configure the Google Chat App”](#).
- For Amazon Quick subscription requirements, see [the section called “Set up integrations in the console”](#).

Configuring Google Cloud

For Custom OAuth app authentication, create an OAuth 2.0 client in the [Google Cloud console](#), enable the Google Chat API for your project, configure the OAuth consent screen with the Chat scopes that you need (for example, `chat.messages`, `chat.spaces`), and add the Amazon Quick callback URL `https://{region}.quicksight.aws.amazon.com/sn/oauthcallback` as an authorized redirect URI. Replace `{region}` with your AWS Region (for example, `us-east-1`). For step-by-step instructions, see [Google Chat API](#) in the Google Workspace developer documentation. Record the Client ID and Client Secret — you need them when you configure Amazon Quick.

Configure the Google Chat App

Before you can use the Google Chat API, you must configure a Google Chat App in the Google Cloud console. The Chat App is the identity under which your integration interacts with Google Chat spaces and threads.

1. In the [Google Cloud console](#), navigate to **APIs & Services** and confirm that the **Google Chat API** is enabled for your project.
2. Choose **Google Chat API**, then choose the **Configuration** tab.
3. Enter the following Chat App details:
 - **App name.** A display name for the Chat App (for example, "Amazon Quick Integration").
 - **Avatar URL (Optional).** A URL to an image that represents the Chat App in Google Chat.
 - **Description.** A brief description of the Chat App's purpose.
4. Under **Interactive features**, configure the features that your integration requires. If your integration only sends messages and does not need to receive events from Google Chat, you can leave interactive features turned off.
5. Under **Visibility**, choose who can install the Chat App in your Google Workspace domain. You can make the app available to specific people or to everyone in your organization.
6. Choose **Save**.

For more information about configuring Google Chat Apps, see [Google Chat app overview](#) in the Google Workspace developer documentation.

Setting up the connector in Amazon Quick

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Google Chat**.
4. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
5. For **Connection type**, choose **Public network**.
6. For **OAuth Configuration**, choose **Custom OAuth app** and configure the following fields:
 - **Base URL** – The Google Chat MCP base URL.
 - **Client ID** – The OAuth client ID from your Google Cloud OAuth 2.0 client.

- **Public OAuth client** (Optional) – Select this option if your Google Cloud OAuth 2.0 client is configured as a public client (no client secret).
 - **Client secret** – The client secret from your Google Cloud OAuth 2.0 client.
 - **Token URL** – The Google OAuth token endpoint.
 - **Authorization URL** – The Google OAuth authorization endpoint.
 - **Redirect URL** – Pre-filled with the Amazon Quick callback URL.
7. Choose **Next**.
 8. A Google sign-in window opens. Review the requested permissions and choose **Allow**.
 9. On the **Review** page, review the available actions for the connector. Choose **Next**.
 10. On the **Publish** page, choose who can access the connector. You can enable access for everyone in your organization or search for specific teams or groups.
 11. Choose **Publish**.

Available actions

After you set up the connector, the actions exposed by Google Chat are available. To see the current set of actions for your connector, go to the connector's **Available actions** view in the Amazon Quick console.

Managing and troubleshooting

To edit, share, or delete your connector, see [the section called “Managing existing integrations”](#).

Authentication issues

- **Sign-in fails** – Verify that your Google Workspace account is active and that you can sign in to Google Chat directly. Confirm that the authorized redirect URI in your Google Cloud OAuth 2.0 client matches the Amazon Quick callback URL.
- **Invalid client credentials** – Verify that the Client ID and Client Secret match the values in your Google Cloud OAuth 2.0 client.
- **Insufficient permissions** – Verify that the Chat API is enabled and that your OAuth consent screen includes the required scopes for the operations you want to use.

Google Docs integration

With the Google Docs connector, you can access Google Docs directly in Amazon Quick through natural language. You can create and edit documents, read content, insert text and images, and manage document structure without leaving Amazon Quick.

Amazon Quick supports multiple authentication methods for Google Docs. Choose the method that best fits your organization's security requirements.

- **Default OAuth app** – Uses an AWS-managed OAuth application. No additional credentials are needed. You authenticate directly with your Google account.
- **Custom OAuth app** – Uses a customer-managed OAuth client created in the Google Cloud Console. This option gives your organization full control over the OAuth configuration.

For more information about the authentication methods that Amazon Quick supports, see [the section called “Authentication methods”](#).

Before you begin

Make sure that you have the following before you set up the integration.

- A Google account with access to Google Docs.
- For **Custom OAuth app**: Access to the [Google Cloud Console](#) on the Google website with permissions to create OAuth clients.
- For Amazon Quick subscription requirements, see [the section called “Set up integrations in the console”](#).

Configuring Google Cloud

If you use **Default OAuth app** authentication, skip this section and see [the section called “Setting up the connector in Amazon Quick”](#).

For Custom OAuth app authentication, complete the following steps in the Google Cloud Console before you configure Amazon Quick. When you enable the API in step 3, search for and enable the **Google Docs API**.

Create an OAuth client in Google Cloud Console

Create an OAuth client in the Google Cloud Console to get the client credentials that you need for Amazon Quick. For more information, see [Using OAuth 2.0 to Access Google APIs](#) on the Google website.

1. Sign in to the [Google Cloud Console](#) on the Google website.
2. Create a new project or select an existing project.
3. In the left navigation pane, choose **APIs & Services**, then choose **Library**. Search for the API that your integration requires and choose **Enable**.
4. Choose **OAuth consent screen** and choose **Get Started**.
5. Configure the consent screen:
 - Enter an **App Name** and select a **User support email**.
 - For **Audience**, choose **Internal** (your organization only) or **External** (any Google user).
 - Add developer contact details and choose **Create**.
6. Choose **Create OAuth client**.
7. Configure the client:
 - For **Application type**, choose **Web application**.
 - Enter a **Name** for your client.
 - Under **Authorized redirect URIs**, add the Amazon Quick callback URL:
`https://{region}.quicksight.aws.amazon.com/sn/oauthcallback`
8. Choose **Create**.
9. Record the following values. You need them when you configure Amazon Quick.
 - **Client ID**
 - **Client secret**

Recommended scopes

The following scopes are requested when you connect to Google Docs.

Google Docs recommended scopes

Scope	Description
https://www.googleapis.com/auth/documents	Reads and writes Google Docs documents.
https://www.googleapis.com/auth/drive	Reads and writes files in Google Drive.
https://www.googleapis.com/auth/drive.readonly	Reads files in Google Drive.
openid	Authenticates the user's identity.
email	Reads the user's email address.

Note

The `openid` and `email` scopes are automatically included in the OAuth consent flow for user authentication. They are not required for Service-to-Service OAuth.

Setting up the connector in Amazon Quick

Connect from the Available tab

If you want to use Default OAuth app authentication, you can connect directly from the **Available** tab without additional configuration.

1. In the Amazon Quick console, choose **Connectors**.
2. On the **Available** tab, find **Google Docs** and choose **Connect**.
3. Complete the Google sign-in flow and grant the requested permissions.

To configure a connector with Custom OAuth app instead, use the **Create for your team** tab as described below.

Create from the Create for your team tab

After you complete any required Google Cloud configuration, create the connector in Amazon Quick.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Google Docs**.

Note

If a Google Docs connector already exists, a dialog appears with your existing connectors. To use an existing connector, choose it. To create a new one, choose **No, create new**.

4. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
5. For **Connection type**, choose **Public network**.
6. For **OAuth Configuration**, choose one of the following authentication methods and configure the required fields.
 - a. For **Default OAuth app**:

No additional credentials are needed. Choose **Next** to continue.
 - b. For **Custom OAuth app**, configure the following fields:
 - **Base URL** (Optional) – The Google Docs API base URL. For example: `https://docs.googleapis.com`
 - **Client ID** – The client ID from your Google Cloud OAuth client.
 - **Client secret** – The client secret from your Google Cloud OAuth client.
 - **Token URL** – The token endpoint. For example: `https://oauth2.googleapis.com/token`
 - **Authorization URL** – The authorization endpoint. For example: `https://accounts.google.com/o/oauth2/v2/auth`
 - **Redirect URL** – Pre-filled with the Amazon Quick callback URL.
7. Choose **Next**.

8. If you chose **Default OAuth app** or **Custom OAuth app**, a Google authorization window opens. Review the requested permissions and choose **Allow**.
9. On the **Review** page, review the available actions for the connector. Choose **Next**.
10. On the **Publish** page, choose who can access the connector. You can enable access for everyone in your organization or search for specific teams or groups.
11. Choose **Publish**.

Available actions

After you set up the connector, the following actions are available.

Google Docs available actions

Category	Action	Description
Documents	Get Document	Retrieves a document by ID.
Documents	Get Document Plaintext	Retrieves the plain text content of a document.
Documents	Search Documents	Searches for documents.
Documents	Create Document	Creates a new document.
Documents	Create Document Markdown	Creates a new document from Markdown content.
Documents	Copy Document	Creates a copy of an existing document.
Documents	Update Document	Updates an existing document.
Documents	Update Document Markdown	Updates a document with Markdown content.
Documents	Update Document Section	Updates a specific section of a document with Markdown.
Documents	Update Document Style	Updates the style of a document.
Documents	Export Pdf	Exports a document as a PDF file.

Category	Action	Description
Content	Insert Text	Inserts text at a specified location.
Content	Update Text	Replaces all occurrences of specified text.
Content	Delete Content Range	Deletes content within a specified range.
Content	Insert Inline Image	Inserts an inline image into a document.
Content	Create Table	Inserts a table into a document.
Content	Create Paragraph Bullets	Adds bullet formatting to paragraphs.
Content	Create Named Range	Creates a named range in a document.
Content	Create Page Break	Inserts a page break.
Structure	Create Header	Creates a header in a document.
Structure	Create Footer	Creates a footer in a document.

Note

The actions that you can use depend on the documents accessible to the authenticated user.

Managing and troubleshooting

To edit, share, or delete your connector, see [the section called “Managing existing integrations”](#).

Common Google authentication issues

- **Sign-in fails (Default OAuth app or Custom OAuth app)** – Verify that your Google account is active and that you can sign in to [the Google website](#) directly. For Custom OAuth app, confirm that the redirect URI in your Google Cloud OAuth client matches the Amazon Quick callback URL.
- **App blocked by administrator** – If your Google Workspace administrator restricts third-party app access, you might see an error when you attempt to sign in. Contact your Google Workspace administrator to allow the Amazon Quick app.

- **Invalid client credentials (Custom OAuth app)** – Verify that the Client ID and Client secret match the values in your Google Cloud OAuth client.
- **Authentication popup fails** – Verify that your browser allows popups from the Amazon Quick console domain. Try using a different browser or clearing your browser cache.
- **Permissions revoked** – If you previously revoked Amazon Quick access from your Google Account permissions settings, you need to re-authenticate by editing the connector and signing in again.
- **Google API rate limiting** – Google might limit requests during high usage periods. If actions fail, retry after a few minutes.

Google Docs-specific issues

- **Google Docs API not enabled** – Verify that the Google Docs API is enabled in your Google Cloud project under **APIs & Services, Library**.

Google Drive integration

With the Google Drive integration, you can manage files and folders through actions, and index your Google Drive content into knowledge bases for AI-powered search and Q&A.

What you can do

Connector

Upload and download files, manage folders, search content, and track changes through the Google Drive API.

Knowledge base

Index Google Drive document libraries, folders, and files. Amazon Quick agents can then search and answer questions about the content. Amazon Quick supports two setup methods: user-managed setup for quick configuration, and admin-managed setup with service credentials for document-level access control.

Google Drive action connector

With the Google Drive connector, you can access Google Drive directly in Amazon Quick through natural language. You can upload and download files, manage folders, search content, and track changes without leaving Amazon Quick.

Amazon Quick supports multiple authentication methods for the Google Drive connector. Choose the method that best fits your organization's security requirements.

- **Default OAuth app** – Uses an AWS-managed OAuth application. No additional credentials are needed. You authenticate directly with your Google account.
- **Custom OAuth app** – Uses a customer-managed OAuth client created in the Google Cloud Console. This option gives your organization full control over the OAuth configuration.

For more information about the authentication methods that Amazon Quick supports, see [the section called “Authentication methods”](#).

Before you begin

Make sure that you have the following before you set up the integration.

- A Google account with access to Google Drive.
- For **Custom OAuth app**: Access to the [Google Cloud Console](#) on the Google website with permissions to create OAuth clients.
- For Amazon Quick subscription requirements, see [the section called “Set up integrations in the console”](#).

Configuring Google Cloud

If you use **Default OAuth app** authentication, skip this section and see [the section called “Setting up the connector in Amazon Quick”](#).

For Custom OAuth app authentication, complete the following steps in the Google Cloud Console before you configure Amazon Quick. When you enable the API in step 3, search for and enable the **Google Drive API**.

Create an OAuth client in Google Cloud Console

Create an OAuth client in the Google Cloud Console to get the client credentials that you need for Amazon Quick. For more information, see [Using OAuth 2.0 to Access Google APIs](#) on the Google website.

1. Sign in to the [Google Cloud Console](#) on the Google website.
2. Create a new project or select an existing project.
3. In the left navigation pane, choose **APIs & Services**, then choose **Library**. Search for the API that your integration requires and choose **Enable**.
4. Choose **OAuth consent screen** and choose **Get Started**.
5. Configure the consent screen:
 - Enter an **App Name** and select a **User support email**.
 - For **Audience**, choose **Internal** (your organization only) or **External** (any Google user).
 - Add developer contact details and choose **Create**.
6. Choose **Create OAuth client**.
7. Configure the client:
 - For **Application type**, choose **Web application**.
 - Enter a **Name** for your client.
 - Under **Authorized redirect URIs**, add the Amazon Quick callback URL:
`https://{region}.quicksight.aws.amazon.com/sn/oauthcallback`
8. Choose **Create**.
9. Record the following values. You need them when you configure Amazon Quick.
 - **Client ID**
 - **Client secret**

Recommended scopes

The following scopes are requested when you connect to Google Drive.

Google Drive recommended scopes

Scope	Description
<code>https://www.googleapis.com/auth/drive</code>	Reads and writes files in Google Drive.
<code>https://www.googleapis.com/auth/drive.readonly</code>	Reads files in Google Drive.
<code>https://www.googleapis.com/auth/drive.metadata.readonly</code>	Reads file metadata in Google Drive.
<code>openid</code>	Authenticates the user's identity.
<code>email</code>	Reads the user's email address.

Note

The `openid` and `email` scopes are automatically included in the OAuth consent flow for user authentication. They are not required for Service-to-Service OAuth.

Setting up the connector in Amazon Quick

Connect from the Available tab

If you want to use Default OAuth app authentication, you can connect directly from the **Available** tab without additional configuration.

1. In the Amazon Quick console, choose **Connectors**.
2. On the **Available** tab, find **Google Drive** and choose **Connect**.
3. Complete the Google sign-in flow and grant the requested permissions.

To configure a connector with Custom OAuth app instead, use the **Create for your team** tab as described below.

Create from the Create for your team tab

After you complete any required Google Cloud configuration, create the connector in Amazon Quick.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Google Drive**.

Note

If a Google Drive connector already exists, a dialog appears with your existing connectors. To use an existing connector, choose it. To create a new one, choose **No, create new**.

4. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
5. For **Connection type**, choose **Public network**.
6. For **OAuth Configuration**, choose one of the following authentication methods and configure the required fields.
 - a. For **Default OAuth app**:

No additional credentials are needed. Choose **Next** to continue.
 - b. For **Custom OAuth app**, configure the following fields:
 - **Base URL** (Optional) – The Google Drive API base URL. For example: `https://www.googleapis.com/drive`
 - **Client ID** – The client ID from your Google Cloud OAuth client.
 - **Client secret** – The client secret from your Google Cloud OAuth client.
 - **Token URL** – The token endpoint. For example: `https://oauth2.googleapis.com/token`
 - **Authorization URL** – The authorization endpoint. For example: `https://accounts.google.com/o/oauth2/v2/auth`
 - **Redirect URL** – Pre-filled with the Amazon Quick callback URL.
7. Choose **Next**.

8. If you chose **Default OAuth app** or **Custom OAuth app**, a Google authorization window opens. Review the requested permissions and choose **Allow**.
9. On the **Review** page, review the available actions for the connector. Choose **Next**.
10. On the **Publish** page, choose who can access the connector. You can enable access for everyone in your organization or search for specific teams or groups.
11. Choose **Publish**.

Available actions

After you set up the connector, the following actions are available.

Google Drive available actions

Category	Action	Description
Files	Get File	Downloads a file from Google Drive.
Files	Search Files	Searches for files by name or content.
Files	Get File Metadata	Retrieves metadata for a file.
Files	Import File	Uploads a file to Google Drive.
Files	Upload File From Url	Uploads a file from a URL.
Files	Create File	Creates a new file.
Files	Create File From Text	Creates a file from text content.
Files	Put File	Replaces the content of an existing file.
Files	Update File Content	Edits the content of an existing file.
Files	Update File Location	Moves a file to a different folder.
Files	Copy File	Creates a copy of a file.
Files	Export File	Exports a Google Workspace file to a different format.

Category	Action	Description
Files	Delete File	Moves a file to the trash.
Folders	Create Folder	Creates a new folder.
Folders	Search Folders	Searches for folders by name.
Permissions	List Permissions	Lists permissions for a file or folder.
Comments	List Comments	Lists comments on a file.
Changes	List Changes	Lists recent changes to files.
Changes	Get Changes Start Page Token	Retrieves a start page token for tracking changes.
Drive	Get Drive Info	Retrieves information about the user's Drive.

Note

The actions that you can use depend on the files and folders accessible to the authenticated user.

Managing and troubleshooting

To edit, share, or delete your connector, see [the section called “Managing existing integrations”](#).

Common Google authentication issues

- **Sign-in fails (Default OAuth app or Custom OAuth app)** – Verify that your Google account is active and that you can sign in to [the Google website](#) directly. For Custom OAuth app, confirm that the redirect URI in your Google Cloud OAuth client matches the Amazon Quick callback URL.
- **App blocked by administrator** – If your Google Workspace administrator restricts third-party app access, you might see an error when you attempt to sign in. Contact your Google Workspace administrator to allow the Amazon Quick app.

- **Invalid client credentials (Custom OAuth app)** – Verify that the Client ID and Client secret match the values in your Google Cloud OAuth client.
- **Authentication popup fails** – Verify that your browser allows popups from the Amazon Quick console domain. Try using a different browser or clearing your browser cache.
- **Permissions revoked** – If you previously revoked Amazon Quick access from your Google Account permissions settings, you need to re-authenticate by editing the connector and signing in again.
- **Google API rate limiting** – Google might limit requests during high usage periods. If actions fail, retry after a few minutes.

Google Drive-specific issues

- **Google Drive API not enabled** – Verify that the Google Drive API is enabled in your Google Cloud project under **APIs & Services, Library**.

Google Drive knowledge base integration

With the Google Drive knowledge base integration, you can index your Google Drive content. Your Amazon Quick agents can then search this content and answer questions about it.

Amazon Quick supports two authentication methods for connecting to Google Drive:

- **User-managed setup** – You sign in to Google Drive directly to authorize the connection. This is the simplest way to get started. For more information, see [the section called “User-managed setup”](#).
- **Admin-managed setup (service credentials)** – A Google Workspace administrator creates a service account with domain-wide delegation to authorize the connection. A key benefit of admin-managed setup is built-in document-level access control (ACL). Amazon Quick automatically syncs access control lists from Google Drive. It verifies each user's permissions at query time, so users see answers only from documents that they are authorized to access. For more information, see [the section called “Admin-managed Google Drive knowledge base setup”](#).

After you connect, Amazon Quick indexes your Google Drive files and folders into a knowledge base. Your Amazon Quick agents can then search this content and generate answers that are grounded in your Google Drive data.

Prerequisites

Before you set up the Google Drive knowledge base integration, make sure that you have the following:

- A Google account with Google Drive access.
- For subscription requirements, see [the section called “Set up integrations in the console”](#).

For admin-managed setup, additional prerequisites apply. For more information, see [the section called “Admin-managed Google Drive knowledge base setup”](#).

Supported content types

The Google Drive connector supports all of the common file types that Amazon Quick knowledge bases support. These include PDF, Word, Excel, PowerPoint, and text files. The connector also supports the following Google Workspace-specific formats:

- Google Docs
- Google Sheets
- Google Slides

For more information about supported file types, size limits, and content processing options, see [Common configuration settings](#).

User-managed setup

With user-managed setup, you sign in to Google Drive directly to authorize the connection. Amazon Quick handles authentication through a managed OAuth flow. No Google Cloud project, service account, or domain-wide delegation is required.

Prerequisites

Before you set up a user-managed Google Drive knowledge base, verify the following:

- You have a Google account with access to Google Drive.
- Your Google Workspace administrator allows third-party app access, or can allow the Amazon Quick app on your behalf.
- Your browser allows popups from the Amazon Quick console domain.

Note

If your organization restricts third-party app access in Google Workspace, your Google Workspace administrator might need to allow the Amazon Quick app before users can sign in. Contact your Google Workspace administrator if you encounter an error during sign-in.

Note

User-managed setup does not support document-level access control (ACL). ACL is a mechanism that controls which users can access specific documents. If you need document-level access control, use [Admin-managed Google Drive knowledge base setup](#) instead.

Permissions granted during consent

When you authorize the connection, Amazon Quick requests the following permissions from your Google account:

See and download all your Google Drive files

- Allows Amazon Quick to see your Google Drive files
- Allows Amazon Quick to download your files
- Allows Amazon Quick to see the names and email addresses of people you share files with

See information about your Google Drive files

- Allows Amazon Quick to see the titles and descriptions of your files
- Allows Amazon Quick to see the names and email addresses of people you share files with
- Allows Amazon Quick to see your folders and how files are organized

Note

You can review and remove this access at any time from your Google Account permissions settings.

Set up a Google Drive knowledge base

To create a user-managed Google Drive knowledge base, complete the following steps in the Amazon Quick console.

1. In the Amazon Quick console, choose **Knowledge**.
2. Find **Google Drive** and choose the **Add (+)** icon.
3. In the **Create Google Drive knowledge base** dialog, under **Authentication method**, choose **Sign in to Google Drive** and complete the Google sign-in and consent flow.
4. Under **Create knowledge base**, enter a name and an optional description for your knowledge base.
5. In the **Content** section, choose **Add content** and select the Google Drive files and folders that you want to index. You can browse content from your personal drive, files shared with you, and shared drives in your organization.
6. Choose **Create**.

After you choose **Create**, the data sync starts automatically.

Access controls

Important

When Amazon Quick indexes Google Drive content through user-managed setup, it does not sync access control lists (ACLs) from Google Drive. All indexed content is accessible to any user who has access to the knowledge base in Amazon Quick, regardless of their permissions in Google Drive. Carefully review which content you include when you create a knowledge base.

If you require document-level access control, use the [Admin-managed Google Drive knowledge base setup](#) instead.

Manage and troubleshoot your integration

For instructions on editing, sharing, or deleting your integration, see [the section called “Managing existing integrations”](#).

For more information about knowledge base troubleshooting, including sync issues and missing documents, see [the section called “Troubleshooting knowledge bases”](#).

Google Drive-specific issues

- **App blocked by administrator** – If your Google Workspace administrator restricts third-party app access, you might see an error when you attempt to sign in. Contact your Google Workspace administrator to allow the Amazon Quick app.
- **Authentication popup fails** – Verify that your browser allows popups from the Amazon Quick console domain. Try using a different browser or clearing your browser cache.
- **Permissions revoked** – If you previously revoked Amazon Quick access from your Google Account permissions settings, you need to re-authenticate by editing the integration and signing in again.
- **Missing content** – Verify that the Google account that you used for authentication has access to the files and folders that you selected. Content that was shared with you after the initial sync requires a resync to be indexed.
- **Google API rate limiting** – Google Drive might limit requests during high usage periods. If syncs fail or are incomplete, retry during off-peak hours.

Known limitations

- Document-level access control (ACL) is not supported with user-managed setup. If you require document-level access control, use [Admin-managed Google Drive knowledge base setup](#).
- Synchronization of file comments is not supported.

Admin-managed Google Drive knowledge base setup

With admin-managed setup, a Google Workspace administrator creates a service account and delegates domain-wide access. Individual users don't need to authorize through sign-in.

Admin-managed setup includes built-in document-level access control list (ACL) support. Amazon Quick automatically syncs ACLs from Google Drive and verifies each user's permissions at query time.

For more information about ACL best practices, see [the section called “Best practices for managing ACLs in knowledge bases”](#).

Prerequisites

Make sure that you have the following before you set up the integration.

- Administrator access to your organization's Google Workspace.
- An Amazon Quick enterprise user account. Administrator access is not required.
- A Google Workspace account with an email domain that matches the email domain that is used for your Amazon Quick identity.
- For subscription requirements, see [the section called "Set up integrations in the console"](#).

Setup overview

The setup involves the following phases:

1. **Configure Google Workspace** – Create a Google Cloud service account with read-only API access and domain-wide delegation. Then create a dedicated admin user for the service account to impersonate. For more information, see [the section called "Configure Google Workspace"](#).
2. **Create the knowledge base in Amazon Quick** – Create a Google Drive knowledge base by using the service account credentials from Phase 1. For more information, see [the section called "Creating a knowledge base in Amazon Quick"](#).

Document-level access control is automatically enabled for all admin-managed knowledge bases. For more information about how access controls work, see [the section called "Document-level access controls"](#).

Configure Google Workspace

To connect Amazon Quick to Google Drive, complete the following tasks in the Google Cloud console and Google Workspace Admin Console. You create a Google Cloud project, turn on the required APIs, generate service account credentials, and configure domain-wide delegation. You also create a dedicated admin user for the service account to impersonate.

Prerequisites

Before you begin, make sure that you have the following:

- A Google Workspace account with administrator access

- Permission to create projects in the Google Cloud console

Creating a Google Cloud project

1. Open the Google Cloud console.
2. From the project selector at the top of the page, choose **New Project**.
3. Enter a project name, then choose **Create**.
4. After the project is created, choose **Select Project** to switch to it. This might take a few moments.

Turning on the required APIs

Amazon Quick requires three Google APIs. Turn on each one from the API Library.

1. In the navigation menu, choose **APIs & Services**, then choose **Library**.
2. Search for each of the following APIs and choose **Enable**:
 - Google Drive API
 - Google Drive Activity API
 - Admin SDK API

Creating the service account

1. In the navigation menu, choose **APIs & Services**, then choose **Credentials**.
2. Choose **Create Credentials**, then choose **Service account**.
3. Enter a name and optional description for the service account, then choose **Done**.

Generating a private key

1. On the **Credentials** page, choose the service account you created.
2. Choose the **Keys** tab, then choose **Add Key, Create new key**.
3. Confirm that **JSON** is selected, then choose **Create**.

The browser downloads a JSON file containing the private key. Store this file securely. You upload it to Amazon Quick in a later step.

 Note

If you receive an error stating that service account key creation is disabled by an organization policy, see [the section called “Resolving organization policy restrictions”](#).

Recording the service account unique ID

1. On the service account detail page, choose the **Details** tab.
2. Copy the value in the **Unique ID** field. You need this value when you configure domain-wide delegation.

Configuring domain-wide delegation

Domain-wide delegation allows the service account to access Google Workspace data on behalf of users in your organization.

1. On the service account detail page, expand **Advanced settings**.
2. Choose **View Google Workspace Admin Console**. The admin console opens in a new tab.
3. In the admin console navigation pane, choose **Security, Access and data control, API controls**.
4. Choose **Manage Domain Wide Delegation**, then choose **Add new**.
5. For **Client ID**, enter the unique ID you copied earlier.
6. For **OAuth scopes**, enter the following comma-separated values:

```
https://www.googleapis.com/auth/drive.readonly,https://www.googleapis.com/auth/drive.metadata.readonly,https://www.googleapis.com/auth/admin.directory.user.readonly,https://www.googleapis.com/auth/admin.directory.group.readonly,https://www.googleapis.com/auth/cloud-platform,https://www.googleapis.com/auth/forms.body.readonly
```

7. Choose **Authorize**.

Creating a delegated admin user

The service account acts on behalf of a Google Workspace admin user. Create a dedicated user for this purpose and assign the minimum required roles.

1. In the Google Workspace Admin Console, choose **Directory**, then choose **Users**.
2. Choose **Add new user**.
3. Enter a first name, last name, and primary email address for the new user, then choose **Add new user**.
4. Choose **Done**.
5. From the user list, choose the user you created. If the user does not appear, refresh the page.
6. On the user detail page, expand the **Admin roles and privileges** section.
7. Under **Roles**, assign the following roles:
 - Groups Reader
 - User Management Admin
 - Storage Admin
8. Choose **Save**.

Record the email address of this user. You need it when you create the knowledge base in Amazon Quick.

Troubleshooting the Google Workspace configuration

Resolving organization policy restrictions

If you receive the following error when creating a service account key:

The organization policy constraint `iam.disableServiceAccountKeyCreation` is enforced on your organization.

Note

For Google Cloud organizations created on or after May 3, 2024, this constraint is enforced by default.

You must override the policy for your project.

1. Open the Google Cloud console and confirm that the correct project is selected.
2. In the navigation menu, choose **IAM & Admin**, then choose **Organization Policies**.
3. In the **Filter** field, enter `iam.disableServiceAccountKeyCreation`. Then, in the policy list, choose **Disable service account key creation**.
4. Choose **Manage policy**.

 Note

If **Manage policy** is unavailable, you need the Organization Policy Administrator role (`roles/orgpolicy.policyAdmin`) at the organization level. See [the section called "Granting the Organization Policy Administrator role"](#).

5. In the **Policy source** section, ensure that **Override parent's policy** is selected.
6. Under **Enforcement**, turn off enforcement for this organization policy constraint.
7. Choose **Set policy**.

The change can take several minutes to propagate.

Granting the Organization Policy Administrator role

The Organization Policy Administrator role (`roles/orgpolicy.policyAdmin`) must be granted at the organization level, not the project level. It does not appear in the role list when assigning roles to a project.

To grant this role, select your organization (not a project) from the project selector in the Google Cloud console. Then, choose **IAM & Admin**, **IAM**, and assign the role to your account. For detailed instructions, see [Manage access to projects, folders, and organizations](#) in the Google Cloud documentation.

The role assignment can take several minutes to propagate.

Creating a knowledge base in Amazon Quick

In this phase, you create a knowledge base in Amazon Quick and provide the service account credentials from the Google Workspace configuration. Any enterprise user can complete this phase. Amazon Quick administrator access is not required.

If a Google Workspace administrator completed the Google Workspace configuration on your behalf, you need the JSON key file and the delegated admin email address before you proceed.

Setting up the knowledge base

1. In the Amazon Quick console, choose **Knowledge**.
2. Under **Knowledge bases**, find **Google Drive**, and then choose the **Add (+)** icon.
3. In the **Create Google Drive knowledge base** dialog, choose **Have admin credentials? Configure document-level access control**.
4. In the **Connected account** dropdown, choose **Add account**.
5. For **Name**, enter a name for the connection. Use a descriptive name such as your Google Workspace domain.

Important

You cannot change the connection name after you save it.

6. Choose **Upload .JSON key**, and then choose the JSON file that you downloaded during the Google Workspace configuration.
7. For **Google workspace admin email**, enter the email address of the delegated admin user that you created during the Google Workspace configuration.
8. Choose **Next**.

Choosing content to sync

1. Enter a **Name** and optional **Description** for your knowledge base.
2. Choose which Google Drive content to include:
 - **My Drive (all users)** – Includes files from all users' My Drive in your organization.
 - **Shared with me (all users)** – Includes files that are shared with your users.
 - **Shared drives** – All shared drives sync by default. To include or exclude specific drives, use the **Filter type** dropdown and **Add shared drive IDs** field. You can enter 1 to 100 shared drive IDs.
3. Choose **Next** to configure advanced settings.

Configuring advanced settings

In the **Advanced settings** step, you can configure optional settings for the knowledge base.

Filter content by date

Limit which documents are crawled based on their last modified date. The start date defaults to one year before today. You can change or clear the start date, and optionally set an end date.

Multi-media content, file size, and file patterns

Choose which content types to include in the knowledge base.

- **Visual content in documents** – Extracts and indexes visual elements from supported document formats. This option is enabled by default.
- **Audio files** – Transcribes and indexes audio files.
- **Video files** – Transcribes and indexes video files.

Choose **Create** to create the knowledge base. After you choose **Create**, the data sync starts automatically.

Managing and troubleshooting

To edit, share, or delete your integration, see [the section called “Managing existing integrations”](#).

For information about knowledge base troubleshooting, including sync issues and missing documents, see [the section called “Troubleshooting knowledge bases”](#).

For information about sync reports, sync schedules, and verifying document-level access controls, see [the section called “Sync reports and observability”](#).

Admin-managed setup issues

- **Google API rate limiting** – Google Drive might throttle requests during high usage periods. If syncs fail or are incomplete, retry during off-peak hours.
- **SSL certificate errors** – If you receive an error about SSL certificate errors when you create your knowledge base, verify the OAuth scopes that you configured during domain-wide delegation.

Document-level access controls

Admin-managed Google Drive knowledge bases include built-in document-level access control. Amazon Quick syncs access control lists (ACLs) from Google Drive during each crawl and verifies

each user's permissions at query time, so users only see answers from documents that they are authorized to access.

How it works

When a user submits a query to an Amazon Quick agent that uses an admin-managed Google Drive knowledge base, the system enforces access controls in two stages:

1. **Pre-retrieval filtering** – Amazon Quick performs a semantic search against the vector index to find the most relevant document passages. The system applies access control lists that are already stored in the index. This produces a preliminary set of candidate documents. This stage is necessary because real-time API calls for every document in the index would be too costly at scale.
2. **Real-time verification** – The system verifies the candidate documents in real time by calling the Google Drive APIs. It uses the service account credential that the administrator provided to generate user-specific access tokens through impersonation. Google Drive maintains the source of truth for access control lists that are associated with each document. The system removes any documents that the user is not authorized to access from the result set.

The system passes only the verified and authorized document passages to the model as context. The model uses this knowledge to generate a response. This two-stage approach provides document-level access control guarantees and maintains performance at scale.

Enable ACL management

Document-level access control is automatically enabled for all admin-managed knowledge bases. No additional configuration is required.

For more information about ACL best practices, see [the section called “Best practices for managing ACLs in knowledge bases”](#).

Known limitations

- File comments synchronization is not supported.

For more information about general ACL limitations and best practices, see [the section called “Best practices for managing ACLs in knowledge bases”](#).

Google Meet integration

With the Google Meet connector, you can access Google Meet directly in Amazon Quick through natural language. You can schedule meetings, view conference records, retrieve transcripts and recordings, and manage meeting spaces without leaving Amazon Quick.

Amazon Quick supports multiple authentication methods for Google Meet. Choose the method that best fits your organization's security requirements.

- **Default OAuth app** – Uses an AWS-managed OAuth application. No additional credentials are needed. You authenticate directly with your Google account.
- **Custom OAuth app** – Uses a customer-managed OAuth client created in the Google Cloud Console. This option gives your organization full control over the OAuth configuration.

For more information about the authentication methods that Amazon Quick supports, see [the section called “Authentication methods”](#).

Before you begin

Make sure that you have the following before you set up the integration.

- A Google account with access to Google Meet.
- For **Custom OAuth app**: Access to the [Google Cloud Console](#) on the Google website with permissions to create OAuth clients.
- For Amazon Quick subscription requirements, see [the section called “Set up integrations in the console”](#).

Configuring Google Cloud

If you use **Default OAuth app** authentication, skip this section and see [the section called “Setting up the connector in Amazon Quick”](#).

For Custom OAuth app authentication, complete the following steps in the Google Cloud Console before you configure Amazon Quick. When you enable the API in step 3, search for and enable the **Google Meet REST API**.

Create an OAuth client in Google Cloud Console

Create an OAuth client in the Google Cloud Console to get the client credentials that you need for Amazon Quick. For more information, see [Using OAuth 2.0 to Access Google APIs](#) on the Google website.

1. Sign in to the [Google Cloud Console](#) on the Google website.
2. Create a new project or select an existing project.
3. In the left navigation pane, choose **APIs & Services**, then choose **Library**. Search for the API that your integration requires and choose **Enable**.
4. Choose **OAuth consent screen** and choose **Get Started**.
5. Configure the consent screen:
 - Enter an **App Name** and select a **User support email**.
 - For **Audience**, choose **Internal** (your organization only) or **External** (any Google user).
 - Add developer contact details and choose **Create**.
6. Choose **Create OAuth client**.
7. Configure the client:
 - For **Application type**, choose **Web application**.
 - Enter a **Name** for your client.
 - Under **Authorized redirect URIs**, add the Amazon Quick callback URL:
`https://{region}.quicksight.aws.amazon.com/sn/oauthcallback`
8. Choose **Create**.
9. Record the following values. You need them when you configure Amazon Quick.
 - **Client ID**
 - **Client secret**

Recommended scopes

The following scopes are requested when you connect to Google Meet.

Google Meet recommended scopes

Scope	Description
<code>https://www.googleapis.com/auth/meetings.space.created</code>	Creates meeting spaces.
<code>https://www.googleapis.com/auth/meetings.space.readonly</code>	Reads meeting space information.
<code>https://www.googleapis.com/auth/meetings.space.settings</code>	Manages meeting space settings.
<code>openid</code>	Authenticates the user's identity.
<code>email</code>	Reads the user's email address.

Note

The `openid` and `email` scopes are automatically included in the OAuth consent flow for user authentication. They are not required for Service-to-Service OAuth.

Setting up the connector in Amazon Quick

Connect from the Available tab

If you want to use Default OAuth app authentication, you can connect directly from the **Available** tab without additional configuration.

1. In the Amazon Quick console, choose **Connectors**.
2. On the **Available** tab, find **Google Meet** and choose **Connect**.
3. Complete the Google sign-in flow and grant the requested permissions.

To configure a connector with Custom OAuth app instead, use the **Create for your team** tab as described below.

Create from the Create for your team tab

After you complete any required Google Cloud configuration, create the connector in Amazon Quick.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Google Meet**.

Note

If a Google Meet connector already exists, a dialog appears with your existing connectors. To use an existing connector, choose it. To create a new one, choose **No, create new**.

4. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
5. For **Connection type**, choose **Public network**.
6. For **OAuth Configuration**, choose one of the following authentication methods and configure the required fields.
 - a. For **Default OAuth app**:

No additional credentials are needed. Choose **Next** to continue.
 - b. For **Custom OAuth app**, configure the following fields:
 - **Base URL** (Optional) – The Google Meet API base URL. For example: `https://meet.googleapis.com`
 - **Client ID** – The client ID from your Google Cloud OAuth client.
 - **Client secret** – The client secret from your Google Cloud OAuth client.
 - **Token URL** – The token endpoint. For example: `https://oauth2.googleapis.com/token`
 - **Authorization URL** – The authorization endpoint. For example: `https://accounts.google.com/o/oauth2/v2/auth`
 - **Redirect URL** – Pre-filled with the Amazon Quick callback URL.
7. Choose **Next**.

8. If you chose **Default OAuth app** or **Custom OAuth app**, a Google authorization window opens. Review the requested permissions and choose **Allow**.
9. On the **Review** page, review the available actions for the connector. Choose **Next**.
10. On the **Publish** page, choose who can access the connector. You can enable access for everyone in your organization or search for specific teams or groups.
11. Choose **Publish**.

Available actions

After you set up the connector, the following actions are available.

Google Meet available actions

Category	Action	Description
Meetings	Create Meeting	Creates a new meeting.
Meetings	Get Meeting	Retrieves details for a specific meeting.
Meetings	List Conference Records	Lists conference records for past meetings.
Spaces	Create Space	Creates a new meeting space.
Spaces	Get Space	Retrieves details for a meeting space.
Spaces	Update Space	Updates meeting space settings.
Participants	List Participants	Lists participants for a conference record.
Participants	List Participant Sessions	Lists sessions for a participant.
Participants	Get Participant Session	Retrieves details for a participant session.
Recordings	List Recordings	Lists recordings for a conference record.
Recordings	Get Recordings	Retrieves recordings by conference record ID.

Category	Action	Description
Transcripts	Get Transcripts	Retrieves transcripts by conference record ID.
Transcripts	List Transcript Entries	Lists individual entries in a transcript.
Transcripts	Get Transcript Entry	Retrieves a specific transcript entry.

Note

The actions that you can use depend on the meetings and conference records accessible to the authenticated user.

Managing and troubleshooting

To edit, share, or delete your connector, see [the section called “Managing existing integrations”](#).

Common Google authentication issues

- **Sign-in fails (Default OAuth app or Custom OAuth app)** – Verify that your Google account is active and that you can sign in to [the Google website](#) directly. For Custom OAuth app, confirm that the redirect URI in your Google Cloud OAuth client matches the Amazon Quick callback URL.
- **App blocked by administrator** – If your Google Workspace administrator restricts third-party app access, you might see an error when you attempt to sign in. Contact your Google Workspace administrator to allow the Amazon Quick app.
- **Invalid client credentials (Custom OAuth app)** – Verify that the Client ID and Client secret match the values in your Google Cloud OAuth client.
- **Authentication popup fails** – Verify that your browser allows popups from the Amazon Quick console domain. Try using a different browser or clearing your browser cache.
- **Permissions revoked** – If you previously revoked Amazon Quick access from your Google Account permissions settings, you need to re-authenticate by editing the connector and signing in again.
- **Google API rate limiting** – Google might limit requests during high usage periods. If actions fail, retry after a few minutes.

Google Meet-specific issues

- **Google Meet REST API not enabled** – Verify that the Google Meet REST API is enabled in your Google Cloud project under **APIs & Services, Library**.

Google Sheets integration

With the Google Sheets connector, you can access Google Sheets directly in Amazon Quick through natural language. You can create and edit spreadsheets, read and write cell ranges, format cells, and search for data without leaving Amazon Quick.

Amazon Quick supports multiple authentication methods for Google Sheets. Choose the method that best fits your organization's security requirements.

- **Default OAuth app** – Uses an AWS-managed OAuth application. No additional credentials are needed. You authenticate directly with your Google account.
- **Custom OAuth app** – Uses a customer-managed OAuth client created in the Google Cloud Console. This option gives your organization full control over the OAuth configuration.

For more information about the authentication methods that Amazon Quick supports, see [the section called “Authentication methods”](#).

Before you begin

Make sure that you have the following before you set up the integration.

- A Google account with access to Google Sheets.
- For **Custom OAuth app**: Access to the [Google Cloud Console](#) on the Google website with permissions to create OAuth clients.
- For Amazon Quick subscription requirements, see [the section called “Set up integrations in the console”](#).

Configuring Google Cloud

If you use **Default OAuth app** authentication, skip this section and see [the section called “Setting up the connector in Amazon Quick”](#).

For Custom OAuth app authentication, complete the following steps in the Google Cloud Console before you configure Amazon Quick. When you enable the API in step 3, search for and enable the **Google Sheets API**.

Create an OAuth client in Google Cloud Console

Create an OAuth client in the Google Cloud Console to get the client credentials that you need for Amazon Quick. For more information, see [Using OAuth 2.0 to Access Google APIs](#) on the Google website.

1. Sign in to the [Google Cloud Console](#) on the Google website.
2. Create a new project or select an existing project.
3. In the left navigation pane, choose **APIs & Services**, then choose **Library**. Search for the API that your integration requires and choose **Enable**.
4. Choose **OAuth consent screen** and choose **Get Started**.
5. Configure the consent screen:
 - Enter an **App Name** and select a **User support email**.
 - For **Audience**, choose **Internal** (your organization only) or **External** (any Google user).
 - Add developer contact details and choose **Create**.
6. Choose **Create OAuth client**.
7. Configure the client:
 - For **Application type**, choose **Web application**.
 - Enter a **Name** for your client.
 - Under **Authorized redirect URIs**, add the Amazon Quick callback URL:
`https://{region}.quicksight.aws.amazon.com/sn/oauthcallback`
8. Choose **Create**.
9. Record the following values. You need them when you configure Amazon Quick.
 - **Client ID**
 - **Client secret**

Recommended scopes

The following scopes are requested when you connect to Google Sheets.

Google Sheets recommended scopes

Scope	Description
https://www.googleapis.com/auth/spreadsheets	Reads and writes Google Sheets spreadsheets.
https://www.googleapis.com/auth/drive	Reads and writes files in Google Drive.
https://www.googleapis.com/auth/drive.readonly	Reads files in Google Drive.
openid	Authenticates the user's identity.
email	Reads the user's email address.

Note

The `openid` and `email` scopes are automatically included in the OAuth consent flow for user authentication. They are not required for Service-to-Service OAuth.

Setting up the connector in Amazon Quick

Connect from the Available tab

If you want to use Default OAuth app authentication, you can connect directly from the **Available** tab without additional configuration.

1. In the Amazon Quick console, choose **Connectors**.
2. On the **Available** tab, find **Google Sheets** and choose **Connect**.
3. Complete the Google sign-in flow and grant the requested permissions.

To configure a connector with Custom OAuth app instead, use the **Create for your team** tab as described below.

Create from the Create for your team tab

After you complete any required Google Cloud configuration, create the connector in Amazon Quick.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Google Sheets**.

Note

If a Google Sheets connector already exists, a dialog appears with your existing connectors. To use an existing connector, choose it. To create a new one, choose **No, create new**.

4. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
5. For **Connection type**, choose **Public network**.
6. For **OAuth Configuration**, choose one of the following authentication methods and configure the required fields.

a. For **Default OAuth app**:

No additional credentials are needed. Choose **Next** to continue.

b. For **Custom OAuth app**, configure the following fields:

- **Base URL** (Optional) – The Google Sheets API base URL. For example: `https://sheets.googleapis.com`
- **Client ID** – The client ID from your Google Cloud OAuth client.
- **Client secret** – The client secret from your Google Cloud OAuth client.
- **Token URL** – The token endpoint. For example: `https://oauth2.googleapis.com/token`
- **Authorization URL** – The authorization endpoint. For example: `https://accounts.google.com/o/oauth2/v2/auth`
- **Redirect URL** – Pre-filled with the Amazon Quick callback URL.

7. Choose **Next**.

8. If you chose **Default OAuth app** or **Custom OAuth app**, a Google authorization window opens. Review the requested permissions and choose **Allow**.
9. On the **Review** page, review the available actions for the connector. Choose **Next**.
10. On the **Publish** page, choose who can access the connector. You can enable access for everyone in your organization or search for specific teams or groups.
11. Choose **Publish**.

Available actions

After you set up the connector, the following actions are available.

Google Sheets available actions

Category	Action	Description
Values	Get Values	Reads values from a cell range.
Values	Batch Get Value	Reads values from multiple cell ranges in a single request.
Values	Get Values By Filter	Reads values using a data filter.
Values	Update Values	Writes values to a cell range.
Values	Batch Update Value	Writes values to multiple cell ranges in a single request.
Values	Append Values	Appends values after the last row of data in a range.
Values	Delete Values	Clears values from a cell range.
Values	Update Text	Finds and replaces text across a spreadsheet.
Rows	Create Row	Creates a new row in a spreadsheet.
Rows	Put Rows	Upserts rows in a spreadsheet.
Rows	Get Spreadsheet Row	Looks up a row by matching criteria.

Category	Action	Description
Spreadsheets	Create Spreadsheet	Creates a new spreadsheet.
Spreadsheets	Get Spreadsheet Info	Retrieves metadata for a spreadsheet.
Spreadsheets	Search Spreadsheets	Searches for spreadsheets.
Sheets	Create Sheet	Adds a new sheet to a spreadsheet.
Sheets	List Sheet Names	Lists sheet names in a spreadsheet.
Sheets	Update Sheet Properties	Updates sheet properties such as name or visibility.
Formatting	Update Cell Format	Formats cells in a range.
Formatting	Update Conditional Format Rules	Creates or updates conditional formatting rules.

Note

The actions that you can use depend on the spreadsheets accessible to the authenticated user.

Managing and troubleshooting

To edit, share, or delete your connector, see [the section called “Managing existing integrations”](#).

Common Google authentication issues

- **Sign-in fails (Default OAuth app or Custom OAuth app)** – Verify that your Google account is active and that you can sign in to [the Google website](#) directly. For Custom OAuth app, confirm that the redirect URI in your Google Cloud OAuth client matches the Amazon Quick callback URL.
- **App blocked by administrator** – If your Google Workspace administrator restricts third-party app access, you might see an error when you attempt to sign in. Contact your Google Workspace administrator to allow the Amazon Quick app.

- **Invalid client credentials (Custom OAuth app)** – Verify that the Client ID and Client secret match the values in your Google Cloud OAuth client.
- **Authentication popup fails** – Verify that your browser allows popups from the Amazon Quick console domain. Try using a different browser or clearing your browser cache.
- **Permissions revoked** – If you previously revoked Amazon Quick access from your Google Account permissions settings, you need to re-authenticate by editing the connector and signing in again.
- **Google API rate limiting** – Google might limit requests during high usage periods. If actions fail, retry after a few minutes.

Google Sheets-specific issues

- **Google Sheets API not enabled** – Verify that the Google Sheets API is enabled in your Google Cloud project under **APIs & Services, Library**.

Google Slides integration

With the Google Slides connector, you can access Google Slides directly in Amazon Quick through natural language. You can create presentations, edit slides, copy templates, and retrieve presentation content without leaving Amazon Quick.

Amazon Quick supports multiple authentication methods for Google Slides. Choose the method that best fits your organization's security requirements.

- **Default OAuth app** – Uses an AWS-managed OAuth application. No additional credentials are needed. You authenticate directly with your Google account.
- **Custom OAuth app** – Uses a customer-managed OAuth client created in the Google Cloud Console. This option gives your organization full control over the OAuth configuration.

For more information about the authentication methods that Amazon Quick supports, see [the section called “Authentication methods”](#).

Before you begin

Make sure that you have the following before you set up the integration.

- A Google account with access to Google Slides.

- For **Custom OAuth app**: Access to the [Google Cloud Console](#) on the Google website with permissions to create OAuth clients.
- For Amazon Quick subscription requirements, see [the section called "Set up integrations in the console"](#).

Configuring Google Cloud

If you use **Default OAuth app** authentication, skip this section and see [the section called "Setting up the connector in Amazon Quick"](#).

For Custom OAuth app authentication, complete the following steps in the Google Cloud Console before you configure Amazon Quick. When you enable the API in step 3, search for and enable the **Google Slides API**.

Create an OAuth client in Google Cloud Console

Create an OAuth client in the Google Cloud Console to get the client credentials that you need for Amazon Quick. For more information, see [Using OAuth 2.0 to Access Google APIs](#) on the Google website.

1. Sign in to the [Google Cloud Console](#) on the Google website.
2. Create a new project or select an existing project.
3. In the left navigation pane, choose **APIs & Services**, then choose **Library**. Search for the API that your integration requires and choose **Enable**.
4. Choose **OAuth consent screen** and choose **Get Started**.
5. Configure the consent screen:
 - Enter an **App Name** and select a **User support email**.
 - For **Audience**, choose **Internal** (your organization only) or **External** (any Google user).
 - Add developer contact details and choose **Create**.
6. Choose **Create OAuth client**.
7. Configure the client:
 - For **Application type**, choose **Web application**.
 - Enter a **Name** for your client.
 - Under **Authorized redirect URIs**, add the Amazon Quick callback URL:
`https://{region}.quicksight.aws.amazon.com/sn/oauthcallback`

8. Choose **Create**.
9. Record the following values. You need them when you configure Amazon Quick.
 - **Client ID**
 - **Client secret**

Recommended scopes

The following scopes are requested when you connect to Google Slides.

Google Slides recommended scopes

Scope	Description
<code>https://www.googleapis.com/auth/presentations</code>	Reads and writes Google Slides presentations.
<code>https://www.googleapis.com/auth/drive</code>	Reads and writes files in Google Drive.
<code>https://www.googleapis.com/auth/drive.readonly</code>	Reads files in Google Drive.
<code>openid</code>	Authenticates the user's identity.
<code>email</code>	Reads the user's email address.

Note

The `openid` and `email` scopes are automatically included in the OAuth consent flow for user authentication. They are not required for Service-to-Service OAuth.

Setting up the connector in Amazon Quick

Connect from the Available tab

If you want to use Default OAuth app authentication, you can connect directly from the **Available** tab without additional configuration.

1. In the Amazon Quick console, choose **Connectors**.
2. On the **Available** tab, find **Google Slides** and choose **Connect**.
3. Complete the Google sign-in flow and grant the requested permissions.

To configure a connector with Custom OAuth app instead, use the **Create for your team** tab as described below.

Create from the Create for your team tab

After you complete any required Google Cloud configuration, create the connector in Amazon Quick.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Google Slides**.

Note

If a Google Slides connector already exists, a dialog appears with your existing connectors. To use an existing connector, choose it. To create a new one, choose **No, create new**.

4. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
5. For **Connection type**, choose **Public network**.
6. For **OAuth Configuration**, choose one of the following authentication methods and configure the required fields.
 - a. For **Default OAuth app**:

No additional credentials are needed. Choose **Next** to continue.
 - b. For **Custom OAuth app**, configure the following fields:
 - **Base URL** (Optional) – The Google Slides API base URL. For example: `https://slides.googleapis.com`
 - **Client ID** – The client ID from your Google Cloud OAuth client.
 - **Client secret** – The client secret from your Google Cloud OAuth client.

- **Token URL** – The token endpoint. For example: `https://oauth2.googleapis.com/token`
- **Authorization URL** – The authorization endpoint. For example: `https://accounts.google.com/o/oauth2/v2/auth`
- **Redirect URL** – Pre-filled with the Amazon Quick callback URL.

7. Choose **Next**.
8. If you chose **Default OAuth app** or **Custom OAuth app**, a Google authorization window opens. Review the requested permissions and choose **Allow**.
9. On the **Review** page, review the available actions for the connector. Choose **Next**.
10. On the **Publish** page, choose who can access the connector. You can enable access for everyone in your organization or search for specific teams or groups.
11. Choose **Publish**.

Available actions

After you set up the connector, the following actions are available.

Google Slides available actions

Category	Action	Description
Presentations	Get Presentation	Retrieves a presentation by ID.
Presentations	Create Presentation	Creates a new presentation.
Presentations	Create Slides Markdown	Creates slides from Markdown content.
Presentations	Copy Presentation Template	Creates a presentation from a template.
Presentations	Batch Update Presentation	Applies multiple updates to a presentation in a single request.
Pages	Get Presentation Page	Retrieves a specific page from a presentation.

Note

The actions that you can use depend on the presentations accessible to the authenticated user.

Managing and troubleshooting

To edit, share, or delete your connector, see [the section called “Managing existing integrations”](#).

Common Google authentication issues

- **Sign-in fails (Default OAuth app or Custom OAuth app)** – Verify that your Google account is active and that you can sign in to [the Google website](#) directly. For Custom OAuth app, confirm that the redirect URI in your Google Cloud OAuth client matches the Amazon Quick callback URL.
- **App blocked by administrator** – If your Google Workspace administrator restricts third-party app access, you might see an error when you attempt to sign in. Contact your Google Workspace administrator to allow the Amazon Quick app.
- **Invalid client credentials (Custom OAuth app)** – Verify that the Client ID and Client secret match the values in your Google Cloud OAuth client.
- **Authentication popup fails** – Verify that your browser allows popups from the Amazon Quick console domain. Try using a different browser or clearing your browser cache.
- **Permissions revoked** – If you previously revoked Amazon Quick access from your Google Account permissions settings, you need to re-authenticate by editing the connector and signing in again.
- **Google API rate limiting** – Google might limit requests during high usage periods. If actions fail, retry after a few minutes.

Google Slides-specific issues

- **Google Slides API not enabled** – Verify that the Google Slides API is enabled in your Google Cloud project under **APIs & Services, Library**.

HG Insights integration

With the HG Insights connector, you can access technographic data, query company technology profiles, and retrieve market intelligence directly in Amazon Quick through natural language.

Amazon Quick supports multiple authentication methods for HG Insights. Choose the method that best fits your organization's security requirements.

- **Default OAuth app** – Uses an AWS-managed OAuth application. No additional credentials are needed. Users authenticate directly with their HG Insights account.
- **Custom OAuth app** – Uses a customer-managed OAuth application. This option gives your organization full control over the OAuth configuration.
- **Service-to-Service OAuth** – Uses client credentials for server-to-server authentication without user interaction. Suitable for automated workflows.
- **API Key** – Uses an API key for authentication.

For more information about the authentication methods that Amazon Quick supports, see [the section called “Authentication methods”](#).

Before you begin

Make sure that you have the following before you set up the integration.

- An active HG Insights account with access to the data products you want to query.
- For **Custom OAuth app** or **Service-to-Service OAuth**: OAuth credentials from your HG Insights account.
- For **API Key**: An HG Insights-issued API key.
- For Amazon Quick subscription requirements, see [the section called “Set up integrations in the console”](#).

Configuring HG Insights

If you are using **Default OAuth app** authentication, skip this section and proceed to [the section called “Setting up the connector in Amazon Quick”](#).

For Custom OAuth app or Service-to-Service OAuth authentication, register an OAuth client in your HG Insights Phoenix account and add the Amazon Quick callback URL `https://{region}.quicksight.aws.amazon.com/sn/oauthcallback` as a redirect URI. Replace `{region}` with your AWS Region (for example, `us-east-1`). For step-by-step instructions, see [Phoenix by HG Insights](#) documentation. Record the Client ID and Client Secret — you need them when you configure Amazon Quick. For API Key authentication, generate an API key from your Phoenix account.

Setting up the connector in Amazon Quick

Connect from the Available tab

If you want to use Default OAuth app authentication, you can connect directly from the **Available** tab without additional configuration.

1. In the Amazon Quick console, choose **Connectors**.
2. On the **Available** tab, find **HG Insights** and choose **Connect**.
3. Complete the HG Insights sign-in flow and grant the requested permissions.

To configure a connector with one of the other authentication methods, use the **Create for your team** tab as described below.

Create from the Create for your team tab

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **HG Insights**.
4. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
5. For **Connection type**, choose **Public network**.
6. For **OAuth Configuration**, choose one of the following authentication methods and configure the required fields.
 - a. For **Default OAuth app**:

No additional credentials are needed. Choose **Next** to continue.
 - b. For **Custom OAuth app**, configure the following fields:
 - **Client ID** – The client ID from your HG Insights OAuth app.
 - **Public OAuth client** (Optional) – Select this option if your HG Insights OAuth app is configured as a public client (no client secret).
 - **Client secret** – The client secret from your HG Insights OAuth app.
 - **Token URL** – The token endpoint. Default: `https://phoenix.hginsights.com/api/ai/token`
 - **Authorization URL** – The authorization endpoint. Default: `https://phoenix.hginsights.com/api/ai/authorize`

- **Redirect URL** – Pre-filled with the Amazon Quick callback URL.
- c. For **Service-to-Service OAuth**, configure the following fields:
 - **Client ID** – The client ID from your HG Insights OAuth app.
 - **Client secret** – The client secret from your HG Insights OAuth app.
 - **Token URL** – The token endpoint. Default: `https://phoenix.hginsights.com/api/ai/token`
- d. For **API Key**, configure the following fields:
 - **API Key** – The HG Insights API key.
 - **Email (Optional)** – The email address associated with the API key.
- 7. Choose **Next**.
- 8. If you chose **Default OAuth app** or **Custom OAuth app**, an HG Insights authorization window opens. Review the requested permissions and choose **Allow**.
- 9. On the **Review** page, review the available actions for the connector. Choose **Next**.
- 10. On the **Publish** page, choose who can access the connector. You can enable access for everyone in your organization or search for specific teams or groups.
- 11. Choose **Publish**.

Available actions

After you set up the connector, the actions exposed by HG Insights are available. To see the current set of actions for your connector, go to the connector's **Available actions** view in the Amazon Quick console.

Managing and troubleshooting

To edit, share, or delete your connector, see [the section called “Managing existing integrations”](#).

Authentication issues

- **Sign-in fails (Default OAuth app or Custom OAuth app)** – Verify that your HG Insights account is active. For Custom OAuth app, confirm that the redirect URI in your HG Insights OAuth app matches the Amazon Quick callback URL.
- **Invalid client credentials (Custom OAuth app or Service-to-Service OAuth)** – Verify that the Client ID and Client secret match the values in your HG Insights OAuth app.

- **API Key authentication fails** – Verify that the API key has not been revoked.

HubSpot integration

Access your HubSpot CRM data directly from Amazon Quick using natural language. With the HubSpot connector, you can retrieve and list contacts, companies, deals, and tickets without leaving Amazon Quick.

HubSpot is available as a built-in connector in Amazon Quick. To set up this integration, complete the following two steps. First, prepare your HubSpot account with the required access. Then, create the connector in Amazon Quick and authenticate with your HubSpot credentials.

This connector supports Custom OAuth app authentication. For information about the authentication methods that Amazon Quick supports, see [the section called "Authentication methods"](#).

Prerequisites

Before you set up the integration, verify that you have the following resources and access.

- An active HubSpot account with an admin role.
- Permissions to access CRM data including contacts, companies, deals, and tickets in your HubSpot account.
- A subscription that meets the requirements described in [the section called "Set up integrations in the console"](#).

Verifying your HubSpot account

Before you configure Amazon Quick, verify that your HubSpot account meets the following requirements.

- Your HubSpot account is active and you can sign in to the [HubSpot sign-in page](#) on the HubSpot website.
- The CRM data that you want to access, including contacts, companies, deals, and tickets, is accessible to your account.

Configuring your HubSpot account

The Custom OAuth app authentication method in Amazon Quick requires a MCP Auth app configured in your HubSpot developer settings.

To configure a MCP Auth App

1. Sign in to your HubSpot account.
2. Navigate to **Development**, and then **MCP Auth Apps**.
3. Choose **Create MCP auth app**.
4. On the **Create MCP Auth App** window, complete the following fields:
 - **Name** – Enter a name for your app.
 - **Description** – Enter a short description.
 - **Redirect URL** – Enter `https://region.quicksight.aws.amazon.com/sn/oauthcallback`. Replace *region* with your AWS Region, for example, `us-east-1`.
5. Choose **Create**. HubSpot creates the app and generates a client ID and client secret.

Important

Record the client secret and client ID.

The client ID and client secret serve as the Client ID and Client Secret when you configure the connector in Amazon Quick with the Custom OAuth app authentication method.

For more information, see [HubSpot MCP server](#) on the HubSpot website.

Setting up the integration in Amazon Quick

After you verify your HubSpot account access, create the connector in Amazon Quick.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Choose **HubSpot** from the options available.
4. In the **HubSpot** dialog, enter the following fields:
 - **Name** – A descriptive name for your HubSpot connector.

- **Description (Optional)** – Choose **+ Add Description** to add notes about how this connector will be used.
 - **Connection type** – Choose **Public network**.
5. For the **Custom OAuth app** authentication method, enter the following fields:
- **Base URL** – This field is auto-populated as `https://mcp.hubspot.com`.
 - **Client ID** – Enter the client ID from your HubSpot MCP Auth app.
 - **Client Secret** – Enter the client secret from your HubSpot MCP Auth app.
 - **Token URL** – This field is auto-populated as `https://api.hubapi.com/oauth/v1/token`.
 - **Authorization URL** – This field is auto-populated as `https://app.hubspot.com/oauth/authorize`.
 - **Redirect URL** – This field is auto-populated as `https://us-east-1.quicksight.aws.amazon.com/sn/oauthcallback`.
6. Choose **Next**, review the actions for HubSpot, and then choose **Next** again.
7. Specify who can access the connector:
- To share with a team, enter a team name or group email.
 - To keep it private, leave the field blank.
 - To share with all users, toggle **Everyone in your organization**.
8. Choose **Publish**.

The connector appears in the **Available** panel with a status of **Connected**.

Using available actions

After you set up the connector, you can use the following read-only actions to access your HubSpot CRM data.

HubSpot available actions

Action	Description
Get CRM Objects	Fetches multiple CRM objects of the same object type in a single request.

Action	Description
Get properties	Fetches properties for the CRM objects.
Get user details	Fetches user details.
Search CRM Objects	Searches across CRM objects.
Search Owners	Searches across owners.
Search properties	Searches across properties.

Note

This connector supports read-only actions. The actions that you can use depend on the scopes configured in your HubSpot app.

Troubleshooting

To edit, share, or delete your connector, see [the section called “Managing existing integrations”](#).

Resolving authentication issues

- **Sign-in fails** – Verify that your HubSpot account is active and that you can sign in to the [HubSpot sign-in page](#) on the HubSpot website. If your organization uses single sign-on (SSO), confirm that your identity provider is configured correctly.
- **Access denied** – Confirm that your HubSpot user has an admin role with permissions to access CRM data. Verify that the client ID and client secret from your app are correct and that the required read scopes are configured.

HuggingFace integration

With HuggingFace integration in Amazon Quick, you can access machine learning models, datasets, and spaces through MCP server connectivity. This integration provides action capabilities for ML workflow operations and model management.

What you can do

HuggingFace integration provides connector capabilities through MCP server connectivity:

- Browse and download models from HuggingFace Hub
- Access and manage datasets
- Interact with HuggingFace Spaces
- Upload and manage your own models
- Run inference on hosted models
- Manage model repositories and versions

Available tools

The HuggingFace MCP server typically provides these tools:

- `search_models` - Search for models on HuggingFace Hub
- `get_model_info` - Get detailed model information
- `download_model` - Download models locally
- `list_datasets` - List available datasets
- `get_dataset_info` - Get dataset information
- `run_inference` - Run inference on hosted models
- `upload_model` - Upload models to Hub
- `list_spaces` - List HuggingFace Spaces

Note

The specific tools and capabilities available through this MCP server may change over time. For the most current information about supported tools, features, and implementation details, check the official HuggingFace documentation and MCP server repository.

Setting up HuggingFace integration

HuggingFace integration uses MCP server connectivity to provide action capabilities. For detailed setup instructions, see [the section called “MCP integration”](#).

You'll need:

- HuggingFace account with appropriate permissions
- HuggingFace API token for authentication

Compatibility

HuggingFace integration supports:

- **Chat Agents:** Yes
- **Flows:** Yes
- **Knowledge Base:** No

Intercom integration

With Intercom integration in Amazon Quick, you can manage customer conversations, support tickets, and user engagement through MCP server connectivity. This integration provides action capabilities for customer support and communication operations.

What you can do

Intercom integration provides connector capabilities through MCP server connectivity:

- Manage customer conversations and messages
- Create and update support tickets
- Manage user profiles and contact information
- Send targeted messages and campaigns
- Track customer engagement and activity
- Manage team assignments and workflows

Available tools

The Intercom MCP server typically provides these tools:

- `create_conversation` - Start new conversations
- `reply_to_conversation` - Reply to existing conversations

- `list_conversations` - List customer conversations
- `create_user` - Create new user profiles
- `update_user` - Update user information
- `send_message` - Send messages to users
- `create_ticket` - Create support tickets
- `search_users` - Search for users

Note

The specific tools and capabilities available through this MCP server may change over time. For the most current information about supported tools, features, and implementation details, check the official Intercom documentation and MCP server repository.

Setting up Intercom integration

Intercom integration uses MCP server connectivity to provide action capabilities. For detailed setup instructions, see [the section called “MCP integration”](#).

You'll need:

- Intercom account with appropriate permissions
- Intercom API access token

Compatibility

Intercom integration supports:

- **Chat Agents:** Yes
- **Flows:** Yes
- **Knowledge Base:** No

Linear integration

With Linear integration in Amazon Quick, you can manage issues, track projects, and streamline development workflows through MCP server connectivity. This integration provides action capabilities for project management and issue tracking operations.

What you can do

Linear integration provides connector capabilities through MCP server connectivity:

- Create and manage issues and tasks
- Track project progress and milestones
- Manage team workflows and assignments
- Update issue status and priorities
- Create and manage project cycles
- Generate reports and track metrics

Available tools

The Linear MCP server typically provides these tools:

- `create_issue` - Create new issues
- `update_issue` - Update issue details
- `list_issues` - List team issues
- `search_issues` - Search for specific issues
- `create_project` - Create new projects
- `list_projects` - List team projects
- `assign_issue` - Assign issues to team members
- `create_cycle` - Create project cycles

Note

The specific tools and capabilities available through this MCP server may change over time. For the most current information about supported tools, features, and implementation details, check the official Linear documentation and MCP server repository.

Setting up Linear integration

Linear integration uses MCP server connectivity to provide action capabilities. For detailed setup instructions, see [the section called “MCP integration”](#).

You'll need:

- Linear account with appropriate team permissions
- Linear API key for authentication

Compatibility

Linear integration supports:

- **Chat Agents:** Yes
- **Flows:** Yes
- **Knowledge Base:** No

Local connectors

In addition to cloud connectors, you can add a local connector that runs on your own machine, such as a local MCP server. A local connector lets Amazon Quick use tools you host yourself, such as a database, an internal API, or a developer tool, so that those tools become available to agents in chat and in scheduled tasks. Because a local connector runs on your machine, its tools are available only when that machine is on and connected. For an overview of cloud connectors, see [Connectors](#).

To add a local connector, open the Desktop App, go to **Customize**, and choose the **Connectors** tab. Choose **Create**, and then choose **Create local connector**. A dialog appears with three connection types: **Local**, **Import**, and **Remote**. Choose the type that matches how your MCP server runs.

Local

Local runs an MCP server as a command on your machine. This is the most common option for development tools and locally installed servers.

Local connection fields

Field	Required	Description
Name	Yes	Enter a descriptive name to identify this MCP server, such as <code>My Database MCP</code> .
Command	Yes	Enter the executable to run, such as <code>python</code> , <code>npx</code> , <code>node</code> , or <code>uvx</code> .
Arguments	No	Enter the command line arguments, separated by spaces, such as <code>-m mcp_server --port 8080</code> .
Description	No	Describe what this MCP server does and what tools it provides. This description helps Amazon Quick understand when to use the server's tools.
Environment variables	No	Add the environment variables that the server requires. Choose + Add variable to add key-value pairs.
Timeout (seconds)	No	Enter the maximum time to wait for the server to start, from 5 to 300 seconds. The default is 30 seconds.

Import

Import loads MCP server configurations from an existing configuration file. This is useful when you already have MCP servers configured for another tool and want to reuse that configuration. When you enter a configuration file path, Amazon Quick scans the file, detects the MCP servers defined in it, and detects the tools installed on your system.

Import connection fields

Field	Required	Description
Config file path	Yes	Enter the path to the configuration file on your machine, such as <code>~/.kiro/settings/mcp.json</code> .

Remote

Remote connects to an MCP server running on a remote machine or cloud service over HTTP. This is useful for shared team servers or hosted MCP services.

Remote connection fields

Field	Required	Description
Name	Yes	Enter a descriptive name to identify this MCP server.
URL	Yes	Enter the URL of the MCP endpoint, such as <code>https://mcp.example.com/sse</code> .
Token	No	Enter a bearer token for authentication with the remote server.
Description	No	Describe what this MCP server does and what tools it provides.
Timeout (seconds)	No	Enter the maximum time to wait for the server to respond, from 5 to 300 seconds. The default is 30 seconds.

Microsoft OneDrive integration

Use the Microsoft OneDrive integration to perform actions on OneDrive files and folders, or to create knowledge bases from OneDrive content for AI-powered search and Q&A.

What you can do

Connector

Create, update, delete, and manage OneDrive files and folders through Microsoft Graph API calls.

Knowledge base

Index OneDrive documents, spreadsheets, and presentations. Amazon Quick agents can then search and answer questions about the content. Amazon Quick supports two setup methods:

user-managed setup for quick configuration, and admin-managed setup with service credentials for document-level access control.

Microsoft OneDrive action integration

Use the Microsoft OneDrive connector to manage OneDrive files, folders, and Excel workbooks directly in Amazon Quick through natural language.

Amazon Quick supports multiple authentication methods for Microsoft OneDrive. Choose the method that best fits your organization's security requirements.

- **Default OAuth app** – Uses an AWS-managed OAuth application. No additional credentials are needed. Users authenticate directly with their Microsoft account.
- **Custom OAuth app** – Uses a customer-managed application registered in Microsoft Entra. This option gives your organization full control over the OAuth configuration. Users authenticate on behalf of a signed-in user (delegated permissions).
- **Service-to-Service OAuth** – Uses client credentials for server-to-server authentication without user interaction (application permissions). Suitable for automated workflows.

For more information about the authentication methods that Amazon Quick supports, see [the section called “Authentication methods”](#).

Before you begin

Make sure you have the following before you set up the integration.

- A Microsoft 365 account with OneDrive access.
- For **Custom OAuth app** or **Service-to-Service OAuth**: Access to the [Microsoft Entra admin center](#) on the Microsoft website with at least Application Developer permissions.
- For subscription requirements, see [the section called “Set up integrations in the console”](#).

Configure Microsoft Entra

If you are using **Default OAuth app** authentication, skip this section and proceed to [the section called “Setting up the connector in Amazon Quick”](#).

Before you configure Amazon Quick, create an app registration in Microsoft Entra. Complete all of the following steps in Entra before moving to the Amazon Quick console.

For more information about app registrations, see [Register an application with the Microsoft identity platform](#) in the Microsoft documentation.

Register the application

1. Open the [Microsoft Entra admin center](#).
2. In the left navigation, choose **Entra ID**, then choose **App registrations**.
3. Choose **New registration**.
4. For **Name**, enter a descriptive name for your integration.
5. For **Supported account types**, choose **Accounts in this organizational directory only**.
6. For **Redirect URI**, select **Web** and enter `https://{region}.quicksight.aws.amazon.com/sn/oauthcallback`. Replace `{region}` with the AWS Region where your Amazon Quick instance is deployed.
7. Choose **Register**.
8. On the overview page, copy the **Application (client) ID** and **Directory (tenant) ID**. You need these values for the Amazon Quick configuration.

Create a client secret

Amazon Quick needs a client secret to authenticate with Microsoft Entra. This secret acts as a password for the app registration.

1. From your app registration, choose **Certificates & secrets**.
2. Choose **New client secret**.
3. Enter a description and choose an expiration period.
4. Choose **Add**.
5. Copy the **Value** immediately. This value is only displayed once.

Important

Copy the secret **Value**, not the Secret ID. The Value is the longer string used for authentication.

Configure API permissions

This integration uses delegated permissions, which allow the app to act on behalf of a signed-in user. For more information, see [Overview of Microsoft Graph permissions](#) in the Microsoft documentation.

1. From your app registration, choose **API permissions**.
2. Choose **Add a permission**, then choose **Microsoft Graph**.
3. Choose **Delegated permissions** and add the permissions from the table below.
4. Choose **Grant admin consent for [your tenant name]** to approve the permissions.

Add the following as Delegated permissions in your Entra app registration. For the full permissions reference, see [Microsoft Graph permissions reference](#) in the Microsoft documentation.

OneDrive action integration – delegated permissions

Permission	Description
Files.ReadWrite	Allows the app to read, create, update, and delete the signed-in user's files.
Files.ReadWrite.All	Allows the app to read, create, update, and delete all files the signed-in user can access.
offline_access	Allows the app to refresh access tokens without requiring the user to sign in again. This reduces how often users need to re-authenticate.
Sites.Read.All	Allows the app to read documents and list items in all site collections on behalf of the signed-in user.
User.Read	Allows the app to read the signed-in user's profile.
User.Read.All	Allows the app to read the full set of profile properties of all users in the organization on behalf of the signed-in user.

Record your credentials

Before leaving the Microsoft Entra admin center, confirm you have the following values. You need them for the Amazon Quick configuration.

Required credentials from Microsoft Entra

Value	Where to find it
Application (client) ID	App registration overview page
Directory (tenant) ID	App registration overview page
Client secret value	Certificates & secrets page

Setting up the connector in Amazon Quick

Connect from the Available tab

If you want to use Default OAuth app authentication, you can connect directly from the **Available** tab without additional configuration.

1. In the Amazon Quick console, choose **Connectors**.
2. On the **Available** tab, find **OneDrive** and choose **Connect**.
3. Complete the Microsoft sign-in flow and grant the requested permissions.

To configure a connector with Custom OAuth app or Service-to-Service OAuth instead, use the **Create for your team** tab as described below.

Create from the Create for your team tab

After you complete any required Entra configuration, create the connector in Amazon Quick.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Microsoft OneDrive**.

 Note

If a Microsoft OneDrive connector already exists, a dialog appears with your existing connectors. To use an existing connector, choose it. To create a new one, choose **No, create new**.

4. On the **Integration type** page, select **Perform actions in Microsoft OneDrive** and choose **Next**.
5. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
6. For **Connection type**, choose **Public network**.
7. For **OAuth Configuration**, choose one of the following authentication methods and configure the required fields.

- a. For **Default OAuth app**:

No additional credentials are needed. Choose **Next** to continue.

- b. For **Custom OAuth app** (user authentication with delegated permissions), configure the following fields:

- **Base URL** (Optional) – The Microsoft Graph API base URL. Example: `https://graph.microsoft.com/v1.0`
- **Client ID** – The Application (client) ID from your Entra app registration.
- **Client secret** – The client secret value from your Entra app registration.
- **Token URL** – The token endpoint. Example: `https://login.microsoftonline.com/{tenant-id}/oauth2/v2.0/token`
- **Authorization URL** – The authorization endpoint. Example: `https://login.microsoftonline.com/{tenant-id}/oauth2/v2.0/authorize`
- **Redirect URL** – Pre-filled with the Amazon Quick callback URL.

- c. For **Service-to-Service OAuth** (service authentication with application permissions), configure the following fields:

- **Base URL** (Optional) – The Microsoft Graph API base URL. Example: `https://graph.microsoft.com/v1.0`
- **Client ID** – The Application (client) ID from your Entra app registration.
- **Client secret** – The client secret value from your Entra app registration.

- **Token URL** – The token endpoint. Example: `https://login.microsoftonline.com/{tenant-id}/oauth2/v2.0/token`

 Note

The scope for the client credentials token request (`https://graph.microsoft.com/.default`) is set automatically by Amazon Quick. You do not need to configure it manually.

8. Choose **Next**.
9. If you chose **Default OAuth app** or **Custom OAuth app**, a Microsoft authorization window opens. Review the requested permissions and choose **Accept**.

If you see an error instead of the consent dialog, your organization might restrict third-party app access. See [the section called "Admin consent for Microsoft 365"](#).

10. On the **Review** page, review the available actions for the connector. Choose **Next**.
11. On the **Publish** page, choose who can access the connector. You can enable access for everyone in your organization or search for specific teams or groups.
12. Choose **Publish**.

Available actions

After you set up the integration, the following actions are available.

Microsoft OneDrive available actions

Category	Action	Description
Drive and items	Get Drive	Retrieve the properties and relationships of a drive.
Drive and items	List Item	Get all items contained in the drive.
Drive and items	Get Item	Get an item contained in the drive.

Category	Action	Description
Drive and items	Create Folder	Create a new folder in the user's drive.
Drive and items	Update Item	Update the metadata for a file or folder.
Drive and items	Delete Item	Delete a file or folder. Moves the item to the recycle bin.
Drive and items	List Child Folders	Return a collection of items in the children of a folder.
Drive and items	Copy Item	Create a copy of a file or folder to another location.
Drive and items	Add Permissions	Send a sharing invitation for a file or folder.
Drive and items	Upload File	Upload a new file or update an existing file. Supports files up to 250 MB.
Excel workbooks	List Sheets	Retrieve a list of worksheet objects.
Excel workbooks	Add Sheet	Add a new worksheet to the workbook.
Excel workbooks	Read Sheet	Retrieve the properties of a worksheet object.
Excel workbooks	Update Sheet	Update the properties of a worksheet object.
Excel workbooks	Delete Sheet	Delete the worksheet from the workbook.
Excel workbooks	Read Cell	Get the value of a single cell by row and column number.

Category	Action	Description
Excel workbooks	Write Cell	Set the value of a single cell by row and column number.
Excel workbooks	Read Range	Get the values of a range.
Excel workbooks	Write Range	Update the values of a range.
Excel workbooks	Clear Range	Clear range values, format, fill, and border.
Excel workbooks	Delete Range	Delete the cells associated with the range.
Excel workbooks	Get Used Range	Get the smallest range that encompasses cells with a value or formatting.

Manage and troubleshoot

To edit, share, or delete your integration, see [the section called “Managing existing integrations”](#).

Authentication issues

- **Incorrect app registration** – Verify the app registration in Microsoft Entra includes the required API permissions and that admin consent has been granted.
- **Expired client secret** – Check if the client secret has expired in **Certificates & secrets** and generate a new one if needed.
- **Incorrect redirect URI** – Verify the redirect URI in Microsoft Entra matches `https://{region}.quicksight.aws.amazon.com/sn/oauthcallback`.

Common error messages

- **Access denied. You do not have permission to perform this action** – The authenticated user does not have the required permissions. Contact your administrator to verify and grant appropriate permissions.

- **AADSTS50020: User account from identity provider does not exist in tenant**
 - The user account is not configured in the correct Microsoft Entra tenant. Verify the user account exists in the tenant that matches the Directory (tenant) ID in your app registration.

Admin consent for Microsoft 365

When you use the **Default OAuth app** authentication method, Amazon Quick uses an AWS-managed application to access Microsoft OneDrive on behalf of the signed-in user. Most users can complete setup without any extra steps. However, if your Microsoft 365 tenant restricts third-party app access, a Microsoft 365 administrator must grant one-time consent before users can connect.

If you see an error when you sign in during connector setup, your organization might restrict third-party app access. Share the following information with your Microsoft 365 administrator:

- **What to do:** Grant admin consent for the Amazon Quick Microsoft OneDrive integration application.
- **Why:** Amazon Quick needs delegated access to OneDrive files, folders, and Excel workbooks to perform actions on behalf of users.

An administrator can grant consent in one of the following ways:

- **Through the consent dialog** – A Global Administrator or Privileged Role Administrator initiates the connector setup flow. In the Microsoft sign-in dialog, they select the **Consent on behalf of your organization** check box and choose **Accept**.
- **Through the Microsoft Entra admin center** – Sign in to the [Microsoft Entra admin center](#) on the Microsoft website. Choose **Enterprise applications**, locate the Amazon Quick application, choose **Permissions**, and choose **Grant admin consent for *Your Organization***.

After consent is granted, any user in your organization can connect without being prompted for individual consent.

Note

To check whether your tenant restricts user consent, go to the Microsoft Entra admin center and choose **Enterprise applications, Consent and permissions, User consent settings**. If

the setting is **Do not allow user consent**, an administrator must grant consent before users can use the connector.

Microsoft OneDrive knowledge base integration

Microsoft OneDrive is a cloud storage service for storing, sharing, and collaborating on files across your organization. With the Amazon Quick OneDrive connector, you can create knowledge bases from your OneDrive content to power AI-driven search and Q&A.

Amazon Quick supports two authentication methods for connecting to OneDrive:

- **User-managed setup** – You sign in to OneDrive directly to authorize the connection. This is the simplest way to get started. For more information, see [the section called “User-managed setup”](#).
- **Admin-managed setup (service credentials)** – An Entra ID app registration authenticates on behalf of the application using certificate-based credentials, and Amazon Quick crawls the OneDrive content of every user in your organization. Admin-managed setup includes built-in document-level access control (ACL). Amazon Quick automatically syncs access control lists from OneDrive and verifies each user's permissions at query time. Users see answers only from documents that they are authorized to access. For more information, see [the section called “Admin-managed setup”](#).

After connecting, Amazon Quick indexes your OneDrive files and folders into a knowledge base. Your Amazon Quick agents can then search this content and generate answers grounded in your OneDrive data.

Prerequisites

Before you set up the OneDrive knowledge base integration, make sure that you have the following:

- An AWS account with an active Amazon Quick instance.
- A Microsoft 365 account with OneDrive access.
- For subscription requirements, see [the section called “Set up integrations in the console”](#).

For admin-managed setup, additional prerequisites apply. For more information, see [the section called “Admin-managed setup”](#).

Supported content types

The OneDrive connector supports the common file types that Amazon Quick knowledge bases support, including the following:

- **Microsoft Office documents:** Word, Excel, PowerPoint
- **PDF files**
- **Text files and rich text documents**
- **Text documents with embedded images**
- **Audio and video files**

For more information about supported file types, size limits, and content processing options, see [Common configuration settings](#).

User-managed setup

With user-managed setup, you sign in to OneDrive directly and Amazon Quick handles authentication through a managed OAuth flow. Amazon Quick uses a pre-registered multi-tenant application, so you don't need to create an app registration. Most users can complete setup in a few minutes.

Prerequisites

Before you begin, make sure you have the following:

- A Microsoft 365 account with access to the OneDrive content you want to index.
- Access to Amazon Quick with permissions to create knowledge bases.
- A browser that allows popups from the Amazon Quick console domain.

Your Microsoft administrator might need to grant organizational consent before users can create a OneDrive knowledge base. Administrators can grant organization-wide consent by signing in and choosing **Consent on behalf of your organization** during the integration creation flow. For more information, see [the section called "Admin consent for Microsoft 365"](#).

Important

User-managed setup does not support document-level access control (ACL). All indexed content is accessible to any user who has access to the knowledge base in Amazon Quick.

Individual permissions in OneDrive are not enforced. Carefully review which content you include when creating a knowledge base. If you require document-level access control, use [Admin-managed setup \(service credentials\)](#) instead.

Create the OneDrive knowledge base

Navigate to Knowledge

1. In Amazon Quick, choose **Knowledge** from the left navigation panel.
2. Under **Set up new knowledge base**, locate **Microsoft OneDrive** and choose the **+** icon.

Sign in to OneDrive

The **Create OneDrive knowledge base** wizard opens on the Authentication method step. **Quick setup** is selected by default.

1. Under **Quick setup**, choose **Sign in to OneDrive**.
2. A Microsoft sign-in window opens. Enter your Microsoft 365 credentials.
3. If a permissions consent dialog appears, review the permissions and choose **Accept**.

If you see an error instead of the consent dialog, your organization might restrict third-party app access. See [the section called "Admin consent for Microsoft 365"](#).

4. After successful authentication, choose **Next**.

Choose content

1. Enter a **Name** and optional **Description** for your knowledge base.
2. In the **Content** section, choose **Add content**.
3. A dialog opens showing OneDrive files and folders accessible to your account. Select the files or folders you want to index.
4. Choose **Add** to confirm your selections. You can add more content or remove items before continuing.
5. Choose **Create**.

Initial sync

After you choose **Create**, you are returned to the knowledge base list page. The knowledge base might take a few minutes to finish provisioning. Once creation is complete, an initial sync is automatically triggered.

Admin consent for Microsoft 365

Most users complete setup without any extra steps. However, if your Microsoft 365 tenant restricts third-party app access, you might see an error when you sign in. In this case, a Microsoft 365 administrator needs to grant one-time consent for the Amazon Quick application. After consent is granted, any user in your organization can connect.

If you are not a Microsoft 365 administrator, share the following information with your administrator:

- **What to do:** Grant admin consent for the Amazon Quick OneDrive integration application.
- **Why:** Amazon Quick needs delegated read access to OneDrive files to index content for knowledge bases.

For detailed instructions on granting admin consent through the consent dialog or the Microsoft Entra admin center, see [the section called "Grant organization-wide admin consent"](#).

Permissions requested

The following delegated permissions are requested when a user signs in. Share this list with your administrator if they need to review the permissions before granting consent.

User-managed setup – permissions

Permission	API	Type	Description
Files.Read.All	Microsoft Graph	Delegated	Read all files the signed-in user can access.
Notes.Read.All	Microsoft Graph	Delegated	Read all OneNote notebooks the signed-in user can access.
User.Read	Microsoft Graph	Delegated	Sign in and read the user's profile.

Permission	API	Type	Description
offline_access	Microsoft Graph	Delegated	Maintain access using refresh tokens.

Manage and troubleshoot user-managed connections

To edit, share, or delete your integration, see [the section called “Managing existing integrations”](#).

- **App blocked by administrator** – Your Microsoft 365 tenant restricts third-party app access. Ask your Microsoft 365 administrator to grant admin consent. For more information, see [the section called “Admin consent for Microsoft 365”](#).
- **Sign-in window closes without completing** – Verify that your browser allows popups from the Amazon Quick console domain and that third-party cookies are enabled.
- **Token expired** – Delegated credentials last approximately 90 days. If syncs fail after this period, you need to re-authenticate. For more information, see [the section called “Token refresh with user-managed setup”](#).
- **Missing content** – Verify that the account you used for authentication has access to the files and folders you selected. Content shared with you after the initial sync requires a resync to be indexed.

For additional troubleshooting, including sync monitoring and reports, see [the section called “Troubleshooting”](#).

Known limitations

- Document-level access control (ACL) is not supported with user-managed setup. If you require document-level access control, use [Admin-managed setup \(service credentials\)](#).
- File comments synchronization is not supported.

Next steps

After your knowledge base is created and the initial sync completes, you can use it in Amazon Quick to answer questions from your OneDrive content. To manage your knowledge base, see [the section called “Managing existing integrations”](#).

Admin-managed setup (service credentials)

With admin-managed setup, an administrator configures an AWS KMS signing key and a Microsoft Entra ID app registration with certificate-based credentials. Individual users don't need to authorize through sign-in. Amazon Quick crawls the OneDrive content of every user in your organization.

Admin-managed setup includes built-in document-level access control list (ACL) support. Because admin-managed setup crawls the OneDrive content of all users, ACL is always enabled and cannot be turned off. Amazon Quick syncs ACLs from OneDrive during each crawl and verifies each user's permissions at query time, so users see answers only from documents that they are authorized to access. For more information, see [the section called "Document-level access controls"](#).

Prerequisites

Before you begin, make sure that you have the following:

- Administrator access to the Amazon Quick admin console.
- Administrator access to Microsoft Entra ID to register an application and grant API permissions.
- A Microsoft 365 tenant with OneDrive content to index.

Setup overview

The setup involves the following phases:

1. **Set up service credentials** – Create a KMS signing key, generate a certificate, register an application in Entra, and grant Amazon Quick permission to use the key. For more information, see [the section called "Set up service credentials"](#).
2. **Create the knowledge base in Amazon Quick** – Create a OneDrive knowledge base using the service credentials from Phase 1. For more information, see [the section called "Create the knowledge base"](#).

Document-level access control is automatically enabled for all admin-managed knowledge bases. For more information about how access controls work, see [the section called "Document-level access controls"](#).

Set up service credentials

Before you create the knowledge base in Amazon Quick, complete the following configuration steps in AWS and Microsoft Entra ID. You create a KMS signing key, generate a certificate, register an application in Entra, and grant Amazon Quick permission to use the key.

This setup involves multiple systems and might require coordination between different administrators in your organization. The following table summarizes each step and the role needed to complete it.

Setup steps and roles

Step	What you do	Role needed
1. KMS key	Create an asymmetric signing key in AWS KMS.	AWS administrator (KMS and IAM console access)
2. Certificate	Generate a self-signed certificate using the KMS public key.	Same as Step 1 (AWS CLI and OpenSSL required)
3. Entra app	Register an application in Microsoft Entra, assign API permissions, and upload the certificate.	Microsoft 365 Global Admin or Privileged Role Admin
4. KMS key access	Grant Amazon Quick permission to use the KMS key for signing.	Amazon Quick administrator (Admin Pro)
5. Create KB	Create the knowledge base in Amazon Quick using the credentials from the previous steps.	Any Amazon Quick user (Author Pro or Admin Pro)

Tip

In many organizations, a single person with both AWS and Microsoft 365 administrator access can complete all steps. If responsibilities are split across teams, share this table to coordinate the setup.

Prerequisites

Before you begin, make sure that you have the following:

- An AWS account with an active Amazon Quick instance.
- Access to the AWS KMS console (for creating the signing key).
- Amazon Quick administrator access (Admin Pro role) for granting KMS key permissions.
- A Microsoft 365 tenant with OneDrive.
- Global Administrator or Privileged Role Administrator access in Microsoft Entra ID.
- OpenSSL 3.0 or later and AWS CLI installed locally.
- The AWS account and Amazon Quick instance must be in the same Region.

Permissions

Admin-managed setup crawls the OneDrive content of every user in your organization and always enforces document-level access control. The Entra app registration requires the following Microsoft Graph application permissions.

Admin-managed setup permissions

Permission	Type	Purpose
Files.Read.All	Application	Read files in all users' OneDrive content.
Sites.Read.All	Application	Enumerate and read the OneDrive drives across the tenant. OneDrive for Business is hosted on SharePoint, so this permission is required to access each user's drive.
User.Read.All	Application	Read user profiles to resolve document-level access control.
Group.Read.All	Application	Read group objects to resolve group-based access control.
GroupMember.Read.All	Application	Read group memberships to resolve document-level access control.

 Important

Select the **Application permissions** tab, not **Delegated permissions**, when you assign these permissions in Entra. Admin-managed setup uses the client credentials flow, which requires application permissions.

 Note

OneNote crawling (Notes.Read.All) is not supported in admin-managed setup. Microsoft retired app-only tokens for OneNote APIs on March 31, 2025. Use [User-managed setup](#) for OneNote content.

Values collected during setup

The following table summarizes the values you create or collect during setup and where you use them.

Values reference

Value	Created in step	Used in step
KMS Key ARN	1 (KMS)	2 (Certificate), 4 (IAM), Quick setup
Certificate file (certificate.cer)	2 (Certificate)	3 (Entra upload)
Certificate thumbprint (base64url)	2 (Certificate)	Quick setup
Application (Client) ID	3 (Entra)	Quick setup
Directory (Tenant) ID	3 (Entra)	Quick setup

Step 1: Create an AWS KMS asymmetric signing key

Amazon Quick uses an AWS KMS asymmetric key to sign OAuth assertions when authenticating with Microsoft Entra ID. The private key never leaves KMS. Only the public key is exported and embedded in a certificate that gets uploaded to your Entra app registration.

Create the KMS key

1. Open the [AWS KMS console](#).
2. In the left navigation, choose **Customer managed keys**.
3. Choose **Create key**.

Configure the key

On the **Configure key** page, set the following values:

KMS key configuration

Setting	Value
Key type	Asymmetric
Key usage	Sign and verify
Key spec	RSA_2048
Key material origin	KMS (recommended)
Regionality	Single-Region key (default). Multi-Region keys are not supported.

Add labels

On the **Add labels** page, enter an alias for the key. For example: quick-onedrive-service-auth.

Note

The key administrator and key usage permissions on the following pages are optional. The defaults are sufficient for this setup. You grant Amazon Quick access to the key separately in Step 4.

Choose **Skip to review**, then choose **Finish** to create the key.

Record the Key ARN

After the key is created, open the key detail page and record the **Key ARN**. The ARN has the following format:

```
arn:aws:kms:us-west-2:123456789012:key/xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxxxx
```

You need this value in Steps 2, 4, and when you create the knowledge base in Quick.

Step 2: Generate a self-signed certificate

Microsoft Entra ID requires an X.509 certificate to validate signed assertions. Because the KMS private key never leaves AWS KMS, you cannot use it directly with OpenSSL. Instead, you generate a temporary local key pair and create a certificate signing request. Then, use the OpenSSL -force_pubkey option to inject the KMS public key into the final certificate. The result is a self-signed certificate whose public key matches the KMS key pair.

Prerequisites

- AWS CLI installed and configured.
- OpenSSL 3.0 or later.
- The KMS Key ARN from Step 1.

Generate the certificate

Run the following commands in a terminal. Replace the *placeholder* values with your own.

Verify OpenSSL version

```
openssl version
```

Confirm the output shows version 3.0 or later.

Export the KMS public key

```
aws kms get-public-key \  
  --key-id KMS_KEY_ARN \  
  --region REGION \  
  --output text \  
  --query PublicKey | base64 --decode > public_key.der
```

Note

On macOS, use `base64 --decode` or `base64 -D` depending on your shell environment.

Convert the public key to PEM format

```
openssl rsa -pubin -inform DER -in public_key.der -outform PEM -out kms_public_key.pem
```

Generate a temporary local key pair

```
openssl genrsa -out temp_private_key.pem 2048
```

Create a certificate signing request

```
openssl req -new \  
  -key temp_private_key.pem \  
  -out cert.csr \  
  -subj "/CN=QuickOneDriveServiceAuth/O=YourOrganization/C=US"
```

Generate the certificate with the KMS public key

```
openssl x509 -req \  
  -in cert.csr \  
  -signkey temp_private_key.pem \  
  -out certificate.pem \  
  -days 730 \  
  -force_pubkey kms_public_key.pem
```

Note

OpenSSL displays the warning `Signature key and public key of cert do not match`. This is expected because the certificate is signed with the temporary local key but contains the KMS public key. The certificate is valid and works correctly with Microsoft Entra.

Convert to DER format for Entra upload

```
openssl x509 -in certificate.pem -outform DER -out certificate.cer
```

Clean up temporary files

```
rm -f temp_private_key.pem cert.csr public_key.der kms_public_key.pem certificate.pem
```

Important

Keep the `certificate.cer` file. You upload it to Microsoft Entra ID in Step 3.

Calculate the certificate thumbprint

Run the following command to calculate the base64url-encoded SHA-1 thumbprint of the certificate:

```
openssl dgst -sha1 -binary certificate.cer | base64 | tr '+/' '-_' | tr -d '='
```

Record this value. You enter it when you create the knowledge base in Quick.

Note

The base64url-encoded thumbprint is different from the hexadecimal thumbprint shown in the Microsoft Entra portal. Quick requires the base64url format.

Step 3: Register an application in Microsoft Entra ID

Register the application

1. Sign in to the [Microsoft Entra admin center](#) on the Microsoft website.
2. In the left navigation, expand **Entra ID** and choose **App registrations**.
3. Choose **New registration**.
4. For **Name**, enter QuickOneDriveServiceAuth.
5. For **Supported account types**, select **Accounts in this organizational directory only (Single tenant)**.
6. Leave **Redirect URI** blank. A redirect URI is not required because the application uses the client credentials flow, not an interactive sign-in flow.
7. Choose **Register**.

Record application details

On the application **Overview** page, record the following values:

Application details

Value	Location
Application (client) ID	Shown on the Overview page under Essentials .
Directory (tenant) ID	Shown on the Overview page under Essentials .

Configure API permissions

Add the Microsoft Graph application permissions listed in the [the section called "Permissions"](#) section.

1. In the left navigation of your app registration, choose **API permissions**.
2. Choose **Add a permission**.
3. Choose **Microsoft Graph**.
4. Choose **Application permissions**.
5. Search for and select `Files.Read.All`, `Sites.Read.All`, `User.Read.All`, `Group.Read.All`, and `GroupMember.Read.All`, then choose **Add permissions**.

⚠ Important

Select the **Application permissions** tab, not **Delegated permissions**. Admin-managed setup uses the client credentials flow, which requires application permissions.

Grant admin consent

1. On the **API permissions** page, choose **Grant admin consent for [Your Organization]**.
2. Confirm the consent when prompted.

⚠ Important

Admin consent is required for application permissions. Without it, the application cannot access OneDrive data.

Upload the certificate

1. In the left navigation of your app registration, choose **Certificates & secrets**.
2. Choose the **Certificates** tab.
3. Choose **Upload certificate**.
4. Select the `certificate.cer` file you generated in Step 2.
5. Choose **Add**.

ℹ Note

The Entra portal displays the certificate thumbprint in hexadecimal format. This is different from the base64url-encoded thumbprint you calculated in Step 2. Use the base64url value when you configure the knowledge base in Quick.

Step 4: Grant Amazon Quick permission to the KMS key

Amazon Quick needs permission to use the KMS key for signing OAuth assertions. You grant this permission from the Amazon Quick admin console.

Note

This step requires Amazon Quick administrator access (Admin Pro role). If you are not an administrator, ask your Amazon Quick admin to complete this step using the KMS key ARN from Step 1.

Important

If your organization manages its own Amazon Quick IAM service role, the following console steps might not apply. Instead, ensure the role has `kms:Sign` permission on the KMS key ARN from Step 1.

1. In Amazon Quick, choose **Manage account** from the left navigation pane.
2. Under **Permissions**, choose **AWS resources**.
3. On the AWS resources page, scroll to **AWS Key Management Service** and select the checkbox.
4. Choose **Select keys**.
5. In the **Select KMS keys** dialog, enter the KMS key ARN you recorded in Step 1 and choose **Add**.
6. The key ARN appears in the list. Choose **Finish**.
7. Choose **Save** at the bottom of the AWS resources page.

Next steps

After you complete the setup, create the OneDrive knowledge base connection in Amazon Quick. For instructions, see [the section called "Create the knowledge base"](#).

Create the knowledge base in Amazon Quick

After you complete the service credentials setup, create the knowledge base in Amazon Quick and provide the credentials. Any enterprise user can complete this step. Amazon Quick administrator access is not required.

You need the following values from [the section called "Set up service credentials"](#). If an administrator completed the setup on your behalf, collect these values before you proceed:

- KMS key ARN (from Step 1)

- Certificate thumbprint in base64url format (from Step 2)
- Entra application (client) ID (from Step 3)
- Directory (tenant) ID (from Step 3)

Navigate to Knowledge

1. In Amazon Quick, choose **Knowledge** from the left navigation pane.
2. Under **Set up new knowledge base**, locate **Microsoft OneDrive** and choose the **Add** icon.

Select service credentials authentication

The **Create OneDrive knowledge base** wizard opens on the **Authentication method** step. Choose **Have admin access? Connect with service credentials to enable document-level access control**.

If you have previously created a knowledge base using service credentials, the **Connected account** dropdown appears with your most recent connection pre-selected. When you select an existing connection, the Tenant ID and Client ID are displayed below the dropdown for verification. You can use an existing connection or choose **+ Add account** to enter new service credentials.

Enter service credentials

After choosing **+ Add account**, fill in the following fields:

Service credentials form

Field	Description	Example
Name	A descriptive name for this OneDrive connection. You see this name when selecting a connection for future knowledge bases.	OneDrive Production
Tenant ID	The Microsoft Entra (Azure AD) tenant identifier.	34567890-1234-1234-1234-123456789012
Client ID	The Application (client) ID from your Entra app registration.	12345678-1234-4321-4321-210987654321

Field	Description	Example
KMS key ARN	The ARN of the AWS KMS asymmetric signing key.	arn:aws:kms:us-west-2:123456789012:key/my-key-id
Certificate Thumbprint	The base64url-encoded SHA-1 thumbprint of the certificate uploaded to Entra.	abc123DEF456ghi789 EXAMPLE

Fill in each field and choose **Next**.

 Tip

Give the connection a recognizable name. This name appears in the **Connected account** dropdown when you create future knowledge bases.

Choose content

Enter a **Name** and optional **Description** for your knowledge base.

Admin-managed setup crawls the OneDrive content of every user in your organization. Under **All users**, Amazon Quick syncs files and permissions for all users. You do not select individual sites, drives, or paths.

Choose **Next**.

 Note

Because admin-managed setup syncs all users' OneDrive content, the Entra app registration must have tenant-wide Sites.Read.All permission. For the full permission set, see [the section called "Permissions"](#).

 Note

Folders shared with a user are not crawled in admin-managed setup. Shared folders are stored in SharePoint and cannot be accessed with application credentials. To sync shared

content, create a SharePoint knowledge base instead. For more information, see [the section called "Known limitations"](#).

Configure additional settings

In the final step of the wizard, you can configure optional settings for the knowledge base.

Note

Document-level access control (ACL) is always enabled for admin-managed OneDrive knowledge bases and cannot be turned off. When you enable ACL by creating an admin-managed knowledge base, the console might display a note that one-time admin consent is required for real-time access verification. If you are a Microsoft 365 administrator, choose the **Grant admin consent** link to grant consent directly. If you are not an administrator, ask your Microsoft 365 admin to grant consent. For more information, see [the section called "Admin consent"](#).

Filter content by date

Limits which documents are crawled based on their last modified date in OneDrive. The start date defaults to one year before today. You can change or clear the start date, and optionally set an end date.

Multi-media content, file size, and file patterns

- **Visual content in documents** – Extracts and indexes visual elements from supported document formats. Enabled by default.
- **Audio files** – Transcribes and indexes audio files.
- **Video files** – Transcribes and indexes video files.

Note

Enabling audio and video indexing increases sync time and storage usage. Enable these options only if your OneDrive content includes relevant media files.

Choose **Create** to create the knowledge base.

Initial sync

After you choose **Create**, you are returned to the knowledge base list page. The knowledge base might take a few minutes to finish provisioning. Once creation is complete, an initial sync is automatically triggered. You do not need to start it manually.

Document-level access controls

Admin-managed OneDrive knowledge bases include built-in document-level access control. Because admin-managed setup crawls the OneDrive content of every user in your organization, ACL is always enabled and cannot be turned off. Amazon Quick syncs access control lists (ACLs) from OneDrive during each crawl. The system verifies each user's permissions at query time, so users only see answers from documents they are authorized to access in OneDrive.

How it works

When a user queries an Amazon Quick agent that uses an admin-managed OneDrive knowledge base, the system enforces access controls in two stages:

1. **Pre-retrieval filtering** – Amazon Quick performs a semantic search against the vector index to find the most relevant document passages. The system applies access control lists that were synced from OneDrive during the last crawl. This produces a preliminary set of candidate documents.
2. **Real-time verification** – The system verifies the candidate documents in real time by checking the querying user's current access in OneDrive. Only documents the user is currently authorized to access are included in the response.

This two-stage approach provides document-level access control that stays current even when OneDrive permissions change between syncs.

ACL management

Document-level access control is automatically enabled for all admin-managed OneDrive knowledge bases. No additional configuration is required, and the setting cannot be turned off.

For ACL enforcement to work, your Entra app registration must have the following Microsoft Graph application permissions:

- `User.Read.All`, `Group.Read.All`, and `GroupMember.Read.All` to resolve user and group membership.

- `Sites.Read.All` to enumerate and read the OneDrive drives, which are hosted on SharePoint.

For more information about ACL best practices, see [the section called “Best practices for managing ACLs in knowledge bases”](#).

Real-time access verification

The real-time verification stage uses a delegated OAuth flow managed automatically by Amazon Quick. Quick creates and manages a separate Microsoft Entra application specifically for this purpose. No customer configuration is required for this app. It is distinct from both the admin-managed app registration you created during setup and any user-managed OAuth app.

1. A user asks a question in the Quick chat assistant.
2. If the answer involves OneDrive content from an admin-managed knowledge base, Quick prompts the user to **Sign in to OneDrive**.
3. The user signs in and accepts the Microsoft consent dialog (if admin consent has not been granted).
4. Quick uses the user's delegated token to verify access to each candidate document in real time.
5. Only documents the user currently has access to in OneDrive are included in the response.

The sign-in is a one-time step. The delegated credentials use a refresh token and last approximately 90 days.

Delegated permissions

The real-time ACL app requests the following delegated permissions:

Real-time ACL – delegated permissions

Permission	Scope	Purpose
Read items in all site collections	<code>Sites.Read.All</code>	Verify user access to OneDrive content hosted on SharePoint.
Have full access to your files	<code>Files.ReadWrite.All</code>	Verify user access to specific files.
View your basic profile	<code>User.Read</code>	Identify the signed-in user.

Permission	Scope	Purpose
Maintain access to data you have given it access to	offline_access	Refresh tokens so users don't need to re-authenticate frequently.

Admin consent

The real-time ACL check uses a separate Microsoft Entra application from the one used in user-managed setup or the admin-managed app registration. If your organization requires admin consent, an administrator must grant consent for each application independently.

When you create an admin-managed knowledge base, the Amazon Quick console provides a direct link to grant admin consent. This link is for the real-time ACL application. If you are a Microsoft 365 administrator, you can grant consent directly from the console. Otherwise, share the link with your administrator.

If admin consent is not granted, each user sees the consent dialog on their first query that involves OneDrive content. After accepting, they are not prompted again for approximately 90 days.

For detailed instructions on granting admin consent through the consent dialog or the Microsoft Entra admin center, see [the section called “Grant organization-wide admin consent”](#).

Next steps

For more information about ACL best practices, see [the section called “Best practices for managing ACLs in knowledge bases”](#). For information about creating admin-managed OneDrive knowledge bases, see [the section called “Admin-managed setup”](#).

Known limitations

- OneNote files are not crawled in admin-managed setup. Microsoft retired app-only tokens for the OneNote APIs on March 31, 2025. To index OneNote content, use [User-managed setup](#).
- Shared folders are not crawled. Folders shared with a user are stored in SharePoint and cannot be accessed with the application credentials used for admin-managed setup. To sync shared content, we recommend creating a [Microsoft SharePoint knowledge base integration](#).

Manage and troubleshoot admin-managed connections

To edit, share, or delete your integration, see [the section called “Managing existing integrations”](#).

- **Unable to access KMS key** – Verify the KMS key ARN and Region. Confirm the KMS key has been added in the Amazon Quick admin console under **Manage account, AWS resources, AWS Key Management Service**. Confirm the key is enabled and has not been scheduled for deletion. Multi-Region keys are not currently supported.
- **Certificate validation failed** – Verify the thumbprint using the base64url-encoded SHA-1 value from the certificate generation step. Ensure the certificate uploaded to Entra has not expired.
- **ACL not enforced** – Confirm the Entra app has `Files.Read.All`, `Sites.Read.All`, `User.Read.All`, `Group.Read.All`, and `GroupMember.Read.All` on Microsoft Graph. Re-run a full sync after fixing permissions. For more information about verifying document access, see [the section called “Check document access \(ACL verification\)”](#).
- **Zero items crawled** – The sync completed but no documents were indexed. This typically indicates a permissions issue. Verify the Entra app has the correct API permissions, including `Sites.Read.All` so that Amazon Quick can enumerate the OneDrive drives hosted on SharePoint. Also verify that users have OneDrive content and that admin consent has been granted.
- **Syncs failing after certificate expiry** – If syncs fail across multiple knowledge bases that share the same data source connection, the certificate uploaded to Entra might have expired. Generate a new certificate (see [the section called “Step 2: Generate a self-signed certificate”](#)), upload it to the Entra app registration, and update the connection details. An Amazon Quick administrator can reassign data source ownership through **Manage assets** if the original creator is unavailable. For more information, see [the section called “Sharing data source connections”](#).
- **No results from ACL-enabled knowledge base** – If users receive no results from an admin-managed knowledge base, admin consent for the real-time ACL application might not have been granted. Your tenant might also block user consent. Grant admin consent using the link provided in the Amazon Quick console, or see [the section called “Admin consent”](#).

For additional troubleshooting, including sync monitoring, reports, and ACL verification, see [the section called “Troubleshooting”](#).

Troubleshooting OneDrive knowledge bases

Use this section to diagnose and resolve common issues with OneDrive knowledge base integrations.

Sign-in errors with user-managed setup

User-managed setup sign-in errors

Issue	Cause	Resolution
"Need admin approval" error during sign-in	Your tenant restricts user consent for third-party apps.	Ask a Global Administrator to grant admin consent. For more information, see the section called "Admin consent for Microsoft 365" .
Sign-in window closes without completing	Browser popup blocker or cookie settings.	Allow popups from the Amazon Quick domain and ensure third-party cookies are enabled.
"AADSTS65004: User declined to consent"	User chose Cancel or Deny on the consent dialog.	Retry the sign-in and choose Accept on the consent dialog.

Token refresh with user-managed setup

User-managed setup uses the `offline_access` scope to obtain refresh tokens. Delegated credentials last approximately 90 days. If the refresh token expires or is revoked (for example, by a password change, session revocation, or admin action), syncs fail and you need to re-authenticate.

To re-authenticate:

1. Navigate to the **Knowledge bases** list page in Amazon Quick.
2. Locate the knowledge base that requires a refresh. In the **Actions** column, choose the three-dot menu and choose **Edit integration**.
3. The **Edit integration** dialog opens. You can optionally update the integration name.
4. Choose **Save and Reauthenticate**.
5. A Microsoft sign-in window opens. Complete the sign-in flow using the same credentials that were originally used to create the integration.

⚠ Important

When you re-authenticate, sign in using the same Microsoft 365 account that was used during the original setup. Using different credentials might cause issues with connected resources. The new account might have different OneDrive permissions than the original account.

Common errors**Common OneDrive knowledge base errors**

Issue	Cause	Resolution
Unable to access KMS key	The KMS key ARN is incorrect, the key does not exist in the specified Region, or the KMS key has not been added in the Amazon Quick admin console.	Verify the KMS key ARN and Region. Confirm the KMS key has been added under Manage account, AWS resources , AWS Key Management Service . Confirm the key is enabled and has not been scheduled for deletion. Multi-Region keys are not supported.
Invalid Tenant ID	The Tenant ID is malformed or does not match a valid Entra tenant.	Copy the Tenant ID directly from the Entra admin center: Microsoft Entra ID, Overview .
Invalid Client ID	The Client ID is incorrect or the app registration does not exist.	Copy the Application (Client) ID from App Registrations , your app, Overview .
Certificate validation failed	The thumbprint does not match the certificate in Entra, or the certificate has expired.	Verify the thumbprint using the base64url-encoded SHA-1 value from the certificate generation step. Ensure the certificate has not expired.
Unable to connect to OneDrive	One or more credentials are incorrect, or the Entra app is missing	Review all field values. Confirm the Entra app has the correct API permissions.

Issue	Cause	Resolution
	required API permissions or admin consent.	ns and that admin consent has been granted.
Error loading the file picker with user-managed setup	The file picker is unable to establish a connection to OneDrive on behalf of the signed-in user.	Close the error message and choose Add content again to retry. If the error persists, close the creation dialog, reopen the flow, and sign in to OneDrive again.

Check document access (ACL verification)

Admin-managed OneDrive knowledge bases always enforce document-level access control. You can verify document-level access control for individual items using the Permission Checker in sync reports. For detailed instructions, see [the section called "Check document access \(ACL verification\)"](#).

Sync monitoring and reports

For detailed information about sync schedules, sync activity, sync reports, filtering items, and downloading reports, see [the section called "Sync reports and observability"](#).

Tip

To trigger a sync on demand, choose **Sync now** on the knowledge base detail page.

Next steps

After you resolve the issue, verify your fix by running a sync. For more information about sync monitoring, see [the section called "Sync reports and observability"](#).

Microsoft OneNote integration

With the Microsoft OneNote connector, you can manage notebooks, sections, and pages from your Microsoft 365 account directly in Amazon Quick through natural language. The connector uses Microsoft Graph for OneNote operations.

Amazon Quick supports two authentication methods for Microsoft OneNote. Choose the method that best fits your organization's security requirements.

- **Default OAuth app** – Uses an AWS-managed OAuth application. No additional credentials are needed. Users authenticate directly with their Microsoft 365 account.
- **Custom OAuth app** – Uses a customer-managed application registered in Microsoft Entra ID. This option gives your organization full control over the OAuth configuration.

For more information about the authentication methods that Amazon Quick supports, see [the section called “Authentication methods”](#).

Before you begin

Make sure that you have the following before you set up the integration.

- An active Microsoft 365 account with access to the OneNote notebooks that you want to use.
- For **Custom OAuth app**: Access to Microsoft Entra ID (formerly Azure Active Directory) to register an application and configure Microsoft Graph permissions for OneNote.
- For Amazon Quick subscription requirements, see [the section called “Set up integrations in the console”](#).

Configuring Microsoft Entra ID

If you are using **Default OAuth app** authentication, skip this section and proceed to [the section called “Setting up the connector in Amazon Quick”](#).

For Custom OAuth app authentication, register an application in the [Microsoft Entra admin center](#) and configure Microsoft Graph delegated permissions for OneNote. Add the Amazon Quick callback URL `https://{region}.quicksight.aws.amazon.com/sn/oauthcallback` as a redirect URI. Replace `{region}` with your AWS Region (for example, `us-east-1`). For step-by-step instructions, see [Authentication and authorization basics](#) in the Microsoft Graph documentation. Record the Application (client) ID and a client secret value — you need them when you configure Amazon Quick.

Add the following as Delegated permissions in your Entra app registration. For the full permissions reference, see [Microsoft Graph permissions reference](#) in the Microsoft documentation.

OneNote action integration – delegated permissions

Permission	Description
<code>Notes.Create</code>	Allows the app to create OneNote notebooks on behalf of the signed-in user.
<code>Notes.Read</code>	Allows the app to read OneNote notebooks on behalf of the signed-in user.
<code>Notes.Read.All</code>	Allows the app to read all OneNote notebooks that the signed-in user has access to.
<code>Notes.ReadWrite</code>	Allows the app to read and write OneNote notebooks on behalf of the signed-in user.
<code>Notes.ReadWrite.All</code>	Allows the app to read and write all OneNote notebooks that the signed-in user has access to.
<code>Notes.ReadWrite.CreatedByApp</code>	Allows the app to read and write OneNote notebooks created by the app on behalf of the signed-in user.
<code>offline_access</code>	Allows the app to refresh access tokens without requiring the user to sign in again. This reduces how often users need to re-authenticate.
<code>Sites.Read.All</code>	Allows the app to read documents and list items in all site collections on behalf of the signed-in user.
<code>Team.ReadBasic.All</code>	Allows the app to read the names and descriptions of teams on behalf of the signed-in user.
<code>User.Read</code>	Allows the app to read the signed-in user's profile.
<code>User.ReadBasic.All</code>	Allows the app to read a basic set of profile properties of all users on behalf of the signed-in user.

Setting up the connector in Amazon Quick

Connect from the Available tab

If you want to use Default OAuth app authentication, you can connect directly from the **Available** tab without additional configuration.

1. In the Amazon Quick console, choose **Connectors**.
2. On the **Available** tab, find **OneNote** and choose **Connect**.
3. Complete the Microsoft sign-in flow and grant the requested permissions.

To configure a connector with Custom OAuth app instead, use the **Create for your team** tab as described below.

Create from the Create for your team tab

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **OneNote**.
4. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
5. For **Connection type**, choose **Public network**.
6. For **OAuth Configuration**, choose one of the following authentication methods and configure the required fields.

- a. For **Default OAuth app**:

No additional credentials are needed. Choose **Next** to continue.

- b. For **Custom OAuth app**, configure the following fields:

- **Base URL** (Optional) – The Microsoft Graph base URL. Example: `https://graph.microsoft.com/v1.0`
- **Client ID** – The Application (client) ID from your Microsoft Entra ID app registration.
- **Public OAuth client** (Optional) – Select this option if your Microsoft Entra ID app is configured as a public client (no client secret).
- **Client secret** – The client secret value from your Microsoft Entra ID app registration.
- **Token URL** – The Microsoft identity platform token endpoint. Example: `https://login.microsoftonline.com/common/oauth2/v2.0/token`

- **Authorization URL** – The Microsoft identity platform authorization endpoint. Example: `https://login.microsoftonline.com/common/oauth2/v2.0/authorize`
- **Redirect URL** – Pre-filled with the Amazon Quick callback URL.

 Note

For tenant-specific authentication, replace common in the Token URL and Authorization URL with your Microsoft Entra ID tenant ID.

7. Choose **Next**.
8. A Microsoft sign-in window opens. Review the requested permissions and choose **Accept**.
9. On the **Review** page, review the available actions for the connector. Choose **Next**.
10. On the **Publish** page, choose who can access the connector. You can enable access for everyone in your organization or search for specific teams or groups.
11. Choose **Publish**.

Available actions

After you set up the connector, the actions exposed by OneNote are available. To see the current set of actions for your connector, go to the connector's **Available actions** view in the Amazon Quick console.

Managing and troubleshooting

To edit, share, or delete your connector, see [the section called “Managing existing integrations”](#).

Authentication issues

- **Sign-in fails (Default OAuth app or Custom OAuth app)** – Verify that your Microsoft 365 account is active and that you can sign in to OneNote on the web directly. For Custom OAuth app, confirm that the redirect URI in your Microsoft Entra ID app matches the Amazon Quick callback URL.
- **Insufficient permissions** – Verify that the Microsoft Graph permissions configured on your Microsoft Entra ID app include the OneNote scopes required for the operations you want to use, and that admin consent has been granted if required.

- **Invalid client credentials (Custom OAuth app)** – Verify that the Client ID and Client secret match the values in your Microsoft Entra ID app registration. Confirm that the client secret has not expired.

Microsoft Outlook integration

With the Microsoft Outlook connector, you can access Outlook's email, calendar, and contact APIs directly in Amazon Quick through natural language.

Amazon Quick supports multiple authentication methods for Microsoft Outlook. Choose the method that best fits your organization's security requirements.

- **Default OAuth app** – Uses an AWS-managed OAuth application. No additional credentials are needed. Users authenticate directly with their Microsoft account.
- **Custom OAuth app** – Uses a customer-managed application registered in Microsoft Entra. This option gives your organization full control over the OAuth configuration. Users authenticate on behalf of a signed-in user (delegated permissions).
- **Service-to-Service OAuth** – Uses client credentials for server-to-server authentication without user interaction (application permissions). Suitable for automated workflows.

For more information about the authentication methods that Amazon Quick supports, see [the section called "Authentication methods"](#).

Before you begin

Make sure that you have the following before you set up the integration.

- A Microsoft 365 account with Outlook or Exchange Online access.
- For **Custom OAuth app** or **Service-to-Service OAuth**: Access to the [Microsoft Entra admin center](#) on the Microsoft website with at least Application Developer permissions.
- For Amazon Quick subscription requirements, see [the section called "Set up integrations in the console"](#).

Configuring Microsoft Entra

If you are using **Default OAuth app** authentication, skip this section and proceed to [the section called "Setting up the connector in Amazon Quick"](#).

Before you configure Amazon Quick, create an app registration in Microsoft Entra. Complete all of the following steps in Entra before moving to the Amazon Quick console.

For more information about app registrations, see [Register an application with the Microsoft identity platform](#) in the Microsoft documentation.

Register the application

1. Open the [Microsoft Entra admin center](#).
2. In the left navigation, choose **Entra ID**, then choose **App registrations**.
3. Choose **New registration**.
4. For **Name**, enter a descriptive name for your integration.
5. For **Supported account types**, choose **Accounts in this organizational directory only**.
6. For **Redirect URI**, select **Web** and enter `https://{region}.quicksight.aws.amazon.com/sn/oauthcallback`. Replace `{region}` with the AWS Region where your Amazon Quick instance is deployed.
7. Choose **Register**.
8. On the overview page, copy the **Application (client) ID** and **Directory (tenant) ID**. You need these values for the Amazon Quick configuration.

Create a client secret

Amazon Quick needs a client secret to authenticate with Microsoft Entra. This secret acts as a password for the app registration.

1. From your app registration, choose **Certificates & secrets**.
2. Choose **New client secret**.
3. Enter a description and choose an expiration period.
4. Choose **Add**.
5. Copy the **Value** immediately. This value is only displayed once.

Important

Copy the secret **Value**, not the Secret ID. The Value is the longer string used for authentication.

Configure API permissions

Microsoft Graph supports two permission types for this integration. Delegated permissions allow the app to act on behalf of a signed-in user. Application permissions allow the app to act without a signed-in user. For more information, see [Overview of Microsoft Graph permissions](#) in the Microsoft documentation.

1. From your app registration, choose **API permissions**.
2. Choose **Add a permission**, then choose **Microsoft Graph**.
3. Choose **Delegated permissions** or **Application permissions** based on your authentication method, and add the permissions from the appropriate table below.
4. Choose **Grant admin consent for [your tenant name]** to approve the permissions.

For user authentication (delegated permissions):

Add the following as Delegated permissions in your Entra app registration. For the full permissions reference, see [Microsoft Graph permissions reference](#) in the Microsoft documentation.

Outlook action integration – delegated permissions

Permission	Description
Mail.ReadWrite	Allows the app to create, read, update, and delete email in user mailboxes.
Mail.Send	Allows the app to send mail as users in the organization.
Mail.Read.Shared	Allows the app to read mail that the user can access, including the user's own mail and shared mail.
Calendars.ReadWrite	Allows the app to create, read, update, and delete events in user calendars.
Calendars.ReadWrite.Shared	Allows the app to create, read, update and delete events in all calendars the user has permissions to access, including delegate and shared calendars.
User.Read	Allows users to sign in to the app and allows the app to read the profile of signed-in users.

Permission	Description
User.Read.All	Allows the app to read the full set of profile properties of other users in your organization.
Contacts.Read	Allows the app to read user contacts.
Place.Read.All	Allows the app to read company places (conference rooms and room lists) for calendar events and other applications.
MailboxSettings.Read	Allows the app to read the user's mailbox settings.
offline_access	Allows the app to refresh access tokens without requiring the user to sign in again. This reduces how often users need to re-authenticate.

Note

User.Read.All and Place.Read.All require administrator consent. An administrator must grant consent before users can authenticate.

For service authentication (application permissions):

Add the following as Application permissions in your Entra app registration.

Outlook action integration – application permissions

Permission	Description
Mail.ReadWrite	Allows the app to create, read, update, and delete mail in all mailboxes.
Mail.Send	Allows the app to send mail as any user.
Calendars.ReadWrite	Allows the app to create, read, update, and delete events of all calendars.
User.Read.All	Allows the app to read user profiles.

Permission	Description
Contacts.Read	Allows the app to read all contacts in all mailboxes.
Place.Read.All	Allows the app to read company places (conference rooms and room lists) for calendar events and other applications.
MailboxSettings.Read	Allows the app to read user's mailbox settings.

Important

With service authentication, all actions execute as the service account. Any user with access to this integration can perform actions across all mailboxes that the service account can access. Scope the application permissions appropriately for your organization's security requirements.

Record your credentials

Before leaving the Microsoft Entra admin center, confirm you have the following values. You need them for the Amazon Quick configuration.

Required credentials from Microsoft Entra

Value	Where to find it
Application (client) ID	App registration overview page
Directory (tenant) ID	App registration overview page
Client secret value	Certificates & secrets page

Setting up the connector in Amazon Quick

Connect from the Available tab

If you want to use Default OAuth app authentication, you can connect directly from the **Available** tab without additional configuration.

1. In the Amazon Quick console, choose **Connectors**.
2. On the **Available** tab, find **Microsoft Outlook** and choose **Connect**.
3. Complete the Microsoft sign-in flow and grant the requested permissions.

To configure a connector with Custom OAuth app or Service-to-Service OAuth instead, use the **Create for your team** tab as described below.

Create from the Create for your team tab

After you complete any required Entra configuration, create the connector in Amazon Quick.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Microsoft Outlook**.

Note

If a Microsoft Outlook connector already exists, a dialog appears with your existing connectors. To use an existing connector, choose it. To create a new one, choose **No, create new**.

4. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
5. For **Connection type**, choose **Public network**.
6. For **OAuth Configuration**, choose one of the following authentication methods and configure the required fields.

a. For **Default OAuth app**:

No additional credentials are needed. Choose **Next** to continue.

b. For **Custom OAuth app** (user authentication with delegated permissions), configure the following fields:

- **Base URL** (Optional) – The Microsoft Graph API base URL. Example: `https://graph.microsoft.com/v1.0`
- **Client ID** – The Application (client) ID from your Entra app registration.
- **Client secret** – The client secret value from your Entra app registration.

- **Token URL** – The token endpoint. Example: `https://login.microsoftonline.com/{tenant-id}/oauth2/v2.0/token`
 - **Authorization URL** – The authorization endpoint. Example: `https://login.microsoftonline.com/{tenant-id}/oauth2/v2.0/authorize`
 - **Redirect URL** – Pre-filled with the Amazon Quick callback URL.
- c. For **Service-to-Service OAuth** (service authentication with application permissions), configure the following fields:
- **Base URL** (Optional) – The Microsoft Graph API base URL. Example: `https://graph.microsoft.com/v1.0`
 - **Client ID** – The Application (client) ID from your Entra app registration.
 - **Client secret** – The client secret value from your Entra app registration.
 - **Token URL** – The token endpoint. Example: `https://login.microsoftonline.com/{tenant-id}/oauth2/v2.0/token`

 Note

The scope for the client credentials token request (`https://graph.microsoft.com/.default`) is set automatically by Amazon Quick. You do not need to configure it manually.

7. Choose **Next**.
8. If you chose **Default OAuth app** or **Custom OAuth app**, a Microsoft authorization window opens. Review the requested permissions and choose **Accept**.

If you see an error instead of the consent dialog, your organization might restrict third-party app access. See [the section called “Admin consent for Microsoft 365”](#).

9. On the **Review** page, review the available actions for the connector. Choose **Next**.
10. On the **Publish** page, choose who can access the connector. You can enable access for everyone in your organization or search for specific teams or groups.
11. Choose **Publish**.

Available actions

After you set up the connector, the following actions are available.

Microsoft Outlook available actions

Category	Action	Description
Email	List User Mails	Lists emails in a mailbox.
Email	List Folder Messages	Lists messages in a specific mail folder.
Email	View Email	Retrieves email details by ID.
Email	Send User Email	Sends a new email message.
Email	Reply To Email	Replies to an existing email.
Email	Forward User Email	Forwards an email to other recipients.
Email	Update Email	Edits email properties.
Email	Delete Email	Removes an email from a mailbox.
Email	Move Email To Folder	Moves an email to a different folder.
Email	List Email Attachments	Lists attachments on an email.
Email	Get Attachment	Retrieves attachment details and content by ID.
Calendar	List Calendar Events	Lists events on a calendar.
Calendar	List Calendar View	Lists meetings in a specified date range.
Calendar	Create Calendar Event	Creates a new meeting or appointment.
Calendar	Update Calendar Event	Modifies an existing event.
Calendar	Delete Calendar Event	Removes an event from a calendar.
Calendar	Find Meeting Times	Suggests meeting times based on attendee availability.
Contacts	List Contacts	Lists contacts.

Category	Action	Description
Users	List Users	Lists users in the organization.
Settings	Get Mailbox Settings	Reads mailbox configuration.
Places	List Places	Lists meeting rooms and room lists.

Manage and troubleshoot

To edit, share, or delete your integration, see [the section called “Managing existing integrations”](#).

Authentication issues

- **Incorrect app registration** – Verify the app registration in Microsoft Entra includes the required API permissions and that admin consent has been granted.
- **Expired client secret** – Check if the client secret has expired in **Certificates & secrets** and generate a new one if needed.
- **Incorrect redirect URI** – Verify the redirect URI in Microsoft Entra matches `https://{region}.quicksight.aws.amazon.com/sn/oauthcallback`.

Common error messages

- **Access denied. You do not have permission to perform this action** – The authenticated user does not have the required permissions. Contact your administrator to verify and grant appropriate permissions.
- **AADSTS50020: User account from identity provider does not exist in tenant** – The user account is not configured in the correct Microsoft Entra tenant. Verify the user account exists in the tenant that matches the Directory (tenant) ID in your app registration.

Admin consent for Microsoft 365

When you use the **Default OAuth app** authentication method, Amazon Quick uses an AWS-managed application to access Microsoft Outlook on behalf of the signed-in user. Most users can complete setup without any extra steps. However, if your Microsoft 365 tenant restricts third-party app access, a Microsoft 365 administrator must grant one-time consent before users can connect.

If you see an error when you sign in during connector setup, your organization might restrict third-party app access. Share the following information with your Microsoft 365 administrator:

- **What to do:** Grant admin consent for the Amazon Quick Microsoft Outlook integration application.
- **Why:** Amazon Quick needs delegated access to Outlook email, calendar, and contact data to perform actions on behalf of users.

An administrator can grant consent in one of the following ways:

- **Through the consent dialog** – A Global Administrator or Privileged Role Administrator initiates the connector setup flow. In the Microsoft sign-in dialog, they select the **Consent on behalf of your organization** check box and choose **Accept**.
- **Through the Microsoft Entra admin center** – Sign in to the [Microsoft Entra admin center](#) on the Microsoft website. Choose **Enterprise applications**, locate the Amazon Quick application, choose **Permissions**, and choose **Grant admin consent for *Your Organization***.

After consent is granted, any user in your organization can connect without being prompted for individual consent.

Note

To check whether your tenant restricts user consent, go to the Microsoft Entra admin center and choose **Enterprise applications, Consent and permissions, User consent settings**. If the setting is **Do not allow user consent**, an administrator must grant consent before users can use the connector.

Microsoft SharePoint integration

With the Microsoft SharePoint integration, you can manage SharePoint lists, items, and files. You can also create knowledge bases from SharePoint content for AI-powered search and Q&A.

What you can do

Connector

Manage SharePoint lists, items, files, and Excel workbooks through Microsoft Graph API calls.

Knowledge base

Index SharePoint document libraries, sites, and pages. Amazon Quick agents can then search and answer questions about the content. Amazon Quick supports two setup methods: user-managed setup for quick configuration, and admin-managed setup with service credentials for document-level access control.

Next steps

After you review the prerequisites and capabilities, continue with one of the following topics:

- To set up the connector, see [the section called “Action integration”](#).
- To create a knowledge base from SharePoint content, see [the section called “Knowledge base integration”](#).

Microsoft SharePoint action integration

Use the Microsoft SharePoint connector to manage lists, items, files, and Excel workbooks directly in Amazon Quick through natural language.

Amazon Quick supports multiple authentication methods for Microsoft SharePoint. Choose the method that best fits your organization's security requirements.

- **Default OAuth app** – Uses an AWS-managed OAuth application. No additional credentials are needed. Users authenticate directly with their Microsoft account.
- **Custom OAuth app** – Uses a customer-managed application registered in Microsoft Entra. This option gives your organization full control over the OAuth configuration. Users authenticate on behalf of a signed-in user (delegated permissions).
- **Service-to-Service OAuth** – Uses client credentials for server-to-server authentication without user interaction (application permissions). Suitable for automated workflows.

For more information about the authentication methods that Amazon Quick supports, see [the section called “Authentication methods”](#).

Before you begin

Make sure you have the following before you set up the integration.

- A Microsoft 365 account with SharePoint access.
- For **Custom OAuth app** or **Service-to-Service OAuth**: Access to the [Microsoft Entra admin center](#) on the Microsoft website with at least Application Developer permissions.
- For subscription requirements, see [the section called “Set up integrations in the console”](#).

Configure Microsoft Entra

If you are using **Default OAuth app** authentication, skip this section and proceed to [the section called “Setting up the connector in Amazon Quick”](#).

Before you configure Amazon Quick, create an app registration in Microsoft Entra. Complete all of the following steps in Entra before moving to the Amazon Quick console.

For more information about app registrations, see [Register an application with the Microsoft identity platform](#) in the Microsoft documentation.

Register the application

1. Open the [Microsoft Entra admin center](#).
2. In the left navigation, choose **Entra ID**, then choose **App registrations**.
3. Choose **New registration**.
4. For **Name**, enter a descriptive name for your integration.
5. For **Supported account types**, choose **Accounts in this organizational directory only**.
6. For **Redirect URI**, select **Web** and enter `https://{region}.quicksight.aws.amazon.com/sn/oauthcallback`. Replace `{region}` with the AWS Region where your Amazon Quick instance is deployed.
7. Choose **Register**.
8. On the overview page, copy the **Application (client) ID** and **Directory (tenant) ID**. You need these values for the Amazon Quick configuration.

Create a client secret

Amazon Quick needs a client secret to authenticate with Microsoft Entra. This secret acts as a password for the app registration.

1. From your app registration, choose **Certificates & secrets**.
2. Choose **New client secret**.

3. Enter a description and choose an expiration period.
4. Choose **Add**.
5. Copy the **Value** immediately. This value is only displayed once.

Important

Copy the secret **Value**, not the Secret ID. The Value is the longer string used for authentication.

Configure API permissions

Microsoft Graph supports two permission types for this integration. Delegated permissions allow the app to act on behalf of a signed-in user. Application permissions allow the app to act without a signed-in user. For more information, see [Overview of Microsoft Graph permissions](#) in the Microsoft documentation.

1. From your app registration, choose **API permissions**.
2. Choose **Add a permission**, then choose **Microsoft Graph**.
3. Choose **Delegated permissions** or **Application permissions** based on your authentication method, and add the permissions from the appropriate table below.
4. Choose **Grant admin consent for [your tenant name]** to approve the permissions.

For user authentication (delegated permissions):

Add the following as Delegated permissions in your Entra app registration. For the full permissions reference, see [Microsoft Graph permissions reference](#) in the Microsoft documentation.

SharePoint action integration – delegated permissions

Permission	Description
Files.ReadWrite	Allows the app to read, create, update, and delete the signed-in user's files.
Sites.ReadWrite.All	Allows the application to edit or delete documents and list items in all site collections on behalf of the signed-in user.

Permission	Description
User.Read	Allows the app to read the signed-in user's profile.
offline_access	Allows the app to refresh access tokens without requiring the user to sign in again. This reduces how often users need to re-authenticate.

For service authentication (application permissions):

Add the following as Application permissions in your Entra app registration.

SharePoint action integration – application permissions

Permission	Description
Sites.ReadWrite.All	Allows the app to create, read, update, and delete documents and list items in all site collections without a signed-in user.

Important

With service authentication, all actions execute as the service account. Any user with access to this integration can perform actions across all site collections that the service account can access. Scope the application permissions appropriately for your organization's security requirements.

Record your credentials

Before leaving the Microsoft Entra admin center, confirm you have the following values. You need them for the Amazon Quick configuration.

Required credentials from Microsoft Entra

Value	Where to find it
Application (client) ID	App registration overview page
Directory (tenant) ID	App registration overview page

Value	Where to find it
Client secret value	Certificates & secrets page

Setting up the connector in Amazon Quick

Connect from the Available tab

If you want to use Default OAuth app authentication, you can connect directly from the **Available** tab without additional configuration.

1. In the Amazon Quick console, choose **Connectors**.
2. On the **Available** tab, find **SharePoint** and choose **Connect**.
3. Complete the Microsoft sign-in flow and grant the requested permissions.

To configure a connector with Custom OAuth app or Service-to-Service OAuth instead, use the **Create for your team** tab as described below.

Create from the Create for your team tab

After you complete any required Entra configuration, create the connector in Amazon Quick.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Microsoft SharePoint**.

Note

If a Microsoft SharePoint connector already exists, a dialog appears with your existing connectors. To use an existing connector, choose it. To create a new one, choose **No, create new**.

4. On the **Integration type** page, select **Perform actions in Microsoft SharePoint Online** and choose **Next**.
5. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
6. For **Connection type**, choose **Public network**.

7. For **OAuth Configuration**, choose one of the following authentication methods and configure the required fields.

a. For **Default OAuth app**:

No additional credentials are needed. Choose **Next** to continue.

b. For **Custom OAuth app** (user authentication with delegated permissions), configure the following fields:

- **Base URL** (Optional) – The Microsoft Graph API base URL. Example: `https://graph.microsoft.com/v1.0`
- **Client ID** – The Application (client) ID from your Entra app registration.
- **Client secret** – The client secret value from your Entra app registration.
- **Token URL** – The token endpoint. Example: `https://login.microsoftonline.com/{tenant-id}/oauth2/v2.0/token`
- **Authorization URL** – The authorization endpoint. Example: `https://login.microsoftonline.com/{tenant-id}/oauth2/v2.0/authorize`
- **Redirect URL** – Pre-filled with the Amazon Quick callback URL.

c. For **Service-to-Service OAuth** (service authentication with application permissions), configure the following fields:

- **Base URL** (Optional) – The Microsoft Graph API base URL. Example: `https://graph.microsoft.com/v1.0`
- **Client ID** – The Application (client) ID from your Entra app registration.
- **Client secret** – The client secret value from your Entra app registration.
- **Token URL** – The token endpoint. Example: `https://login.microsoftonline.com/{tenant-id}/oauth2/v2.0/token`

 Note

The scope for the client credentials token request (`https://graph.microsoft.com/.default`) is set automatically by Amazon Quick. You do not need to configure it manually.

8. Choose **Next**.

9. If you chose **Default OAuth app** or **Custom OAuth app**, a Microsoft authorization window opens. Review the requested permissions and choose **Accept**.

If you see an error instead of the consent dialog, your organization might restrict third-party app access. See [the section called "Admin consent for Microsoft 365"](#).

10. On the **Review** page, review the available actions for the connector. Choose **Next**.
11. On the **Publish** page, choose who can access the connector. You can enable access for everyone in your organization or search for specific teams or groups.
12. Choose **Publish**.

Available actions

After you set up the integration, the following actions are available.

Microsoft SharePoint available actions

Category	Action	Description
Lists and items	View items	Get the collection of items in a list.
Lists and items	Get Item	Returns the metadata for an item in a list.
Lists and items	Get List	Returns the metadata for a list.
Lists and items	Update Item	Update the properties on a list item.
Lists and items	Delete Item	Removes an item from a list.
Files	Upload File	Upload a new file or update an existing file. Supports files up to 250 MB.
Files	Search Site Drive Items	Search the hierarchy of items matching a query.

Category	Action	Description
Excel workbooks	List Sheets	Retrieve a list of worksheet objects.
Excel workbooks	Add Sheet	Add a new worksheet to the workbook.
Excel workbooks	Read Sheet	Retrieve the properties of a worksheet object.
Excel workbooks	Update Sheet	Update the properties of a worksheet object.
Excel workbooks	Delete Sheet	Delete the worksheet from the workbook.
Excel workbooks	Read Cell	Get the value of a single cell by row and column number.
Excel workbooks	Write Cell	Set the value of a single cell by row and column number.
Excel workbooks	Read Range	Get the values of a range.
Excel workbooks	Write Range	Update the values of a range.
Excel workbooks	Clear Range	Clear range values, format, fill, and border.
Excel workbooks	Delete Range	Delete the cells associated with the range.
Excel workbooks	Get Used Range	Get the smallest range that encompasses cells with a value or formatting.

Manage and troubleshoot

To edit, share, or delete your integration, see [the section called “Managing existing integrations”](#).

Authentication issues

- **Incorrect app registration** – Verify the app registration in Microsoft Entra includes the required API permissions and that admin consent has been granted.
- **Expired client secret** – Check if the client secret has expired in **Certificates & secrets** and generate a new one if needed.
- **Incorrect redirect URI** – Verify the redirect URI in Microsoft Entra matches `https://{region}.quicksight.aws.amazon.com/sn/oauthcallback`.

Common error messages

- **Access denied. You do not have permission to perform this action** – The authenticated user does not have the required permissions. Contact your administrator to verify and grant appropriate permissions.
- **AADSTS50020: User account from identity provider does not exist in tenant** – The user account is not configured in the correct Microsoft Entra tenant. Verify the user account exists in the tenant that matches the Directory (tenant) ID in your app registration.

Admin consent for Microsoft 365

When you use the **Default OAuth app** authentication method, Amazon Quick uses an AWS-managed application to access Microsoft SharePoint on behalf of the signed-in user. Most users can complete setup without any extra steps. However, if your Microsoft 365 tenant restricts third-party app access, a Microsoft 365 administrator must grant one-time consent before users can connect.

If you see an error when you sign in during connector setup, your organization might restrict third-party app access. Share the following information with your Microsoft 365 administrator:

- **What to do:** Grant admin consent for the Amazon Quick Microsoft SharePoint integration application.
- **Why:** Amazon Quick needs delegated access to SharePoint sites, lists, files, and Excel workbooks to perform actions on behalf of users.

An administrator can grant consent in one of the following ways:

- **Through the consent dialog** – A Global Administrator or Privileged Role Administrator initiates the connector setup flow. In the Microsoft sign-in dialog, they select the **Consent on behalf of your organization** check box and choose **Accept**.
- **Through the Microsoft Entra admin center** – Sign in to the [Microsoft Entra admin center](#) on the Microsoft website. Choose **Enterprise applications**, locate the Amazon Quick application, choose **Permissions**, and choose **Grant admin consent for *Your Organization***.

After consent is granted, any user in your organization can connect without being prompted for individual consent.

 Note

To check whether your tenant restricts user consent, go to the Microsoft Entra admin center and choose **Enterprise applications, Consent and permissions, User consent settings**. If the setting is **Do not allow user consent**, an administrator must grant consent before users can use the connector.

Microsoft SharePoint knowledge base integration

Microsoft SharePoint Online is a collaborative platform for building websites, managing document libraries, and organizing content across your organization. With the Amazon Quick SharePoint connector, you can create knowledge bases from your SharePoint content to power AI-driven search and Q&A.

Amazon Quick supports two authentication methods for connecting to SharePoint Online:

- **User-managed setup** – You sign in to SharePoint directly to authorize the connection. This is the simplest way to get started. For more information, see [the section called “User-managed setup”](#).
- **Admin-managed setup (service credentials)** – An Entra ID app registration authenticates on behalf of the application using certificate-based credentials. A key benefit of admin-managed setup is built-in document-level access control (ACL). Amazon Quick automatically syncs access control lists from SharePoint and verifies each user's permissions at query time. Users see answers only from documents that they are authorized to access. For more information, see [the section called “Admin-managed setup”](#).

After connecting, Amazon Quick indexes your SharePoint document libraries, sites, lists, and pages into a knowledge base. Your Amazon Quick agents can then search this content and generate answers grounded in your SharePoint data.

Prerequisites

Before you set up the SharePoint knowledge base integration, make sure that you have the following:

- An AWS account with an active Amazon Quick instance.
- A Microsoft 365 account with SharePoint Online access.
- For subscription requirements, see [the section called “Set up integrations in the console”](#).

For admin-managed setup, additional prerequisites apply. For more information, see [the section called “Admin-managed setup”](#).

Tip

Custom SharePoint domains are supported. If your organization uses a custom domain instead of the default `https://tenant.sharepoint.com` format, you can use your custom SharePoint URL when configuring the knowledge base.

User-managed setup

With user-managed setup, you sign in to SharePoint directly and Amazon Quick handles authentication. Most users can complete setup in a few minutes.

Prerequisites

Before you begin, make sure you have the following:

- A Microsoft 365 account with access to the SharePoint sites you want to index.
- Access to Amazon Quick with permissions to create knowledge bases.
- A browser that allows popups from the Amazon Quick console domain.

Important

User-managed setup does not support document-level access control (ACL). All indexed content is accessible to any user who has access to the knowledge base in Amazon Quick. Individual permissions in SharePoint are not enforced. Carefully review which content you include when creating a knowledge base. If you require document-level access control, use [Admin-managed setup \(service credentials\)](#) instead.

Create the SharePoint knowledge base

Navigate to Knowledge

1. In Amazon Quick, choose **Knowledge** from the left navigation panel.
2. Under **Set up new knowledge base**, locate **Microsoft SharePoint Online** and choose the **+** icon.

Sign in to SharePoint

The **Create SharePoint knowledge base** wizard opens on the Authentication method step. **Quick setup** is selected by default.

1. Under **Quick setup**, choose **Sign in to SharePoint**.
2. A Microsoft sign-in window opens. Enter your Microsoft 365 credentials.
3. If a permissions consent dialog appears, review the permissions and choose **Accept**.

If you see an error instead of the consent dialog, your organization might restrict third-party app access. See [the section called "Admin consent for Microsoft 365"](#).

4. After successful authentication, choose **Next**.

Choose content

1. Enter a **Name** and optional **Description** for your knowledge base.
2. In the **Content** section, choose **Add content**.
3. A dialog opens showing SharePoint sites and content accessible to your account. Select the pages, lists, files, or folders you want to index.

4. Choose **Add** to confirm your selections. You can add more content or remove items before continuing.
5. Choose **Create**.

Tip

If the site you are looking for does not appear in the dialog, choose the search link at the top of the Content section. Enter the full URL of the SharePoint site (for example, `https://contoso.sharepoint.com/sites/marketing`) and choose **Browse**. The dialog then displays the document libraries, lists, pages, folders, and files within that site. Selecting a folder includes all files and subfolders within it.

Initial sync

After you choose **Create**, you are returned to the knowledge base list page. The knowledge base might take a few minutes to finish provisioning. Once creation is complete, an initial sync is automatically triggered.

Admin consent for Microsoft 365

Most users complete setup without any extra steps. However, if your Microsoft 365 tenant restricts third-party app access, you might see an error when you sign in. In this case, a Microsoft 365 administrator needs to grant one-time consent for the Amazon Quick application. After consent is granted, any user in your organization can connect.

If you are not a Microsoft 365 administrator, share the following information with your administrator:

- **What to do:** Grant admin consent for the Amazon Quick SharePoint integration application.
- **Why:** Amazon Quick needs delegated read access to SharePoint sites and files to index content for knowledge bases.

Grant organization-wide admin consent

Some Amazon Quick features require delegated permissions from Microsoft Entra. By default, each user sees a Microsoft consent dialog the first time they use the feature. A Microsoft 365

administrator can pre-consent on behalf of the entire organization so that individual users aren't prompted. This is a one-time action per application.

 Note

If your Microsoft 365 tenant is configured to restrict user consent for third-party applications, admin consent is required, not optional. Without it, users see an error when they attempt to use the feature.

The following table describes the user experience with and without admin consent.

Admin consent scenarios

Scenario	User experience
Admin consent not granted	Each user sees the Microsoft permissions consent dialog on first use. Users might be blocked if your tenant restricts user consent for third-party apps.
Admin consent granted	Users aren't prompted for consent. The feature works immediately for all users in the organization.

Granting consent through the consent dialog

The simplest way to grant admin consent is through the Microsoft consent dialog that appears during the feature flow.

To grant consent through the consent dialog

1. Have a Global Administrator or Privileged Role Administrator initiate the feature flow that triggers the consent dialog.
2. In the Microsoft sign-in dialog, select the **Consent on behalf of your organization** check box.
3. Choose **Accept**.

This grants consent for the requested delegated permissions for all users in your Microsoft 365 tenant.

Granting consent through the Microsoft Entra admin center

Administrators can also grant consent directly from the Microsoft Entra admin center.

To grant consent through the Microsoft Entra admin center

1. Sign in to the [Microsoft Entra admin center](#).
2. In the left navigation pane, expand **Entra ID** and choose **Enterprise applications**.
3. Locate the enterprise application for the Amazon Quick feature.

Note

The application name appears in the consent dialog that users see when they first use the feature.

4. In the left navigation pane, choose **Permissions**.
5. Choose **Grant admin consent for *Your Organization***.
6. Confirm the consent.

Verifying consent

After you grant consent, the Enterprise application's **Permissions** page shows all delegated permissions with a status indicator under the **Admin consent** column.

Note

When an administrator grants organizational consent, Microsoft Entra automatically creates an Enterprise Application (service principal) in your tenant. To revoke access, disable or delete this service principal from **Enterprise applications** in the Microsoft Entra admin center.

Checking tenant consent settings

To check whether your tenant restricts user consent, complete the following steps.

To check tenant consent settings

1. In the Microsoft Entra admin center, choose **Entra ID, Enterprise applications, Consent and permissions, User consent settings**.
2. If the setting is **Do not allow user consent**, an administrator must grant consent before users can use the feature.

Permissions requested

The following delegated permissions are requested when a user signs in. Share this list with your administrator if they need to review the permissions before granting consent.

User-managed setup – permissions

Permission	API	Type	Description
Files.Read.All	Microsoft Graph	Delegated	Read all files the signed-in user can access.
Notes.Read.All	Microsoft Graph	Delegated	Read all OneNote notebooks the signed-in user can access.
User.Read	Microsoft Graph	Delegated	Sign in and read the user's profile.
Sites.Read.All	Microsoft Graph	Delegated	Read documents and list items in all site collections.
offline_access	Microsoft Graph	Delegated	Maintain access using refresh tokens.
AllSites.Read	Office 365 SharePoint Online	Delegated	Read items in all site collections.

Manage and troubleshoot user-managed connections

To edit, share, or delete your integration, see [the section called “Managing existing integrations”](#).

- **App blocked by administrator** – Your Microsoft 365 tenant restricts third-party app access. Ask your Microsoft 365 administrator to grant admin consent. For more information, see [the section called “Admin consent for Microsoft 365”](#).
- **Sign-in window closes without completing** – Verify that your browser allows popups from the Amazon Quick console domain and that third-party cookies are enabled.
- **Token expired** – Delegated credentials last approximately 90 days. If syncs fail after this period, you need to re-authenticate. For more information, see [the section called “Token refresh with user-managed setup”](#).
- **Missing content** – Verify that the account you used for authentication has access to the files and folders you selected. Content shared with you after the initial sync requires a resync to be indexed.

For additional troubleshooting, including sync monitoring and reports, see [the section called “Troubleshooting”](#).

Next steps

After your knowledge base is created and the initial sync completes, you can use it in Amazon Quick to answer questions from your SharePoint content. To manage your knowledge base, see [the section called “Managing existing integrations”](#).

Admin-managed setup (service credentials)

With admin-managed setup, an administrator configures an AWS KMS signing key and a Microsoft Entra ID app registration with certificate-based credentials. Individual users don't need to authorize through sign-in.

Admin-managed setup optionally includes document-level access control list (ACL) support. When enabled, Amazon Quick syncs ACLs from SharePoint and verifies each user's permissions at query time. For more information, see [the section called “Document-level access controls”](#).

Prerequisites

Before you begin, make sure that you have the following:

- Administrator access to the Amazon Quick admin console.
- Administrator access to Microsoft Entra ID to register an application and grant API permissions.
- A SharePoint Online site with content to index.

Setup overview

The setup involves the following phases:

1. **Set up service credentials** – Create a KMS signing key, generate a certificate, register an application in Entra, and grant Amazon Quick permission to use the key. For more information, see [the section called “Set up service credentials”](#).
2. **Create the knowledge base in Amazon Quick** – Create a SharePoint knowledge base using the service credentials from Phase 1. For more information, see [the section called “Create the knowledge base”](#).

Document-level access control is optionally available for all admin-managed knowledge bases. For more information about how access controls work, see [the section called “Document-level access controls”](#).

Set up service credentials

Before you create the knowledge base in Amazon Quick, complete the following configuration steps in AWS and Microsoft Entra ID. You create a KMS signing key, generate a certificate, register an application in Entra, and grant Amazon Quick permission to use the key.

This setup involves multiple systems and might require coordination between different administrators in your organization. The following table summarizes each step and the role needed to complete it.

Setup steps and roles

Step	What you do	Role needed
1. KMS key	Create an asymmetric signing key in AWS KMS.	AWS administrator (KMS and IAM console access)
2. Certificate	Generate a self-signed certificate using the KMS public key.	Same as Step 1 (AWS CLI and OpenSSL required)
3. Entra app	Register an application in Microsoft Entra, assign API permissions, and upload the certificate.	Microsoft 365 Global Admin or Privileged Role Admin

Step	What you do	Role needed
3b. Sites.Selected (optional)	Create a temporary admin app and grant per-site permissions via the Microsoft Graph API.	Microsoft 365 Global Admin (same as Step 3)
4. KMS key access	Grant Amazon Quick permission to use the KMS key for signing.	Amazon Quick administrator (Admin Pro)
5. Create KB	Create the knowledge base in Amazon Quick using the credentials from the previous steps.	Any Amazon Quick user (Author Pro or Admin Pro)

 Tip

In many organizations, a single person with both AWS and Microsoft 365 administrator access can complete all steps. If responsibilities are split across teams, share this table to coordinate the setup.

Prerequisites

Before you begin, make sure that you have the following:

- An AWS account with an active Amazon Quick instance.
- Access to the AWS KMS console (for creating the signing key).
- Amazon Quick administrator access (Admin Pro role) for granting KMS key permissions.
- A Microsoft 365 tenant with SharePoint Online.
- Global Administrator or Privileged Role Administrator access in Microsoft Entra ID.
- OpenSSL 3.0 or later and AWS CLI installed locally.
- The AWS account and Amazon Quick instance must be in the same Region.

Permissions

The permissions you assign depend on two choices:

- Whether you plan to enable document-level access control (ACL crawling).

- Whether you want to grant access to all SharePoint sites or only specific sites.

Choose your permission scope

By default, the Entra app registration uses `Sites.Read.All` or `Sites.FullControl.All`, which grants access to all SharePoint sites in your tenant. If your organization requires least-privilege access, you can use `Sites.Selected` instead. With `Sites.Selected`, the app can only access sites that you explicitly grant permission to.

Permission scope comparison

Scope	Access	Additional steps
All sites (default)	App can read all SharePoint sites in the tenant.	—
<code>Sites.Selected</code>	App can only access sites you explicitly grant.	Requires a temporary admin app and a Microsoft Graph API call for each site. See the section called “Step 3b: Grant site-level permissions (Sites.Selected only)” .

Note

If you use `Sites.Selected`, you must grant access for each site individually. Any new sites added to the knowledge base in the future also require a separate permission grant.

All sites – content only (no ACL)

Content-only permissions

API	Permission	Type
Microsoft Graph	<code>Sites.Read.All</code>	Application
SharePoint REST	<code>Sites.Read.All</code>	Application

All sites – with ACL crawling

ACL crawling permissions

API	Permission	Type
Microsoft Graph	Sites.Read.All	Application
Microsoft Graph	User.Read.All	Application
Microsoft Graph	GroupMember.Read.All	Application
SharePoint REST	Sites.FullControl.All	Application

Important

Choose either the all-sites permissions in the preceding tables or the Sites.Selected permissions in the following tables. Do not combine both. If you are unsure, start with all-sites. You can create a new Entra app registration with Sites.Selected later if needed.

Sites.Selected – content only (no ACL)

Sites.Selected content-only permissions

API	Permission	Type
Microsoft Graph	Sites.Selected	Application
SharePoint REST	Sites.Selected	Application

Sites.Selected – with ACL crawling

Sites.Selected ACL crawling permissions

API	Permission	Type
Microsoft Graph	Sites.Selected	Application
Microsoft Graph	User.Read.All	Application

API	Permission	Type
Microsoft Graph	GroupMember.Read.All	Application
SharePoint REST	Sites.Selected	Application

 **Note**

OneNote crawling (Notes.Read.All) is not supported in admin-managed setup. Microsoft retired app-only tokens for OneNote APIs on March 31, 2025. Use [User-managed setup](#) for OneNote content.

Values collected during setup

The following table summarizes the values you create or collect during setup and where you use them.

Values reference

Value	Created in step	Used in step
KMS Key ARN	1 (KMS)	2 (Certificate), 4 (IAM), Quick setup
Certificate file (certificate.cer)	2 (Certificate)	3 (Entra upload)
Certificate thumbprint (base64url)	2 (Certificate)	Quick setup
Application (Client) ID	3 (Entra)	Quick setup
Directory (Tenant) ID	3 (Entra)	Quick setup
SharePoint domain URL	Your M365 tenant	Quick setup

Step 1: Create an AWS KMS asymmetric signing key

Amazon Quick uses an AWS KMS asymmetric key to sign OAuth assertions when authenticating with Microsoft Entra ID. The private key never leaves KMS. Only the public key is exported and embedded in a certificate that gets uploaded to your Entra app registration.

Create the KMS key

1. Open the [AWS KMS console](#).
2. In the left navigation, choose **Customer managed keys**.
3. Choose **Create key**.

Configure the key

On the **Configure key** page, set the following values:

KMS key configuration

Setting	Value
Key type	Asymmetric
Key usage	Sign and verify
Key spec	RSA_2048
Key material origin	KMS (recommended)
Regionality	Single-Region key (default). Multi-Region keys are not supported.

Add labels

On the **Add labels** page, enter an alias for the key. For example: quick-sharepoint-service-auth.

Note

The key administrator and key usage permissions on the following pages are optional. The defaults are sufficient for this setup. You grant Amazon Quick access to the key separately in Step 4.

Choose **Skip to review**, then choose **Finish** to create the key.

Record the Key ARN

After the key is created, open the key detail page and record the **Key ARN**. The ARN has the following format:

```
arn:aws:kms:us-west-2:123456789012:key/xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxxxx
```

You need this value in Steps 2, 4, and when you create the knowledge base in Quick.

Step 2: Generate a self-signed certificate

Microsoft Entra ID requires an X.509 certificate to validate signed assertions. Because the KMS private key never leaves AWS KMS, you cannot use it directly with OpenSSL. Instead, you generate a temporary local key pair and create a certificate signing request. Then, use the OpenSSL -force_pubkey option to inject the KMS public key into the final certificate. The result is a self-signed certificate whose public key matches the KMS key pair.

Prerequisites

- AWS CLI installed and configured.
- OpenSSL 3.0 or later.
- The KMS Key ARN from Step 1.

Generate the certificate

Run the following commands in a terminal. Replace the *placeholder* values with your own.

Verify OpenSSL version

```
openssl version
```

Confirm the output shows version 3.0 or later.

Export the KMS public key

```
aws kms get-public-key \  
  --key-id KMS_KEY_ARN \  
  --region REGION \  
  --output text \  
  --query PublicKey | base64 --decode > public_key.der
```

Note

On macOS, use `base64 --decode` or `base64 -D` depending on your shell environment.

Convert the public key to PEM format

```
openssl rsa -pubin -inform DER -in public_key.der -outform PEM -out kms_public_key.pem
```

Generate a temporary local key pair

```
openssl genrsa -out temp_private_key.pem 2048
```

Create a certificate signing request

```
openssl req -new \  
  -key temp_private_key.pem \  
  -out cert.csr \  
  -subj "/CN=QuickSharePointServiceAuth/0=YourOrganization/C=US"
```

Generate the certificate with the KMS public key

```
openssl x509 -req \  
  -in cert.csr \  
  -signkey temp_private_key.pem \  
  -out certificate.pem \  
  -days 730 \  
  -force_pubkey kms_public_key.pem
```

Note

OpenSSL displays the warning `Signature key and public key of cert do not match`. This is expected because the certificate is signed with the temporary local key but contains the KMS public key. The certificate is valid and works correctly with Microsoft Entra.

Convert to DER format for Entra upload

```
openssl x509 -in certificate.pem -outform DER -out certificate.cer
```

Clean up temporary files

```
rm -f temp_private_key.pem cert.csr public_key.der kms_public_key.pem certificate.pem
```

Important

Keep the `certificate.cer` file. You upload it to Microsoft Entra ID in Step 3.

Calculate the certificate thumbprint

Run the following command to calculate the base64url-encoded SHA-1 thumbprint of the certificate:

```
openssl dgst -sha1 -binary certificate.cer | base64 | tr '+/' '-_' | tr -d '='
```

Record this value. You enter it when you create the knowledge base in Quick.

Note

The base64url-encoded thumbprint is different from the hexadecimal thumbprint shown in the Microsoft Entra portal. Quick requires the base64url format.

Step 3: Register an application in Microsoft Entra ID

This step is required regardless of whether you use all-sites permissions or Sites.Selected. The only difference is which API permissions you assign in the [the section called "Configure API permissions"](#) section.

Register the application

1. Sign in to the [Microsoft Entra admin center](#).
2. In the left navigation, expand **Entra ID** and choose **App registrations**.
3. Choose **New registration**.
4. For **Name**, enter QuickSharePointServiceAuth.
5. For **Supported account types**, select **Accounts in this organizational directory only (Single tenant)**.
6. Leave **Redirect URI** blank. A redirect URI is not required because the application uses the client credentials flow, not an interactive sign-in flow.
7. Choose **Register**.

Record application details

On the application **Overview** page, record the following values:

Application details

Value	Location
Application (client) ID	Shown on the Overview page under Essentials .
Directory (tenant) ID	Shown on the Overview page under Essentials .

Configure API permissions

Add the permissions that match your use case. Choose the permissions from the tables in the [the section called "Permissions"](#) section. Base your selection on your permission scope (all sites or Sites.Selected) and whether you enable ACL crawling.

Content only – Microsoft Graph

- Sites.Read.All

Content only – SharePoint

- `Sites.Read.All`

ACL crawling – Microsoft Graph (additional)

- `Sites.Read.All`
- `User.Read.All`
- `GroupMember.Read.All`

ACL crawling – SharePoint

- `Sites.FullControl.All`

Note

`Sites.FullControl.All` is required for ACL crawling because the SharePoint REST API requires full control permissions to read site-level and item-level permission assignments. If you are using `Sites.Selected`, see [the section called “Step 3b: Grant site-level permissions \(Sites.Selected only\)”](#) for the alternative permission set.

1. In the left navigation of your app registration, choose **API permissions**.
2. Choose **Add a permission**.
3. Choose **Microsoft Graph**.
4. Choose **Application permissions**.
5. Search for and select the required Microsoft Graph permissions for your use case, then choose **Add permissions**.
6. Choose **Add a permission** again.
7. Choose **SharePoint** (under Microsoft APIs).
8. Choose **Application permissions**.
9. Search for and select the required SharePoint permissions for your use case, then choose **Add permissions**.

 Important

Select the **Application permissions** tab, not **Delegated permissions**. Admin-managed setup uses the client credentials flow, which requires application permissions.

Grant admin consent

1. On the **API permissions** page, choose **Grant admin consent for [Your Organization]**.
2. Confirm the consent when prompted.

 Important

Admin consent is required for application permissions. Without it, the application cannot access SharePoint data.

Upload the certificate

1. In the left navigation of your app registration, choose **Certificates & secrets**.
2. Choose the **Certificates** tab.
3. Choose **Upload certificate**.
4. Select the `certificate.cer` file you generated in Step 2.
5. Choose **Add**.

 Note

The Entra portal displays the certificate thumbprint in hexadecimal format. This is different from the base64url-encoded thumbprint you calculated in Step 2. Use the base64url value when you configure the knowledge base in Quick.

Step 3b: Grant site-level permissions (Sites.Selected only)

If you chose `Sites.Selected` as your permission scope, you must explicitly grant your Amazon Quick Entra app access to each SharePoint site. This requires a temporary admin app with `Sites.FullControl.All` permission to call the Microsoft Graph API.

Skip this step if you are using the all-sites permission scope (`Sites.Read.All` or `Sites.FullControl.All`).

Get the Site ID for each SharePoint site

You need the Site ID for each SharePoint site you want to grant access to. To get a Site ID:

1. In your browser, navigate to the SharePoint site (for example, `https://yourcompany.sharepoint.com/sites/SiteName`).
2. Append `/_api/site/id` to the URL and press Enter. For example:
`https://yourcompany.sharepoint.com/sites/SiteName/_api/site/id`
3. The page displays an XML response containing the Site ID (a GUID). Record this value.

Repeat for each site you want to include in the knowledge base.

Create a temporary admin app

The admin app is used only to grant site-level permissions to your Amazon Quick app. You can delete it after completing this step.

1. In the [Microsoft Entra admin center](#), go to **App registrations** and choose **New registration**.
2. For **Name**, enter a descriptive name such as `Quick-SharePoint-PermissionGranter`.
3. For **Supported account types**, select **Accounts in this organizational directory only (Single tenant)**.
4. Leave **Redirect URI** blank and choose **Register**.
5. Record the **Application (client) ID** from the Overview page.
6. Choose **API permissions**, then **Add a permission**.
7. Choose **Microsoft Graph**, then **Application permissions**. Search for and select `Sites.FullControl.All`. Choose **Add permissions**.
8. Choose **Grant admin consent for [Your Organization]** and confirm.

9. Choose **Certificates & secrets**, then **New client secret**. Enter a description, choose an expiration period, and choose **Add**.
10. Record the secret **Value** immediately. This value is only displayed once.

Important

Copy the secret **Value**, not the Secret ID. The Value is the longer string used for authentication.

Get an access token

Use the admin app credentials to retrieve an OAuth token from Microsoft Entra. Replace the *placeholder* values with your admin app's client ID, secret value, and tenant ID.

macOS and Linux (bash)

```
curl -s --location "https://login.microsoftonline.com/TENANT_ID/oauth2/v2.0/token" \  
  --header "Content-Type: application/x-www-form-urlencoded" \  
  --data-urlencode "grant_type=client_credentials" \  
  --data-urlencode "client_id=ADMIN_APP_CLIENT_ID" \  
  --data-urlencode "client_secret=ADMIN_APP_SECRET_VALUE" \  
  --data-urlencode "scope=https://graph.microsoft.com/.default"
```

Windows (PowerShell)

```
$tokenResponse = Invoke-RestMethod `   
  -Uri "https://login.microsoftonline.com/TENANT_ID/oauth2/v2.0/token" `   
  -Method Post `   
  -ContentType "application/x-www-form-urlencoded" `   
  -Body @{   
    grant_type    = "client_credentials"   
    client_id     = "ADMIN_APP_CLIENT_ID"   
    client_secret = "ADMIN_APP_SECRET_VALUE"   
    scope        = "https://graph.microsoft.com/.default"   
  }   
$adminToken = $tokenResponse.access_token
```

The response contains an `access_token` field. Record this value for the next step.

Grant site-level permissions

Use the admin token to grant your Amazon Quick Entra app `fullcontrol` access to each SharePoint site. Replace the *placeholder* values with your Site ID, admin token, and the client app ID and display name from Step 3.

macOS and Linux (bash)

```
curl -s --location "https://graph.microsoft.com/v1.0/sites/SITE_ID/permissions" \
  --header "Content-Type: application/json" \
  --header "Authorization: Bearer ADMIN_TOKEN" \
  --data '{
    "roles": ["fullcontrol"],
    "grantedToIdentities": [{
      "application": {
        "id": "CLIENT_APP_ID",
        "displayName": "CLIENT_APP_NAME"
      }
    }]
  }'
```

Windows (PowerShell)

```
$body = @{
    roles = @("fullcontrol")
    grantedToIdentities = @(
        @{
            application = @{
                id = "CLIENT_APP_ID"
                displayName = "CLIENT_APP_NAME"
            }
        }
    )
} | ConvertTo-Json -Depth 10

Invoke-RestMethod `
  -Uri "https://graph.microsoft.com/v1.0/sites/SITE_ID/permissions" `
  -Method Post `
  -Headers @{
    "Content-Type" = "application/json"
    "Authorization" = "Bearer $adminToken"
  } `
```

```
-Body $body
```

A successful response includes "roles": ["fullcontrol"] and the client app ID in the grantedToIdentities field.

Important

Repeat this command for each SharePoint site you want to include in the knowledge base. Any new sites added in the future also require a separate permission grant.

Clean up

After you have granted permissions to all required sites, you can delete the temporary admin app from the Microsoft Entra admin center. The site-level permissions you granted remain in effect independently of the admin app.

Note

The temporary admin app is used only in your local environment to call the Microsoft Graph API. Amazon Quick never sees or has access to the admin app or its credentials. Only the client app credentials are provided to Amazon Quick when you create the knowledge base.

Step 4: Grant Amazon Quick permission to the KMS key

Amazon Quick needs permission to use the KMS key for signing OAuth assertions. You grant this permission from the Amazon Quick admin console.

Note

This step requires Amazon Quick administrator access (Admin Pro role). If you are not an administrator, ask your Amazon Quick admin to complete this step using the KMS key ARN from Step 1.

Important

If your organization manages its own Amazon Quick IAM service role, the following console steps might not apply. Instead, ensure the role has `kms:Sign` permission on the KMS key ARN from Step 1.

1. In Amazon Quick, choose **Manage account** from the left navigation pane.
2. Under **Permissions**, choose **AWS resources**.
3. On the AWS resources page, scroll to **AWS Key Management Service** and select the checkbox.
4. Choose **Select keys**.
5. In the **Select KMS keys** dialog, enter the KMS key ARN you recorded in Step 1 and choose **Add**.
6. The key ARN appears in the list. Choose **Finish**.
7. Choose **Save** at the bottom of the AWS resources page.

Next steps

After you complete the setup, create the SharePoint Online knowledge base connection in Amazon Quick. For instructions, see [the section called "Create the knowledge base"](#).

Create the knowledge base in Amazon Quick

After you complete the service credentials setup, create the knowledge base in Amazon Quick and provide the credentials. Any enterprise user can complete this step. Amazon Quick administrator access is not required.

You need the following values from [the section called "Set up service credentials"](#). If an administrator completed the setup on your behalf, collect these values before you proceed:

- KMS key ARN (from Step 1)
- Certificate thumbprint in base64url format (from Step 2)
- Entra application (client) ID (from Step 3)
- Directory (tenant) ID (from Step 3)
- SharePoint domain URL (from your Microsoft 365 tenant)

Navigate to Knowledge

1. In Amazon Quick, choose **Knowledge** from the left navigation pane.
2. Under **Set up new knowledge base**, locate **Microsoft SharePoint Online** and choose the **Add** icon.

Select service credentials authentication

The **Create SharePoint knowledge base** wizard opens on the **Authentication method** step. Choose **Have admin access? Connect with service credentials to enable document-level access control**.

If you have previously created a knowledge base using service credentials, the **Connected account** dropdown appears with your most recent connection pre-selected. When you select an existing connection, the SharePoint domain, Tenant ID, and Client ID are displayed below the dropdown for verification. You can use an existing connection or choose **+ Add account** to enter new service credentials.

Enter service credentials

After choosing **+ Add account**, fill in the following fields:

Service credentials form

Field	Description	Example
Connection name	A descriptive name for this SharePoint connection. You see this name when selecting a connection for future knowledge bases.	SharePoint Production
SharePoint domain	Your organization's SharePoint Online domain.	https://contoso.sharepoint.com
Tenant ID	The Microsoft Entra (Azure AD) tenant identifier.	34567890-1234-1234-1234-123456789012
Client ID	The Application (client) ID from your Entra app registration.	12345678-1234-4321-4321-210987654321

Field	Description	Example
KMS key ARN	The ARN of the AWS KMS asymmetric signing key.	arn:aws:kms:us-west-2:123456789012:key/my-key-id
Certificate Thumbprint	The base64url-encoded SHA-1 thumbprint of the certificate uploaded to Entra.	abc123DEF456ghi789EXAMPLE

Fill in each field and choose **Next**.

 Tip

Give the connection a recognizable name. This name appears in the **Connected account** dropdown when you create future knowledge bases.

Choose content

Enter a **Name** and optional **Description** for your knowledge base.

SharePoint site URLs

Enter the URLs of SharePoint sites or subsites you want to sync, such as `https://contoso.sharepoint.com/sites/finance`. Enter one or more site URLs separated by commas and choose **Add Site**. Do not add file or folder URLs here.

You can add up to 350 entries total across both **SharePoint site URLs** and **Specific SharePoint Paths** combined.

Specific SharePoint Paths (optional)

Enter the paths of specific folders, files, lists, libraries, or pages within a SharePoint site. Enter one or more paths separated by commas and choose **Add Path**. The 350-entry limit is shared with **SharePoint site URLs**.

If a site is already added under **SharePoint site URLs**, all content from that site is synced. Adding individual items from the same site does not limit what is synced.

 Important

Do not use browser URLs for paths. To get the correct path, navigate to the item in SharePoint, choose the three dot menu (...), select **Details**, then scroll to **Path** and choose **Copy**.

Example paths:

- Folder: `https://contoso.sharepoint.com/sites/finance/Shared%20Documents/Reports/Q1`
- File: `https://contoso.sharepoint.com/sites/finance/Shared%20Documents/Reports/Q1/data.docx`

After adding your content, choose **Next**.

 Tip

Each site URL and path must be accessible by the Entra app registration. If you are using `Sites.Selected`, ensure per-site permissions have been granted. For more information, see [the section called “Step 3b: Grant site-level permissions \(Sites.Selected only\)”](#).

Configure additional settings

In the final step of the wizard, you can configure optional settings for the knowledge base.

ACL management

Access Control List (ACL) management enables document-level access control for your SharePoint knowledge base. When enabled, Amazon Quick syncs the permission metadata from SharePoint during each crawl. At query time, Quick uses this metadata with a real-time access check. This check ensures that users only see answers from documents they can access in SharePoint.

ACL management is unchecked (disabled) by default. To enable, select the **Control document access with ACLs** checkbox.

When you enable ACL management, the console displays a note that one-time admin consent might be required for real-time access verification. If you are a Microsoft 365 administrator,

choose the **Grant admin consent** link to grant consent directly. If you are not an administrator, ask your Microsoft 365 admin to grant consent. For more information about admin consent, see [the section called "Admin consent"](#).

 Important

ACL management cannot be changed after the knowledge base is created. This setting is immutable. If you need to change this setting, you must create a new knowledge base. Plan your ACL requirements carefully before creating the knowledge base.

 Note

If you enable ACL management, ensure your Entra app has the ACL permission set (User.Read.All, GroupMember.Read.All on Graph, and Sites.FullControl.All on SharePoint). Without these, the knowledge base creation might succeed but ACL enforcement fails during sync.

Filter content by date

Limits which documents are crawled based on their last modified date in SharePoint. The start date defaults to one year before today. You can change or clear the start date, and optionally set an end date.

Multi-media content, file size, and file patterns

- **Visual content in documents** – Extracts and indexes visual elements from supported document formats. Enabled by default.
- **Audio files** – Transcribes and indexes audio files.
- **Video files** – Transcribes and indexes video files.

 Note

Enabling audio and video indexing increases sync time and storage usage. Enable these options only if your SharePoint content includes relevant media files.

Choose **Create** to create the knowledge base.

Initial sync

After you choose **Create**, you are returned to the knowledge base list page. The knowledge base might take a few minutes to finish provisioning. Once creation is complete, an initial sync is automatically triggered. You do not need to start it manually.

Document-level access controls

Admin-managed SharePoint knowledge bases optionally support document-level access control. When enabled, Amazon Quick syncs access control lists (ACLs) from SharePoint during each crawl. The system verifies each user's permissions at query time, so users only see answers from documents they are authorized to access in SharePoint.

How it works

When a user queries an Amazon Quick agent that uses an admin-managed SharePoint knowledge base with ACL management enabled, the system enforces access controls in two stages:

1. **Pre-retrieval filtering** – Amazon Quick performs a semantic search against the vector index to find the most relevant document passages. The system applies access control lists that were synced from SharePoint during the last crawl. This produces a preliminary set of candidate documents.
2. **Real-time verification** – The system verifies the candidate documents in real time by checking the querying user's current access in SharePoint. Only documents the user is currently authorized to access are included in the response.

This two-stage approach provides document-level access control that stays current even when SharePoint permissions change between syncs.

Enable ACL management

ACL management is configured during knowledge base creation in the **Additional settings** step. Select the **Control document access with ACLs** checkbox to enable it.

Important

ACL management cannot be changed after the knowledge base is created. If you need to change this setting, you must create a new knowledge base.

To enable ACL management, your Entra app registration must have the following permissions:

- `User.Read.All` and `GroupMember.Read.All` on Microsoft Graph.
- `Sites.FullControl.All` on the SharePoint resource, or `Sites.Selected` with per-site permissions granted.

For more information about ACL best practices, see [the section called “Best practices for managing ACLs in knowledge bases”](#).

Real-time access verification

The real-time verification stage uses a delegated OAuth flow managed automatically by Amazon Quick. Quick creates and manages a separate Microsoft Entra application specifically for this purpose. No customer configuration is required for this app. It is distinct from both the admin-managed app registration you created during setup and any user-managed OAuth app.

1. A user asks a question in the Quick chat assistant.
2. If the answer involves SharePoint content from an ACL-enabled knowledge base, Quick prompts the user to **Sign in to SharePoint**.
3. The user signs in and accepts the Microsoft consent dialog (if admin consent has not been granted).
4. Quick uses the user's delegated token to verify access to each candidate document in real time.
5. Only documents the user currently has access to in SharePoint are included in the response.

The sign-in is a one-time step. The delegated credentials use a refresh token and last approximately 90 days.

Delegated permissions

The real-time ACL app requests the following delegated permissions:

Real-time ACL – delegated permissions

Permission	Scope	Purpose
Read items in all site collections	<code>Sites.Read.All</code>	Verify user access to SharePoint site content.

Permission	Scope	Purpose
Read your files	Files.Read.All	Verify user access to specific files.
View your basic profile	User.Read	Identify the signed-in user.
Maintain access to data you have given it access to	offline_access	Refresh tokens so users don't need to re-authenticate frequently.

Admin consent

The real-time ACL check uses a separate Microsoft Entra application from the one used in user-managed setup or the admin-managed app registration. If your organization requires admin consent, an administrator must grant consent for each application independently.

When you enable ACL management during knowledge base creation, the Amazon Quick console provides a direct link to grant admin consent. This link is for the real-time ACL application. If you are a Microsoft 365 administrator, you can grant consent directly from the console. Otherwise, share the link with your administrator.

If admin consent is not granted, each user sees the consent dialog on their first query that involves SharePoint content. After accepting, they are not prompted again for approximately 90 days.

For detailed instructions on granting admin consent through the consent dialog or the Microsoft Entra admin center, see [the section called “Grant organization-wide admin consent”](#).

Next steps

For more information about ACL best practices, see [the section called “Best practices for managing ACLs in knowledge bases”](#). For information about creating admin-managed SharePoint knowledge bases, see [the section called “Admin-managed setup”](#).

Manage and troubleshoot admin-managed connections

To edit, share, or delete your integration, see [the section called “Managing existing integrations”](#).

- **Unable to access KMS key** – Verify the KMS key ARN and Region. Confirm the KMS key has been added in the Amazon Quick admin console under **Manage account, AWS resources, AWS Key Management Service**. Confirm the key is enabled and has not been scheduled for deletion. Multi-Region keys are not currently supported.

- **Certificate validation failed** – Verify the thumbprint using the base64url-encoded SHA-1 value from the certificate generation step. Ensure the certificate uploaded to Entra has not expired.
- **ACL not enforced** – Confirm the Entra app has `User.Read.All` and `GroupMember.Read.All` on Microsoft Graph. For the SharePoint resource, confirm the app has `Sites.FullControl.All`. If using `Sites.Selected`, confirm that per-site permissions have been granted for each site in the knowledge base. Re-run a full sync after fixing permissions. For more information about verifying document access, see [the section called “Check document access \(ACL verification\)”](#).
- **Zero items crawled** – The sync completed but no documents were indexed. This typically indicates a permissions issue. Verify the Entra app has the correct API permissions for your permission scope. If using `Sites.Selected`, confirm that per-site permissions have been granted for each site included in the knowledge base (see [the section called “Step 3b: Grant site-level permissions \(Sites.Selected only\)”](#)). Also verify that the SharePoint sites contain content and are accessible.
- **New site not crawled (Sites.Selected)** – If you added a new site URL to the knowledge base but no content from that site is indexed, the Microsoft Graph API permission grant might be missing. Verify that you ran the grant for the new site. Each site requires a separate grant when using `Sites.Selected`. For more information, see [the section called “Grant site-level permissions”](#).
- **Specific paths returning no results** – Verify that you used the SharePoint path, not the browser URL. To get the correct path, navigate to the item in SharePoint, choose the **More options** menu (:), select **Details**, then scroll to **Path** and choose **Copy**. Also verify the path still exists and has not been renamed or moved in SharePoint.
- **Syncs failing after certificate expiry** – If syncs fail across multiple knowledge bases that share the same data source connection, the certificate uploaded to Entra might have expired. Generate a new certificate (see [the section called “Step 2: Generate a self-signed certificate”](#)), upload it to the Entra app registration, and update the connection details. A Amazon Quick administrator can reassign data source ownership through **Manage assets** if the original creator is unavailable. For more information, see [the section called “Sharing data source connections”](#).
- **No results from ACL-enabled knowledge base** – If users receive no results from a knowledge base with ACL management enabled, admin consent for the real-time ACL application might not have been granted. Your tenant might also block user consent. Grant admin consent using the link provided in the Amazon Quick console when ACL management is enabled, or see [the section called “Admin consent”](#).
- **Documents skipped with "File has no ACL" error** – If sync reports show items with status SKIPPED and error type VALIDATION_ERROR with the message "File has no ACL while crawlACL

is true, skipping ingestion," the Entra app registration is missing the required ACL permissions. Verify the app has the correct permissions for your setup. For the required permissions, see [the section called "Permissions"](#).

For additional troubleshooting, including sync monitoring, reports, and ACL verification, see [the section called "Troubleshooting"](#).

Troubleshooting SharePoint knowledge bases

Use this section to diagnose and resolve common issues with SharePoint knowledge base integrations.

Sign-in errors with user-managed setup

User-managed setup sign-in errors

Issue	Cause	Resolution
"Need admin approval" error during sign-in	Your tenant restricts user consent for third-party apps.	Ask a Global Administrator to grant admin consent. For more information, see the section called "Admin consent for Microsoft 365" .
Sign-in window closes without completing	Browser popup blocker or cookie settings.	Allow popups from the Amazon Quick domain and ensure third-party cookies are enabled.
"AADSTS65004: User declined to consent"	User chose Cancel or Deny on the consent dialog.	Retry the sign-in and choose Accept on the consent dialog.

Token refresh with user-managed setup

User-managed setup uses the `offline_access` scope to obtain refresh tokens. Delegated credentials last approximately 90 days. If the refresh token expires or is revoked (for example, by a password change, session revocation, or admin action), syncs fail and you need to re-authenticate.

To re-authenticate:

1. Navigate to the **Knowledge bases** list page in Amazon Quick.

2. Locate the knowledge base that requires a refresh. In the **Actions** column, choose the three-dot menu and choose **Edit integration**.
3. The **Edit integration** dialog opens. You can optionally update the integration name.
4. Choose **Save and Reauthenticate**.
5. A Microsoft sign-in window opens. Complete the sign-in flow using the same credentials that were originally used to create the integration.

Important

When you re-authenticate, sign in using the same Microsoft 365 account that was used during the original setup. Using different credentials might cause issues with connected resources. The new account might have different SharePoint permissions than the original account.

Common errors

Common SharePoint knowledge base errors

Issue	Cause	Resolution
Unable to access KMS key	The KMS key ARN is incorrect, the key does not exist in the specified Region, or the KMS key has not been added in the Amazon Quick admin console.	Verify the KMS key ARN and Region. Confirm the KMS key has been added under Manage account, AWS resources , AWS Key Management Service . Confirm the key is enabled and has not been scheduled for deletion. Multi-Region keys are not supported.
Invalid Tenant ID	The Tenant ID is malformed or does not match a valid Entra tenant.	Copy the Tenant ID directly from the Entra admin center: Microsoft Entra ID, Overview .
Invalid Client ID	The Client ID is incorrect or the app registration does not exist.	Copy the Application (Client) ID from App Registrations , your app, Overview .

Issue	Cause	Resolution
Certificate validation failed	The thumbprint does not match the certificate in Entra, or the certificate has expired.	Verify the thumbprint using the base64url-encoded SHA-1 value from the certificate generation step. Ensure the certificate has not expired.
Unable to connect to SharePoint	One or more credentials are incorrect, or the Entra app is missing required API permissions or admin consent.	Review all field values. Confirm the Entra app has the correct API permissions and that admin consent has been granted.
Error loading the file picker with user-managed setup	The file picker is unable to establish a connection to SharePoint on behalf of the signed-in user.	Close the error message and choose Add content again to retry. If the error persists, close the creation dialog, reopen the flow, and sign in to SharePoint again.

Check document access (ACL verification)

If you enabled ACL management, you can verify document-level access control for individual items using the Permission Checker in sync reports. For detailed instructions, see [the section called "Check document access \(ACL verification\)"](#).

If you see "No access control list found" for a SharePoint document:

- Verify **Enable ACL management** is selected in the knowledge base's additional settings.
- Confirm the Entra app has `User.Read.All` and `GroupMember.Read.All` on Microsoft Graph.
- Confirm the Entra app has `Sites.FullControl.All` on the SharePoint resource (or `Sites.Selected` with per-site permissions granted).
- Re-run a full sync after fixing permissions.

Sync monitoring and reports

For detailed information about sync schedules, sync activity, sync reports, filtering items, and downloading reports, see [the section called "Sync reports and observability"](#).

Tip

To trigger a sync on demand, choose **Sync now** on the knowledge base detail page.

Next steps

After you resolve the issue, verify your fix by running a sync. For more information about sync monitoring, see [the section called “Sync reports and observability”](#).

Microsoft Teams integration

Use the Microsoft Teams connector to send messages, manage channels, schedule meetings, and manage team collaboration directly in Amazon Quick through natural language.

Amazon Quick supports multiple authentication methods for Microsoft Teams. Choose the method that best fits your organization's security requirements.

- **Default OAuth app** – Uses an AWS-managed OAuth application. No additional credentials are needed. Users authenticate directly with their Microsoft account.
- **Custom OAuth app** – Uses a customer-managed application registered in Microsoft Entra. This option gives your organization full control over the OAuth configuration. Users authenticate on behalf of a signed-in user (delegated permissions).
- **Service-to-Service OAuth** – Uses client credentials for server-to-server authentication without user interaction (application permissions). Suitable for automated workflows.

For more information about the authentication methods that Amazon Quick supports, see [the section called “Authentication methods”](#).

Before you begin

Make sure you have the following before you set up the integration.

- A Microsoft 365 account with Teams access.
- For **Custom OAuth app** or **Service-to-Service OAuth**: Access to the [Microsoft Entra admin center](#) on the Microsoft website with at least Application Developer permissions.
- For subscription requirements, see [the section called “Set up integrations in the console”](#).

Configure Microsoft Entra

If you are using **Default OAuth app** authentication, skip this section and proceed to [the section called "Setting up the connector in Amazon Quick"](#).

Before you configure Amazon Quick, create an app registration in Microsoft Entra. Complete all of the following steps in Entra before moving to the Amazon Quick console.

For more information about app registrations, see [Register an application with the Microsoft identity platform](#) in the Microsoft documentation.

Register the application

1. Open the [Microsoft Entra admin center](#).
2. In the left navigation, choose **Entra ID**, then choose **App registrations**.
3. Choose **New registration**.
4. For **Name**, enter a descriptive name for your integration.
5. For **Supported account types**, choose **Accounts in this organizational directory only**.
6. For **Redirect URI**, select **Web** and enter `https://{region}.quicksight.aws.amazon.com/sn/oauthcallback`. Replace `{region}` with the AWS Region where your Amazon Quick instance is deployed.
7. Choose **Register**.
8. On the overview page, copy the **Application (client) ID** and **Directory (tenant) ID**. You need these values for the Amazon Quick configuration.

Create a client secret

Amazon Quick needs a client secret to authenticate with Microsoft Entra. This secret acts as a password for the app registration.

1. From your app registration, choose **Certificates & secrets**.
2. Choose **New client secret**.
3. Enter a description and choose an expiration period.
4. Choose **Add**.
5. Copy the **Value** immediately. This value is only displayed once.

⚠ Important

Copy the secret **Value**, not the Secret ID. The Value is the longer string used for authentication.

Configure API permissions

Microsoft Graph supports two permission types for this integration. Delegated permissions allow the app to act on behalf of a signed-in user. Application permissions allow the app to act without a signed-in user. For more information, see [Overview of Microsoft Graph permissions](#) in the Microsoft documentation.

1. From your app registration, choose **API permissions**.
2. Choose **Add a permission**, then choose **Microsoft Graph**.
3. Choose **Delegated permissions** or **Application permissions** based on your authentication method, and add the permissions from the appropriate table below.
4. Choose **Grant admin consent for [your tenant name]** to approve the permissions.

For user authentication (delegated permissions):

Add the following as Delegated permissions in your Entra app registration. For the full permissions reference, see [Microsoft Graph permissions reference](#) in the Microsoft documentation.

Teams action integration – delegated permissions

Permission	Description
Calendars.ReadWrite	Allows the app to read and write events in user calendars on behalf of the signed-in user.
Channel.Create	Allows the app to create channels in any team on behalf of the signed-in user.
Channel.ReadBasic.All	Allows the app to read channel names and descriptions on behalf of the signed-in user.
ChannelMessage.Read.All	Allows the app to read all channel messages on behalf of the signed-in user.

Permission	Description
<code>ChannelMessage.ReadWrite</code>	Allows the app to read, send, update, and delete messages in channels on behalf of the signed-in user.
<code>ChannelMessage.Send</code>	Allows the app to send messages in channels on behalf of the signed-in user.
<code>ChannelSettings.ReadWrite.All</code>	Allows the app to read and write the settings of all channels on behalf of the signed-in user.
<code>Chat.Create</code>	Allows the app to create chats on behalf of the signed-in user.
<code>Chat.ReadWrite</code>	Allows the app to read and write the signed-in user's chat messages.
<code>ChatMessage.Send</code>	Allows the app to send chat messages on behalf of the signed-in user.
<code>Files.Read</code>	Allows the app to read the signed-in user's files.
<code>offline_access</code>	Allows the app to refresh access tokens without requiring the user to sign in again. This reduces how often users need to re-authenticate.
<code>OnlineMeetingRecording.Read.All</code>	Allows the app to read all recordings of online meetings on behalf of the signed-in user.
<code>OnlineMeetings.ReadWrite</code>	Allows the app to read and create online meetings on behalf of the signed-in user.
<code>OnlineMeetingTranscript.Read.All</code>	Allows the app to read all transcripts of online meetings on behalf of the signed-in user.
<code>People.Read</code>	Allows the app to read a list of people relevant to the signed-in user.
<code>Presence.ReadWrite</code>	Allows the app to read and write the presence information of the signed-in user.

Permission	Description
<code>Sites.Read.All</code>	Allows the app to read documents and list items in all site collections on behalf of the signed-in user.
<code>Team.Create</code>	Allows the app to create teams on behalf of the signed-in user.
<code>Team.ReadBasic.All</code>	Allows the app to read the names and descriptions of teams on behalf of the signed-in user.
<code>TeamMember.ReadWrite.All</code>	Allows the app to add and remove members from all teams on behalf of the signed-in user.
<code>User.Read</code>	Allows the app to read the signed-in user's profile.
<code>User.Read.All</code>	Allows the app to read the full set of profile properties of all users on behalf of the signed-in user.
<code>User.ReadBasic.All</code>	Allows the app to read a basic set of profile properties of all users on behalf of the signed-in user.

For service authentication (application permissions):

Add the following as Application permissions in your Entra app registration.

Teams action integration – application permissions

Permission	Description
<code>Chat.Read.All</code>	Allows the app to read all chat messages in your organization without a signed-in user.
<code>Chat.Send</code>	Allows the app to send chat messages without a signed-in user.
<code>Team.ReadBasic.All</code>	Allows the app to read the names and descriptions of all teams without a signed-in user.
<code>Channel.ReadBasic.All</code>	Allows the app to read all channel names and descriptions without a signed-in user.

Permission	Description
<code>ChannelMessage.Read.All</code>	Allows the app to read all channel messages without a signed-in user.
<code>ChannelMessage.Send</code>	Allows the app to send messages to any channel without a signed-in user.
<code>ChannelMember.ReadWrite.All</code>	Allows the app to add and remove members from all channels without a signed-in user.
<code>TeamMember.ReadWrite.All</code>	Allows the app to add and remove members from all teams without a signed-in user.
<code>User.Read.All</code>	Allows the app to read the full set of profile properties of all users without a signed-in user.
<code>OnlineMeetingTranscript.Read.All</code>	Allows the app to read all transcripts of online meetings without a signed-in user.

Important

With service authentication, all actions execute as the service account. Any user with access to this integration can perform actions across all teams and channels that the service account can access. Scope the application permissions appropriately for your organization's security requirements.

Record your credentials

Before leaving the Microsoft Entra admin center, confirm you have the following values. You need them for the Amazon Quick configuration.

Required credentials from Microsoft Entra

Value	Where to find it
Application (client) ID	App registration overview page

Value	Where to find it
Directory (tenant) ID	App registration overview page
Client secret value	Certificates & secrets page

Setting up the connector in Amazon Quick

Connect from the Available tab

If you want to use Default OAuth app authentication, you can connect directly from the **Available** tab without additional configuration.

1. In the Amazon Quick console, choose **Connectors**.
2. On the **Available** tab, find **MSTeams** and choose **Connect**.
3. Complete the Microsoft sign-in flow and grant the requested permissions.

To configure a connector with Custom OAuth app or Service-to-Service OAuth instead, use the **Create for your team** tab as described below.

Create from the Create for your team tab

After you complete any required Entra configuration, create the connector in Amazon Quick.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Microsoft Teams**.

Note

If a Microsoft Teams connector already exists, a dialog appears with your existing connectors. To use an existing connector, choose it. To create a new one, choose **No, create new**.

4. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
5. For **Connection type**, choose **Public network**.

6. For **OAuth Configuration**, choose one of the following authentication methods and configure the required fields.

a. For **Default OAuth app**:

No additional credentials are needed. Choose **Next** to continue.

b. For **Custom OAuth app** (user authentication with delegated permissions), configure the following fields:

- **Base URL** (Optional) – The Microsoft Graph API base URL. Example: `https://graph.microsoft.com/v1.0`
- **Client ID** – The Application (client) ID from your Entra app registration.
- **Client secret** – The client secret value from your Entra app registration.
- **Token URL** – The token endpoint. Example: `https://login.microsoftonline.com/{tenant-id}/oauth2/v2.0/token`
- **Authorization URL** – The authorization endpoint. Example: `https://login.microsoftonline.com/{tenant-id}/oauth2/v2.0/authorize`
- **Redirect URL** – Pre-filled with the Amazon Quick callback URL.

c. For **Service-to-Service OAuth** (service authentication with application permissions), configure the following fields:

- **Base URL** (Optional) – The Microsoft Graph API base URL. Example: `https://graph.microsoft.com/v1.0`
- **Client ID** – The Application (client) ID from your Entra app registration.
- **Client secret** – The client secret value from your Entra app registration.
- **Token URL** – The token endpoint. Example: `https://login.microsoftonline.com/{tenant-id}/oauth2/v2.0/token`

 Note

The scope for the client credentials token request (`https://graph.microsoft.com/.default`) is set automatically by Amazon Quick. You do not need to configure it manually.

7. Choose **Next**.

8. If you chose **Default OAuth app** or **Custom OAuth app**, a Microsoft authorization window opens. Review the requested permissions and choose **Accept**.

If you see an error instead of the consent dialog, your organization might restrict third-party app access. See [the section called "Admin consent for Microsoft 365"](#).

9. On the **Review** page, review the available actions for the connector. Choose **Next**.
10. On the **Publish** page, choose who can access the connector. You can enable access for everyone in your organization or search for specific teams or groups.
11. Choose **Publish**.

Available actions

After you set up the integration, the following actions are available.

Microsoft Teams available actions

Category	Action	Description
Chats	List Chats	View your chat conversations.
Chats	Create Chat	Start a new chat conversation.
Chats	Send Chat Message	Send a message in a chat.
Teams	List Teams	View teams you're a member of.
Teams	List Team Members	View members of a team.
Teams	Add Team Member	Add a member to a team.
Channels	List Channels	View channels in a team.
Channels	Create Channel	Create a new channel in a team.
Channels	List Channel Messages	View messages in a channel.
Channels	Send Channel Message	Post a message to a channel.
Channels	List Channel Members	View members of a channel.

Category	Action	Description
Channels	Add Channel Member	Add a member to a channel.
Users	List Users	View users in your organization.
Meetings	List Online Meetings	View your scheduled online meetings.
Meetings	Create Online Meeting	Schedule a new online meeting.
Meetings	List Meeting Transcripts	View transcripts from meetings.
Calendar	List Calendar Events	View events on your calendar.
Calendar	Create Calendar Event	Create a new calendar event.

Manage and troubleshoot

To edit, share, or delete your integration, see [the section called “Managing existing integrations”](#).

Authentication issues

- **Incorrect app registration** – Verify the app registration in Microsoft Entra includes the required API permissions and that admin consent has been granted.
- **Expired client secret** – Check if the client secret has expired in **Certificates & secrets** and generate a new one if needed.
- **Incorrect redirect URI** – Verify the redirect URI in Microsoft Entra matches `https://{region}.quicksight.aws.amazon.com/sn/oauthcallback`.

Common error messages

- **Access denied. You do not have permission to perform this action** – The authenticated user does not have the required permissions. Contact your administrator to verify and grant appropriate permissions.
- **AADSTS50020: User account from identity provider does not exist in tenant** – The user account is not configured in the correct Microsoft Entra tenant. Verify the user account exists in the tenant that matches the Directory (tenant) ID in your app registration.

Admin consent for Microsoft 365

When you use the **Default OAuth app** authentication method, Amazon Quick uses an AWS-managed application to access Microsoft Teams on behalf of the signed-in user. Most users can complete setup without any extra steps. However, if your Microsoft 365 tenant restricts third-party app access, a Microsoft 365 administrator must grant one-time consent before users can connect.

If you see an error when you sign in during connector setup, your organization might restrict third-party app access. Share the following information with your Microsoft 365 administrator:

- **What to do:** Grant admin consent for the Amazon Quick Microsoft Teams integration application.
- **Why:** Amazon Quick needs delegated access to Teams channels, chats, meetings, and calendar data to perform actions on behalf of users.

An administrator can grant consent in one of the following ways:

- **Through the consent dialog** – A Global Administrator or Privileged Role Administrator initiates the connector setup flow. In the Microsoft sign-in dialog, they select the **Consent on behalf of your organization** check box and choose **Accept**.
- **Through the Microsoft Entra admin center** – Sign in to the [Microsoft Entra admin center](#) on the Microsoft website. Choose **Enterprise applications**, locate the Amazon Quick application, choose **Permissions**, and choose **Grant admin consent for *Your Organization***.

After consent is granted, any user in your organization can connect without being prompted for individual consent.

Note

To check whether your tenant restricts user consent, go to the Microsoft Entra admin center and choose **Enterprise applications, Consent and permissions, User consent settings**. If the setting is **Do not allow user consent**, an administrator must grant consent before users can use the connector.

Model Context Protocol (MCP) integration

Model Context Protocol (MCP) is an open standard that defines how AI applications communicate with external tools and data sources. MCP uses a client-server architecture. AI applications act

as clients that connect to MCP servers. Each MCP server exposes a set of tools. These tools are structured operations that the AI application can invoke to perform tasks, such as querying databases, calling APIs, or interacting with third-party services.

With MCP integration in Amazon Quick, you can connect to remote MCP servers so that your AI assistant can use the tools that those servers provide. For example, you can connect to an MCP server that provides access to your project management system. This connection allows the assistant to create tickets, look up issues, or update statuses as part of a conversation. Because MCP is an open standard, you can connect to any compatible server without building custom integrations for each tool.

You can connect to MCP servers that are reachable over the public internet. You can also connect to private MCP servers that are reachable from a virtual private cloud (VPC) in your AWS account by using a Amazon Quick VPC connection. The MCP server can be in the VPC, in another VPC reachable through peering or transit gateway, or on-premises reachable through AWS Direct Connect or VPN. For information about creating a VPC connection in Amazon Quick, see [Configuring VPC connections in Amazon Quick Sight](#).

Important

When you connect to a private MCP server through a VPC connection, you can configure two independent VPC connections:

- **Resource-server VPC connection** (`VpcConnectionArn`) – Carries traffic between Amazon Quick and the MCP server endpoint (tool invocations, capability discovery).
- **Auth-server VPC connection** (`AuthVpcConnectionArn`) – Carries OAuth traffic between Amazon Quick and the authorization server (token requests, authorization code exchange, Dynamic Client Registration, and metadata discovery).

You can set one, both, or neither connection depending on your network topology. If you do not set an auth-server VPC connection, OAuth endpoints must be reachable over the public internet (the default behavior). If your OAuth provider is reachable only from within a VPC, set an auth-server VPC connection. The resource-server and auth-server VPC connections are independent. They can point to different VPCs. MCP servers that do not require authentication are also supported.

Supported capabilities

MCP integration registers MCP server tools as actions in Amazon Quick.

Connector

Each tool that an MCP server exposes registers as an action that your AI assistant can invoke during conversations. The integration secures these connections by using Proof Key for Code Exchange (PKCE) with the S256 challenge method and Resource Indicators (RFC 8707) to bind access tokens to specific MCP servers.

Before you begin

Before you set up MCP integration, make sure that you have the following:

- An MCP server endpoint with appropriate access.
- Authentication credentials for the MCP server, if required. For more information, see [the section called “Prepare MCP server setup and authentication”](#).
- An Amazon Quick Enterprise subscription.
- If you are connecting to a private MCP server, an active Amazon Quick VPC connection that has network access to the MCP server. For more information, see [Configuring VPC connections in Amazon Quick Sight](#).

Note

MCP integration supports remote servers only. HTTP streaming is preferred over Server-Sent Events (SSE). Local stdio connections are not supported.

Prepare MCP server setup and authentication

When you connect to an MCP server, Amazon Quick uses OAuth 2.0 Protected Resource Metadata (RFC 9728) to automatically discover authorization server information. The client sends an initial unauthenticated request to the MCP server. If the server responds with a 401 status that contains a WWW-Authenticate header with a resource_metadata URL, then Amazon Quick uses that URL to fetch the metadata document. If the header is not present, then Amazon Quick falls back to the well-known URI at the server root.

When an auth-server VPC connection is configured, Amazon Quick performs all OAuth discovery over that connection instead of the public internet. This includes fetching the `/.well-known/oauth-authorization-server` document, the `resource_metadata` URL from the MCP server's `WWW-Authenticate` header, and the `registration_endpoint` for Dynamic Client Registration (DCR). DNS resolution for the authorization server hostname must be reachable from the subnets and DNS resolver endpoints that are associated with the auth-server VPC connection.

If the authorization server supports Dynamic Client Registration (DCR), then Amazon Quick automatically registers itself by using the discovered `registration_endpoint` from the authorization server metadata. No manual credential configuration is required. Amazon Quick supports both confidential and public client flows. DCR applies regardless of the authentication method that you choose.

If the authorization server does not support DCR, then you must manually provide credentials. Choose the authentication method that matches your MCP server requirements.

User authentication (OAuth)

Gather the following information from your MCP server configuration:

- **Client ID** – The OAuth client ID.
- **Public OAuth client** (Optional) – Select this checkbox if your OAuth application uses public client configuration (no client secret).
- **Client Secret** – The OAuth client secret.
- **Token URL** – The OAuth token endpoint.
- **Authorization URL** – The OAuth authorization endpoint.
- **Redirect URL** – The OAuth redirect URI.

Note

Select **Public OAuth client** if your MCP server's OAuth application does not use a client secret. This is common for public clients that rely solely on PKCE for security. When this option is selected, the **Client Secret** field is not required.

Service authentication (Service-to-Service)

Gather the following information from your MCP server configuration:

- **Client ID** – The service client ID.

- **Client Secret** – The service client secret.
- **Token URL** – The service token endpoint.

No authentication

If the MCP server does not require authentication, no credentials are needed. Select this option for MCP servers that allow unauthenticated access.

Set up MCP integration

After you prepare your MCP server configuration and authentication credentials, create your MCP integration.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Model Context Protocol (MCP)**.
4. On the **Create Integration** page, enter the integration details:
 - **Name** – A descriptive name for your MCP integration.
 - **Description** (Optional) – The purpose of the integration.
 - **MCP server endpoint** – The URL of the MCP server.
 - **Connection type** – Choose how Amazon Quick connects to the MCP server (resource server):
 - **Public network** – Use this option for MCP servers that are reachable over the public internet.
 - A named VPC connection – Use this option for private MCP servers. The dropdown lists the VPC connections that are configured on your Amazon Quick account. Choose the connection that has network access to your MCP server. If you don't see your VPC connection in the list, confirm that it is fully provisioned and active. For more information, see [Configuring VPC connections in Amazon Quick Sight](#).
 - **Auth server connection type** – Choose how Amazon Quick connects to the OAuth authorization server. This setting is independent of the resource-server connection type.
 - **Public network** (default) – Use this option when the OAuth endpoints (authorization, token, and registration endpoints) are reachable over the public internet. This preserves the default behavior for existing integrations.
 - A named VPC connection – Use this option when the OAuth provider is reachable only from within a VPC. Choose the VPC connection that has network access to the

authorization server. The auth-server VPC connection can be the same as or different from the resource-server VPC connection. For example, your MCP server and OAuth provider might reside in separate VPCs.

5. Choose **Next**.
6. Select the authentication method (user, service, or no authentication).
7. Enter the appropriate configuration details.
8. Choose **Create and continue**.
9. Review the integration details.
10. Choose **Next**.
11. Share the integration with other users if needed.

After you create your MCP integration, Amazon Quick discovers the available tools and registers them as actions.

Review integration

After you configure authentication, review the MCP integration capabilities:

1. The system connects to the MCP server and discovers available capabilities.
2. Review the list of available actions and tasks that the MCP server provides.
3. Confirm the integration configuration and capabilities.

Capability discovery

During the connection process that is described in [the section called “Prepare MCP server setup and authentication”](#), Amazon Quick also discovers and registers the tools that the MCP server provides. After discovery completes, each tool is listed as an action that you can review and turn on.

Manage MCP integrations

To edit, share, or delete your integration, see [the section called “Managing existing integrations”](#).

MCP Sync

As external MCP servers add new tools, update descriptions, and evolve their capabilities, MCP Sync keeps your connectors current. When an MCP server adds, removes, or modifies tools, MCP Sync updates your connector to reflect those changes without requiring you to reconnect.

Amazon Quick supports two connector types with different sync behaviors:

Built-in MCP connectors

Built-in connectors sync automatically. When the MCP server updates its tools, Amazon Quick detects the change and applies it without any action from you. Auto-sync is mandatory for built-in connectors and cannot be turned off. This prevents action failures caused by schema changes or removed tools on the server side. Built-in connectors sync automatically twice a month, on the first and third Monday of each month at 9:00 AM Pacific time.

Custom MCP connectors

Custom connectors require the connector owner to trigger a sync manually. To sync a custom connector, open the connector details page, and then choose **Sync**.

Note

Triggering a sync initiates a re-authorization flow. If the MCP server now requires OAuth scopes that were not granted during the original connection, the sync fails. Confirm that all required scopes are authorized before you sync.

Security considerations

When you use an auth-server VPC connection with MCP integrations, the following security behaviors apply.

Data in transit

When an auth-server VPC connection (`AuthVpcConnectionArn`) is configured, all OAuth credential exchange, including authorization codes, refresh tokens, and ID tokens, transits your VPC over TLS. Tokens do not traverse the public internet on the auth-server path and remain within AWS internal infrastructure.

Logging

The auth-server VPC connection does not introduce new AWS CloudTrail event types. Existing CloudTrail coverage on `CreateActionConnector`, `UpdateActionConnector`, and `PatchActionConnector` API operations continues to apply. The `AuthVpcConnectionArn` field appears in the request body of those existing events when it is set.

Troubleshooting

Use the following guidance to diagnose and resolve common issues when you create or use an MCP integration in Amazon Quick.

Connector creation issues

- **Connector passes discovery but fails at publish with `Creation failed`** – This error usually means that one or more tool definitions in your MCP server's `tools/list` response contain an invalid `inputSchema`. Amazon Quick validates each tool's `inputSchema` against JSON Schema Draft 7 or later during the publish phase.

The most common cause is the deprecated Draft 3 syntax, where `required` is a boolean inside a property definition (for example, `"required": true`). In JSON Schema Draft 7 and later, `required` must be an array of property names at the schema root, as a sibling of `properties`.

Update your tool definitions to use the correct format and redeploy your MCP server. After you redeploy, delete the failed connector and create a new one to retrigger discovery and publish.

The following example shows the incorrect Draft 3 syntax:

```
{
  "type": "object",
  "properties": {
    "logNumber": {
      "type": "string",
      "description": "The permit log number",
      "required": true
    }
  }
}
```

The following example shows the correct Draft 7 syntax:

```
{
  "type": "object",
  "properties": {
    "logNumber": {
      "type": "string",
      "description": "The permit log number"
    }
  },
  "required": ["logNumber"]
}
```

Some MCP framework libraries and code generators emit Draft 3 syntax by default. Check your framework documentation for the option that selects the JSON Schema output version. You can also validate your schemas with any JSON Schema Draft 7 validator before you deploy. For more information about `inputSchema` requirements, see [Tools](#) in the Model Context Protocol specification.

You might also notice that connector creation hangs for two to five minutes before it fails. The elapsed time reflects internal retries during the publish phase, not a network timeout. The fix is the same: check your tool `inputSchema` definitions for JSON Schema Draft 7 compliance.

VPC connection issues

- **VPC connection is not listed in the Connection type dropdown, or MCP creation fails immediately after you select it** – The VPC connection might appear in the dropdown before provisioning is complete. Wait until the VPC connection shows as available on the Amazon Quick admin page before you create an MCP integration against it. For more information, see [Configuring VPC connections in Amazon Quick Sight](#).
- **MCP creation fails because the MCP server hostname cannot be resolved** – Amazon Quick does not use the default VPC DNS resolver for MCP integrations. You must populate the **DNS resolver endpoints** field on the VPC connection with Route 53 Resolver inbound endpoint IP addresses that can resolve your MCP server hostname. This requirement applies to both private hostnames and to public hostnames that you want to resolve to a private address from within the VPC, such as endpoints fronted by AWS PrivateLink or a Route 53 private hosted zone. Without these resolver endpoints, the MCP server hostname cannot be resolved and integration creation fails. For more information, see [Configuring VPC connections in Amazon Quick Sight](#).

- **MCP server is unreachable from the VPC connection** – Traffic from Amazon Quick to your MCP server originates from the subnets that you selected during VPC connection setup. Confirm that route tables, network ACLs, and security groups allow traffic between those subnets and the MCP server endpoint. For general VPC networking guidance, see [Configuring VPC connections in Amazon Quick Sight](#).
- **Authorization server hostname cannot be resolved from the auth-server VPC connection** – The same DNS resolver requirement that applies to the resource-server VPC connection also applies to the auth-server VPC connection. You must populate the **DNS resolver endpoints** field on the auth-server VPC connection with Route 53 Resolver inbound endpoint IP addresses that can resolve the authorization server hostname. If the resource server and authorization server are in different VPCs, each VPC connection needs its own DNS resolver endpoints. For more information, see [Configuring VPC connections in Amazon Quick Sight](#).
- **Authorization server is unreachable from the auth-server VPC connection** – Traffic from Amazon Quick to the authorization server originates from the subnets that are associated with the auth-server VPC connection. Confirm that route tables, network ACLs, and security groups in those subnets allow outbound traffic to the authorization server endpoints. The resource-server and auth-server VPC connections might use different subnets in different VPCs, so verify networking requirements independently for each connection.
- **Authentication fails when you use a private MCP server** – If the OAuth endpoints that the MCP server advertises are reachable only from within a VPC, you must configure an auth-server VPC connection. Without an auth-server VPC connection, Amazon Quick attempts to reach the OAuth endpoints over the public internet, and requests fail if those endpoints are not publicly accessible.

To resolve this issue, edit the MCP integration and set the **Auth server connection type** to the VPC connection that has network access to the authorization server. After you save the change, Amazon Quick routes all OAuth traffic (token requests, authorization code exchange, metadata discovery, and Dynamic Client Registration) through that VPC connection.

If an auth-server VPC connection is already configured and authentication still fails, confirm the following:

- The **DNS resolver endpoints** on the auth-server VPC connection can resolve the authorization server hostname.
- Route tables, network ACLs, and security groups in the auth-server VPC connection's subnets allow outbound traffic to the authorization server endpoints.

- The OAuth URLs returned in the MCP server's protected resource metadata match the endpoints that the auth-server VPC connection can reach.

Microsoft Entra ID issues

If your MCP server uses Microsoft Entra ID as the authorization server, the following errors are common during connector setup. These issues apply to both public network connections and private MCP servers that you reach through a VPC connection.

- **AADSTS9010010 – the v2.0 endpoint rejects the resource parameter** – Amazon Quick sends a resource parameter on OAuth requests as required by the MCP specification (RFC 8707). The Entra ID v2.0 endpoint rejects requests that include both a resource parameter and scope values. To resolve this error, configure your app registration to use the Entra ID v1.0 OAuth endpoints and set `accessTokenAcceptedVersion` to 2 in the app manifest.
- **AADSTS90009 – application requests a token for itself** – When you use user authentication (authorization code flow) and the OAuth client and the MCP resource resolve to the same Entra ID application, Entra ID blocks the request. Create two separate app registrations: one client app for Amazon Quick and one resource app for the MCP server. This issue does not affect service authentication (client credentials flow), where a single app registration works.

Snowflake MCP server issues

If your MCP server is hosted on Snowflake, the following issue is common during connector setup. This issue applies to both public network and VPC connection configurations.

- **Connection fails or returns unexpected errors when the endpoint URL does not include the correct Region** – Snowflake MCP server endpoint URLs are Region-specific. If the endpoint URL omits the AWS Region or defaults to a different Region than where your Snowflake account is deployed, the connection fails.

Verify that the **MCP server endpoint** URL that you provide during integration setup includes the Region where your Snowflake account is deployed. The general endpoint format is:

```
https://account-identifier.region.snowflakecomputing.com/api/v2/cortex/mcp
```

If you connect through AWS PrivateLink, use the following format:

```
https://account-identifier.region.privatelink.snowflakecomputing.com/api/v2/cortex/mcp
```

Replace *account-identifier* with your Snowflake account identifier and *region* with the AWS Region where your Snowflake account is deployed (for example, *us-east-1*). For the correct endpoint URL format for your account, see your Snowflake documentation.

If you encounter an issue that is not covered in the preceding sections, contact AWS Support through the Amazon Quick console or AWS Support Center.

Limitations

When you use MCP integrations in Amazon Quick, be aware of the following limitations:

- MCP operations have a fixed 60-second timeout. Operations that exceed this limit automatically fail with an HTTP 424 error.
- For MCP servers that you reach through a VPC connection, DNS resolution for the authorization server hostname must be reachable from the auth-server VPC connection's subnets and DNS resolver endpoints. This is the same constraint that applies to the resource-server VPC connection for the MCP server hostname. If you do not configure an auth-server VPC connection, the OAuth endpoints must be reachable over the public internet.
- Custom HTTP headers are not supported in MCP operations. Only standard system headers are transmitted.
- For custom MCP connectors, tool lists do not update automatically. To pick up server-side tool changes, open the connector details page and choose **Sync**. Built-in MCP connectors sync automatically. For more information, see [MCP Sync](#).
- Amazon Quick supports a maximum of 100 tools per MCP server connection. If the MCP server exposes more than 100 tools, only the first 100 are registered.
- Connector creation might fail if the Amazon Quick callback URI is not allow-listed by third-party providers.
- Server connectivity issues result in immediate failure without retry attempts.
- Step-up authorization is not supported. If an MCP server requires additional scopes after the initial authorization (HTTP 403 with `insufficient_scope`), then you must re-authorize the entire connection. Incremental permission upgrades are not available.
- Scope handling has the following limitations:

- Amazon Quick does not extract the scope parameter from the server's initial 401 WWW-Authenticate challenge. Amazon Quick determines scopes from the Protected Resource Metadata document instead.
- When the metadata does not specify supported scopes, Amazon Quick applies default scopes rather than omitting them. This behavior might cause authentication failures with servers that do not recognize the default scopes.
- Only Dynamic Client Registration (DCR) is supported for automatic client registration. Client ID Metadata Documents are not supported.
- Well-known URI discovery uses the server root path only. Path-specific metadata locations (path-insertion discovery) are not supported. This limitation might prevent discovery of servers that serve metadata only at path-specific URIs.

Monday.com integration

With Monday.com integration in Amazon Quick, you can manage project boards, track items, and coordinate team workflows through MCP server connectivity. This integration provides action capabilities for project management and team collaboration operations.

What you can do

Monday.com integration provides connector capabilities through MCP server connectivity:

- Create and manage project boards
- Add and update board items and tasks
- Manage team assignments and workloads
- Track project timelines and deadlines
- Update item status and progress
- Generate reports and analytics

Available tools

The Monday.com MCP server typically provides these tools:

- `create_board` - Create new project boards
- `get_board` - Get board information

- `create_item` - Create new board items
- `update_item` - Update item details
- `list_items` - List board items
- `create_column` - Create board columns
- `update_column_value` - Update column values
- `search_boards` - Search for boards

Note

The specific tools and capabilities available through this MCP server may change over time. For the most current information about supported tools, features, and implementation details, check the official Monday.com documentation and MCP server repository.

Setting up Monday.com integration

Monday.com integration uses MCP server connectivity to provide action capabilities. For detailed setup instructions, see [the section called “MCP integration”](#).

You'll need:

- Monday.com account with appropriate board permissions
- Monday.com API token for authentication

Compatibility

Monday.com integration supports:

- **Chat Agents:** Yes
- **Flows:** Yes
- **Knowledge Base:** No

Moodys GenAI Ready Data integration

With the Moodys GenAI Ready Data connector, you can access credit ratings, financial research, and risk analytics data directly in Amazon Quick through natural language.

Amazon Quick supports two authentication methods for Moodys GenAI Ready Data. Choose the method that best fits your organization's security requirements.

- **Default OAuth app** – Uses an AWS-managed OAuth application. No additional credentials are needed. Users authenticate directly with their Moody's account.
- **Custom OAuth app** – Uses a customer-managed OAuth application. This option gives your organization full control over the OAuth configuration.

For more information about the authentication methods that Amazon Quick supports, see [the section called "Authentication methods"](#).

Before you begin

Make sure that you have the following before you set up the integration.

- An active Moody's account with access to Moodys GenAI Ready Data.
- For **Custom OAuth app**: An OAuth app configured in your Moody's developer portal with the Amazon Quick callback URL added as a redirect URI.
- For Amazon Quick subscription requirements, see [the section called "Set up integrations in the console"](#).

Configuring Moody's

If you are using **Default OAuth app** authentication, skip this section and proceed to [the section called "Setting up the connector in Amazon Quick"](#).

For Custom OAuth app authentication, register an OAuth app in your Moody's developer portal and add the Amazon Quick callback URL `https://{region}.quicksight.aws.amazon.com/sn/oauthcallback` as a redirect URI. Replace `{region}` with your AWS Region (for example, `us-east-1`). Record the Client ID and Client Secret — you need them when you configure Amazon Quick.

Setting up the connector in Amazon Quick

Connect from the Available tab

If you want to use Default OAuth app authentication, you can connect directly from the **Available** tab without additional configuration.

1. In the Amazon Quick console, choose **Connectors**.
2. On the **Available** tab, find **Moody's GenAI Ready Data** and choose **Connect**.
3. Complete the Moody's sign-in flow and grant the requested permissions.

To configure a connector with Custom OAuth app instead, use the **Create for your team** tab as described below.

Create from the Create for your team tab

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Moody's GenAI Ready Data**.
4. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
5. For **Connection type**, choose **Public network**.
6. For **OAuth Configuration**, choose one of the following authentication methods and configure the required fields.

- a. For **Default OAuth app**:

No additional credentials are needed. Choose **Next** to continue.

- b. For **Custom OAuth app**, configure the following fields:

- **Client ID** – The client ID from your Moody's OAuth app.
- **Public OAuth client** (Optional) – Select this option if your Moody's OAuth app is configured as a public client (no client secret).
- **Client secret** – The client secret from your Moody's OAuth app.
- **Token URL** – The token endpoint. Default: `https://api.moody's.com/genai-ready-data/oauth/token`
- **Authorization URL** – The authorization endpoint. Default: `https://api.moody's.com/genai-ready-data/oauth/authorize`
- **Redirect URL** – Pre-filled with the Amazon Quick callback URL.

7. Choose **Next**.
8. A Moody's authorization window opens. Review the requested permissions and choose **Allow**.
9. On the **Review** page, review the available actions for the connector. Choose **Next**.

10. On the **Publish** page, choose who can access the connector. You can enable access for everyone in your organization or search for specific teams or groups.
11. Choose **Publish**.

Available actions

After you set up the connector, the actions exposed by Moodys GenAI Ready Data are available. To see the current set of actions for your connector, go to the connector's **Available actions** view in the Amazon Quick console.

Managing and troubleshooting

To edit, share, or delete your connector, see [the section called “Managing existing integrations”](#).

Authentication issues

- **Sign-in fails (Default OAuth app or Custom OAuth app)** – Verify that your Moody's account is active and that you can sign in to the Moody's portal directly. For Custom OAuth app, confirm that the redirect URI in your Moody's OAuth app matches the Amazon Quick callback URL.
- **Invalid client credentials (Custom OAuth app)** – Verify that the Client ID and Client secret match the values in your Moody's OAuth app.

New Relic integration

With the New Relic connector, you can access the New Relic observability platform directly in Amazon Quick through natural language. You can investigate incidents, analyze application performance, query telemetry data, and generate reports without leaving Amazon Quick.

New Relic is available as a built-in connector in Amazon Quick. To set up this integration, complete the following two steps. First, prepare your New Relic account with the required access. Then, create the integration in Amazon Quick and authenticate with your New Relic credentials. This integration uses OAuth 2.0 user authentication. For information about the authentication methods that Amazon Quick supports, see [the section called “Authentication methods”](#).

Prerequisites

Before you set up the integration, make sure that you have the following resources and access.

- An active New Relic account with the required permissions and access. For information about account requirements and access configuration, see [New Relic AI MCP](#) in the New Relic documentation.
- For information about subscription requirements, see [the section called “Set up integrations in the console”](#).

Verify your New Relic account

Before you configure Amazon Quick, verify that your New Relic account meets the following requirements.

- Your New Relic account is active and you can sign in to login.newrelic.com.
- The entities and data that you want to query are accessible to your account.

Set up the integration in Amazon Quick

After you verify your New Relic account access, create the integration in Amazon Quick.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **New Relic**.
4. In the **Create integration** dialog, enter the following fields:
 - **Name** – A descriptive name for your New Relic integration.
 - **Description** (Optional) – Notes about how you plan to use this connection.
 - **Connection type** – Choose **Public network**.
5. Choose **Create and continue**.
6. On the integration detail page, choose **Sign in** and authenticate with your New Relic account credentials. This step authorizes Amazon Quick to access New Relic on behalf of the authenticated user.
7. (Optional) Choose the users to share the integration with.
8. Choose **Done**.

The integration appears in the **Existing actions** panel with a status of **Available**.

Available actions

After you set up the integration, you can use the following actions.

New Relic available actions

Category	Action	Description
Incident analysis	Generate Alert Insights Report	Generates an alert intelligence analysis report for a specific issue. Provides insights into root cause, impact, and recommended actions.
Incident analysis	Generate User Impact Report	Analyzes affected entities and their relationships to quantify end-user impact through metrics like affected user count, degraded services, and severity indicators.
Incident analysis	Search Incident	Retrieves alert incident events with flexible filtering by issue ID, entity GUID, or policy and condition pair.
Incident analysis	List Recent Issues	Lists all recent issues (last 24 hours) for a specified account.
Performance analysis	Analyze Transactions	Identifies slow and error-prone transactions, their traces, common transaction paths, and error distributions.
Performance analysis	Analyze Golden Metrics	Analyzes key health indicators (throughput, response time, error rate, and saturation) across application and infrastructure entities.
Performance analysis	Analyze Deployment Impact	Compares metrics before and after a deployment to identify regressions or improvements.
Performance analysis	Analyze Kafka Metrics	Analyzes Kafka metrics including consumer lag, producer throughput, message latency, partition balance, and resource utilization.

Category	Action	Description
Performance analysis	Analyze Threads	Analyzes thread metric data including thread state, CPU usage, and memory consumption. Provides language-specific insights for applications.
Performance analysis	List Garbage Collection Metrics	Retrieves garbage collection and memory metrics for a given entity. Use this action to identify whether GC issues are affecting application performance.
Log analysis	Analyze Entity Logs	Analyzes application logs to identify error patterns, anomalous behavior, and recurring issues within a specified time window.
Log analysis	List Recent Logs	Retrieves recent logs for a specified account and entity GUID.
Error analysis	List Entity Error Groups	Retrieves error groups from the Errors Inbox within a time window. Groups errors by message and prioritizes by user impact.
Queries	Natural Language to NRQL Query	Converts a natural language request into a New Relic Query Language (NRQL) query, runs it against New Relic, and returns the results.
Queries	Execute NRQL Query	Runs an NRQL query directly against New Relic telemetry data.
Entities	Get Entity	Retrieves entities by GUID or searches by name pattern.
Entities	List Related Entities	Retrieves entities that are related to a given entity GUID.
Entities	Search Entity with Tag	Searches for entities by using tag key and value pairs.

Category	Action	Description
Entities	List Entity Types	Lists the complete catalog of New Relic entity types with their domain, type, and metric definitions.
Alerts	List Alert Policies	Lists alert policies for a specified account, with optional filtering by policy name.
Alerts	List Alert Conditions	Retrieves alert condition details for a specific alert policy.
Dashboards	List Dashboards	Lists all dashboards for a New Relic account.
Dashboards	Get Dashboard	Retrieves detailed information for a specific dashboard by entity GUID.
Change tracking	List Change Events	Retrieves a history of change events such as deployments, configuration changes, and other tracked activities for an entity.
Monitoring	List Synthetic Monitors	Lists synthetic monitors that check service availability and performance from multiple geographic locations.
Account	List Available New Relic Accounts	Lists all New Relic account IDs that are accessible to the authenticated user.
Utilities	Convert Time Period to Epoch Ms	Converts a natural language time period to epoch milliseconds for use with time-based queries.

Note

The actions that you can use depend on the permissions that are configured in your New Relic account and the entities that are accessible to the authenticated user.

Manage and troubleshoot

To edit, share, or delete your integration, see [the section called “Managing existing integrations”](#).

Authentication issues

- **Sign-in fails** – Verify that your New Relic account is active and that you can sign in to login.newrelic.com directly. If your organization uses single sign-on (SSO), confirm that your identity provider is configured correctly.
- **MCP server access denied** – Verify that your user has the required permissions to access the New Relic MCP server. For information about access requirements, see [New Relic AI MCP](#) in the New Relic documentation.

Notion integration

With Notion integration in Amazon Quick, you can manage pages, databases, and collaborative workspaces through MCP server connectivity. This integration provides action capabilities for knowledge management and content organization operations.

What you can do

Notion integration provides connector capabilities through MCP server connectivity:

- Create and edit pages and documents
- Manage databases and structured content
- Organize content with tags and properties
- Share pages and collaborate with team members
- Search across workspaces and content
- Manage workspace permissions and access

Available tools

The Notion MCP server typically provides these tools:

- `create_page` - Create new pages
- `update_page` - Update page content
- `get_page` - Retrieve page information

- `search_pages` - Search for pages
- `create_database` - Create new databases
- `query_database` - Query database entries
- `create_database_entry` - Add database entries
- `update_database_entry` - Update database entries

Note

The specific tools and capabilities available through this MCP server may change over time. For the most current information about supported tools, features, and implementation details, check the official Notion documentation and MCP server repository.

Setting up Notion integration

Notion integration uses MCP server connectivity to provide action capabilities. For detailed setup instructions, see [the section called “MCP integration”](#).

You'll need:

- Notion account with appropriate workspace permissions
- Notion integration token for API access

Compatibility

Notion integration supports:

- **Chat Agents:** Yes
- **Flows:** Yes
- **Knowledge Base:** No

OpenAPI Specification integration

With OpenAPI Specification integration, you can create custom integrations based on OpenAPI schemas. This allows you to connect to any API that provides an OpenAPI specification. For Amazon Quick subscription requirements, see [the section called “Set up integrations in the console”](#).

What you can do

OpenAPI Specification integration provides schema-based connectivity to help you work with custom APIs.

Connector

Perform actions based on OpenAPI specifications. Execute API calls, manage resources, and interact with custom services through dynamically generated actions based on the provided schema.

Schema-based configuration

Import OpenAPI specifications to automatically generate available actions and actions. Support for JSON schema validation and parameter mapping.

Before you begin

Before you set up OpenAPI Specification integration, make sure you have the following:

- OpenAPI specification (version 3.0.0 or higher) for your target API.
- API authentication credentials (API key, OAuth, or other).
- Amazon Quick Author or higher.
- API documentation and endpoint access.

Prepare OpenAPI specification and authentication

Before setting up the integration in Amazon Quick, prepare your OpenAPI specification and authentication credentials. Your OpenAPI specification must meet specific requirements for successful integration.

Basic requirements

Your OpenAPI specification must meet these basic requirements.

- **OpenAPI version** - Version 3.0.0 or higher is required.
- **File format** - JSON format only (application/json).
- **File size limit** - Maximum 1MB for the entire OpenAPI specification.
- **Operation limit** - Minimum 1 and maximum 100 API operations per connector.

Required schema fields

Your OpenAPI specification must include these required sections.

openapi

The OpenAPI version being used (must be "3.0.0" or higher).

info

Service information including title, description, and version.

servers

Base URL and server information for API connectivity.

paths

API endpoint definitions with HTTP methods and operations.

Supported authentication schemes

Prepare authentication credentials based on the supported authentication methods in OpenAPI specifications.

OAuth 2.0

Supports both Authorization Code Grant and Client Credentials Grant flows. Requires `authorizationUrl`, `tokenUrl`, and scopes definitions in the security scheme.

API Key

API key authentication passed in query parameters or headers.

No authentication

Default option when no security schemes are defined in the specification.

Note

Unsupported authentication schemes in the OpenAPI specification will be ignored, and the connector will default to no authentication.

Set up OpenAPI Specification integration

After preparing your OpenAPI specification and authentication credentials, follow these steps to create your OpenAPI Specification integration.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **OpenAPI Specification**.
4. On the Add Schema page, select **Import Schema** and choose a schema to import.
5. Select **Next**.
6. Fill in the integration details including name and description.
7. Review the available actions generated from your OpenAPI specification.
8. Select **Create and continue**.
9. Choose users to share the integration with.
10. Click **Next**.

Expected results

After successful setup, your OpenAPI Specification integration appears in the integrations list with dynamically generated actions based on your schema. The integration is available for use in Amazon Quick workflows, automations, and AI agents, with tasks corresponding to the endpoints defined in your OpenAPI specification.

Format and pattern requirements

Your OpenAPI specification must follow these format requirements.

- **Path patterns** - Must follow the pattern: `^/[^\/*]*(/[^\/*]*)*$` and begin with a forward slash (/).
- **Operation IDs** - Must follow the pattern: `^[a-zA-Z0-9_]{1,256}$`.
- **Descriptions** - Required for all operations and parameters, maximum 5000 characters.
- **Content type** - Only application/json is supported for request and response bodies.

Unsupported features

The following OpenAPI features are not supported and will cause validation errors.

- **Array types** - Schemas with array types (for example, {"type": "array", "items": {"string"}}) are not supported.
- **Composition keywords** - allOf, oneOf, anyOf, and not keywords are not supported.
- **Circular references** - Circular or cyclic references (\$ref inside of \$ref) are not supported.
- **Complex nested structures** - Avoid deeply nested object structures when possible.

Schema best practices

Follow these best practices when creating your OpenAPI specification.

Write effective descriptions

Use these guidelines to write clear and helpful descriptions.

- **Operation descriptions** - Describe what the operation does, when to use it, and how it behaves.
- **Parameter descriptions** - Concisely explain the parameter's purpose and impact on operation behavior.
- **Self-contained content** - Ensure descriptions provide sufficient guidance without external references.
- **Dependency clarity** - Make dependencies between operations explicit in descriptions.
- **Operation references** - Use operationId when referring to other operations, not API paths.

Parameter structure recommendations

Structure your parameters for optimal usability.

- **Flatten complex objects** - Instead of nested objects, use separate parameters (for example, start_date, start_time, end_date, end_time).
- **Use standard formats** - Use standard format values like "date-time" or "date" for ISO-8601 dates and times.
- **Clear parameter names** - Use descriptive parameter names that clearly indicate their purpose.
- **Required field marking** - Properly mark parameters as required or optional based on API behavior.

Supported extensions

We support custom OpenAPI extensions to enhance the user experience.

x-amzn-form-display-name

Use at the parameter level to override the default field name displayed in confirmation forms. Currently supported for request body parameters only.

```
"x-amzn-form-display-name": "User Name"
```

x-amzn-operation-type

Define whether an operation should be treated as "read" or "write". By default, GET methods are "read" operations and all other HTTP methods are "write" operations.

```
"x-amzn-operation-type": "read"
```

Schema validation and error handling

When you upload an OpenAPI specification, we perform comprehensive validation.

- **File size validation** - Ensures the specification doesn't exceed 1MB.
- **Operation count validation** - Verifies between 1-100 operations are defined.
- **Schema structure validation** - Checks for required fields and proper formatting.
- **Security scheme validation** - Validates supported authentication methods.
- **Content type validation** - Ensures only application/json is used.

Validation errors appear below the schema editor and must be resolved before the integration can be created. Common validation issues include:

- Missing required fields (openapi, info, servers, paths).
- Invalid path patterns or operation IDs.
- Unsupported schema features (arrays, composition keywords).
- Missing or overly long descriptions.

- Circular references in schema definitions.

Manage OpenAPI Specification integration

After you create your OpenAPI Specification integration, you can manage it through several options.

Share integration

You can share OpenAPI Specification connectors with other users in your organization.

1. From the OpenAPI integration details page, choose **Share**.
2. Configure sharing options:
 - **Share with specific users** - Enter user names or email addresses.
 - **Share with organization** - Make available to all users in your organization.
3. Set permission levels for shared access.
4. Choose **Share integration** to apply the sharing settings.

Delete integration

Follow these steps to permanently remove your OpenAPI integration.

1. From the OpenAPI integration details page, choose **Delete**.
2. Review the deletion impact, including any workflows or automations using this integration.
3. Type the integration name to confirm deletion.
4. Choose **Delete integration** to permanently remove it.

Troubleshoot OpenAPI Specification integration

Use these troubleshooting tips to resolve common OpenAPI Specification integration issues.

Schema validation errors

Ensure your OpenAPI specification follows the correct format and includes all required fields. Use an OpenAPI validator to check your schema before importing.

No tasks generated

Verify that your OpenAPI specification includes path definitions with HTTP methods and operation IDs. Actions are generated based on the operations defined in your schema.

Authentication failures

Check that the authentication scheme defined in your OpenAPI specification matches the actual API requirements and that credentials are properly configured.

Action execution failures

Review the action parameters and ensure they match the parameter definitions in your OpenAPI specification, including required fields and data types.

PagerDuty integration

Connect Amazon Quick to your PagerDuty system to manage incidents, alerts, schedules, and on-call rotations. You can perform these actions without leaving your Amazon Quick environment. For Amazon Quick subscription requirements, see [the section called "Set up integrations in the console"](#).

What you can do

With PagerDuty integration, you can perform actions within your PagerDuty systems through the PagerDuty API.

Connector

Create, update, and manage incidents, alerts, schedules, and escalation policies through the PagerDuty API.

Set up PagerDuty integration

Follow these steps to connect Amazon Quick to your PagerDuty system.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **PagerDuty**.
4. Fill in the integration details:

- **Name** - Enter a descriptive name for your PagerDuty integration.
 - **Description** (Optional) - Describe the purpose of this integration.
5. Choose your connection type:
 - **User authentication** - OAuth for individual user access to PagerDuty.
 - **Service authentication** - API key-based authentication for service-to-service access.
 6. Fill in the connection settings based on your selected authentication method (either user or service).
 7. Select **Create and continue**.
 8. Choose users to share the integration with.
 9. Click **Next**.

What happens next

After you complete the setup, your PagerDuty integration appears in the integrations list. You can use it in Amazon Quick workflows, automations, and AI agents.

Manage PagerDuty integrations

You can perform these management tasks for your PagerDuty integrations:

- **Edit integration** - Update authentication settings or PagerDuty configuration.
- **Share integration** - Make the integration available to other users in your organization.
- **Delete integration** - Remove the integration and revoke authentication.

PagerDuty Advance integration

Connect Amazon Quick to the PagerDuty Advance MCP and use AI to securely contact PagerDuty Advance. Teams can access incident context, history, and runbooks from the SRE agent, query the Insights agent for proactive ways to improve, or alter on-call coverage with Shift agent from their AI-enabled platform of choice.

What you can do

The PagerDuty Advance integration enables you to:

- Access incident context, history, and runbooks for active incident response
- Perform root cause analysis and technical troubleshooting
- Query on-call schedules and manage shift coverage
- Analyze historical trends and performance metrics (MTTR, MTTA)
- Generate insights for service reliability and team performance
- Collaborate with PagerDuty Advance agents from your AI-enabled platform of choice

Available tools

The MCP server for PagerDuty Advance typically provides these tools:

- `analytics_agent_tool` - Runs an analytics agent for historical reporting and trend analysis, including performance metrics (MTTR, MTTA), team benchmarking, service reliability statistics, and executive KPI tracking.
- `schedules_agent_tool` - Runs a schedules agent for on-call and scheduling information, including shift assignments, schedule configurations, escalation policies, user availability conflicts, and coverage management.
- `sre_agent_tool` - Runs an SRE agent for incident response and technical troubleshooting, including active incident triage, root cause analysis, diagnostics, alert explanations, change event analysis, and runbook generation.

Note

The specific tools and capabilities available through this MCP server may change over time. For the most current information about supported tools, features, and implementation details, check the official PagerDuty documentation and MCP server repository.

Setting up PagerDuty Advance integration

PagerDuty Advance integration uses MCP server connectivity to provide agent capabilities. For detailed setup instructions, see [the section called “MCP integration”](#).

You'll need:

- PagerDuty account with appropriate permissions

- PagerDuty API credentials (Client ID and Client Secret)
- Amazon Quick with MCP integration enabled

Compatibility

PagerDuty Advance integration supports:

- **Chat Agents:** Yes
- **Flows:** Yes
- **Knowledge Base:** No

QuickBooks integration

With the QuickBooks connector, you can access QuickBooks Online directly in Amazon Quick through natural language. You can manage invoices, customers, vendors, accounts, and generate financial reports without leaving Amazon Quick.

Amazon Quick supports multiple authentication methods for QuickBooks. Choose the method that best fits your organization's security requirements.

- **Default OAuth app** – Uses an AWS-managed OAuth application. No additional credentials are needed. Users authenticate directly with their Intuit account.
- **Custom OAuth app** – Uses a customer-managed application registered in the Intuit Developer portal. This option gives your organization full control over the OAuth configuration.

For more information about the authentication methods that Amazon Quick supports, see [the section called “Authentication methods”](#).

Before you begin

Make sure that you have the following before you set up the integration.

- An active QuickBooks Online account with access to the company data that you want to use.
- For **Custom OAuth app**: Access to the [Intuit Developer portal](#) on the Intuit website to create an app.
- For Amazon Quick subscription requirements, see [the section called “Set up integrations in the console”](#).

Configuring QuickBooks

If you are using **Default OAuth app** authentication, skip this section and proceed to [the section called "Setting up the connector in Amazon Quick"](#).

For Custom OAuth app authentication, complete the following steps in the Intuit Developer portal before configuring Amazon Quick.

Create an Intuit Developer app (Custom OAuth app)

Create an app in the Intuit Developer portal to obtain the client credentials that you need for Amazon Quick. For more information, see [OAuth 2.0](#) on the Intuit Developer website.

1. Sign in to the [Intuit Developer portal](#) on the Intuit website.
2. From your workspace, choose the plus (+) button to create a new app.
3. For **Type**, select the QuickBooks Online platform.
4. Enter an **App name** for your application.
5. For **Permissions**, under **QuickBooks Online and Payments**, select the authorization scopes that your integration requires. For the recommended scopes, see [the section called "Recommended scopes"](#).
6. Complete the app creation. On the confirmation page, choose **Show credentials** to view your development credentials.
7. Record the following values. You need them when you configure Amazon Quick.
 - **Client ID**
 - **Client secret**
8. In the app settings, choose the **Redirect URIs** tab. Add the Amazon Quick callback URL:
`https://{region}.quicksight.aws.amazon.com/sn/oauthcallback`
9. Choose **Save**.

Recommended scopes

When you create an Intuit Developer app, select the following authorization scopes based on the actions that you want to use.

QuickBooks recommended scopes

Scope	Description
com.intuit.quickbooks.accounting	Accesses QuickBooks Online accounting data, including invoices, customers, vendors, accounts, and financial reports.
com.intuit.quickbooks.payment	Accesses QuickBooks Online payment data, including purchases and payment transactions.
openid	Authenticates the user's identity.
email	Reads the user's email address.
profile	Reads the user's profile information.
phone	Reads the user's phone number.
address	Reads the user's address.

Note

The openid, email, profile, phone, and address scopes are used for user authentication with Custom OAuth app.

Setting up the connector in Amazon Quick

Connect from the Available tab

If you want to use Default OAuth app authentication, you can connect directly from the **Available** tab without additional configuration.

1. In the Amazon Quick console, choose **Connectors**.
2. On the **Available** tab, find **QuickBooks** and choose **Connect**.
3. Complete the QuickBooks sign-in flow and grant the requested permissions.

To configure a connector with Custom OAuth app instead, use the **Create for your team** tab as described below.

Create from the Create for your team tab

After you complete any required QuickBooks configuration, create the connector in Amazon Quick.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **QuickBooks**.

Note

If a QuickBooks connector already exists, a dialog appears with your existing connectors. To use an existing connector, choose it. To create a new one, choose **No, create new**.

4. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
5. For **Connection type**, choose **Public network**.
6. For **OAuth Configuration**, choose one of the following authentication methods and configure the required fields.
 - a. For **Default OAuth app**:

No additional credentials are needed. Choose **Next** to continue.
 - b. For **Custom OAuth app**, configure the following fields:
 - **Base URL** (Optional) – The QuickBooks API base URL. Example: `https://quickbooks.api.intuit.com`
 - **Client ID** – The client ID from your Intuit Developer app.
 - **Client secret** – The client secret from your Intuit Developer app.
 - **Token URL** – The token endpoint. Example: `https://oauth.platform.intuit.com/oauth2/v1/tokens/bearer`
 - **Authorization URL** – The authorization endpoint. Example: `https://appcenter.intuit.com/connect/oauth2`
 - **Redirect URL** – Pre-filled with the Amazon Quick callback URL.
7. Choose **Next**.

8. If you chose **Default OAuth app** or **Custom OAuth app**, an Intuit authorization window opens. Review the requested permissions and choose **Connect**.
9. On the **Review** page, review the available actions for the connector. Choose **Next**.
10. On the **Publish** page, choose who can access the connector. You can enable access for everyone in your organization or search for specific teams or groups.
11. Choose **Publish**.

Available actions

After you set up the connector, the following actions are available.

QuickBooks available actions

Category	Action	Description
Queries	Search Entities	Searches across QuickBooks entities using a query.
Accounts	Get Account Details	Retrieves details for a specific account by query.
Accounts	Get Account	Retrieves a specific account by ID.
Accounts	Create Account	Creates a new account in the chart of accounts.
Invoices	Get Invoice	Retrieves a specific invoice by ID.
Invoices	List Invoices	Lists invoices with optional filtering.
Invoices	Create Invoice	Creates a new invoice.
Customers	Get Customer	Retrieves a specific customer by ID.
Customers	Create Customer	Creates a new customer record.
Vendors	Create Vendor	Creates a new vendor record.
Purchases	Create Purchase	Creates a new purchase transaction.

Category	Action	Description
Purchases	Create Bill	Creates a new bill from a vendor.
Journal entries	Create Journal Entry	Creates a new journal entry.
Reports	Get Profit and Loss Report	Generates a profit and loss report.
Reports	Get Customer Balance Report	Generates a customer balance summary report.
Reports	Get Customer Balance Detail	Generates a detailed customer balance report.
Reports	Get Vendor Balance Report	Generates a vendor balance summary report.
Reports	Get Vendor Balance Detail	Generates a detailed vendor balance report.
Reports	Get General Ledger Report	Generates a general ledger report.
Batch operations	Batch Execute Operations	Runs multiple operations in a single batch request.
Company	Get Company Info	Retrieves information about the connected company.

Note

The actions that you can use depend on the company data accessible to the authenticated user.

Managing and troubleshooting

To edit, share, or delete your connector, see [the section called “Managing existing integrations”](#).

Authentication issues

- **Sign-in fails (Default OAuth app or Custom OAuth app)** – Verify that your Intuit account is active and that you can sign in to quickbooks.intuit.com on the Intuit website directly. For

Custom OAuth app, confirm that the redirect URI in your Intuit Developer app matches the Amazon Quick callback URL.

- **Invalid client credentials (Custom OAuth app)** – Verify that the Client ID and Client secret match the values in your Intuit Developer app. You can view your credentials from the app settings in the Intuit Developer portal.
- **Insufficient permissions** – Verify that the scopes configured for your Intuit Developer app include the permissions required for the actions that you want to use. See [the section called “Recommended scopes”](#).

REST API Connection integration

With REST API Connection integration in Amazon Quick, you can perform actions with custom REST APIs and web services. This integration supports action execution only.

What you can do

With REST API Connection integration, you can perform actions with custom REST APIs and web services through the connector.

Connector

Perform HTTP requests, retrieve data, and interact with APIs using flexible authentication options.

Note

REST API Connection integration doesn't support data access or knowledge base creation. It's designed specifically for task execution and API interactions with custom web services.

Before you begin

Before you set up REST API integration, make sure you have the following:

- REST API endpoint with appropriate access permissions.
- API authentication credentials (OAuth, API key, or other).
- API documentation for the target web service.

Prepare API endpoint and authentication

Before configuring the integration in Amazon Quick, prepare your REST API endpoint and authentication credentials. REST API Connection integration supports multiple authentication methods. Choose the method that matches your API requirements:

User authentication (OAuth)

Gather the following information from your API provider:

- **Base URL** - REST API base URL.
- **Client ID** - OAuth application client ID.
- **Client Secret** - OAuth application client secret.
- **Token URL** - OAuth token endpoint.
- **Auth URL** - OAuth authorization endpoint.
- **Redirect URL** - OAuth redirect URI.

Service authentication (Service-to-service OAuth)

Gather the following information from your API provider:

- **Authentication type** - OAuth 2.0 client credentials grant flow for service-to-service authentication.
- **Base URL** - REST API base URL.
- **Client ID** - OAuth application client identifier for service authentication.
- **Client secret** - OAuth application client secret for service authentication.
- **Token URL** - OAuth token endpoint for obtaining access tokens.

Custom headers and parameters

You can use custom headers and parameters for flexible authentication and API interaction:

- Custom authentication headers.
- API version headers.
- Content-Type specifications.
- Custom query parameters.

Set up REST API integration

After you have prepared your API endpoint and authentication credentials, follow these steps to create your REST API integration:

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **REST API Connection**.
4. Fill in the integration details:
 - **Name** - Descriptive name for your REST API integration.
 - **Description** (Optional) - Purpose of the integration.
5. Choose your connection type:
 - **User authentication** - OAuth-based authentication for individual user access.
 - **Service authentication** - API key-based authentication for service access.
6. Fill in the connection settings based on your selected authentication method (either user or service).
7. Select **Next**.
8. Review the actions that are available.
9. Select **Create and continue**.

Available task actions

After you create your REST API integration, you can review the available actions for interacting with the REST API. Common REST API actions include:

- HTTP GET requests for data retrieval.
- HTTP POST requests for data creation.
- HTTP PUT/PATCH requests for data updates.
- HTTP DELETE requests for data removal.
- Custom endpoint interactions.
- JSON and XML data processing.
- Query parameter and header management.

 Note

The specific actions available depend on the REST API endpoints and the authentication permissions configured for your integration.

API configuration options

You can configure various aspects of your REST API integration to match your specific requirements.

Endpoint configuration

Configure these endpoint settings:

- Base URL and endpoint paths.
- HTTP method specifications.
- Request and response format handling.
- Error handling and retry logic.

Data handling

Configure how your integration processes different data formats:

- JSON request and response processing.
- XML data transformation.
- Form data and multipart uploads.
- Binary data handling.

Manage REST API integrations

After you create your REST API integration, you can manage it using these options:

- **Edit integration** - Update authentication settings, base URL, or API configuration.
- **Share integration** - Make the integration available to other users in your organization.
- **Monitor usage** - View integration activity and API call metrics.

- **Review actions** - See the complete list of available REST API actions.
- **Test endpoints** - Validate API connectivity and authentication.
- **Delete integration** - Remove the integration and revoke associated authentication.

Important

REST API integrations depend on the availability and configuration of the target web service. Changes to the API or authentication requirements may affect integration functionality.

Salesforce integration

With the Salesforce connector in Amazon Quick, you can perform actions within Salesforce organizations, including managing records, querying data, and interacting with Salesforce APIs. For Amazon Quick subscription requirements, see [the section called "Set up integrations in the console"](#).

Amazon Quick supports the following authentication options for Salesforce.

Salesforce authentication flows

Flow	Description
Managed OAuth (Default OAuth app)	Uses an AWS managed OAuth application with no additional credentials or External Client App configuration required. Requires the Amazon Quick Salesforce package and an activated Model Context Protocol (MCP) server in Salesforce.
User authentication (three-legged OAuth, 3LO)	Authorization code flow. Each user authenticates through a browser. Best for multi-user environments where actions run on behalf of the signed-in user.
Service authentication (two-legged OAuth, 2LO)	Client credentials flow. Machine-to-machine authentication with no user interaction. All actions run as a designated "Run As" user that you configure in Salesforce.

Note

As of the Salesforce Spring '26 release (February 2026), new Connected App creation is disabled by default across all Salesforce organizations. This guide uses Salesforce's External Client Apps (ECAs), which are fully compatible with the Amazon Quick Salesforce connector.

Prerequisites

Before you set up the Salesforce integration, make sure you have the following:

- A Salesforce organization with System Administrator access.
- Amazon Quick Author role or higher.
- Your Amazon Quick instance URL (for example, `https://us-east-1.quicksight.aws.amazon.com`).
- For Managed OAuth: The [Amazon Quick Salesforce package](#) installed from Salesforce AppExchange.
- The headless-360 MCP server activated in your Salesforce organization. This is required for all authentication flows. For activation steps, see [the section called "Activate the MCP server"](#).

Activate the MCP server

Before you configure any authentication flow, activate the headless-360 MCP server in your Salesforce organization. This step is required for Managed OAuth, user authentication (3LO), and service authentication (2LO).

1. Sign in to your Salesforce organization.
2. From **Setup**, in the **Quick Find** box, enter MCP Servers, and then select **MCP Servers**.
3. Find headless-360 in the list of servers.
4. Choose **Activate**.

Set up Managed OAuth

If you are using user authentication (three-legged OAuth, 3LO) or service authentication (two-legged OAuth, 2LO), skip this section and proceed to [the section called "Step 1: Create an External Client App in Salesforce"](#).

Managed OAuth is the simplest setup option. It uses an AWS managed OAuth application, so you do not need to create an External Client App or configure OAuth credentials manually.

Install the Amazon Quick Salesforce package

1. Sign in to your Salesforce organization as a System Administrator.
2. Go to the Amazon Quick Salesforce package listing on Salesforce AppExchange (linked in the prerequisites).
3. Choose **Get It Now** and follow the installation prompts to install the package in your Salesforce organization.

After you install the package, proceed to [the section called "Step 4: Configure Salesforce connector in Amazon Quick"](#) to configure the connector in Amazon Quick. In Step 4, choose **Default OAuth app** as the **Auth Type** instead of **Custom OAuth app**.

Step 1: Create an External Client App in Salesforce

Create an External Client App (ECA) in Salesforce to enable OAuth authentication with Amazon Quick.

Navigate to External Client App Manager

1. Sign in to your Salesforce organization and choose **Setup** (gear icon in the top right).
2. In the navigation pane, expand **Platform Tools > Apps > External Client Apps > External Client App Manager**.
3. Choose **New External Client App**.

Fill in basic information

Enter the following basic information for your External Client App:

External Client App basic information

Field	Value
External Client App Name	A descriptive name (for example, "Amazon Quick Integration")
API Name	Auto-generated from the app name

Field	Value
Contact Email	Your admin email address
Distribution State	Local (default)

Step 2: Configure OAuth settings

Enable OAuth

In the **API (Enable OAuth Settings)** section, select **Enable OAuth** to expand the OAuth configuration panel.

Set callback URL

Enter the Amazon Quick OAuth callback URL in the **Callback URL** field:

<your-quick-instance-url>/sn/oauthcallback

For example: `https://us-east-1.quicksight.aws.amazon.com/sn/oauthcallback`

Add OAuth scopes

Move the following scopes from **Available OAuth Scopes** to **Selected OAuth Scopes**:

- Access the identity URL service (id, profile, email, address, phone)
- Manage user data via APIs (api)
- Manage user data via Web browsers (web)
- Full access (full)
- Access Visualforce applications (visualforce)
- Perform requests at any time (refresh_token, offline_access)
- Access unique user identifiers (openid)
- Access custom permissions (custom_permissions)
- Access Connect REST API resources (chatter_api)
- Access Analytics REST API resources (wave_api)
- Access Analytics REST API Charts Geodata resources (eclair_api)
- Manage Pardot services (pardot_api)

Enable OAuth flows

Select the following flow options:

For both user authentication (3LO) and service authentication (2LO):

- **Enable Client Credentials Flow**
- **Enable Authorization Code and Credentials Flow**
- **Enable Token Exchange Flow**

For user authentication (3LO) only:

- **Require user credentials in the POST body for Authorization Code and Credentials Flow.** This setting sends user credentials in the POST body during authorization code exchange. It applies only to user authentication and has no effect on service authentication.

Note

If you plan to use only service authentication (2LO), you do not need to select **Require user credentials in the POST body for Authorization Code and Credentials Flow**.

Enable security settings

Select the following security options:

For user authentication (3LO):

- **Require Proof Key for Code Exchange (PKCE).** Select this option.
- **Require Secret for Web Server Flow** (selected by default)
- **Require Secret for Refresh Token Flow** (selected by default)

For service authentication (2LO):

- **Require Proof Key for Code Exchange (PKCE).** Clear this option. PKCE is designed for browser-based authorization code flows and is incompatible with client credentials.
- **Require Secret for Web Server Flow** (selected by default)

- **Require Secret for Refresh Token Flow** (selected by default)

Important

If you need to support both user authentication (3LO) and service authentication (2LO) on the same External Client App, clear the **Require Proof Key for Code Exchange (PKCE)** option. PKCE cannot be enabled alongside client credentials on the same app. Create separate External Client Apps if you require PKCE for user authentication.

Choose **Create** to save the External Client App.

Step 3: Get consumer credentials

1. After creation, you are on the ECA detail page.
2. Navigate to the **Settings** tab or choose **Manage Consumer Details**.
3. You might need to verify your identity (email verification code).
4. Copy the **Consumer Key** (Client ID) and **Consumer Secret** (Client Secret).

Important

Save these credentials securely. You need them when you configure the connector in Amazon Quick.

Step 3b: Configure service authentication (2LO)

If you are using user authentication (3LO) only, skip this section and proceed to [the section called "Step 4: Configure Salesforce connector in Amazon Quick"](#).

Service authentication requires additional configuration in the External Client App's Policies tab. These steps enable the client credentials flow operationally and designate the user identity under which all actions run.

Enable client credentials and set the Run As user

1. In Salesforce Setup, navigate to your External Client App and choose the **Policies** tab.

2. Choose **Edit**.
3. Under **OAuth Policies**, select **Enable Client Credentials Flow**.
4. In the **Run As** field that appears, choose the user account under which all service authentication actions run. This is typically an administrator or dedicated service account.
5. Choose **Save**.

Important

The **Enable Client Credentials Flow** option exists in two places: the **Settings** tab (enables the capability) and the **Policies** tab (enables it operationally and sets the Run As user). You must enable it in both places. Salesforce tokens are always user-scoped. The Run As user determines the identity and permissions for all actions that run through service authentication.

Verify the token endpoint

Before you configure Amazon Quick, verify that the client credentials flow works by requesting a token from the Salesforce token endpoint. Run the following command from a terminal:

```
curl -X POST https://your-domain.my.salesforce.com/services/oauth2/token \  
-d "grant_type=client_credentials" \  
-d "client_id=CONSUMER_KEY" \  
-d "client_secret=CONSUMER_SECRET"
```

A successful response returns a JSON object that contains `access_token`, `instance_url`, and `token_type` fields.

If the response contains the error `no_client_credentials_user_enabled`, the Run As user is not configured. Return to [the section called “Enable client credentials and set the Run As user”](#) and verify that you enabled client credentials and assigned a Run As user on the **Policies** tab.

Step 4: Configure Salesforce connector in Amazon Quick

Navigate to Connectors

1. Open Amazon Quick and choose **Connectors**.
2. Choose the **Create for your team** tab.

3. Find and choose **Salesforce**.
4. If prompted that a connector already exists, choose **No, create new**.

Managed OAuth connection details

If you are using Managed OAuth, enter the following connection details.

Name

A descriptive name (for example, "Salesforce Managed").

Network

Public network.

Auth Type

Default OAuth app.

No other fields are required. You do not need to enter a Client ID, Client Secret, Token URL, or Authorization URL.

Choose **Next**. Complete the Salesforce sign-in flow and grant the requested permissions.

User authentication (3LO) connection details

If you are using user authentication, enter the following connection details:

Salesforce connector: user authentication (3LO)

Field	Value
Name	A descriptive name (for example, "Salesforce ECA")
Network	Public network
Auth Type	Custom OAuth app
Base URL	https://<your-domain>.my.salesforce.com/services/data/v60.0
Client ID	Consumer Key from Step 3

Field	Value
Client Secret	Consumer Secret from Step 3
Token URL	https://<your-domain>.my.salesforce.com/services/oauth2/token
Authorization URL	https://<your-domain>.my.salesforce.com/services/oauth2/authorize
Redirect URL	Pre-filled (do not change)

Choose **Next** to proceed.

Service authentication (2LO) connection details

If you are using service authentication, enter the following connection details:

Salesforce connector: service authentication (2LO)

Field	Value
Name	A descriptive name (for example, "Salesforce Service Auth")
Network	Public network
Auth Type	Custom OAuth (Service Auth)
Base URL	https://<your-domain>.my.salesforce.com/services/data/v60.0
Client ID	Consumer Key from Step 3
Client Secret	Consumer Secret from Step 3
Token URL	https://<your-domain>.my.salesforce.com/services/oauth2/token
Authorization URL	Leave blank. Do not enter a value for service authentication.
Scopes	api (use space-separated short-form scope names only)

⚠ Important

Do not populate **Authorization URL** for service authentication. Amazon Quick rejects the form if an authorization URL is entered for a client credentials flow.

Choose **Next** to proceed.

Step 5: Verify and publish

1. On the **Review** page, verify the available Salesforce actions (up to 42 actions).
2. Choose **Next** to proceed to user sharing.
3. Select users or groups who should have access to this connector.
4. Choose **Publish** to publish the connector.

After you publish the connector, you can use Salesforce actions in Amazon Quick chat, flows, and automations.

Available actions

After you set up the connector, the Salesforce Headless 360 MCP server provides four tools that Amazon Quick uses to interact with Salesforce.

Discover

Finds available Salesforce operations by running a semantic search across the operation index. Returns a ranked set of candidate operations that match your request.

Describe

Returns the technical contract for an operation, including APIs, parameters, dependencies, and ordered steps.

Dispatch

Runs the chosen operation. Routes the request to the correct endpoint and enforces access controls before the operation runs.

Dispatch (Read-Only)

Runs read-only operations. This tool never changes data or configuration. Use it when you only need to retrieve information.

Through these tools, you can perform tasks such as the following.

- Query, create, and update Salesforce records.
- Manage users, including creating, deactivating, freezing, and assigning permission sets.
- Read, write, and deploy Apex triggers.
- Build event-driven integrations with platform events, Change Data Capture, and event relays.
- Create named credentials, including authentication mechanisms and endpoints.
- Manage Commerce Cloud orders.

 Note

The library of available operations grows with each Salesforce release. Your connector discovers the current set of operations at runtime through the Discover tool.

 Note

Salesforce integration supports action execution only. Data access and knowledge base creation are not available for Salesforce systems.

Troubleshooting

To edit, share, or delete your connector, see [the section called “Managing existing integrations”](#).

- **URL no longer exists error.** Verify that you are using the correct Salesforce domain in the Token URL and Authorization URL. Do not use legacy endpoints.
- **OAuth validation fails (user authentication).** Verify that PKCE is enabled on the ECA and that the Callback URL exactly matches your Amazon Quick instance URL with `/sn/oauthcallback` appended.
- **Missing scopes error.** Go back to the ECA configuration in Salesforce and ensure all required OAuth scopes are in the **Selected** list, not still in **Available**.
- **Connected App option is unavailable.** This is expected after Salesforce Spring '26. Use an External Client App instead. ECAs are the supported replacement.

Service authentication (2LO) issues

- **no client credentials user enabled error.** The client credentials flow is not enabled on the **Policies** tab, or no Run As user is assigned. Navigate to the External Client App, choose the **Policies** tab, choose **Edit**, select **Enable Client Credentials Flow**, assign a Run As user, and save. For more information, see [the section called “Enable client credentials and set the Run As user”](#).
- **One or more parameters are invalid error in Amazon Quick.** This error typically indicates one of the following issues:
 - The **Authorization URL** field contains a value. Leave this field blank for service authentication.
 - The **Scopes** field uses commas instead of spaces. Use space-separated short-form scope names only.
 - The **Client ID** or **Client Secret** contains leading or trailing whitespace.
 - The **Token URL** contains a trailing slash.
- **request not supported on this domain error.** Use your Salesforce runtime domain (*your-domain*.my.salesforce.com), not the setup domain (*.salesforce-setup.com).
- **PKCE errors with service authentication.** PKCE is incompatible with the client credentials flow. Clear the **Require Proof Key for Code Exchange (PKCE)** option in the External Client App's security settings. For more information, see [the section called “Enable security settings”](#).

SAP workload integrations

With SAP workload integrations, you can perform actions within various SAP systems. Manage business data, inventory, materials, and business processes. For Amazon Quick subscription requirements, see [the section called “Set up integrations in the console”](#).

What you can do

SAP workload integrations provide enterprise-level connectivity to help you work with your SAP systems.

Connector

Perform actions within SAP systems. Create, update, and manage business data, inventory records, material information, and other enterprise operations through SAP APIs.

Multiple SAP modules

Support for five different integration types: Bill of Materials, Business Partner, Material Stock, Physical Inventory Documents, and Product Master.

Before you begin

Before you set up SAP workload integrations, make sure you have the following:

- SAP system with appropriate modules installed and configured.
- SAP user account with necessary permissions and authorizations.
- Amazon Quick Author or higher.
- Network connectivity between Amazon Quick and your SAP system.

Prepare SAP system configuration and authentication

Before setting up the integration in Amazon Quick, prepare your SAP system configuration and user authentication. SAP workload integrations support multiple authentication methods and require proper system setup.

Authentication methods

SAP workload integrations support two authentication methods:

OAuth 2.0 (Recommended)

Secure authentication method for automated workflows. Requires OAuth configuration in your SAP system.

Required parameters:

- **Client ID** - SAP OAuth Client ID
- **Client Secret** - SAP OAuth Client Secret
- **Token URL** - OAuth token endpoint (e.g., `https://hostname:port/sap/bc/sec/oauth2/token?sap-client=100`)
- **Domain URL** - SAP system API endpoint (e.g., `https://hostname:port/sap/opu/odata/sap/API_BUSINESS_PARTNER`)

Basic Authentication

Username and password authentication for direct SAP system access.

Required parameters:

- **Username** - SAP system username
- **Password** - SAP system password
- **Domain URL** - SAP system API endpoint

SAP system configuration requirements

Before using SAP workload integrations, ensure your SAP system is properly configured:

OAuth 2.0 setup

For OAuth 2.0 authentication:

- Configure the OAuth authorization server with appropriate scopes
- Verify OAuth is enabled for the service using transaction code /IWFND/MAINT_SERVICE
- Refer to SAP documentation for detailed OAuth 2.0 configuration: [OAuth 2.0 Configuration Guide](#)

SAP API activation

Ensure the required SAP API services are active:

- Activate the specific API service for your chosen SAP connector
- Verify API service status in your SAP system
- Refer to SAP documentation for API activation: [SAP API Service Activation Guide](#)

Available SAP workload integration types

Choose the SAP integration type that matches your business needs and ensure the corresponding SAP module is available in your system.

SAP Bill of Materials

Manage bill of materials data, including component lists, quantities, and manufacturing specifications.

Required scope: ZAPI_BILL_OF_MATERIAL_SRV_0002

SAP Business Partner

Handle business partner information, including customer and vendor data, contact details, and relationship management.

Required scope: ZAPI_BUSINESS_PARTNER_0001

SAP Material Stock

Access and manage material stock levels, inventory movements, and warehouse information.

Required scope: ZAPI_MATERIAL_STOCK_SRV_0001

SAP Physical Inventory Documents

Create and manage physical inventory documents, stock counts, and inventory reconciliation processes.

Required scope: ZAPI_MATERIAL_STOCK_SRV_0001

SAP Product Master

Maintain product master data, including material specifications, classifications, and product hierarchies.

Required scope: ZAPI_PRODUCT_SRV_0001

SAP workload authentication setup

Prepare SAP user authentication credentials and ensure proper system access permissions.

- **SAP system URL** - Obtain the base URL or server address for your SAP system.
- **User credentials** - Create or identify a SAP user account with appropriate permissions.
- **System permissions** - Ensure the user account has the necessary SAP authorizations and transaction codes for the specific SAP modules you plan to integrate.
- **Network access** - Verify that your SAP system is accessible from external connections and that firewall rules allow the integration.

Set up SAP integrations

After preparing your SAP system configuration and authentication credentials, the setup process is similar for all SAP integration types. Choose between OAuth 2.0 or Basic Authentication based on your security requirements.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Select one of the available SAP connectors:
 - **SAP Bill of Materials**
 - **SAP Business Partner**
 - **SAP Material Stock**
 - **SAP Physical Inventory Documents**
 - **SAP Product Master**
4. Click **Add** (plus "+" button).
5. Fill in the name and description for your SAP integration.
6. Choose the connection type for your integration.
7. Configure authentication using one of the supported methods:

- a. **OAuth 2.0 configuration**

For OAuth 2.0 authentication, provide:

- **Client ID** - Your SAP OAuth Client ID
- **Client Secret** - Your SAP OAuth Client Secret
- **Token URL** - OAuth token endpoint URL
- **Domain URL** - SAP system API endpoint URL

- b. **Basic Authentication configuration**

For Basic Authentication, provide:

- **Username** - Your SAP system username
- **Password** - Your SAP system password
- **Domain URL** - SAP system API endpoint URL

8. Select **Create and continue**.

9. Choose users to share the integration with.
10. Click **Next**.

Expected results

After successful setup, your SAP workload integration appears in the integrations list and is available for use in Amazon Quick workflows, automations, and AI agents. You can perform SAP-specific actions directly from Amazon Quick using the configured authentication credentials.

Available operations by connector type

Each SAP workload connector provides specific operations tailored to its business domain. Review the available operations for your chosen connector type.

SAP Bill of Materials operations

Available operations for managing bill of materials data:

- **Get Material BOM Item** - Retrieves bill of material details for specified materials

Operation ID: getMaterialBOMItem

Endpoint: GET /MaterialBOMItem

SAP Business Partner operations

Available operations for managing business partner data:

- **Get Business Partner** - Retrieves business partner general data

Operation ID: getBusinessPartner

- **Get Business Partner Addresses** - Retrieves business partner address data

Operation ID: getBusinessPartnerAddress

- **Get Business Partner Roles** - Retrieves business partner role data

Operation ID: getBusinessPartnerRole

- **Get Business Partner by ID** - Retrieves business partner data by business partner number

Operation ID: getBusinessPartnerByID

Required parameter: BusinessPartner (string, max 10 characters)

- **Get Business Partner Role by ID** - Retrieves business partner role data using key fields

Operation ID: getBusinessPartnerRoleByID

Required parameters: BusinessPartner (string, max 10 characters), BusinessPartnerRole (string, max 6 characters)

SAP Material Stock operations

Available operations for managing material stock data:

- **Get Material Stock In Account** - Retrieves material stock information posted in the account model

Operation ID: getMaterialStockInAccount

SAP Physical Inventory Documents operations

Available operations for managing physical inventory documents:

- **Get PhysInventory Doc Item** - Reads information on physical inventory items

Operation ID: getPhysInventoryDocItem

SAP Product Master operations

Available operations for managing product master data:

- **Get Product Master Item** - Returns product master records

Operation ID: getProductMaster

- **Get Plant Data By Material** - Returns plant data of product master record

Operation ID: getPlantDataByMaterial

Required parameter: Product (string, max 40 characters)

- **Get Supply Planning Data By Material** - Returns supply planning data by product number and plant

Operation ID: getSupplyPlanningDataByMaterial

Required parameters: Product (string, max 40 characters), Plant (string, max 4 characters)

Query parameters

SAP connectors support standard query parameters to filter, sort, and format API responses. Use these parameters to optimize data retrieval and processing.

Supported Query Parameters

#	Parameter	Description	Type
1	\$top	Limits the number of returned items	integer
2	\$skip	Skips the specified number of items	integer
3	\$filter	Filters results based on specified criteria	string
4	\$orderby	Orders results by specified fields	array
5	\$select	Selects specific properties to return	array
6	\$expand	Expands related entities	array
7	\$inlinecount	Includes count of items in response	string

Manage SAP workload integrations

After you create your SAP workload integration, you can manage it through several options.

Edit integration settings

Follow these steps to modify your SAP workload integration settings.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose your SAP workload connector from the connector list.
3. Select your integration from the list and choose **Edit**.
4. Modify integration settings:

- Update authentication credentials (username and password).
 - Change SAP system URL or connection settings.
 - Modify integration name or description.
5. Choose **Save changes** to apply your modifications.

Share integration

You can share SAP workload connectors with other users in your organization.

1. From the SAP integration details page, choose **Share**.
2. Configure sharing options:
 - **Share with specific users** - Enter user names or email addresses.
 - **Share with organization** - Make available to all users in your organization.
3. Set permission levels for shared access.
4. Choose **Share integration** to apply the sharing settings.

Delete integration

Follow these steps to permanently remove your SAP integration.

1. From the SAP workload integration details page, choose **Delete**.
2. Review the deletion impact, including any workflows or automations using this integration.
3. Type the integration name to confirm deletion.
4. Choose **Delete integration** to permanently remove it.

Troubleshoot SAP workload integrations

Use these troubleshooting tips to resolve common SAP workload integration issues.

Authentication issues

OAuth 2.0 authentication failures

Symptoms: Token generation fails, invalid client credentials, or OAuth scope errors.

Resolution:

- Verify OAuth client ID and client secret are correct
- Check that OAuth is properly configured in SAP using transaction /IWFND/MAINT_SERVICE
- Ensure the required scopes are properly configured for your SAP workload connector type
- Verify the token URL format matches your SAP system configuration

Basic authentication failures

Symptoms: Login failures, invalid credentials, or access denied errors.

Resolution:

- Verify SAP username and password are correct
- Check that the user account has necessary SAP authorizations
- Ensure the user account is not locked or expired
- Verify the domain URL is accessible and correctly formatted

SAP system configuration issues

API service not activated

Symptoms: Service unavailable errors, API endpoint not found, or HTTP 404 responses.

Resolution:

- Verify the required SAP API service is activated in your system
- Check API service status using SAP transaction codes
- Ensure the API service corresponds to your chosen SAP connector type
- Contact your SAP administrator to activate missing API services

Connection timeouts

Symptoms: Request timeouts, network connectivity errors, or slow response times.

Resolution:

- Check that your SAP system URL is correct and accessible
- Verify network connectivity allows connections to SAP system
- Ensure firewall rules permit the integration traffic

- Check SAP system performance and availability

Permission and authorization errors

Insufficient SAP authorizations

Symptoms: Access denied errors, missing authorization messages, or restricted operation failures.

Resolution:

- Ensure the authenticated user has required SAP authorizations for the specific module
- Verify the user has access to necessary transaction codes
- Check that the user account has appropriate role assignments
- Contact your SAP administrator to grant missing permissions

Scope permission errors

Symptoms: OAuth scope errors, insufficient permissions for API operations, or restricted access messages.

Resolution:

- Verify the OAuth configuration includes the required scope for your connector type
- Check that the scope permissions are properly granted in SAP system
- Ensure the OAuth client has been granted the necessary API access rights

Data format and parameter errors

Invalid parameter formats

Symptoms: Data validation errors, invalid field length messages, or parameter format exceptions.

Resolution:

- Review action parameters and ensure they match expected SAP data formats
- Check field lengths match SAP system requirements (e.g., BusinessPartner max 10 characters)
- Verify data types are correct for the specific SAP module

- Ensure all required fields are provided for the operation

Query parameter errors

Symptoms: Query syntax errors, unsupported parameter messages, or malformed request errors.

Resolution:

- Verify parameters use correct syntax (e.g., `$filter`, `$top`, `$skip`)
- Check that the parameter values are properly formatted
- Ensure the SAP API supports the specific parameters being used
- Refer to SAP API documentation for supported query options

SAP system availability issues

SAP system unavailability

Symptoms: Connection refused errors, system not responding, or service unavailable messages.

Resolution:

- Check SAP system status and availability with your SAP administrator
- Verify if there are scheduled maintenance windows affecting the system
- Check for any SAP system alerts or known issues
- Retry the operation after confirming system availability

ServiceNow integration

Use the ServiceNow integration to perform actions within your ServiceNow instances, including managing incidents, problems, change requests, knowledge base articles, and attachments. This integration uses the ServiceNow REST API. For more information, see [REST API](#) in the ServiceNow documentation.

Setting up this integration involves two steps. First, you configure an OAuth application in your ServiceNow instance. Then, you create the integration in Amazon Quick and connect it to your ServiceNow app. For information about the authentication methods that Amazon Quick supports, see [the section called "Authentication methods"](#).

Before you begin

Before you set up the integration, verify that you have the following.

- A ServiceNow instance. This integration is validated against the Xanadu release.
- A ServiceNow user account with permissions to create OAuth applications (admin role required).
- For service authentication (client credentials), your instance must be running the Washington DC release or later.
- For subscription requirements, see [the section called "Set up integrations in the console"](#).

Configure ServiceNow OAuth

Before you configure Amazon Quick, create an OAuth application endpoint in your ServiceNow instance. Complete all of the following steps in ServiceNow before moving to the Amazon Quick console.

For more information, see [Create an endpoint for clients to access the instance](#) in the ServiceNow documentation.

Register the OAuth application

To register the OAuth application, complete the following steps.

1. In your ServiceNow instance, navigate to **All > System OAuth > Application Registry** and choose **New**.
2. Choose **Create an OAuth API endpoint for external clients**.
3. Complete the form:
 - **Name** – A descriptive name for the OAuth application.
 - **Redirect URL** – `https://{region}.quicksight.aws.amazon.com/sn/oauthcallback`

Replace `{region}` with your AWS Region (for example, `us-east-1`).
4. Choose **Submit**.
5. Reopen the application registry entry and choose the lock icon next to **Client Secret** to reveal the value.
6. Copy the **Client ID** and **Client Secret** values. You need these when you configure the integration in Amazon Quick.

Additional steps for service authentication (client credentials)

If you plan to use service authentication, complete these additional steps after registering the OAuth application. The client credentials grant type was introduced in the ServiceNow Washington DC release. For more information, see [Up Your OAuth2.0 Game: Inbound Client Credentials with Washington DC](#) in the ServiceNow Community.

1. Enable the client credentials grant type. Navigate to `sys_properties.list` using the filter navigator and create a new system property with the following values:
 - **Name** – `glide.oauth.inbound.client.credential.grant_type.enabled`
 - **Type** – `true | false`
 - **Value** – `true`
2. Verify that the following plugins are installed (navigate to **Admin > Application Manager**):
 - OAuth 2.0 (`com.snc.platform.security.oauth`)
 - REST API Provider (`com.glide.rest`)
 - Authentication scope (`com.glide.auth.scope`)
 - REST API Auth Scope Plugin (`com.glide.rest.auth.scope`)
3. Return to your OAuth application in **System OAuth > Application Registry**. Add the **OAuth Application User** field to the form if it isn't visible (use **Configure > Form Builder** to add it).
4. Set the **OAuth Application User** to an appropriately permissioned user, such as a user with the System Administrator role.

Important

With service authentication, all actions execute as the configured OAuth application user. Any Amazon Quick user with access to this integration can perform actions using that account's permissions. Configure the account permissions to match your organization's security requirements.

Set up the integration in Amazon Quick

After you complete the ServiceNow OAuth configuration, create the integration in Amazon Quick.

1. In the Amazon Quick console, choose **Connectors**.

2. Choose the **Create for your team** tab.
3. Find and choose **ServiceNow**.
4. Enter the integration details:
 - **Name** – Descriptive name for your ServiceNow integration.
 - **Description** (Optional) – Purpose of the integration.
5. Choose your connection type and fill in the connection settings:
 - a. For **User authentication (OAuth)**, configure the following fields:
 - **Base URL** – `https://{your-instance}.service-now.com`
 - **Client ID** – Client ID from your ServiceNow OAuth application.
 - **Client Secret** – Client secret from your ServiceNow OAuth application.
 - **Token URL** – `https://{your-instance}.service-now.com/oauth_token.do`
 - **Auth URL** – `https://{your-instance}.service-now.com/oauth_auth.do`
 - **Redirect URL** – `https://{region}.quicksight.aws.amazon.com/sn/oauthcallback`
 - b. For **Service authentication (client credentials)**, configure the following fields:
 - **Authentication type** – Service-to-service OAuth
 - **Base URL** – `https://{your-instance}.service-now.com`
 - **Client ID** – Client ID from your ServiceNow OAuth application.
 - **Client Secret** – Client secret from your ServiceNow OAuth application.
 - **Token URL** – `https://{your-instance}.service-now.com/oauth_token.do`
6. Choose **Create and continue**.
7. Choose users to share the integration with.
8. Choose **Next**.

For user authentication, navigate to **Connectors** > your ServiceNow connector name, and choose **Sign in** to complete the OAuth authorization flow.

Available actions

After you set up the integration, the following actions are available.

ServiceNow available actions

Category	Action	Description
Incidents	List Incidents	Retrieve existing incidents.
Incidents	Create Incident	Create an incident record to document a deviation from an expected standard of operation.
Incidents	View Incident	Retrieve the details of a specific incident.
Incidents	Update Incident	Update an incident record.
Incidents	Delete Incident	Delete an incident.
Problems	List Problems	Retrieve existing problems.
Problems	Create Problem	Create a new problem record.
Problems	View Problem	Retrieve the details of a specific problem record.
Problems	Update Problem	Update a problem record.
Problems	Delete Problem	Delete a problem.
Change requests	List Change Requests	Retrieve all change requests.
Change requests	Create Change Request	Create a change request to implement a controlled process for modifying approved and supported configuration items (CIs).
Change requests	View Change Request	Retrieve detailed information about a specific change request.
Change requests	Update Change Request	Modify a change request.
Change requests	Delete Change Request	Delete a change request.

Category	Action	Description
Knowledge base articles	Create Knowledge Base Article	Create a knowledge base article. Requires the Knowledge API (sn_km_api) plugin.
Knowledge base articles	Update Knowledge Base Article	Modify a knowledge base article.
Knowledge base articles	Delete Knowledge Base Article	Delete a knowledge base article.
Attachments	Retrieve Attachments Metadata	Retrieve metadata for attachment files.
Attachments	Retrieve Attachment Metadata	Retrieve metadata for a specific attachment file.
Attachments	Retrieve Attachment Content	Retrieve the binary file attachment content.
Attachments	Upload Binary Attachment	Upload a binary file as an attachment to a specified record.
Attachments	Upload Multipart Form Attachment	Upload a multipart file attachment.
Attachments	Delete Attachment	Delete an attachment.
Users	List Users	List all user records.
System	List Choices	Retrieve choice list values from the sys_choice table.

 Note

The specific actions available depend on the permissions configured in your ServiceNow instance and the authentication method used.

Limitations

This integration interacts with ServiceNow through the REST API, which does not enforce UI policies, UI actions, or client scripts. These rules only apply in the ServiceNow browser interface. Server-side business rules, ACLs, and data policies are enforced. For more information, see [REST API](#) in the ServiceNow documentation.

Manage and troubleshoot

To edit, share, or delete your integration, see [the section called “Managing existing integrations”](#).

Authentication issues

- **OAuth authorization fails** – Verify that the Client ID and Client Secret match the values in your ServiceNow Application Registry. Confirm the Redirect URL in ServiceNow matches the URL in your Amazon Quick configuration exactly.
- **Service authentication fails** – Verify that the `glide.oauth.inbound.client.credential.grant_type.enabled` system property is set to `true`. Confirm the **OAuth Application User** field is populated on the application registry record.

Common error messages

- **Actions return permission errors** – Verify that the ServiceNow user or OAuth application user has the required roles to access the target tables (for example, `itil` role for incident management).
- **Connection timeout or unreachable instance** – Verify the Base URL uses the correct ServiceNow instance name. Confirm the ServiceNow instance is accessible and not in maintenance mode.

Shopify integration

With the Shopify connector, you can manage products, orders, customers, and store operations directly in Amazon Quick through natural language.

Shopify uses Custom OAuth app authentication. For more information about the authentication methods that Amazon Quick supports, see [the section called “Authentication methods”](#).

Before you begin

Make sure that you have the following before you set up the integration.

- An active Shopify store with admin access.
- A custom app registered in your Shopify admin or in the Shopify Partners portal, with the Admin API access scopes that you need.
- For Amazon Quick subscription requirements, see [the section called “Set up integrations in the console”](#).

Configuring Shopify

For Custom OAuth app authentication, create a custom app in your Shopify store admin or in the [Shopify Partners portal](#) on the Shopify website. Configure the Admin API access scopes that match the operations you want to use, and add the Amazon Quick callback URL `https://{region}.quicksight.aws.amazon.com/sn/oauthcallback` as an allowed redirection URL. Replace `{region}` with your AWS Region (for example, `us-east-1`). For step-by-step instructions, see [Authentication and authorization](#) in the Shopify developer documentation. Record the Client ID (API key) and Client Secret (API secret key) — you need them when you configure Amazon Quick.

Setting up the connector in Amazon Quick

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Shopify**.
4. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
5. For **Connection type**, choose **Public network**.
6. For **OAuth Configuration**, choose **Custom OAuth app** and configure the following fields:
 - **Base URL** – The Shopify MCP base URL for your store.
 - **Client ID** – The Client ID (API key) from your Shopify custom app.
 - **Public OAuth client** (Optional) – Select this option if your Shopify custom app is configured as a public client (no client secret).
 - **Client secret** – The Client Secret (API secret key) from your Shopify custom app.

- **Token URL** – The Shopify OAuth token endpoint for your store.
 - **Authorization URL** – The Shopify OAuth authorization endpoint for your store.
 - **Redirect URL** – Pre-filled with the Amazon Quick callback URL.
7. Choose **Next**.
 8. A Shopify authorization window opens. Review the requested permissions and choose **Install app** or the equivalent button.
 9. On the **Review** page, review the available actions for the connector. Choose **Next**.
 10. On the **Publish** page, choose who can access the connector. You can enable access for everyone in your organization or search for specific teams or groups.
 11. Choose **Publish**.

Available actions

After you set up the connector, the actions exposed by Shopify are available. To see the current set of actions for your connector, go to the connector's **Available actions** view in the Amazon Quick console.

Managing and troubleshooting

To edit, share, or delete your connector, see [the section called “Managing existing integrations”](#).

Authentication issues

- **Sign-in fails** – Verify that you can sign in to your Shopify store admin directly. Confirm that the allowed redirection URL in your Shopify custom app matches the Amazon Quick callback URL.
- **Invalid client credentials** – Verify that the Client ID (API key) and Client Secret (API secret key) match the values in your Shopify custom app.
- **Insufficient permissions** – Verify that the Admin API access scopes configured on your Shopify custom app match the operations you want to use.

Slack integration

With the Slack connector, you can access the Slack platform directly in Amazon Quick through natural language. You can send messages, manage channels, search content, and interact with users and user groups without leaving Amazon Quick.

Amazon Quick supports multiple authentication methods for Slack. Choose the method that best fits your organization's security requirements.

- **Default OAuth app** – Uses an AWS-managed OAuth application. No additional credentials are needed. You authenticate directly with your Slack workspace.
- **Custom OAuth app** – Uses a customer-managed Slack app. This option gives your organization full control over the OAuth configuration.
- **Bearer Token** – Uses a Slack bot token for authentication. This method is suitable for bot-level access to a workspace.

For more information about the authentication methods that Amazon Quick supports, see [the section called “Authentication methods”](#).

Before you begin

Make sure that you have the following before you set up the integration.

- A Slack workspace with access to the channels and data that you want to use.
- For **Custom OAuth app**: Access to the [Slack API dashboard](#) on the Slack website to create an app.
- For **Bearer Token**: A bot token (starts with xoxb-) from a Slack app. For more information, see [Quickstart app settings](#) on the Slack website.
- For Amazon Quick subscription requirements, see [the section called “Set up integrations in the console”](#).

Configuring Slack

If you are using **Default OAuth app** authentication, skip this section and go to [the section called “Setting up the connector in Amazon Quick”](#).

For Custom OAuth app or Bearer Token authentication, complete the applicable steps in Slack before you configure Amazon Quick.

Create a Slack app for Custom OAuth app or Bearer Token

Create a Slack app to get the client credentials or bot token that you need for Amazon Quick.

1. Go to the [Slack API dashboard](#) on the Slack website and choose **Create New App**.
2. Choose **From scratch**.

3. Enter an **App Name** and select your Slack workspace. Choose **Create App**.
4. In the left sidebar, choose **OAuth & Permissions**.
5. Under **Redirect URLs**, choose **Add New Redirect URL** and enter the Amazon Quick callback URL: `https://{region}.quicksight.aws.amazon.com/sn/oauthcallback`

Choose **Add**, then choose **Save URLs**.

6. Under **Scopes**, add the Bot Token Scopes that your integration requires. For the recommended scopes, see [the section called "Recommended scopes"](#).
7. In the left sidebar, choose **Basic Information**. Under **App Credentials**, record the following values:
 - **Client ID**
 - **Client secret**
8. For **Bearer Token**: Install the app to your workspace from the **OAuth & Permissions** page. After installation, copy the **Bot User OAuth Token** (starts with xoxb-).

Recommended scopes

The following scopes are requested when you connect to Slack. When you create a custom Slack app, add these scopes on the **OAuth & Permissions** page. For Custom OAuth app, add them as **User Token Scopes**. For Bearer Token, add them as **Bot Token Scopes**.

Slack recommended scopes

Scope	Description
<code>calls:read</code>	Reads call information.
<code>calls:write</code>	Creates and manages calls.
<code>channels:history</code>	Reads message history in public channels.
<code>channels:read</code>	Reads information about public channels.
<code>channels:write</code>	Manages public channels.
<code>chat:write</code>	Sends messages to channels and conversations.
<code>dnd:read</code>	Reads Do Not Disturb settings.

Scope	Description
<code>dnd:write</code>	Updates Do Not Disturb settings.
<code>emoji:read</code>	Reads custom emoji.
<code>files:read</code>	Reads files shared in channels.
<code>files:write</code>	Uploads and manages files.
<code>groups:history</code>	Reads message history in private channels.
<code>groups:read</code>	Reads information about private channels.
<code>groups:write</code>	Manages private channels.
<code>im:history</code>	Reads message history in direct messages.
<code>im:read</code>	Reads information about direct messages.
<code>im:write</code>	Starts direct messages.
<code>links:read</code>	Reads link previews.
<code>links:write</code>	Manages link previews.
<code>mpim:history</code>	Reads message history in group direct messages.
<code>mpim:read</code>	Reads information about group direct messages.
<code>mpim:write</code>	Starts group direct messages.
<code>pins:read</code>	Reads pinned messages.
<code>pins:write</code>	Pins and unpins messages.
<code>reactions:read</code>	Reads emoji reactions on messages.
<code>reactions:write</code>	Adds and removes emoji reactions.
<code>reminders:read</code>	Reads reminders.

Scope	Description
<code>reminders:write</code>	Creates reminders.
<code>remote_files:read</code>	Reads remote files.
<code>remote_files:share</code>	Shares remote files.
<code>search:read</code>	Searches messages and files.
<code>stars:read</code>	Reads starred items.
<code>stars:write</code>	Stars and unstars items.
<code>team:read</code>	Reads workspace information.
<code>usergroups:read</code>	Reads user group information.
<code>usergroups:write</code>	Manages user groups.
<code>users:read</code>	Reads user information.
<code>users:read.email</code>	Reads user email addresses.
<code>users:write</code>	Updates user information.
<code>users.profile:read</code>	Reads user profile information.
<code>users.profile:write</code>	Updates user profile information.

Note

Not all scopes are available for both User Token Scopes and Bot Token Scopes. Some scopes, such as `search:read` and `stars:read`, are available only as User Token Scopes. When you configure scopes for Bearer Token authentication, verify scope availability in the [Slack API scopes reference](#) on the Slack website.

Setting up the connector in Amazon Quick

Connect from the Available tab

If you want to use Default OAuth app authentication, you can connect directly from the **Available** tab without additional configuration.

1. In the Amazon Quick console, choose **Connectors**.
2. On the **Available** tab, find **Slack** and choose **Connect**.
3. Complete the Slack sign-in flow and grant the requested permissions.

To configure a connector with Custom OAuth app or Bearer Token instead, use the **Create for your team** tab as described below.

Create from the Create for your team tab

After you complete any required Slack configuration, create the connector in Amazon Quick.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Slack**.

Note

If a Slack connector already exists, a dialog appears with your existing connectors. To use an existing connector, choose it. To create a new one, choose **No, create new**.

4. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
5. For **Connection type**, choose **Public network**.
6. For **OAuth Configuration**, choose one of the following authentication methods and configure the required fields.
 - a. For **Default OAuth app**:

No additional credentials are needed. Choose **Next** to continue.
 - b. For **Custom OAuth app**, configure the following fields:
 - **Base URL** (Optional) – The Slack API base URL. Example: `https://slack.com/api`

- **Client ID** – The client ID from your Slack app.
 - **Client secret** – The client secret from your Slack app.
 - **Token URL** – The token endpoint. Example: `https://slack.com/api/oauth.v2.access`
 - **Authorization URL** – The authorization endpoint. Example: `https://slack.com/oauth/v2/authorize`
 - **Redirect URL** – Pre-filled with the Amazon Quick callback URL.
- c. For **Bearer Token**, configure the following fields:
- **Base URL** (Optional) – The Slack API base URL. Example: `https://slack.com/api`
 - **Bot token** – Your Slack bot token (starts with xoxb-).
7. Choose **Next**.
 8. If you chose **Default OAuth app** or **Custom OAuth app**, a Slack authorization window opens. Review the requested permissions, select your workspace, and choose **Allow**.
 9. On the **Review** page, review the available actions for the connector. Choose **Next**.
 10. On the **Publish** page, choose who can access the connector. You can enable access for everyone in your organization or search for specific teams or groups.
 11. Choose **Publish**.

Available actions

After you set up the connector, the following actions are available.

Slack available actions

Category	Action	Description
Messages	Chat Post Message	Posts a message to a channel, direct message, or private group.
Messages	Send Me Message	Sends a third-person action message to a channel.
Messages	Get Message Permalink	Retrieves a permalink URL for a specific message.

Category	Action	Description
Channels	Conversations Create	Creates a public or private channel.
Channels	Conversations History	Retrieves message history from a channel. Returns main timeline messages only, not threaded replies.
Channels	Conversations Replies	Retrieves threaded replies to a specific parent message.
Channels	Conversations Invite	Invites users to an existing channel.
Channels	Conversations Join	Joins an existing channel.
Channels	Conversations Kick	Removes a user from a channel.
Channels	Conversations Leave	Leaves a channel.
Channels	Conversations Members	Lists member IDs for a channel.
Channels	Conversations Open	Opens or resumes a direct message or multi-person direct message.
Channels	Conversations Set Topic	Sets or updates the topic for a channel.
Channels	Get Conversation	Retrieves metadata for a channel by ID.
Channels	List Channels	Lists channels available to the user.
Channels	List Conversations For User	Lists channels and direct messages accessible to a user.
Reactions	Create Reaction	Adds an emoji reaction to a message.
Reactions	Delete Reaction	Removes an emoji reaction from a message.
Reactions	List Reactions	Lists reactions on a message, file, or file comment.

Category	Action	Description
Files	Upload Or Create File	Uploads files or media to channels or threads.
Files	Upload To URL External	Adds a reference to an external file for sharing in Slack.
Files	Download File	Downloads a file shared in Slack.
Files	Files Info	Retrieves metadata and comments for a file.
Files	Files List	Lists files in a workspace with optional filters.
Search	Search All	Searches messages and files across the workspace.
Search	Search Messages	Searches messages with date ranges and filters.
Search	Search Channels	Searches channels by name, topic, or purpose.
Search	Search Users	Searches users by email, name, or display name.
Search	Search Context	Searches across messages, files, channels, and users. Supports semantic search on workspaces with Slack AI.
Search	Get Search Configuration	Checks whether semantic search is available on the workspace.
Users	Get User Details	Retrieves information for a user by ID.
Users	Get User Profile	Retrieves profile information for a user.
Users	Users Profile Set	Updates a user's profile fields.

Category	Action	Description
Users	Users List	Lists all users in the workspace.
User groups	User Groups Create	Creates a new user group.
User groups	User Groups List	Lists user groups in the workspace.
User groups	User Groups Users Update	Replaces all members of a user group.
Reminders	Reminders Add	Creates a reminder with specified text and time.
Workspace	Get Team	Retrieves metadata about the Slack workspace.

Note

The actions that you can use depend on the scopes configured for your Slack app and the channels accessible to the authenticated user.

Managing and troubleshooting

To edit, share, or delete your connector, see [the section called “Managing existing integrations”](#).

Authentication issues

- **Sign-in fails (Default OAuth app or Custom OAuth app)** – Verify that your Slack workspace is active and that you can sign in to [the Slack website](#) directly. For Custom OAuth app, confirm that the redirect URL in your Slack app matches the Amazon Quick callback URL.
- **Invalid client credentials (Custom OAuth app)** – Verify that the Client ID and Client secret match the values in your Slack app's Basic Information section.
- **Bearer Token rejected** – Verify that your bot token is active and starts with xoxb-. Tokens can be revoked from the Slack API dashboard.
- **Insufficient permissions** – Verify that the scopes configured for your Slack app include the permissions required for the actions that you want to use. See [the section called “Recommended scopes”](#).

- **Channel not found or not in channel** – Verify that the bot has been added to the channel. Invite the bot to the channel before attempting to post messages or read history.

Smartsheet integration

With the Smartsheet connector, you can manage sheets, rows, reports, and search across your Smartsheet workspaces directly in Amazon Quick through natural language.

Prerequisites

Before you set up the integration, make sure that you meet the following requirements.

- A Smartsheet account with a Business, Enterprise, or Advanced Work Management plan. Free accounts cannot generate API access tokens or register OAuth apps. For more information, see [Smartsheet pricing](#) on the Smartsheet website and [Smartsheet OAuth](#) in the Smartsheet documentation.
- [Smartsheet Developer Tools](#) activated for your account.
- For subscription requirements, see [the section called “Set up integrations in the console”](#).

Configure Smartsheet Developer Tools

Before you configure Amazon Quick, set up credentials in Smartsheet. Each user signs in with their own Smartsheet account, and actions run with that user's permissions. This method uses Custom OAuth app. Complete the [the section called “Register for Developer Tools and create a developer profile”](#) and [the section called “Register the OAuth application”](#) sections below.

For more information about authentication methods, see [the section called “Authentication methods”](#).

Register for Developer Tools and create a developer profile

1. Go to the [Developer Tools Registration](#) page and register the Smartsheet account you want to use with your apps. For more information, see [Register for Developer Tools](#) in the Smartsheet API documentation.
2. After Smartsheet activates Developer Tools, sign in to the Smartsheet application and choose your **Account** icon in the lower-left corner, then choose **Developer Tools**.
3. Choose **Create Developer Profile** and enter a profile name. For more information, see [Create your developer profile](#) in the Smartsheet API documentation.

 Tip

Smartsheet recommends using a dedicated service account for OAuth apps rather than a personal account.

Register the OAuth application

1. In Smartsheet Developer Tools, choose **Create New App**.
2. Complete the form:
 - **App name** – A name to identify your app to users.
 - **App description** – A brief description of the integration.
 - **App URL** – The URL that launches your app, or a landing page.
 - **App contact/support** – Support contact information.
 - **App redirect URL** – `https://{region}.quicksight.aws.amazon.com/sn/oauthcallback`

Replace `{region}` with your AWS Region (for example, `us-east-1`).
3. Choose **Save**. Smartsheet generates the **App client ID** and **App secret**.
4. Copy the **Client ID** and **Client Secret** values. You need these when you configure the integration in Amazon Quick.

For more information, see [Register an app](#) in the Smartsheet API documentation.

 Note

When you configure the OAuth app, the connector requests access scopes from Smartsheet that determine what it can do on behalf of the authenticated user. Access scopes don't override existing sharing permissions. For more information, see [Access scopes](#) in the Smartsheet API documentation.

Set up the integration in Amazon Quick

1. In the Amazon Quick console, choose **Connectors**.

2. Choose the **Create for your team** tab.
3. Find and choose **Smartsheet**.
4. Enter the integration details:
 - **Name** – Descriptive name for your Smartsheet integration.
 - **Description** (Optional) – Purpose of the integration.
 - **Base URL** – `https://mcp.smartsheet.com`
 - **Client ID** – App client ID from your Smartsheet Developer Tools app registration.
 - **Client Secret** – App secret from your Smartsheet Developer Tools app registration.
 - **Token URL** – `https://api.smartsheet.com/2.0/token`
 - **Auth URL** – `https://app.smartsheet.com/b/authorize`
5. Choose **Create and continue**.
6. Choose users to share the integration with.
7. Choose **Next**.

Note

If you're using a Smartsheet regional server outside of the US, replace the MCP server URL with one for your region:

- For Europe, use `https://mcp.smartsheet.eu`
- For Australia, use `https://mcp.smartsheet.au`

Available actions

After you set up the connector, the actions exposed by the Smartsheet MCP server are available. To see the current set of actions for your connector, open the connector's **Available actions** view in the Amazon Quick console. For a full list of available MCP tools, see [MCP Server Tools](#) in the Smartsheet documentation.

Managing and troubleshooting

To edit, share, or delete your connector, see [the section called “Managing existing integrations”](#).

Authentication issues

- **OAuth authorization fails** – Verify that the Client ID and Client Secret match the values in your Smartsheet Developer Tools app registration. Confirm the redirect URL in Smartsheet matches the URL in your Amazon Quick configuration exactly. For a list of OAuth error types, see [OAuth error types](#) in the Smartsheet API documentation.
- **Developer Tools not available** – Verify that Developer Tools is activated for your Smartsheet account. Free accounts do not support Developer Tools. If your request was denied, contact your Smartsheet Customer Success Manager.

Common error messages

- **Actions return permission errors** – Verify that the authenticated user has the required sharing permissions on the target sheets. OAuth scopes don't override sharing-level access controls. For more information, see [Resource access levels](#) in the Smartsheet API documentation.
- **Sheet not found** – Verify the sheet ID is correct and that the authenticated user has at least viewer access to the sheet.
- **API rate limit errors** – The Smartsheet API enforces rate limits. For more information, see [Limitations](#) in the Smartsheet API documentation.

Snowflake Cortex Agent integration

Note

This guide covers an integration validated with a third-party MCP server. Snowflake manages the setup and availability of the Cortex Agent MCP server.

With the Snowflake Cortex Agent connector, you can query Snowflake data and run AI-powered analytics through Cortex Agent directly in Amazon Quick via Model Context Protocol (MCP) server connectivity.

Snowflake Cortex Agent uses MCP server connectivity. To set up this integration, complete the following two steps. First, enable the Cortex Agent MCP server in your Snowflake account and obtain the server endpoint URL. Then, create the integration in Amazon Quick. For more information about Snowflake's Cortex Agent MCP server, see [Cortex Agents MCP server](#) in the Snowflake documentation.

Prerequisites

Before you set up the integration, make sure that you have the following resources and access.

- An active Snowflake account with Cortex Agent enabled and the Cortex Agent MCP server configured. For information about enabling the Cortex Agent MCP server, see [Cortex Agents MCP server](#) in the Snowflake documentation.
- The MCP server endpoint URL from your Snowflake account.
- Appropriate roles, warehouses, databases, and schemas configured in your Snowflake account for the operations you want to perform.
- For information about subscription requirements, see [the section called “Set up integrations in the console”](#).

Set up the integration in Amazon Quick

After you verify your Snowflake account and obtain the MCP server endpoint, create the integration in Amazon Quick.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Snowflake Cortex Agent**.
4. On the **Connect to Snowflake Cortex Agent** page, enter the following fields:
 - **Name** – A descriptive name for your Snowflake Cortex Agent connector.
 - **Description** (Optional) – Notes about how you plan to use this connection.
 - **MCP server endpoint** – The Cortex Agent MCP server endpoint URL from your Snowflake account. Example: `https://mcp.example.com/sse`.
 - **Connection type** – Choose **Public network**.
5. Choose **Next**.
6. If the Cortex Agent MCP server requires authentication, Amazon Quick uses MCP OAuth discovery to handle the sign-in flow. If a Snowflake sign-in popup appears, enter your Snowflake credentials and grant the requested permissions. For more information about how Amazon Quick handles MCP authentication, see [the section called “Prepare MCP server setup and authentication”](#).

7. On the **Review** page, Amazon Quick discovers the tools that Cortex Agent exposes and displays them in a table. Review the list of available actions and choose **Next**.
8. (Optional) On the **Share integration** page, search for teams or groups to share the integration with.
9. Choose **Done**.

The integration appears in the **Existing actions** panel with a status of **Available**.

Available actions

After you set up the integration, the actions exposed by Snowflake Cortex Agent are available. To see the current set of actions for your connector, go to the connector's **Available actions** view in the Amazon Quick console.

Manage and troubleshoot

To edit, share, or delete your integration, see [the section called "Managing existing integrations"](#). For general MCP integration troubleshooting, see [the section called "Troubleshooting"](#).

Visier Agent integration

With the Visier Agent connector, you can access Visier's people analytics platform directly in Amazon Quick through natural language. You can query live workforce data, analyze headcount trends, assess retention health, generate workforce briefings, and more without leaving Amazon Quick.

Visier Agent uses Custom OAuth app authentication. For more information about the authentication methods that Amazon Quick supports, see [the section called "Authentication methods"](#).

Before you begin

Make sure that you have the following before you set up the integration.

- An active Visier account with API access and Visier Agent enabled. For information about enabling Visier Agent and configuring authentication, see [Visier MCP Server documentation](#).
- Appropriate data access scopes configured in your Visier account for the workforce data you want to query.

- OAuth credentials (Client ID and Client Secret) from your Visier administrator.
- For Amazon Quick subscription requirements, see [the section called “Set up integrations in the console”](#).

Configuring Visier

Before you configure Amazon Quick, complete the following steps in your Visier admin console.

1. Sign in to your Visier admin console and confirm that your account is active.
2. Enable the Visier Agent capability under **Settings, API & Integrations**.
3. Register an OAuth client for Amazon Quick and add the Amazon Quick callback URL to the list of redirect URLs: `https://{region}.quicksight.aws.amazon.com/sn/oauthcallback`

Replace `{region}` with your AWS Region (for example, `us-east-1`).

4. Record the **Client ID** and **Client Secret**. You need them when you configure Amazon Quick.
5. Confirm that the workforce data and analytics you want to query are accessible to your account.

Setting up the connector in Amazon Quick

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Visier Agent**.
4. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
5. For **Connection type**, choose **Public network**.
6. For **OAuth Configuration**, choose **Custom OAuth app** and configure the following fields:
 - **Base URL** – The Visier Agent MCP base URL, pre-filled by Amazon Quick.
 - **Client ID** – The OAuth client ID from your Visier admin console.
 - **Public OAuth client** (Optional) – Select this option if your Visier OAuth client is configured as a public client (no client secret).
 - **Client secret** – The OAuth client secret from your Visier admin console.
 - **Token URL** – The OAuth token endpoint, pre-filled by Amazon Quick.
 - **Authorization URL** – The OAuth authorization endpoint, pre-filled by Amazon Quick.

- **Redirect URL** – Pre-filled with the Amazon Quick callback URL.
7. Choose **Next**.
 8. In the Visier sign-in popup that appears, enter your Visier credentials and choose **Sign in** to authorize Amazon Quick to access Visier on your behalf.
 9. On the **Review** page, Amazon Quick discovers the tools that Visier Agent exposes and displays them in a table. Review the list of available actions and choose **Next**.
 10. On the **Publish** page, choose who can access the connector. You can enable access for everyone in your organization or search for specific teams or groups.
 11. Choose **Publish**.

Available actions

After you set up the connector, you can use the following actions. Visier Agent exposes its people analytics capabilities as callable tools.

Visier Agent available actions

Action	Description
ask_vee_question	Asks Visier's Vee AI a natural language workforce question, such as headcount, turnover, or requisitions.
aggregate_metric_values	Computes aggregate values for a metric, optionally grouped by a dimension and filtered by specific members.
sample_vee_questions	Returns a list of sample questions that you can ask Vee to get started.
search_analytic_objects	Finds analytic objects (for example, Employee or Applicant) matching a search string.
search_analytic_object_properties	Returns all available properties for a given analytic object.
list_analytic_object_property_values	Lists property values for specific analytic object members, such as employee tenure or pay.
search_metrics	Finds metrics matching a search string.

Action	Description
search_dimensions_for_metric	Finds dimensions available for a given metric, usable for grouping or filtering.
search_dimensions_for_analytic_object	Finds dimensions available for a given analytic object.
search_filter_dimension_members	Returns filterable members for a given dimension.
get_object_reference_graph	Returns the reference graph showing how a given analytic object connects to others.

Managing and troubleshooting

To edit, share, or delete your connector, see [the section called “Managing existing integrations”](#).

Authentication issues

- **MCP server connection fails** – Verify that you enabled the Visier Agent capability in your Visier admin console under **Settings, API & Integrations**. Confirm that you entered the Base URL, Token URL, and Authorization URL correctly in Amazon Quick.
- **Invalid client credentials** – Verify that the Client ID and Client secret match the values from your Visier admin console. Confirm that the redirect URI in your Visier OAuth client matches the Amazon Quick callback URL.
- **Data access errors** – Verify that the data access scopes configured in your Visier account include the workforce data you are trying to query. Contact your Visier administrator to review your account permissions.
- **No tools discovered** – If Amazon Quick does not discover any tools after you create the connector, confirm that Visier Agent is active and that your authentication credentials have not expired.

Web Crawler integration

Applies to: Enterprise Edition

With Web Crawler integration in Amazon Quick, you can create knowledge bases from website content by crawling and indexing web pages. This integration supports data ingestion capabilities with different authentication options.

Web Crawler capabilities

You can ask questions about content stored on websites and web pages. For example, you can search documentation sites, knowledge bases, or specific information across multiple web pages.

With this integration, you can access and understand web content regardless of location or type. You also get contextual details such as publication dates, modification history, and page ownership for more efficient information discovery.

Note

Web Crawler integration supports data ingestion only. It doesn't provide action capabilities for managing websites or web services.

Prerequisites

Before you set up Web Crawler integration, make sure you have the following:

- Website URLs to crawl and index.
- You need a Amazon Quick account with Enterprise Edition.
- A website that is not behind a firewall and does not require special browser plugins to connect.

Prepare website access and authentication

Before setting up the integration in Amazon Quick, prepare your website access credentials. Web Crawler integration supports different authentication methods:

No authentication

Use for crawling websites that don't require authentication.

Basic authentication

Standard HTTP Basic Authentication for secured websites. When you visit a protected site, your browser displays a dialog box that asks for your credentials.

Required credentials:

- **Login page URL** - The URL of the login page
- **Username** - Basic auth username
- **Password** - Basic auth password

Form authentication

For websites that use HTML form-based login pages. You specify XPath expressions to identify the form fields on the login page.

XPath (XML Path Language) is a query language for navigating elements in an HTML or XML document. To find an XPath for a web page element, right-click the element in your browser and choose **Inspect**. In the developer tools, right-click the highlighted HTML code, choose **Copy**, and then choose **Copy XPath**.

Required information:

- **Login page URL** - URL of the login form (for example, `https://example.com/login`)
- **Username** - Login username
- **Password** - Login password
- **Username field XPath** - XPath to username input field (for example, `//input[@id='username']`)
- (Optional) **Username button XPath** - XPath to username button field (for example, `//input[@id='username_button']`)
- **Password field XPath** - XPath to password input field (for example, `//input[@id='password']`)
- **Password button XPath** - XPath to password button (for example, `//button[@type='password']`)

SAML authentication

For websites that use SAML-based single sign-on (SSO) authentication.

SAML (Security Assertion Markup Language) authentication is a federated identity standard that enables SSO. You authenticate through a centralized identity provider (such as Microsoft Azure AD or Okta) instead of entering credentials directly into each application. The identity provider passes a secure token back to the application to grant access.

Required information:

- **Login page URL** - URL of the SAML login page
- **Username** - SAML username
- **Password** - SAML password
- **Username field XPath** - XPath to username input field (for example, `//input[@id='username']`)
- (Optional) **Username button XPath** – XPath to username button field (for example, `//input[@id='username_button']`)
- **Password field XPath** - XPath to password input field (for example, `//input[@id='password']`)
- **Password button XPath** - XPath to password button (for example, `//button[@type='password']`)

XPath configuration examples

Use these XPath examples to configure form and SAML authentication:

Username field examples:

```
//input[@id='username']  
//input[@name='user']  
//input[@class='username-field']
```

Password field examples:

```
//input[@id='password']  
//input[@name='pass']  
//input[@type='password']
```

Submit button examples:

```
//button[@type='submit']  
//input[@type='submit']  
//button[contains(text(), 'Login')]
```

Set up Web Crawler integration

After preparing your website access requirements, create the Web Crawler integration in Amazon Quick.

1. In the Amazon Quick console, choose **Knowledge**.

2. Find **Web Crawler** and choose the **Add (+)** icon.
 3. Choose **Access data from Web Crawler**. Web Crawler integration supports data access only - action execution is not available for web crawling.
 4. Configure integration details and authentication method, then create knowledge bases as needed.
 1. Choose the authentication type for your web crawler integration.
 2. Enter the required details based on your chosen authentication method.
 3. (Optional) Choose a VPC connection to crawl sites hosted in your private network. The VPC connection must be configured in admin settings before you can choose it here. For more information, see [the section called "Setting up a VPC to use with Amazon Quick"](#).
-  **Note**

You can't change the VPC connection after the integration is created. To use a different VPC connection, create a new integration.
4. Choose **Create and continue**.
 5. Enter the name and description for your knowledge base.
 6. Add the content URLs that you want to crawl.
 7. Choose **Create**.

After you choose **Create**, the data sync starts automatically.

Configure crawling

You can configure which websites and pages to crawl and how to filter the content.

Configure URLs and content sources

Configure which websites and pages to crawl:

Direct URLs

Specify individual URLs to crawl:

`https://example.com/docs`

```
https://example.com/blog  
https://example.com/support
```

Limit: Maximum 10 URLs per dataset

Content filters and crawl settings

Crawl scope settings

To view these settings, you must first set up a knowledge base and then examine the advanced settings option.

Crawl depth

- Range: 0-10 (default: 1)
- 0 = crawl only specified URLs
- 1 = include linked pages one level deep
- Higher values follow links deeper into the site

Maximum links per page

- Default: 100
- Maximum: 1,000
- Controls how many links to follow from each page

Wait time

- Default: 1
- The time (in seconds) that the web crawler waits for each page after the page reaches a ready state. Increase this value for pages with dynamic JavaScript content that loads after the main template.

Manage knowledge bases

After setting up your Web Crawler integration, you can create and manage knowledge bases from your crawled website content.

Edit existing knowledge bases

You can modify your existing Web Crawler knowledge bases:

1. In the Amazon Quick console, choose **Knowledge bases**.
2. Choose your Web Crawler knowledge base from the list.
3. Choose the three-dot icon under **Actions**, then choose **Edit knowledge base**.
4. Update your configuration settings as needed and choose **Save**.

Attachments and file crawling

Control whether the system processes files and attachments linked from web pages:

- **Enable file attachment crawling** – Choose this option to crawl and index files and attachments found on web pages, such as PDFs, documents, and media files.

Crawling behavior and sync configuration

Your Web Crawler integration follows these crawling practices:

- **Incremental sync model:** First sync performs full crawl. Subsequent syncs capture changes only.
- **Automatic retry:** Built-in retry logic for failed requests.
- **Duplicate handling:** Automatic detection and deduplication of URLs.
- **Crawler identification:** Identifies itself with the user-agent string `amazon-Quick-on-behalf-of-<UUID>` in request headers. You can target this user-agent in your `robots.txt` file to allow or disallow the crawler specifically. For more information, see [the section called “Robots.txt compliance”](#).

Sitemap discovery

Web Crawler automatically checks for sitemaps by appending common sitemap paths to your seed URLs. You don't need to provide sitemap URLs separately. The following paths are checked:

```
sitemap.xml
sitemap_index.xml
sitemap/sitemap.xml
sitemap/sitemap_index.xml
sitemaps/sitemap.xml
sitemap/index.xml
```

For example, if your seed URL is `https://example.com/docs`, the crawler checks for `https://example.com/docs/sitemap.xml`, `https://example.com/docs/sitemap_index.xml`, and so on.

Note

Web Crawler does not follow recursive sitemap index references. Only the URLs listed directly in a discovered sitemap are used. Sitemap directives in `robots.txt` are not used for sitemap discovery.

Robots.txt compliance

Web Crawler respects the `robots.txt` protocol and honors user-agent and allow or disallow directives. Use these directives to control how the crawler accesses your site.

How robots.txt checking works

- **Host-level checking:** Web Crawler reads `robots.txt` files at the host level (for example, `example.com/robots.txt`).
- **Multiple host support:** For domains with multiple hosts, Web Crawler honors robots rules for each host separately.
- **Fallback behavior:** If Web Crawler can't fetch `robots.txt` due to blocking, parsing errors, or timeouts, it behaves as if `robots.txt` doesn't exist. In this case, the crawler proceeds to crawl the site.

Supported robots.txt fields

Web Crawler recognizes these `robots.txt` fields (field names are case-insensitive, values are case-sensitive):

`user-agent`

Identifies which crawler the rules apply to.

`allow`

A URL path that may be crawled.

disallow

A URL path that may not be crawled.

crawl-delay

The time (in seconds) to wait between requests to your website.

Meta tag support

Web Crawler supports page-level robots meta tags that you can use to control how your data is used. You can specify page-level settings by including a meta tag on HTML pages or in an HTTP header.

Supported meta tags

noindex

Do not index the page. If you don't specify this rule, the page may be indexed and eligible to appear in experiences.

nofollow

Do not follow the links on this page. If you don't specify this rule, Web Crawler may use the links on the page to discover those linked pages.

You can combine multiple values using a comma (for example, "noindex, nofollow").

Note

To detect meta tags, Web Crawler must access your page. Don't block your page with robots.txt, because this prevents the page from being recrawled.

Troubleshooting

Use this section to resolve common issues with Web Crawler integration.

Authentication failures

Symptoms:

- "Unable to authenticate" error messages

- 401/403 HTTP responses
- Login page redirect loops
- Session timeout errors

Resolution steps:

1. Verify the site is reachable from the AWS Region where the Amazon Quick instance is set up.
2. Verify that your credentials are correct and haven't expired.
3. Check authentication endpoint availability and accessibility.
4. Validate XPath configurations by testing them in browser developer tools.
5. Review browser network logs to understand the authentication flow.
6. Ensure the login page URL is correct and accessible.
7. Test authentication manually using the same credentials.

Access and connectivity issues**Symptoms:**

- Connection timeouts and network errors
- Network unreachable errors
- DNS resolution failures

Resolution steps:

1. Verify network connectivity to target websites.
2. Validate site accessibility:
 - Check DNS resolution for target domains.
 - Verify SSL/TLS configuration and certificates.
 - Test access from different networks if possible.

DNS resolution

The Web Crawler uses DNS to resolve website hostnames (for example, `www.example.com`) to IP addresses. By default, it uses public DNS resolution.

When crawling sites inside a VPC, you may need to configure a private DNS server so the crawler can resolve hostnames for internal sites. Choose one of the following options based on your VPC configuration:

1. **Use the VPC-provided DNS server** — If your VPC has both **DNS hostnames** and **DNS resolution** enabled, you can use the default VPC DNS resolver (typically 10.0.0.2, or more generally the VPC CIDR base+2). For more information, see [the section called "VPC"](#).
2. **Use a custom DNS server** — If your VPC uses a custom DNS resolver, provide the IP address of your organization's internal DNS server. Work with your network administrator to obtain this address.

If you don't configure a DNS server, the crawler resolves only publicly registered hostnames.

JavaScript-dependent navigation

Symptoms:

- Only the seed URL is indexed, no additional pages discovered
- Crawl completes successfully but returns only one document

Resolution steps:

1. Web Crawler executes JavaScript and renders page content, but does not simulate user interactions such as clicks, scrolls, or hover actions. If your site loads navigation links through user interaction (for example, click handlers, infinite scroll, or dynamic menus), the crawler cannot discover those links.
2. Inspect your page in browser developer tools to check if navigation links use standard `<a href="...">` elements. If links are wired through JavaScript event handlers instead, the crawler will not follow them.
3. If your site provides a sitemap, Web Crawler automatically checks for common sitemap paths on your seed URLs. Ensure your sitemap is available at a standard location (for example, `/sitemap.xml`) so the crawler can discover additional URLs without relying on in-page link extraction.
4. Alternatively, provide all target page URLs directly as seed URLs.
5. If content can be exported as HTML, PDF, or text files, consider using the Amazon S3 connector as your data source instead.

Crawl and content issues

Symptoms:

- Missing or incomplete content
- Incomplete crawls or early termination
- Rate limiting errors (429 responses)
- Content not being indexed properly

Resolution steps:

1. Review robots.txt restrictions:
 - Check robots.txt file for crawl restrictions.
 - Verify that the crawler is allowed to access target paths.
 - Ensure robots.txt compliance isn't blocking content.
2. Check rate limiting and throttling:
 - Monitor response headers for rate limit information.
 - Implement appropriate crawl delays.
3. Verify URL patterns and filters:
 - Test regex patterns for accuracy.
 - Check URL formatting and structure.
 - Validate include/exclude pattern logic.
4. Review content restrictions:
 - Check for noindex meta tags on pages.
 - Verify content type support.
 - Ensure content size is within limits.
5. Update the wait time so that the content loads on the page before the crawler starts crawling.

Known limitations

Web Crawler integration has the following limitations:

- **URL limits:** Maximum of 10 seed URLs per dataset. You can't provide sitemap URLs in the seed URL field.
- **Crawl depth:** Maximum crawl depth of 10 levels
- **Security requirements:** HTTPS required for web proxy configurations

The following limitations apply when using the Web Crawler with a VPC connection:

- **No HTTP/3 (QUIC) support:** HTTP/3 is not supported. Most sites will fall back to HTTP/2 automatically, but sites configured for HTTP/3 only will not be accessible.
- **DNS over TCP required:** DNS resolution must use TCP. Verify that your DNS server supports DNS over TCP before configuring VPC crawling.
- **Publicly trusted SSL certificates required:** Internal sites must use a certificate from a well-known certificate authority (for example, Let's Encrypt or DigiCert). Sites using self-signed or private CA certificates fail to connect.
- **IPv4 only:** Only IPv4 addresses are supported. Sites accessible exclusively over IPv6 cannot be crawled.

WhatsApp integration

With the WhatsApp connector, you can send and manage messages through WhatsApp Business directly in Amazon Quick through natural language.

WhatsApp uses Custom OAuth app authentication. For more information about the authentication methods that Amazon Quick supports, see [the section called "Authentication methods"](#).

Before you begin

Make sure that you have the following before you set up the integration.

- An active WhatsApp Business account with access to the WhatsApp Business Platform.
- A registered phone number for sending messages.
- An app registered in the Meta for Developers portal with the WhatsApp Business product configured.
- For Amazon Quick subscription requirements, see [the section called "Set up integrations in the console"](#).

Configuring Meta for Developers

For Custom OAuth app authentication, register an app in [Meta for Developers](#) on the Meta website and add the WhatsApp Business product. Configure your phone number and message templates, and add the Amazon Quick callback URL `https://{region}.quicksight.aws.amazon.com/sn/oauthcallback` as a valid OAuth redirect URI. Replace `{region}` with your AWS Region (for example, `us-east-1`). For step-by-step instructions, see [WhatsApp Cloud API](#) in the Meta for Developers documentation. Record the App ID (Client ID) and App Secret (Client Secret) — you need them when you configure Amazon Quick.

Setting up the connector in Amazon Quick

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **WhatsApp**.
4. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
5. For **Connection type**, choose **Public network**.
6. For **OAuth Configuration**, choose **Custom OAuth app** and configure the following fields:
 - **Base URL** – The WhatsApp MCP base URL.
 - **Client ID** – The App ID from your Meta for Developers app.
 - **Public OAuth client** (Optional) – Select this option if your Meta app is configured as a public client (no client secret).
 - **Client secret** – The App Secret from your Meta for Developers app.
 - **Token URL** – The Meta OAuth token endpoint.
 - **Authorization URL** – The Meta OAuth authorization endpoint.
 - **Redirect URL** – Pre-filled with the Amazon Quick callback URL.
7. Choose **Next**.
8. A Meta authorization window opens. Review the requested permissions and choose **Continue**.
9. On the **Review** page, review the available actions for the connector. Choose **Next**.
10. On the **Publish** page, choose who can access the connector. You can enable access for everyone in your organization or search for specific teams or groups.
11. Choose **Publish**.

Available actions

After you set up the connector, the actions exposed by WhatsApp are available. To see the current set of actions for your connector, go to the connector's **Available actions** view in the Amazon Quick console.

Managing and troubleshooting

To edit, share, or delete your connector, see [the section called “Managing existing integrations”](#).

Authentication issues

- **Sign-in fails** – Verify that your Meta for Developers app is active and that the WhatsApp Business product is configured. Confirm that the OAuth redirect URI in your Meta app matches the Amazon Quick callback URL.
- **Invalid client credentials** – Verify that the App ID (Client ID) and App Secret (Client Secret) match the values in your Meta for Developers app.
- **Phone number or template errors** – Verify that the phone number is registered and that any message templates you reference are approved in the WhatsApp Business Platform.

Zapier integration

With the Zapier connector, you can trigger workflows across thousands of applications that Zapier connects to, directly in Amazon Quick through natural language. Use this connector to extend the action capabilities of Amazon Quick to any application that you have already configured in your Zapier account.

Amazon Quick supports multiple authentication methods for Zapier. Choose the method that best fits your organization's security requirements.

- **Default OAuth app** – Uses an AWS-managed OAuth application. No additional credentials are needed. Users authenticate directly with their Zapier account.
- **Custom OAuth app** – Uses a customer-managed OAuth application configured in your Zapier account. This option gives your organization full control over the OAuth configuration.
- **Service-to-Service OAuth** – Uses client credentials for server-to-server authentication without user interaction. Suitable for automated workflows.
- **API Key** – Uses an API key for authentication.

For more information about the authentication methods that Amazon Quick supports, see [the section called "Authentication methods"](#).

Before you begin

Make sure that you have the following before you set up the integration.

- An active Zapier account with the actions or Zaps that you want to expose configured.
- The Amazon Quick integration requires Zapier MCP **Agentic Mode** to work correctly. Managed Mode is not supported.
- For **Custom OAuth app** or **Service-to-Service OAuth**: OAuth credentials from your Zapier MCP configuration.
- For **API Key**: A Zapier-issued API key.
- For Amazon Quick subscription requirements, see [the section called "Set up integrations in the console"](#).

Configuring Zapier

If you are using **Default OAuth app** authentication, skip this section and proceed to [the section called "Setting up the connector in Amazon Quick"](#).

For Custom OAuth app or Service-to-Service OAuth authentication, configure your [Zapier MCP](#) settings on the Zapier website and add the Amazon Quick callback URL `https://{region}.quicksight.aws.amazon.com/sn/oauthcallback` as a redirect URI. Replace `{region}` with your AWS Region (for example, `us-east-1`). Record the Client ID and Client Secret — you need them when you configure Amazon Quick. For API Key authentication, generate an API key from your Zapier account.

Setting up the connector in Amazon Quick

Connect from the Available tab

If you want to use Default OAuth app authentication, you can connect directly from the **Available** tab without additional configuration.

1. In the Amazon Quick console, choose **Connectors**.
2. On the **Available** tab, find **Zapier** and choose **Connect**.
3. Complete the Zapier sign-in flow and grant the requested permissions.

To configure a connector with one of the other authentication methods, use the **Create for your team** tab as described below.

Create from the Create for your team tab

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Zapier**.
4. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
5. For **Connection type**, choose **Public network**.
6. For **OAuth Configuration**, choose one of the following authentication methods and configure the required fields.

a. For **Default OAuth app**:

No additional credentials are needed. Choose **Next** to continue.

b. For **Custom OAuth app**, configure the following fields:

- **Client ID** – The client ID from your Zapier OAuth app.
- **Public OAuth client** (Optional) – Select this option if your Zapier OAuth app is configured as a public client (no client secret).
- **Client secret** – The client secret from your Zapier OAuth app.
- **Token URL** – The token endpoint. Default: `https://mcp.zapier.com/token`
- **Authorization URL** – The authorization endpoint. Default: `https://mcp.zapier.com/authorize`
- **Redirect URL** – Pre-filled with the Amazon Quick callback URL.

c. For **Service-to-Service OAuth**, configure the following fields:

- **Client ID** – The client ID from your Zapier OAuth app.
- **Client secret** – The client secret from your Zapier OAuth app.
- **Token URL** – The token endpoint. Default: `https://mcp.zapier.com/token`

d. For **API Key**, configure the following fields:

- **API Key** – The Zapier API key.
- **Email** (Optional) – The email address associated with the API key.

7. Choose **Next**.
8. If you chose **Default OAuth app** or **Custom OAuth app**, a Zapier authorization window opens. Review the requested permissions and choose **Allow**.
9. On the **Review** page, review the available actions for the connector. The available actions depend on the Zaps that you have configured in your Zapier account. Choose **Next**.
10. On the **Publish** page, choose who can access the connector. You can enable access for everyone in your organization or search for specific teams or groups.
11. Choose **Publish**.

Available actions

After you set up the connector, the actions that you exposed in your Zapier account are available. Each Zap or action that you authorized in Zapier registers as a callable tool in Amazon Quick. To see the current set of actions for your connector, go to the connector's **Available actions** view in the Amazon Quick console.

Managing and troubleshooting

To edit, share, or delete your connector, see [the section called “Managing existing integrations”](#).

Authentication issues

- **Sign-in fails (Default OAuth app or Custom OAuth app)** – Verify that your Zapier account is active and that you can sign in to Zapier directly. For Custom OAuth app, confirm that the redirect URI in your Zapier OAuth app matches the Amazon Quick callback URL.
- **Invalid client credentials (Custom OAuth app or Service-to-Service OAuth)** – Verify that the Client ID and Client secret match the values in your Zapier OAuth app.
- **API Key authentication fails** – Verify that the API key has not been revoked.
- **Expected actions are missing** – Verify that the Zaps or actions that you want to use are configured and enabled in your Zapier account.

Zendesk Suite integration

Manage your Zendesk support tickets directly from Amazon Quick using natural language. With the Zendesk Suite connector, you can create, update, search, and list support tickets without leaving Amazon Quick.

Zendesk Suite is available as a built-in connector in Amazon Quick. To set up this integration, complete the following two steps. First, prepare your Zendesk account with the required access. Then, create the connector in Amazon Quick and authenticate with your Zendesk credentials.

This connector supports OAuth user authentication and API key service authentication. For information about the authentication methods that Amazon Quick supports, see [the section called "Authentication methods"](#).

Prerequisites

Before you set up the integration, verify that you have the following resources and access.

- An active Zendesk account with an admin role.
- Permissions to access tickets and support data in your Zendesk instance.
- A subscription that meets the requirements described in [the section called "Set up integrations in the console"](#).

Verify your Zendesk account

Before you configure Amazon Quick, verify that your Zendesk account meets the following requirements.

- Your Zendesk account is active and you can sign in to the [Zendesk sign-in page](#) on the Zendesk website.
- The tickets and support data that you want to access are accessible to your account.

Configure Zendesk account

The Custom OAuth app authentication method in Amazon Quick requires an OAuth client configured in Zendesk. The API key authentication method requires an API token.

To configure an OAuth client

1. In your Zendesk instance, navigate to **Admin Center**, then **Apps and integrations**, and then **OAuth clients** under **API**.
2. Choose **Add OAuth Client**.
3. Complete the form with the following fields:

- **Name** – Enter a name for your app.
 - **Description** – Enter a short description.
 - **Identifier** – Enter a unique identifier for the OAuth client.
 - **Redirect URLs** – Enter `https://region.quicksight.aws.amazon.com/sn/oauthcallback`. Replace *region* with your AWS Region, for example, `us-east-1`.
4. Choose **Save**. Zendesk generates a client secret.

 Important

Record the client secret now. You cannot retrieve it after you leave this page.

5. After you capture the secret, choose **Save** again to create the OAuth client.

The Identifier and the secret serve as the Client ID and Client Secret when you configure the connector in Amazon Quick with the Custom OAuth app authentication method.

For more information, see [Using OAuth authentication with your application](#) on the Zendesk website.

To configure an API token

1. Navigate to **Admin Center**, then **Apps and integrations**, and then **API tokens**.
2. Choose **Add API token**.
3. For **Description**, enter a short description for the API token.
4. Choose **Save**. Zendesk generates an API token.

 Important

Record the API token now. You cannot retrieve it after you leave this page.

If you choose the API key authentication method in Amazon Quick, use this API token as the API key value.

For more information, see [Managing API token access to the Zendesk API](#) on the Zendesk website.

Set up the integration in Amazon Quick

After you verify your Zendesk account access, create the connector in Amazon Quick.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Choose **Zendesk Suite** from the options available.
4. In the **Zendesk Suite** dialog, enter the following fields:
 - **Name** – A descriptive name for your Zendesk connector.
 - **Description (Optional)** – Choose **+ Add Description** to add notes about how this connector will be used.
 - **Connection type** – Choose **Public network**.
5. Choose your authentication method and configure the connector settings:
 - **Custom OAuth app** – Enter the following fields for your Zendesk instance:
 - **Base URL**
 - **Client ID**
 - **Client Secret**
 - **Token URL**
 - **Authorization URL**
 - **Redirect URL**
 - **API Key** – Enter the following fields:
 - **Base URL**
 - **API Key** (Zendesk API token)
 - **Email** associated with your Zendesk account
6. Choose **Next**.
7. Review the actions for Zendesk Suite and choose **Next**.
8. Specify who can access the connector:
 - To share with a team, enter a team name or group email.
 - To keep it private, leave the field blank.
 - To share with all users, toggle **Everyone in your organization**.
9. Choose **Publish**.

The connector appears in the **Available** panel with a status of **Connected**.

Available actions

After you set up the connector, you can use the following ticket management actions.

Zendesk Suite available actions

Action	Description
Create Ticket	Create new ticket
List Search Results	Search tickets
List Tickets	View all tickets
Show Ticket	View ticket details
Update Ticket	Edit ticket details

Note

The actions that you can use depend on the permissions that are configured in your Zendesk account.

Troubleshooting

To edit, share, or delete your connector, see [the section called “Managing existing integrations”](#).

Authentication issues

- **Sign-in fails** – Verify that your Zendesk account is active and that you can sign in to the [Zendesk sign-in page](#) on the Zendesk website. If your organization uses single sign-on (SSO), confirm that your identity provider is configured correctly.
- **Access denied** – Confirm that your Zendesk user has an admin role with permissions to access tickets and support data. For API key connections, verify that the API token is valid and the associated email address is correct.

Zoom integration

With the Zoom connector, you can access the Zoom platform directly in Amazon Quick through natural language. You can create and manage meetings, access recordings and meeting summaries, view webinar details, and search contacts without leaving Amazon Quick.

Amazon Quick supports multiple authentication methods for Zoom. Choose the method that best fits your organization's security requirements.

- **Default OAuth app** – Uses an AWS-managed OAuth application. No additional credentials are needed. Users authenticate directly with their Zoom account.
- **Custom OAuth app** – Uses a customer-managed OAuth application registered in the Zoom App Marketplace. This option gives your organization full control over the OAuth configuration.

For more information about the authentication methods that Amazon Quick supports, see [the section called “Authentication methods”](#).

Before you begin

Make sure that you have the following before you set up the integration.

- An active Zoom account with access to the meetings, recordings, and webinars that you want to use.
- For **Custom OAuth app**: Access to the [Zoom App Marketplace](#) on the Zoom website to create an app.
- For Amazon Quick subscription requirements, see [the section called “Set up integrations in the console”](#).

Configuring Zoom

If you are using **Default OAuth app** authentication, skip this section and proceed to [the section called “Setting up the connector in Amazon Quick”](#).

For Custom OAuth app authentication, complete the following steps in the Zoom App Marketplace before configuring Amazon Quick.

Create a Zoom app (Custom OAuth app)

Create an app in the Zoom App Marketplace to obtain the client credentials that you need for Amazon Quick. For more information, see [OAuth](#) on the Zoom Developer website.

1. Sign in to the [Zoom App Marketplace](#) on the Zoom website and go to the app creation portal.
2. Create a new application. Choose **General** for user-based OAuth or **Server-to-Server OAuth** for service-to-service authentication.
3. On the **Basic Information** tab, under **App Credentials**, record the following values. You need them when you configure Amazon Quick.
 - **Client ID**
 - **Client secret**
4. In the **OAuth Information** section, for **Authorized Redirect URI**, add the Amazon Quick callback URL: `https://{region}.quicksight.aws.amazon.com/sn/oauthcallback`
5. Choose the **Scopes** tab and choose **+ Add Scopes** to select the permissions that your integration requires. For the recommended scopes, see [the section called "Recommended scopes"](#).

Recommended scopes

The following scopes are requested when you connect to Zoom. When you create a custom Zoom app, add these scopes on the **Scopes** tab.

Zoom recommended scopes

Scope	Description
meeting:read:list_meetings	Lists meetings.
meeting:read:meeting	Reads meeting details.
meeting:read:summary	Reads meeting summaries.
meeting:read:list_past_participants	Lists past meeting participants.
meeting:read:list_past_instances	Lists past meeting instances.

Scope	Description
meeting:write:meeting	Creates meetings.
meeting:update:meeting	Updates meetings.
meeting:delete:meeting	Deletes meetings.
meeting:write:registrant	Adds meeting registrants.
cloud_recording:read:list_user_recordings	Lists user recordings.
cloud_recording:read:list_recording_files	Lists recording files.
cloud_recording:delete:meeting_recording	Deletes meeting recordings.
webinar:read:webinar	Reads webinar details.
webinar:read:list_webinars	Lists webinars.
webinar:read:list_past_participants	Lists past webinar participants.
webinar:read:list_registrants	Lists webinar registrants.
webinar:write:registrant	Adds webinar registrants.
user:read:user	Reads user information.
user:read:settings	Reads user settings.
user:read:list_collaboration_devices	Lists collaboration devices.
contact:read:list_contacts	Lists contacts.

Note

Additional scopes for whiteboard and marketplace features are also requested. The scopes listed above cover the primary meeting, recording, webinar, user, and contact actions.

Setting up the connector in Amazon Quick

Connect from the Available tab

If you want to use Default OAuth app authentication, you can connect directly from the **Available** tab without additional configuration.

1. In the Amazon Quick console, choose **Connectors**.
2. On the **Available** tab, find **Zoom** and choose **Connect**.
3. Complete the Zoom sign-in flow and grant the requested permissions.

To configure a connector with Custom OAuth app instead, use the **Create for your team** tab as described below.

Create from the Create for your team tab

After you complete any required Zoom configuration, create the connector in Amazon Quick.

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **Zoom**.

Note

If a Zoom connector already exists, a dialog appears with your existing connectors. To use an existing connector, choose it. To create a new one, choose **No, create new**.

4. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
5. For **Connection type**, choose **Public network**.
6. For **OAuth Configuration**, choose one of the following authentication methods and configure the required fields.

a. For **Default OAuth app**:

No additional credentials are needed. Choose **Next** to continue.

b. For **Custom OAuth app**, configure the following fields:

- **Base URL** (Optional) – The Zoom API base URL. Example: `https://api.zoom.us`
- **Client ID** – The client ID from your Zoom app.
- **Client secret** – The client secret from your Zoom app.
- **Token URL** – The token endpoint. Example: `https://zoom.us/oauth/token`
- **Authorization URL** – The authorization endpoint. Example: `https://zoom.us/oauth/authorize`
- **Redirect URL** – Pre-filled with the Amazon Quick callback URL.

7. Choose **Next**.

8. If you chose **Default OAuth app** or **Custom OAuth app**, a Zoom authorization window opens. Review the requested permissions and choose **Allow**.

9. On the **Review** page, review the available actions for the connector. Choose **Next**.

10. On the **Publish** page, choose who can access the connector. You can enable access for everyone in your organization or search for specific teams or groups.

11. Choose **Publish**.

Available actions

After you set up the connector, the following actions are available.

Zoom available actions

Category	Action	Description
Meetings	List Meetings	Lists meetings for a user.
Meetings	Get Meeting	Retrieves details for a specific meeting.
Meetings	Create Meeting	Creates a new meeting.
Meetings	Update Meeting	Updates an existing meeting.

Category	Action	Description
Meetings	Get Meeting Summary	Retrieves the AI-generated summary for a meeting.
Meetings	List Meeting Summary Templates	Lists available meeting summary templates .
Meetings	Get Past Meeting Participants	Retrieves participants from a past meeting.
Meetings	List Past Meeting Instances	Lists instances of a recurring meeting.
Meetings	Create Meeting Registrant	Adds a registrant to a meeting.
Recordings	List Recordings	Lists all recordings for a user.
Recordings	Get Meeting Recordings	Retrieves recordings for a specific meeting.
Recordings	List Archived Files	Lists archived recording files.
Webinars	List Webinars	Lists webinars for a user.
Webinars	Get Webinar	Retrieves details for a specific webinar.
Webinars	List Webinar Participants	Lists participants for a webinar.
Contacts	Search Company Contacts	Searches for contacts in the company directory.
Devices	List Devices	Lists Zoom devices.
Reports	Get Daily Usage Report	Retrieves a daily usage report.
Users	Get User	Retrieves information about the authenticated user.

Note

The actions that you can use depend on the permissions configured for your Zoom account and the data accessible to the authenticated user.

Managing and troubleshooting

To edit, share, or delete your connector, see [the section called “Managing existing integrations”](#).

Authentication issues

- **Sign-in fails (Default OAuth app or Custom OAuth app)** – Verify that your Zoom account is active and that you can sign in to zoom.us on the Zoom website directly. For Custom OAuth app, confirm that the redirect URI in your Zoom app matches the Amazon Quick callback URL.
- **Invalid client credentials (Custom OAuth app)** – Verify that the Client ID and Client secret match the values in your Zoom app. You can view your credentials from the app settings in the Zoom App Marketplace.
- **Insufficient permissions** – Verify that the scopes configured for your Zoom app include the permissions required for the actions that you want to use. See [the section called “Recommended scopes”](#).

ZoomInfo integration

With the ZoomInfo connector, you can look up company and contact data, and query firmographic and intent data directly in Amazon Quick through natural language.

Amazon Quick supports multiple authentication methods for ZoomInfo. Choose the method that best fits your organization's security requirements.

- **Default OAuth app** – Uses an AWS-managed OAuth application. No additional credentials are needed. Users authenticate directly with their ZoomInfo account.
- **Custom OAuth app** – Uses a customer-managed OAuth application. This option gives your organization full control over the OAuth configuration.
- **Service-to-Service OAuth** – Uses client credentials for server-to-server authentication without user interaction. Suitable for automated workflows.
- **API Key** – Uses an API key for authentication.

For more information about the authentication methods that Amazon Quick supports, see [the section called "Authentication methods"](#).

Before you begin

Make sure that you have the following before you set up the integration.

- An active ZoomInfo account with access to the data products you want to query.
- For **Custom OAuth app** or **Service-to-Service OAuth**: OAuth credentials from your ZoomInfo administrator. ZoomInfo uses Okta for OAuth.
- For **API Key**: A ZoomInfo-issued API key.
- For Amazon Quick subscription requirements, see [the section called "Set up integrations in the console"](#).

Configuring ZoomInfo

If you are using **Default OAuth app** authentication, skip this section and proceed to [the section called "Setting up the connector in Amazon Quick"](#).

For Custom OAuth app or Service-to-Service OAuth authentication, work with your ZoomInfo administrator to register an OAuth client in the ZoomInfo Okta tenant and add the Amazon Quick callback URL `https://{region}.quicksight.aws.amazon.com/sn/oauthcallback` as a redirect URI. Replace `{region}` with your AWS Region (for example, `us-east-1`). For step-by-step instructions, see [ZoomInfo MCP Overview](#) and [Developer Portal Guide](#) in the ZoomInfo documentation. Record the Client ID and Client Secret — you need them when you configure Amazon Quick. For API Key authentication, generate an API key from your ZoomInfo account.

Setting up the connector in Amazon Quick

Connect from the Available tab

If you want to use Default OAuth app authentication, you can connect directly from the **Available** tab without additional configuration.

1. In the Amazon Quick console, choose **Connectors**.
2. On the **Available** tab, find **ZoomInfo** and choose **Connect**.
3. Complete the ZoomInfo sign-in flow and grant the requested permissions.

To configure a connector with one of the other authentication methods, use the **Create for your team** tab as described below.

Create from the Create for your team tab

1. In the Amazon Quick console, choose **Connectors**.
2. Choose the **Create for your team** tab.
3. Find and choose **ZoomInfo**.
4. Enter a **Name** for your connector. Optionally, choose **+ Add Description** to add a description.
5. For **Connection type**, choose **Public network**.
6. For **OAuth Configuration**, choose one of the following authentication methods and configure the required fields.

a. For **Default OAuth app**:

No additional credentials are needed. Choose **Next** to continue.

b. For **Custom OAuth app**, configure the following fields:

- **Client ID** – The client ID from your ZoomInfo OAuth client.
- **Public OAuth client** (Optional) – Select this option if your ZoomInfo OAuth client is configured as a public client (no client secret).
- **Client secret** – The client secret from your ZoomInfo OAuth client.
- **Token URL** – The token endpoint. Default: `https://okta-login.zoominfo.com/oauth2/default/v1/token`
- **Authorization URL** – The authorization endpoint. Default: `https://okta-login.zoominfo.com/oauth2/default/v1/authorize`
- **Redirect URL** – Pre-filled with the Amazon Quick callback URL.

c. For **Service-to-Service OAuth**, configure the following fields:

- **Client ID** – The client ID from your ZoomInfo OAuth client.
- **Client secret** – The client secret from your ZoomInfo OAuth client.
- **Token URL** – The token endpoint. Default: `https://okta-login.zoominfo.com/oauth2/default/v1/token`

d. For **API Key**, configure the following fields:

- **API Key** – The ZoomInfo API key.

- **Email** (Optional) – The email address associated with the API key.
7. Choose **Next**.
 8. If you chose **Default OAuth app** or **Custom OAuth app**, a ZoomInfo authorization window opens. Review the requested permissions and choose **Allow**.
 9. On the **Review** page, review the available actions for the connector. Choose **Next**.
 10. On the **Publish** page, choose who can access the connector. You can enable access for everyone in your organization or search for specific teams or groups.
 11. Choose **Publish**.

Available actions

After you set up the connector, the actions exposed by ZoomInfo are available. To see the current set of actions for your connector, go to the connector's **Available actions** view in the Amazon Quick console.

Managing and troubleshooting

To edit, share, or delete your connector, see [the section called “Managing existing integrations”](#).

Authentication issues

- **Sign-in fails (Default OAuth app or Custom OAuth app)** – Verify that your ZoomInfo account is active. For Custom OAuth app, confirm that the redirect URI in your ZoomInfo OAuth client matches the Amazon Quick callback URL.
- **Invalid client credentials (Custom OAuth app or Service-to-Service OAuth)** – Verify that the Client ID and Client secret match the values in your ZoomInfo OAuth client.
- **API Key authentication fails** – Verify that the API key has not been revoked.

Support escalation path

If you cannot resolve an issue for an integration using the troubleshooting steps, follow this escalation path:

1. Gather diagnostic information:
 - Integration configuration details

- Error messages and timestamps
 - Steps to reproduce the issue
 - Environment details if applicable (Online vs. Server, version)
2. Check Amazon Quick service health and known issues in the console.
 3. Contact AWS Support through the Amazon Quick console or AWS Support Center.
 4. For complex authentication or permission issues, be prepared to involve your administrator.

Bring Your Own Amazon Q Business Index (BYOI)

Amazon Quick enables you to use your existing Amazon Q Business indexes as data sources. You can leverage your enterprise data without having to recreate indexes. This capability, known as Bring Your Own Index (BYOI), lets you connect your Amazon Q Business indexes to Amazon Quick and use them alongside other data sources for comprehensive analytics and intelligent responses.

BYOI supports two implementation methods:

IDC Implementation

Uses IAM Identity Center for authentication. Requires both Amazon Q Business and Amazon Quick to authenticate through IAM Identity Center in the same AWS account and region.

Non-IDC Implementation

Supports multiple authentication methods including native identities, AWS Managed Microsoft AD, and IAM federation. All Amazon Quick users automatically receive access to connected Amazon Q Business indexes.

Overview of Amazon Q Business indexes in Amazon Quick

Amazon Q Business indexes contain indexed enterprise data that you can now use directly in Amazon Quick. When you connect an Amazon Q Business index to Amazon Quick, it becomes available as a knowledge base. You can use it in spaces, agents, and automations, just like any other knowledge base in Amazon Quick.

Key benefits of using Amazon Q Business indexes in Amazon Quick include:

Leverage existing data investments

Use your existing Amazon Q Business indexes and indexed data directly in Amazon Quick. You don't need to recreate indexes or upload the same data again.

Unified analytics experience

Query across multiple data sources including Amazon Q Business indexes, uploaded documents, and structured data. Use Amazon Quick's unified analytical environment for all your data.

Consistent security and permissions

Amazon Q Business index knowledge bases in Amazon Quick maintain the same security and access controls as in Amazon Q Business. Users only see content they have permission to access.

Enhanced collaboration

Share Amazon Q Business index knowledge bases with other users in Amazon Quick, add them to spaces, and use them with agents and automations to create comprehensive business solutions.

Prerequisites

Before you can use Amazon Q Business indexes in Amazon Quick, ensure that you meet the following prerequisites:

Common Prerequisites

- You have an existing Amazon Q Business index with indexed data.
- Both the Amazon Q Business index and the Amazon Quick instance are in the same AWS account and region.
- You have administrator permissions in Amazon Quick.

IDC Implementation Prerequisites

- AWS Identity Center is enabled and configured.
- Both Amazon Q Business and Amazon Quick authenticate through IAM Identity Center.
- The IAM Identity Center region and Amazon Q Business index region are the same.
- You have access to both the Amazon Q Business index and AWS Identity Center administration.

Supported authentication methods

The authentication methods supported depend on your implementation type:

IDC Implementation

- Amazon Quick: AWS Identity Center authentication only
- Amazon Q Business: AWS_IAM_IDC

Non-IDC Implementation

- Amazon Quick:
 - Native identities (username/password)
 - AWS Managed Microsoft AD
 - IAM federation
- Amazon Q Business: AWS_QUICKSIGHT_IDP

Setting up permissions

To use Amazon Q Business indexes in Amazon Quick, you need to set up the appropriate permissions based on your implementation method:

Initial Setup

1. Sign in to the Amazon Quick console as an administrator.
2. Navigate to the **Admin** section.
3. Select **AWS Resources**.
4. Choose **Amazon Q Business** from the list of available data sources.
5. Choose **Select Applications**.

Application Setup

You can either connect to an existing Amazon Q Business application or create a new one:

1. Choose one of the following options:
 - **Connect to existing Amazon Q Business application** - Select an existing application from your account.
 - **Create new Amazon Q Business application** - Create a new application. The new application will use the same authentication used by your Amazon Quick instance setup.
2. For new applications, the system automatically configures authentication based on your Amazon Quick instance setup.
3. Wait for application creation to complete.
4. You will be redirected to the Amazon Q Business application to configure indexes and data sources.

Access Management by Implementation

IDC Implementation

- Access is managed through AWS Identity Center.
- Access to the Amazon Q Business application is managed through the Amazon Q Business console.

Non-IDC Implementation

- All Amazon Quick users automatically gain access to connected Amazon Q Business indexes.
- No additional access management required in Amazon Q Business.

Once permissions are set up, you can use your Amazon Q Business index as a knowledge base in Amazon Quick, and Admin users can create knowledge bases from Amazon Q Business indexes.

Creating knowledge bases from Amazon Q Business indexes

After setting up permissions, Admin or Admin Pro users can create knowledge bases from Amazon Q Business indexes:

1. Sign in to the Amazon Quick console as an Admin or Admin pro user.
2. Navigate to **Knowledge bases**.
3. Choose **Create knowledge base**.
4. Select **Amazon Q Business** as the data source.
5. Choose the Amazon Q Business index you want to use from the list of available indexes.
6. Provide a name and description for the knowledge base.
7. Choose **Create** to create the knowledge base.

Note

If multiple Admin users create knowledge bases from the same Amazon Q Business index, these knowledge bases will functionally be identical.

Sharing Amazon Q Business index knowledge bases

Users who have access to an Amazon Q Business index in Amazon Q Business will automatically have the corresponding knowledge base in Amazon Quick shared with them when it is created. The knowledge base can be shared with other users after creation, but only the user who created the knowledge base can share it with other users.

In an IDC implementation, any changes to the permissions in Amazon Q Business application after the creation of knowledge base will not take effect in Amazon Quick.

If you are an admin and want to share the knowledge base with other users in Amazon Quick:

1. Navigate to **Knowledge bases**.
2. Select the Amazon Q Business index knowledge base you want to share.
3. Choose **Share**.
4. Select the users or groups you want to share the knowledge base with.
5. Choose **Share** to confirm.

Using Amazon Q Business index knowledge bases

Once created, Amazon Q Business index knowledge bases can be used in Amazon Quick just like any other knowledge base:

Using in spaces

Admins can add Amazon Q Business index knowledge bases to spaces:

1. Navigate to the space where you want to add the knowledge base.
2. Choose **Add resources**.
3. Select **Knowledge bases**.
4. Choose the Amazon Q Business index knowledge base from the list.
5. Choose **Add** to confirm.

Using in output cards

Admins can use Amazon Q Business index knowledge bases via Spaces in output cards.

Using with agents

Admins can add Amazon Q Business index knowledge bases to custom agents:

1. Navigate to **Agents**.
2. Select an existing agent or create a new one.
3. In the agent configuration, choose **Add knowledge bases**.
4. Select the Amazon Q Business index knowledge base from the list.
5. Choose **Add** to confirm.

Using with automations

Admins can add Amazon Q Business index knowledge bases to automations:

1. Navigate to **Automations**.
2. Select an existing automation or create a new one.
3. In the automation configuration, add a step that uses knowledge bases.
4. Select the Amazon Q Business index knowledge base from the list.
5. Configure the step and save the automation.

Querying knowledge bases

Readers can query Amazon Q Business index knowledge bases through the Amazon Quick web application. However, a user will only be able to get a response from the Amazon Q Business index if they also have access to the Amazon Q Business application. To query the knowledge base:

1. Navigate to the Amazon Quick web application.
2. Select a space that contains the Amazon Q Business index knowledge base or use the default agent.
3. Enter your query in the chat interface.
4. View the response, which includes citations and clickable links to the source documents from the Amazon Q Business index.

Limitations

Note

In an IDC implementation, when a Amazon Q Business knowledge base is first created in Amazon Quick, access to the knowledge base is automatically granted to users with access to the selected Amazon Q Business index. For additional users to have access to a knowledge base, the admin must configure user access in both the Amazon Q Business console and Amazon Quick knowledge base permissions pages.

When using Amazon Q Business indexes in Amazon Quick, be aware of the following limitations:

General Limitations

- Amazon Q Business index knowledge bases cannot be changed like other knowledge bases in Amazon Quick.
- Amazon Q Business index knowledge bases only support the docs types supported by Amazon Q Business.
- QApps, Actions, and Amazon Q Business chat guardrails are not included in the BYOI capability.
- Amazon Q Business indexes must be in the same AWS account and region as Amazon Quick.

IDC Implementation Limitations

- Both Amazon Quick and Amazon Q Business must use the same instance of IAM Identity Center.

Index Quotas

- You can connect up to two Amazon Q Business indexes per Region to Amazon Quick in the current release.
- This quota cannot be increased.
- Once indexes are selected and saved in a Amazon Quick instance, they cannot be directly unselected.

Billing

When using Amazon Q Business indexes in Amazon Quick, billing works as follows:

IDC Implementation Billing

- You are billed for index and subscription costs in Amazon Q Business (recommended at least 1 user).
- You are billed for subscription costs in Amazon Quick based on your Amazon Quick user subscriptions.
- There are no additional charges for connecting Amazon Q Business indexes to Amazon Quick.

Non-IDC Implementation Billing

- No explicit Amazon Q Business subscription charges apply in this implementation model.
- You are billed for subscription costs in Amazon Quick based on your Amazon Quick user subscriptions.

For more information about Amazon Quick pricing, see [Amazon Quick pricing](#).

Feature comparison

The following table compares key features between IDC and Amazon Q Business implementations:

Feature	IDC Implementation	Non-IDC Implementation
User management	AWS Identity Center	Amazon Quick
Amazon Quick authentication methods	Identity Center Only	Native identities (username /password), AWS Managed Microsoft AD, IAM federation
Amazon Q Business authentication methods	AWS_IAM_IDC	AWS_QUICKSIGHT_IDP
Share permissions	Amazon Q Business Console and Knowledge base permissions page	Amazon Quick Knowledge Base Permission page (Automatic)
Index compatibility	All indexes	All indexes

Troubleshooting

Amazon Q Business not seen in Integrations page

Symptoms

- Amazon Q Business option missing from Integrations page
- Cannot create new Amazon Q Business integration

Resolution

- Only Admin users have access to create a Amazon Q Business/BYOI knowledge base
- Verify user has Admin persona permissions

Failed to fetch Amazon Q Business applications

Resolution

- Confirm Amazon Q Business is enabled in the Admin console
- Try logging out and back in to refresh the session, then retry the operation

Amazon Q Business application not seen in the list of applications displayed during knowledge base creation

Symptoms

- Amazon Q Business applications list is empty on Create Knowledge Base page
- Amazon Q Business applications list is populated but missing expected applications

Resolution

- Check if missing Amazon Q Business applications were granted permissions in the AWS resources page of the Admin console

Failed to create dataset. Chat instance is not ready. Please try again later

Symptoms

- Knowledge base creation fails with error "Chat instance is not ready. Please try again later"
- Unable to complete knowledge base creation process

Resolution

- If this is the first time creating a knowledge base in Amazon Quick, wait 5 minutes and retry the operation

Security best practices

- Regularly review access permissions
- Monitor user activities
- Implement least-privilege access
- Maintain authentication method security

User types and capabilities

Different user types have different capabilities when working with Amazon Q Business indexes in Amazon Quick:

Amazon Q Business Administrator

Manages Amazon Q Business indexes in the Amazon Q Business console.

Amazon Quick Administrator

Enables permissions for Amazon Quick to access Amazon Q Business indexes in the same AWS account and region.

Amazon Quick Admin

Creates knowledge bases from Amazon Q Business indexes, shares them with other users, and adds them to spaces.

Amazon Quick Admin

Creates agents and automations that leverage Amazon Q Business index knowledge bases.

Amazon Quick Reader

Uses agents and automations that leverage Amazon Q Business index knowledge bases, and queries these knowledge bases through the Amazon Quick web application.

Common use cases

Here are some common use cases for using Amazon Q Business indexes in Amazon Quick:

Finding relevant information

Query about specific topics across your enterprise data, such as HR policies, support documentation, or compliance guidelines.

Example: "What is the maternity leave policy for my company in Washington state?" where national guidelines are in an Amazon Q Business index and state-specific information is in Amazon Quick.

Business analytics and insights

Extract key findings from status updates across multiple groups or analyze the health of your product portfolio.

Example: "Analyze the health of my product portfolio" where product sales data is in an Amazon Q Business index, and product engineering and support data is in Amazon Quick.

Content creation and summarization

Create summaries or reports based on documents from multiple sources.

Example: "Summarize last week's Service WBR and Sales update into a one-pager reflecting key initiatives" where the Service WBR is indexed in an Amazon Q Business index and the latest sales update is uploaded to Amazon Quick.

Interacting with your Amazon Q Business indexes

Once you've connected your Amazon Q Business index to Amazon Quick, you can interact with it through chat using agents.

1. From the left navigation menu in the console, select **Agents**.
2. From the **Actions** column for the agent you want to share, select the menu icon, and then select **Chat**.
3. You can then narrow down the resource to just the Knowledge Base created from the Amazon Q Business index by selecting the All Resources option and clicking on your Amazon Q Business index from the Knowledge Bases sub-tab.

When you ask questions, the agent analyzes data from your Amazon Q Business index alongside other data sources to provide comprehensive responses.

You can ask complex questions in plain language about your enterprise data and get detailed responses that draw from your Amazon Q Business index's indexed content. The chat interface allows you to:

- Query your enterprise data using natural language
- Get contextual responses that combine data from your Amazon Q Business index with other Amazon Quick data sources
- View source citations with clickable references to see where information originated
- Continue conversations and build on previous queries

For detailed information about using the chat interface and working with agents, see [the section called "Use a chat agent"](#).

Bring your own Amazon Bedrock managed knowledge base

Amazon Quick can connect Amazon Bedrock managed knowledge bases as knowledge sources. After connection, a managed knowledge base is treated like any other knowledge base in Amazon Quick. You can add it to spaces and it is queried automatically during chat. You can connect up to 2 managed knowledge bases per Amazon Quick instance. The managed knowledge base can live in the same AWS account as Amazon Quick or in a different account.

Topics

- [Prerequisites](#)
- [Setting up permissions](#)
- [Creating knowledge bases from Amazon Bedrock managed knowledge bases](#)
- [Access control list \(ACL\) support](#)
- [Billing](#)
- [Limitations](#)
- [Security best practices](#)
- [Monitoring and observability](#)
- [Troubleshooting](#)

Prerequisites

- A Amazon Bedrock managed knowledge base that has been created and configured. For more information, see [Build a managed knowledge base](#) in the *Amazon Bedrock User Guide*.
- The managed knowledge base and the Amazon Quick instance are in the same AWS Region.
- Administrator-level permissions in Amazon Quick to manage AWS resource integrations.
- For cross-account setups: the ability to attach a resource policy to the knowledge base, or coordination with the knowledge base owner to attach the policy.

Setting up permissions

Amazon Quick authenticates to Amazon Bedrock using IAM SigV4 credentials via the Amazon Quick service role. The service role requires the following actions on the knowledge base:

- `bedrock:Retrieve`
- `bedrock:GetDocumentContent`

The following example shows the ARN format for Amazon Bedrock managed knowledge bases:

```
arn:aws:bedrock:REGION:ACCOUNT_ID:knowledge-base/KB_ID
```

Cross-account setup

Cross-account access is required when the managed knowledge base is owned by a different AWS account than the one running your Amazon Quick instance. For example, a central data team might own the knowledge base in one account while your Amazon Quick instance runs in a separate account.

In this case, you must attach a resource policy to the knowledge base in the owner's account before granting the service role access. The resource policy authorizes the Amazon Quick service role to call the knowledge base across account boundaries.

The following resource policy example grants the Amazon Quick service role permission to access your managed knowledge base. Replace the placeholder values with your specific account IDs, Region, and knowledge base ID:

```
{
```

```
"Version": "2012-10-17",
"Statement": [
  {
    "Effect": "Allow",
    "Principal": {
      "AWS": "arn:aws:iam::QUICK_ACCOUNT_ID:role/service-role/aws-quicksight-
service-role-v0"
    },
    "Action": [
      "bedrock:Retrieve",
      "bedrock:GetDocumentContent"
    ],
    "Resource": "arn:aws:bedrock:REGION:KB_OWNER_ACCOUNT_ID:knowledge-
base/KB_ID"
  }
]
```

See [Share a managed knowledge base across accounts](#) in the *Amazon Bedrock User Guide*.

Granting the service role access

For both same-account and cross-account setups, grant the Amazon Quick service role access to the managed knowledge base through the admin console:

1. Sign in to the Amazon Quick console as an administrator.
2. Navigate to **Manage account > AWS Resources > Bedrock**.
3. Add your managed knowledge base ARN to the Amazon Quick service role using the provided form. Amazon Quick attaches the necessary IAM policy to the service role, scoped to the entered ARN.

Creating knowledge bases from Amazon Bedrock managed knowledge bases

This topic shows you how to create a knowledge base in Amazon Quick from an existing Amazon Bedrock managed knowledge base. After completing the permission setup, administrators can use this procedure to integrate the managed knowledge base into Amazon Quick.

To create a knowledge base from an Amazon Bedrock managed knowledge base

1. Sign in to the Amazon Quick console as an administrator.
2. Navigate to **Knowledge bases > Set up new knowledge base**.
3. Select **Amazon Bedrock managed knowledge base** as the source type.
4. Complete the form and choose **Create**.

After creation, the managed knowledge base is available in Amazon Quick and can be added to spaces, agents, and automations.

Access control list (ACL) support

Amazon Bedrock managed knowledge bases with ACL-enabled data source connectors support document-level access control. When a user queries the knowledge base, Amazon Quick automatically passes the user's identity to Amazon Bedrock. Amazon Bedrock then filters retrieval results so that users only see documents they are authorized to access in the original data source.

No additional configuration is required in Amazon Quick to enable ACL support. The access control rules are configured on the Amazon Bedrock managed knowledge base data source connectors. See [Connect a data source](#) in the *Amazon Bedrock User Guide*.

Billing

The knowledge base owner is charged for Amazon Bedrock usage costs, including retrieval requests and data ingestion. Amazon Quick subscription costs are billed separately based on your Amazon Quick user subscriptions. There are no additional charges from Amazon Quick for connecting an Amazon Bedrock managed knowledge base.

Limitations

- This feature is available in the following AWS Regions: US East (N. Virginia), US West (Oregon), Europe (Ireland), and Asia Pacific (Sydney).
- You can connect up to 2 managed knowledge bases per Amazon Quick instance.
- The managed knowledge base and Amazon Quick instance must be in the same AWS Region.
- Only Amazon Bedrock managed knowledge bases are supported. Custom knowledge bases with self-managed vector stores are not supported.
- Cross-account access requires a resource policy on the knowledge base.

Security best practices

- Use cross-account resource policies with specific role ARNs rather than granting access to entire accounts.
- Regularly review the resource policies attached to your managed knowledge bases.
- Monitor access patterns and review audit logs regularly.

Monitoring and observability

Amazon Bedrock emits AWS CloudTrail data events for Retrieve and GetDocumentContent API calls on your managed knowledge base. You can use these events to monitor successful usage and detect access failures. The following walkthrough sets up a CloudTrail trail that delivers data events to a Amazon CloudWatch Logs log group, then creates metric filters and alarms to alert on errors.

Step 1: Enable CloudTrail to Amazon CloudWatch for Amazon Bedrock knowledge base events

Set up a CloudTrail trail that captures Amazon Bedrock knowledge base data events and delivers them to a Amazon CloudWatch Logs log group. Create the trail and log group in the same Region as your managed knowledge base. You can also do this through the CloudTrail console, which creates the log group and IAM role automatically.

Create the S3 bucket, apply a bucket policy that allows CloudTrail to write, and create the Amazon CloudWatch Logs log group:

```
aws s3 mb s3://YOUR_TRAIL_BUCKET

aws s3api put-bucket-policy --bucket YOUR_TRAIL_BUCKET --policy '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {"Service": "cloudtrail.amazonaws.com"},
      "Action": "s3:GetBucketAcl",
      "Resource": "arn:aws:s3:::YOUR_TRAIL_BUCKET"
    },
    {
      "Effect": "Allow",
      "Principal": {"Service": "cloudtrail.amazonaws.com"},
```

```

    "Action": "s3:PutObject",
    "Resource": "arn:aws:s3:::YOUR_TRAIL_BUCKET/AWSLogs/ACCOUNT_ID/*",
    "Condition": {"StringEquals": {"s3:x-amz-acl": "bucket-owner-full-control"}}
  }
]
}'

```

```
aws logs create-log-group --log-group-name bedrock-kb-cloudtrail
```

Create an IAM role that allows CloudTrail to deliver logs to the log group:

```

aws iam create-role \
  --role-name CloudTrail-CWLogs-Role \
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [{
      "Effect": "Allow",
      "Principal": {"Service": "cloudtrail.amazonaws.com"},
      "Action": "sts:AssumeRole"
    }]
  }'

aws iam put-role-policy \
  --role-name CloudTrail-CWLogs-Role \
  --policy-name CWLogsPolicy \
  --policy-document '{
    "Version": "2012-10-17",
    "Statement": [{
      "Effect": "Allow",
      "Action": ["logs:CreateLogStream", "logs:PutLogEvents"],
      "Resource": "arn:aws:logs:REGION:ACCOUNT_ID:log-group:bedrock-kb-cloudtrail:*"
    }]
  }'

```

Create the trail, configure it to capture Amazon Bedrock knowledge base data events, and start logging:

```

aws cloudtrail create-trail \
  --name bedrock-kb-data-events \
  --s3-bucket-name YOUR_TRAIL_BUCKET \
  --cloud-watch-logs-log-group-arn "arn:aws:logs:REGION:ACCOUNT_ID:log-group:bedrock-kb-cloudtrail:*" \
  --cloud-watch-logs-role-arn "arn:aws:iam::ACCOUNT_ID:role/CloudTrail-CWLogs-Role"

```

```
aws cloudtrail put-event-selectors \
  --trail-name bedrock-kb-data-events \
  --advanced-event-selectors '[{
    "Name": "BedrockKBDataEvents",
    "FieldSelectors": [
      {"Field": "eventCategory", "Equals": ["Data"]},
      {"Field": "resources.type", "Equals": ["AWS::Bedrock::KnowledgeBase"]}
    ]
  }]'

aws cloudtrail start-logging --name bedrock-kb-data-events
```

Step 2: Create metric filters for Amazon Quick retrieval calls

Create metric filters to track retrieval calls and errors when Amazon Quick invokes your managed knowledge base.

Call volume metric — tracks retrieval call volume to your managed knowledge base.

```
aws logs put-metric-filter \
  --log-group-name bedrock-kb-cloudtrail \
  --filter-name QuickSight-Retrieve-CallCount-KB_ID \
  --filter-pattern '{ $.eventSource = "bedrock.amazonaws.com" && $.eventName
= "Retrieve" && $.userIdentity.invokedBy = "quicksight.amazonaws.com" &&
$.resources[0].ARN = "*KB_ID*" }' \
  --metric-transformations '[{
    "metricName": "RetrieveCallCount",
    "metricNamespace": "QuickSight/BedrockKB",
    "metricValue": "1",
    "dimensions": {"KnowledgeBaseId": "$.resources[0].ARN"}
  }]'
```

Error metric — the following example counts Retrieve calls from Amazon Quick that fail with `AccessDenied`. This alarm fires when the Amazon Quick service role is missing permissions or when a cross-account resource policy is misconfigured. You can create additional metric filters for other error codes such as `ThrottlingException` depending on your monitoring needs.

```
aws logs put-metric-filter \
  --log-group-name bedrock-kb-cloudtrail \
  --filter-name QuickSight-Retrieve-AccessDenied-KB_ID \
```

```
--filter-pattern '{ $.eventSource = "bedrock.amazonaws.com" && $.eventName
= "Retrieve" && $.userIdentity.invokedBy = "quicksight.amazonaws.com" &&
$.resources[0].ARN = "*KB_ID*" && $.errorCode = "AccessDenied" }' \
--metric-transformations '[{
  "metricName": "RetrieveAccessDeniedCount",
  "metricNamespace": "QuickSight/BedrockKB",
  "metricValue": "1",
  "dimensions": {"KnowledgeBaseId": "$.resources[0].ARN"}
}]'
```

Step 3: Create a CloudWatch alarm

Create an alarm that triggers when access denied errors occur. Optionally add an SNS topic ARN to `--alarm-actions` for notifications.

```
aws cloudwatch put-metric-alarm \
  --alarm-name QuickSight-Retrieve-AccessDenied-KB_ID \
  --metric-name RetrieveAccessDeniedCount \
  --namespace "QuickSight/BedrockKB" \
  --dimensions Name=KnowledgeBaseId,Value="arn:aws:bedrock:REGION:ACCOUNT_ID:knowledge-
base/KB_ID" \
  --statistic Sum \
  --period 300 \
  --threshold 1 \
  --comparison-operator GreaterThanOrEqualToThreshold \
  --evaluation-periods 1 \
  --treat-missing-data notBreaching
```

Troubleshooting

Troubleshoot access denied errors

When you query an Amazon Bedrock managed knowledge base in Amazon Quick, retrieval is authorized only when every permission layer allows it. If you receive the error *Insufficient permissions to access this knowledge base*, work through the following layers in order and stop at the first layer that is not satisfied.

Tip

First, check AWS CloudTrail for the AccessDenied event to identify which principal and action were rejected. Then go directly to the matching layer in the following list.

1. **Service role permissions.** Confirm that the Amazon Quick service role grants `bedrock:Retrieve` and `bedrock:GetDocumentContent` on the knowledge base.
2. **Cross-account resource policy.** For cross-account setups, confirm that the knowledge base resource policy grants those same actions to the Amazon Quick service role.
3. **Customer managed key.** If the knowledge base is encrypted with a customer managed key, confirm that the service role has `kms:Decrypt` and `kms:DescribeKey` on that key.
4. **Knowledge base ARN.** Confirm that the knowledge base ARN is correct in the Amazon Quick admin configuration. Amazon Quick scopes the service role policy to the ARN you enter, so an incorrect ARN denies retrieval.
5. **IAM policy assignments.** If IAM policy assignments are enabled in the account, Amazon Quick applies a per-user session policy at retrieval time and intersects it with the service role permissions. An action succeeds only if both the service role and the user's assigned IAM policy allow it. Check this layer when the knowledge base works for an administrator but fails for a specific user or group.

To grant retrieval permissions to affected users

1. Open the [Quick console](#).
2. Choose **Manage account**, and then choose **IAM policy assignments**.
3. Create a new assignment, or edit the IAM policy behind an existing assignment, to allow the knowledge base retrieval actions. For example:

```
{
  "Sid": "AllowQuickFMKBRetrieve",
  "Effect": "Allow",
  "Action": ["bedrock:Retrieve", "bedrock:GetDocumentContent"],
  "Resource": "arn:aws:bedrock:REGION:ACCOUNT_ID:knowledge-base/KB_ID"
}
```

4. Add the affected users or groups to the assignment, and then save and enable it.

For more information about IAM policy assignments, see [the section called “IAM policy assignments”](#).

Connect Amazon Quick to your existing tools with extensions

Note

The Amazon Quick browser extension, Microsoft Outlook extension, Microsoft Word extension, Microsoft Excel extension, and Microsoft PowerPoint extension don't require admin setup to install and use. For the Slack and Microsoft Teams extensions, your Quick admin must [configure Amazon Quick access](#) before authors can deploy them.

Amazon Quick extensions enable you to optimize your daily tasks with assistance from an AI tool added to the tools you already use. Whether you're browsing the web, collaborating in team channels, managing emails, or creating documents, Quick extensions bring AI-powered assistance directly into your existing workflows without requiring you to switch between applications.

The following extension types are available:

- **Browser Extension** - Enhance your web browsing experience with AI-powered page summarization, content analysis, and knowledge access across Google Chrome, Firefox, and Microsoft Edge browsers. No admin setup required.
- **Microsoft Outlook extension** - Manage your entire inbox using natural language. Summarize unread messages, organize your inbox, schedule meetings, and draft contextual responses using your Quick enterprise data. No admin setup required.
- **Microsoft Excel extension** - Perform in-depth analysis of your workbooks, import and clean up data, generate tables and charts, and automate spreadsheet operations using natural language. No admin setup required.
- **Microsoft Word extension** - Generate formatted documents, make edits while maintaining writing style and structure, and redline documents with track changes and comments. No admin setup required.
- **Microsoft PowerPoint extension** - Create visually appealing presentations, edit slides using natural language, and streamline operations such as restructuring presentations and applying transitions. No admin setup required.

- **Slack extension** - Access Quick capabilities directly within Slack channels and direct messages, enabling seamless collaboration and knowledge sharing without leaving your team communication platform. Requires admin to configure extension access.
- **Microsoft Teams extension** - Integrate Quick into your Teams workspace for real-time collaboration, thread analysis, and knowledge retrieval during meetings and conversations. Requires admin to configure extension access.

Each extension maintains enterprise-grade security and privacy standards while providing contextual AI assistance tailored to the specific application environment. All extensions integrate with your organization's Quick knowledge bases, custom agents, and configured data sources to provide relevant, accurate responses based on your permissions and access levels.

Amazon Quick user interaction with extensions

Amazon Quick extensions enable different user roles to collaborate effectively in creating, managing, and utilizing AI-powered analytics tools. Each role—administrators, authors, and end users—has distinct responsibilities and capabilities when working with extensions. Understanding these role-based interactions ensures proper governance, security, and optimal user experience across your organization's Amazon Quick deployment.

Topics

- [User capabilities and permissions](#)
- [Amazon Quick administrator responsibilities](#)
- [Amazon Quick author capabilities](#)

- [Amazon Quick end user access](#)
- [Extension access troubleshooting](#)

User capabilities and permissions

Amazon Quick implements a hierarchical permission model for extensions that balances organizational control with user productivity. Administrators establish the foundational policies and infrastructure, authors manage the deployment and configuration of specific extension instances, and readers benefit from the AI-powered assistance within their authorized scope. The following table shows how each user type in Amazon Quick interacts with extensions.

User Type	Capabilities
Administrators	• Enable/remove extension access to their organization's workspaces and organizations • Create extensions for Slack, Teams, Word, and Outlook • Assign owners for extensions created • Control whether extensions are available for users in Amazon Quick • Use all enabled extensions
Authors	• Create and install extensions using administrator enabled extension access • Edit/delete extensions for which they are owners • Use all enabled extensions
Readers (Reader Pro only)	• Use all enabled extensions

Beyond the broad user type categories, Amazon Quick implements granular permission controls that determine specific actions users can perform with individual extensions. These permissions operate independently of user types, allowing administrators to fine-tune access based on organizational needs and security requirements. The following table outlines how user permissions determine what you can do with a extension:

Permissions Type	Permissions
Owners	• Edit extension name and description • Install the extension in a workspace or organization • Grant ownership and editing permissions to specific users and groups
Viewers	• View extension name and description • Access links to open in Slack, M365, and browser • Use the extensions

Important

The Amazon Quick browser extension extension doesn't need any admin setup to install and use.

These permission structures ensure that extension access aligns with your organization's security requirements while enabling appropriate levels of functionality for each user role. Administrators maintain control over extension availability and initial setup, authors handle deployment and configuration, and all users can benefit from the AI-powered assistance once extensions are properly configured.

Amazon Quick administrator responsibilities

Amazon Quick administrators, or users granted admin privileges, establish the foundational infrastructure that enables extension functionality across the organization. They handle the critical setup and security configurations that allow Amazon Quick authors to deploy extensions and end users to access them safely.

Note

Creating and adjusting extension access requires IAM administrator privileges. All administrators will see the extension links, but if not [signed in with IAM credentials](#), you will need to sign in with appropriate IAM permissions to manage extension access. This must be an IAM user who is an Amazon Quick administrator and not non-IAM admin users.

Responsibility area	Administrator capabilities
Infrastructure setup	• Connect extension applications to organizational systems (Slack workspaces, Microsoft 365 tenants) • Handle OAuth authorization and tenant-level permissions • Manage platform-specific installation methods: manifest-only for Word/Outlook, OAuth-only for Slack/Teams
Security and compliance	• Manage enterprise security and compliance settings • Control which extension types are available to the organization

Amazon Quick author capabilities

Authors bridge the gap between administrative infrastructure and end-user access by creating, configuring, and deploying specific extension instances. They manage the day-to-day operational aspects of extension deployment and maintenance.

Author capabilities depend on the permission level granted by administrators. There are two permission types that determine what authors can do:

- **Viewers:** Can view extension name and description, access links to open extensions, and use the extensions.
- **Owners:** Can edit extension name and description, install extensions in workspaces or organizations, and share ownership permissions with users and groups.

This translates to two main setup flows:

- **Limited permissions (view, share, delete only):** Authors can only use the basic landing page functionality to view, share, and delete extensions after admin completes all setup.
- **Full permissions (deploy, view, share, delete, edit):** Authors can download manifests or use OAuth deployments to complete app setup, rename extensions, and access editing features.

Capability area	Author functions
Configuration and deployment	• Download and manage installation manifests for deployment (with full permissions) • Deploy extension instances using OAuth or manifest-based methods (with full permissions) • Complete app setup and installation (with full permissions)
Management and sharing	• Manage extension sharing and access permissions • View, share, and delete deployed extensions • Edit extensions and access creation features (with full permissions)

Amazon Quick end user access

End users represent the primary beneficiaries of extension functionality, accessing AI-powered assistance directly within their existing workflow applications. Their interaction with extensions focuses on daily productivity and seamless integration with organizational knowledge.

Access level	User capabilities
Daily usage and productivity	• Access extensions directly within existing workflow applications • Use extensions for knowledge access, document analysis, and action taking • Benefit from seamless integration without context switching between applications
Knowledge and actions	• Access organizational knowledge bases and custom agents through extension interfaces • Perform external actions in third-party applications using configured action connectors • Receive permissions-aware responses based on individual access levels

The following table shows how each user type in Amazon Quick interacts with extensions.

User Type	Capabilities
Administrators	• Enable/remove extension access to their organization's workspaces and organizations • Create extensions for Slack, Teams, Word, and Outlook • Assign owners for extensions created • Control whether extensions are available for users in Amazon Quick • Use all enabled extensions
Authors	• Create and install extensions using administrator enabled extension access • Edit/delete extensions for which they are owners • Use all enabled extensions
Readers (Reader Pro only)	• Use all enabled extensions

The following table outlines how user permissions determine what you can do with a extension:

Permissions Type	Permissions
Owners	• Edit extension name and description • Install the extension in a workspace or organization • Grant ownership and editing permissions to specific users and groups
Viewers	• View extension name and description • Access links to open in Slack, M365, and browser • Use the extensions

 Important

The Amazon Quick browser extension extension doesn't need any admin setup to install and use.

Extension access troubleshooting

If you encounter issues accessing or creating extensions:

- **Cannot create extensions:** Your IAM user who is a Amazon Quick administrator must first configure extension access for the extension type you want to use. Other administrators will not be able to create/edit/delete extension access.
- **Cannot find my extensions:** Check that extension access has been configured by your administrator and that you have the appropriate permissions to view extensions.
- **Extensions appear but cannot edit:** You have view-only access. Ask your administrator or extension owner to share edit permissions with you.
- **No extensions visible:** Contact your administrator to set up extension access and create default extensions for your organization.

Amazon Quick browser extension

Important

The Amazon Quick browser extension extension doesn't need any admin setup to install and use.

The Amazon Quick browser extension integrates AI-powered assistance directly into your web browsing experience. Users can access Quick capabilities within their browser to enhance productivity, streamline research, and get instant help without switching between applications.

Key capabilities include:

- Summarize web pages for quick understanding.
- Ask questions about multiple web pages and access organizational knowledge from spaces.
- Use actions from [connectors](#) configured in Quick.
- Analyze files uploaded to Quick during browsing sessions.

The AI-powered assistance enables you to maximize reading productivity, streamline research and analysis of complex information, and get instant help when creating content without context switching during web browsing.

- [Install and configure the browser extension](#)
- [Deploy the browser extension in your organization](#)
- [Browser extension usage guidelines](#)
- [Browser extension known limitations](#)
- [Using Amazon Quick Flows in the browser extension](#)

Supported browsers

The Quick browser extension is compatible with the following browsers:

- Google Chrome
- Mozilla Firefox
- Microsoft Edge

Browser extension benefits

The Quick browser extension provides powerful AI-driven capabilities that transform how you interact with web content. These key benefits help you work more efficiently and make better use of information you encounter while browsing, bringing enterprise knowledge directly into your web research workflows without requiring application switching.

Embedded productivity features

- Summarize a snapshot of any web page for quick understanding and analysis.
- Ask questions about one or more web pages using your organizational knowledge.
- Analyze both files you upload to Quick and specific spaces it can access.
- Execute actions from configured connectors without leaving your browser.

Browser extension use cases

The following are common use cases that help you make the best use of your Quick browser extension:

Summarize web pages

Use this procedure to quickly understand web page content without reading the entire page.

1. Open the Quick browser extension.
2. Log in and navigate to the web page you want to summarize.
3. From the chat interface, select **Summarize** for a summary of a snapshot of that web page.

Your conversation now contains a snapshot of this web page. You can continue to chat about the web page and ask follow-up questions.

Add individual pages to your conversation scope

Use this procedure to include multiple web pages in your conversation context for comprehensive analysis.

1. Navigate to the web page you want to add to your conversation.
2. Select the **+** icon to add the page to your scope.
3. Navigate from tab to tab and select the **+** icon for each page you want to chat about.
4. You can now chat about all the pages you've added to your scope.

This allows you to analyze and compare information across multiple web pages in a single conversation.

Add files to a conversation

Upload files to enhance your conversation with document analysis capabilities.

1. Select the **paperclip** icon.
2. Select the files to add to the conversation.
3. Select **Add to chat**.

The files are now available to use in the Quick conversation.

Add webpages as context to a conversation

Include multiple browser tabs in your conversation for comprehensive web content analysis.

1. Select **No tabs selected**.
2. From **Add tabs**, choose the tabs you want to include in your Quick conversation.
3. Select **Confirm**.

The tabs are now available in your Quick conversation.

Reset conversation context

Start fresh when you need to clear your current conversation context.

1. Select the **+ icon inside the bubble** to start a new conversation.
2. Alternatively, you can reset your conversation by selecting the **X** icon to end the current conversation and then open the Quick extension to start a new conversation.

This clears all previous context and allows you to begin with a clean slate.

Use actions in chat

Execute external actions directly from your browser extension conversation.

1. Ask the chat to perform a specific action.
2. Follow the prompts in the chat and on-screen to complete the action.

This enables you to perform tasks in external applications without leaving your browser.

Install and configure the browser extension

As a user, you can install and configure the browser extensions with the following steps.

- Mozilla based browsers — [Mozilla Firefox Add-ons web store](#)
- Chromium based browsers (including Microsoft Edge) — [Chrome Web Store](#)

Once you have successfully logged on, you can use your Quick browser extension.

Note

You can also **pin** your Quick browser extension to have it readily accessible while using your browser. Instructions for this are specific to your browser of choice. The following third-party information about pinning extensions might be helpful.

- Google Chrome — <https://www.howtogeek.com/683099/how-to-pin-and-unpin-extensions-from-the-chrome-toolbar>
- Mozilla Firefox — https://support.mozilla.org/en-US/kb/extensions-button#w_manage-pinned-extensions
- Microsoft Edge — <https://www.microsoft.com/en-us/edge/features/pin-to-taskbar>

Deploy the browser extension in your organization

As an author, after enabling the browser extension in your Quick application, you can deploy it across your organization using enterprise management tools and policies.

For Google Chrome Enterprise environments, you can use organizational unit policies to manage extension deployment. The Chrome Web Store for Enterprise provides additional deployment options specifically designed for organizational use. Mozilla Firefox Enterprise offers similar capabilities through policy templates and enterprise distribution methods that allow for automated extension deployment across the organization. Microsoft Edge Enterprise provides policy settings for managing extensions through mobile device management (MDM) software.

Policy settings from browser vendors: [Firefox](#), [Chrome](#), and [Edge](#).

Deploy to Google Chrome Enterprise

Follow these steps to deploy the browser extension across your Chrome Enterprise environment.

1. Access your Google Admin console and navigate to the Chrome management section.
2. Configure extension policies using organizational units to target specific user groups or departments.
3. Use the [Chrome extension management guide](#) to set up automated installation policies.
4. Reference the [Chrome Web Store Enterprise documentation](#) for advanced deployment configurations.

The extension will now be automatically installed for all users in your Chrome Enterprise environment.

Deploy to Mozilla Firefox Enterprise

Use these steps to deploy the extension across your Firefox Enterprise environment.

1. Configure Firefox deployment policies using the enterprise policy framework.
2. Follow the [Firefox extension deployment guide](#) for step-by-step instructions.
3. Use the [enterprise distribution documentation](#) to configure organization-wide deployment.
4. Apply extension settings using [Mozilla policy templates](#) for centralized configuration management.

The extension is now deployed across your Firefox Enterprise environment with centralized management.

Deploy to Microsoft Edge Enterprise

Deploy the extension to Microsoft Edge Enterprise using these organizational deployment steps.

1. Install the browser extension for all users using the software deployment processes of your organization.
2. Configure extension settings using [Edge policy settings](#) through mobile device management (MDM) software.
3. Follow the [Microsoft Edge extension management guide](#) for detailed deployment instructions.

Your Microsoft Edge Enterprise deployment is complete with centralized policy management.

Browser extension usage guidelines

As a user, you are responsible for keeping company information safe. The following guidelines help you use Quick browser extensions securely while maintaining data privacy and compliance.

Using the browser extension

When using the Quick browser extension, users can review past conversations and attachments to maintain context across browsing sessions.

Conversation retention and data privacy

Amazon Quick maintains strict data privacy through automated retention policies:

- Amazon Quick automatically deletes conversations and related files after 30 days of inactivity.
- Browser extension conversation retention follows your company's specific history rules.
- Browser extension retention periods may exceed Amazon Quick's standard 30-day limit based on organizational policies.

Browser extension known limitations

The following are known limitations of the Amazon Quick browser extension:

- The browser extension supports up to a total of 20 web pages and uploaded files at a time. For more information, see [Upload files and chat](#).

Using Amazon Quick Flows in the browser extension

Amazon Quick Flows in the browser extension enables you to run pre-defined workflows directly within your web browsing context. You can invoke flows that you've created or that have been shared with you, pass web page content as input, and execute multi-step workflows without leaving your browser.

When you use flows in the browser extension, you can:

- Invoke flows explicitly from the browser extension interface.
- Pass web pages as context to your flows.
- View flow execution history in your browser extension.

Prerequisites

Before using flows in the browser extension, ensure you have:

- Appropriate permissions to execute flows in your Amazon Quick account.

Invoking flows

You can invoke flows from the browser extension to run workflows on the web pages you're viewing.

To invoke a flow in the browser extension:

1. Open the Amazon Quick browser extension.
2. In the chat interface, choose the **Flows** icon.
3. Select a flow from the list or use the search bar to search through your flows.
4. The flow begins execution in the browser extension chat.
5. When prompted, select the tab you want to include as context and choose **Confirm**.

When a flow is active, the browser extension displays a progress tracker showing the current step. The dropdown menu on the progress tracker shows all steps in the flow.

Flow execution process

Once a flow is invoked in your browser extension, you interact with the flow through natural language chat as follows:

1. You're greeted with a summary of its capabilities.
2. You're prompted for required inputs through chat messages.
3. The extension displays outputs and results in the chat interface.
4. The extension shows a progress tracker indicating completed and remaining steps.

To view flow capabilities, see the [flows documentation](#).

Flow execution history

All flow executions in the browser extension are recorded in your conversation history. You can view past executions and resume incomplete flows. To view flow execution history:

1. In the browser extension, go to menu and choose the **Conversation history** icon.
2. Select a conversation that includes a flow execution.
3. The conversation displays the flow execution details, including all inputs and outputs.

If you closed the browser extension while a flow was running, you can resume the flow by selecting it from your history.

Stopping flow execution

You can stop a flow at any time during execution. To stop a running flow:

1. While the flow is running, choose the **End** button in the progress tracker.
2. The flow stops at the current step and you can continue your conversation with your My Assistant or Chat agent.

Amazon Quick Microsoft Outlook extension

The Amazon Quick extension for Outlook helps you manage your entire inbox using natural language. You can summarize unread messages, organize your inbox, schedule meetings, and draft responses, all without leaving Outlook.

You can search for Amazon Quick in the Microsoft Outlook app store or visit the [Quick for Outlook Microsoft store page](#) to add the extension.

Key capabilities include:

- **Inbox management:** Summarize and prioritize your unread emails, search for specific emails or discussions using natural language queries, and organize your inbox by moving emails to folders, flagging messages for follow-up, and more.
- **Calendar and meeting management:** Summarize your calendar, find optimal meeting times with coworkers, and schedule meetings using natural language instructions.
- **Email summaries and replies:** Open the Quick side panel to ask questions about an email thread in focus or generate a contextual reply.
- **Enterprise knowledge integration:** Use Quick's knowledge sources to draft contextual responses to emails or to perform inbox and calendar tasks.
- **External actions:** Perform actions in third-party applications using your configured [connectors](#) or apps directly from Outlook.

⚠ Important

- The Amazon Quick Outlook extension uses generative AI to create and execute code within your Outlook application sandbox. AI can make mistakes and perform inaccurate actions within your Outlook mailbox. No email or content is read when the side panel is closed, and no data is sent to Amazon Quick unless you explicitly send a prompt.
- Amazon Quick does not use your user data for service improvement or for training its underlying large language models (LLMs).

ℹ Note

Some features, such as inbox prioritization, calendar management, and email organization, require Microsoft Graph API permissions that must be granted by your administrator. If you are unable to perform these tasks, contact your administrator to ensure the required Graph API permissions have been approved for your organization. For more information, see [Microsoft Outlook extension permissions](#) in the admin guide.

Amazon Quick Microsoft Outlook extension usage guidelines

As a user, you are responsible for keeping company information safe. The following guidance helps you use Amazon Quick apps securely while maintaining data privacy and compliance.

Conversation retention and accuracy

Each conversation is stored for 30 days. You can review and manage your conversation history by choosing the conversation history button in the Outlook extension.

Amazon Quick uses generative AI. You should review responses for accuracy.

Usage of the Amazon Quick extension for Microsoft Outlook is subject to the [AWS Responsible AI Policy](#).

Security considerations

When you use Amazon Quick with email content, remember that responses reflect individual user permissions and content may include information not accessible to all email recipients. It may generate responses that contain sensitive data that can't be publicly shared.

To protect your organization's data, carefully evaluate email usage and plan deployment with data privacy in mind. Amazon Quick maintains strict data privacy by not using customer data for service improvements, not using customer data to enhance language models, and not indexing Microsoft Outlook conversations into your company's Amazon Quick instance.

Sample prompts

The following prompts demonstrate common ways to use Quick within Outlook. You can adapt these to your specific needs.

- "Summarize all unread emails and highlight any that need urgent responses today."
- "Draft a follow-up email to [contact name] referencing the key points from this thread."
- "Schedule a 30-minute meeting with the contacts in this email thread for next week."
- "Find all emails discussing [project name] and create a summary of action items."
- "Using data from my Quick space, draft a status update email for the leadership team on our quarterly metrics."

Tip

For best results, be specific in your prompts. Include names, dates, and goals. You can also reference your Quick spaces, dashboards, and knowledge bases for personalized results.

Amazon Quick Microsoft Excel extension

The Amazon Quick extension for Excel helps you work with data faster by automating data cleaning, analysis, and visualization tasks while integrating with your enterprise data sources.

You can search for Amazon Quick in the Microsoft Excel app store or visit the [Quick for Excel Microsoft store page](#) to add the extension.

Key capabilities include:

- **Data import and preparation:** Pull data from Quick dashboards, structured datasets, spaces, and uploaded files directly into your spreadsheet. Identify inconsistencies and clean data automatically, and apply formatting and templates based on your data and objectives.

- **Spreadsheet debugging:** Ask Quick to explain calculations behind cells or tables, debug and fix formula errors, and highlight anomalies and inconsistencies in your data.
- **Data analysis and insights:** Automatically analyze patterns and trends, create pivot tables and charts with natural language prompts, and perform sensitivity analysis and scenario planning.
- **Spreadsheet automation:** Apply filters, transformations, and conditional formatting using prompts, and generate appropriate templates based on your content and objectives.
- **Enterprise knowledge integration:** Choose an agent or a space to respond from and incorporate relevant information from your organization's knowledge into your spreadsheets. Integrate data from Quick dashboards, spaces, and knowledge bases.
- **External actions:** Perform actions in third-party applications using your configured [connectors](#) or apps directly from Excel.

Important

- The Amazon Quick Excel extension uses generative AI to create and execute code within your Excel application sandbox. AI can make mistakes and perform inaccurate actions within your Excel workbook. No spreadsheet data is read when the side panel is closed, and no data is sent to Amazon Quick unless you explicitly send a prompt.
- Amazon Quick does not use your user data for service improvement or for training its underlying large language models (LLMs).

Amazon Quick Microsoft Excel extension usage guidelines

As a user, you are responsible for keeping company information safe. The following guidance helps you use Amazon Quick apps securely while maintaining data privacy and compliance.

Conversation retention and accuracy

Each conversation is stored for 30 days. You can review and manage your conversation history by choosing the conversation history button in the Excel extension.

Amazon Quick uses generative AI. You should review responses for accuracy.

Usage of the Amazon Quick extension for Microsoft Excel is subject to the [AWS Responsible AI Policy](#).

Security considerations

To protect your organization's data, carefully evaluate usage and plan deployment with data privacy in mind. Amazon Quick maintains strict data privacy by not using customer data for service improvements, not using customer data to enhance language models, and not indexing Microsoft Excel conversations into your company's Amazon Quick instance.

Sample prompts

The following prompts demonstrate common ways to use Quick within Excel. You can adapt these to your specific needs.

- "Import data from my Quick dashboard and identify which items are trending above or below target."
- "Create a pivot table showing totals by category and region."
- "Generate a chart comparing this quarter's performance to last quarter."
- "Explain the formula in cell D5 and suggest a more efficient approach."
- "Apply conditional formatting to highlight any values that exceed the threshold by more than 10%."

Tip

For best results, be specific in your prompts. Include names, dates, and goals. You can also reference your Quick spaces, dashboards, and knowledge bases for personalized results.

Amazon Quick Microsoft Word extension

The Amazon Quick extension for Word helps you create professional documents faster by working directly in your document to generate, edit, and review content using natural language instructions.

You can search for Amazon Quick in the Microsoft Word app store or visit the [Quick for Word Microsoft store page](#) to add the extension.

Key capabilities include:

- **Content generation and editing:** Generate formatted content including headings, tables, and styled text using plain language instructions. Go from a blank page to a review-ready draft without manually formatting. Quick works directly in the document itself, automatically applying proper formatting and structure.
- **Document review with track changes:** Ask Quick to review your document and suggest edits based on any criteria or Quick data of your choice. Suggestions appear in Word's built-in track changes and comments, so you stay in control of what gets accepted.
- **Style and formatting matching:** Quick automatically matches your document's existing style, structure, and formatting. Attach reference documents or templates to apply specific formatting standards.
- **Enterprise knowledge integration:** Include relevant information from your Quick knowledge sources directly into your document.
- **External actions:** Perform actions in third-party applications using your configured [connectors](#) or apps directly from Word.

Important

- The Amazon Quick Word extension uses generative AI to create and execute code within your Word application sandbox. AI can make mistakes and perform inaccurate actions within your Word document. No document content is read when the side panel is closed, and no data is sent to Amazon Quick unless you explicitly send a prompt.
- Amazon Quick does not use your user data for service improvement or for training its underlying large language models (LLMs).

Amazon Quick Microsoft Word extension usage guidelines

As a user, you are responsible for keeping company information safe. The following guidance helps you use Amazon Quick apps securely while maintaining data privacy and compliance.

Conversation retention and accuracy

Each conversation is stored for 30 days. You can review and manage your conversation history by choosing the conversation history button in the Word extension.

Amazon Quick uses generative AI. You should review responses for accuracy.

Usage of the Amazon Quick extension for Microsoft Word is subject to the [AWS Responsible AI Policy](#).

Security considerations

To protect your organization's data, carefully evaluate usage and plan deployment with data privacy in mind. Amazon Quick maintains strict data privacy by not using customer data for service improvements, not using customer data to enhance language models, and not indexing Microsoft Word conversations into your company's Amazon Quick instance.

Sample prompts

The following prompts demonstrate common ways to use Quick within Word. You can adapt these to your specific needs.

- "Create a project proposal including an executive summary, timeline, and budget section, pulling data from my Quick space."
- "Review this document with Track Changes enabled and suggest edits to improve clarity and tone."
- "Read the comments in this document and address each piece of feedback, making the requested changes directly."
- "Generate a one-page executive summary of this report highlighting the key findings."
- "Add a competitive comparison table to this document using data from my Quick dashboard."

Tip

For best results, be specific in your prompts. Include names, dates, and goals. You can attach reference documents or templates to guide formatting and style.

Amazon Quick Microsoft PowerPoint extension

The Amazon Quick extension for PowerPoint helps you create compelling, data-driven presentations by integrating your enterprise data, AI-powered design assistance, and intelligent content generation directly into PowerPoint.

You can search for Amazon Quick in the Microsoft PowerPoint app store or visit the [Quick for PowerPoint Microsoft store page](#) to add the extension.

Key capabilities include:

- **Presentation creation with enterprise data:** Generate complete presentations using data from Quick dashboards, spaces, and knowledge bases. Pull real-time metrics and insights directly from your organization's data sources, or create presentations from outlines, topics, or natural language descriptions.
- **Visual narratives from enterprise knowledge:** Use Quick's enterprise knowledge to create contextual, accurate presentations. Import and visualize data from your Quick spaces, dashboards, and knowledge bases in compelling slides.
- **Brand consistency and professional design:** Apply your organization's themes and templates to presentations, respect existing presentation formatting and primary slide layouts, and generate professionally formatted tables, layouts, and design elements.
- **Natural language editing:** Select slides or content and request modifications using conversational prompts. Add, delete, reorder, or reorganize slides effortlessly, and chat about your presentation content to get insights and suggestions.

Important

- The Amazon Quick PowerPoint extension uses generative AI to create and execute code within your PowerPoint application sandbox. AI can make mistakes and perform inaccurate actions within your PowerPoint slide deck. No presentation data is read when the side panel is closed, and no data is sent to Amazon Quick unless you explicitly send a prompt.
- Amazon Quick does not use your user data for service improvement or for training its underlying large language models (LLMs).

Amazon Quick Microsoft PowerPoint extension usage guidelines

As a user, you are responsible for keeping company information safe. The following guidance helps you use Amazon Quick apps securely while maintaining data privacy and compliance.

Conversation retention and accuracy

Each conversation is stored for 30 days. You can review and manage your conversation history by choosing the conversation history button in the PowerPoint extension.

Amazon Quick uses generative AI. You should review responses for accuracy.

Usage of the Amazon Quick extension for Microsoft PowerPoint is subject to the [AWS Responsible AI Policy](#).

Security considerations

To protect your organization's data, carefully evaluate usage and plan deployment with data privacy in mind. Amazon Quick maintains strict data privacy by not using customer data for service improvements, not using customer data to enhance language models, and not indexing Microsoft PowerPoint conversations into your company's Amazon Quick instance.

Sample prompts

The following prompts demonstrate common ways to use Quick within PowerPoint. You can adapt these to your specific needs.

- "Create a 10-slide presentation on [topic] including key metrics and recommendations, pulling data from my Quick dashboard."
- "Add a slide with a competitive comparison showing our advantages over the top 3 competitors."
- "Make this deck more executive-friendly by reducing text and emphasizing key numbers."
- "Reorganize this presentation to lead with results instead of methodology."
- "Create a chart slide comparing actual vs. target performance by department using data from my Quick space."

Tip

For best results, be specific in your prompts. Include names, dates, and goals. You can also reference your Quick spaces, dashboards, and knowledge bases for personalized results.

Amazon Quick Slack extension

Note

Before you deploy a Slack extension as an author, your Amazon Quick admin must [configure Amazon Quick access to Slack](#).

The Amazon Quick Slack extension brings AI-powered assistance directly into team conversations, enabling access to organizational knowledge and document analysis without leaving Slack.

Key capabilities include:

- Extension access through Slack's AI assistant side panel for continuous availability.
- Engagement with Quick through **@Amazon Quick** mentions in channels for contextual team assistance. Contextual responses with relevant content from the Slack channel are not supported at this time.
- Direct interaction through private messages for individual productivity.
- External actions in third-party applications from Slack using [connectors](#) configured by your organization.
- Unlimited usage for enhanced team collaboration and knowledge sharing.
- General knowledge capabilities.
- Company-specific information search when enabled.
- Source-attributed responses.
- File upload and processing of up to 20 files simultaneously.
- Contextual summaries and insights generation.

Amazon Quick Slack extension author guide

As an Amazon Quick author, you can deploy Quick Slack extensions after your admin establishes the foundational connection to your organization's Slack workspace. Your capabilities depend on the permission level granted by your administrator.

With **limited permissions** (view, share, delete only), you can manage basic extension operations through the landing page after admin completes all setup. With **full permissions** (deploy, view, share, delete, edit), you can complete the Slack OAuth application deployment, rename extensions, and access all editing features.

Author capabilities for Slack extensions:

- Deploy extensions to your organization's Slack workspace using OAuth (requires full permissions).
- Customize extension settings - names, descriptions (requires full permissions).
- Manage sharing and access permissions (available with limited or full permissions).

Note

Before you deploy a Slack extension as an author, your Quick admin must [configure Amazon Quick access to Slack](#).

Topics

- [Deploy a Slack extension](#)
- [Edit Slack extension](#)
- [Share Slack extension](#)
- [Delete Slack extension](#)

Deploy a Slack extension

Deploy a new Slack extension instance in the Quick console. This process establishes the foundation for connecting AI-powered assistance to your Slack workspace.

Note

This action requires full author permissions.

1. Sign in to the Amazon Quick console.
2. In the left navigation, under **CONNECTIONS**, select **Extensions**.
3. Select **Create extension**.
4. Select **Slack**. Then, select **Next**.
5. Configure the following fields:
 - **Name** - A name for your extension is pre-filled for you. You can edit this and enter a descriptive name for the Slack extension.

- **Description** (optional) - A description for your extension is pre-filled for you. You can edit this and enter a new description to provide additional context about this extension configuration.
 - **Installation** type - Your Slack extension supports OAuth installation by default.
6. Select **Next** to save your configuration.
 7. From the **Extension** summary page, navigate to the extension you just configured.
 8. Then, from the **Actions** menu, navigate to the extension you just configured.
 9. Select **Install**. Then, from the **Complete installation for Slack assistant** dialog box that opens, select **Install**.

A success message will open up on the top right of your screen.

10. From the success message, select **Install extension** to finish installing your extension.

 Note

You can also navigate to the extensions summary page and deploy your extension from the **Actions** menu.

11. The link will open to a Slack login page where after you login (as admin) you will need to find and be asked to install the Amazon Quick app within your Slack workspace.

 Note

You may see a "This app is not approved by Slack banner." This message can be ignored.

12. Choose **Allow** to install your Amazon Quick App for Slack.
13. Once the installation is complete, you will see the page confirming that the **Congratulations! Your Slack App has been successfully installed.**
14. Choose **Open the Amazon Quick App in Slack.**
15. This will open your Slack workspace where all users will be required to sign-in.

Your Slack extension has now been successfully deployed and is available for users.

Edit Slack extension

Note

This action requires full author permissions.

As an author, you can edit the extensions you deploy to your users. Modify extension settings to update names, descriptions, or configuration options. Changes take effect immediately and apply to all users with access to the extension.

1. Sign in to the Amazon Quick console.
2. In the left navigation, under **CONNECTIONS**, select **Extensions**.
3. Select the three dot menu icon for the Slack extension you need to edit.
4. Select **Edit**.
5. Edit the configuration as required and select **Save** to confirm the changes.

Share Slack extension

Share ownership and management permissions with specific users and groups, enabling multiple users to manage extensions and assist with installation. You can assign different permission levels and manage access as needed.

1. Sign in to the Amazon Quick console.
2. In the left navigation, under **CONNECTIONS**, select **Extensions**.
3. Select the three dot menu icon for the Slack extension you need to share.
4. Select **Share**.
5. Enter the users and groups you would like to share the extension with.
6. Select **Share** to send the access email to each group and user.
7. From the drop-down next to each name, you can edit their access levels (**Viewer** or **Owner**).
8. **Optional:** You could select **Remove access** to delete the access for the selected group or user.

Delete Slack extension

As an author, you can delete the extensions you deploy to your users. Permanently remove a extension from your Quick console and revoke access for all users. This action cannot be undone and requires confirmation.

1. Sign in to Amazon Quick console.
2. In the left navigation, under **CONNECTIONS**, select **Extensions**.
3. Select the three dot menu icon for the Slack extension you need to delete.
4. Select **Delete**.
5. Enter the word, "confirm", and select **DELETE**.

Amazon Quick Slack extension user guide

As a user, you can access Amazon Quick directly within Slack to get AI-powered assistance without leaving your workspace. The extension integrates seamlessly into your Slack environment, providing instant access to knowledge bases and intelligent responses.

Topics

- [Add a Slack Extension to your Slack](#)
- [Access Quick in your Slack side panel at any time](#)
- [Slack extension use cases](#)
- [Amazon Quick Slack extension usage guidelines](#)
- [Slack extension known limitations](#)

Add a Slack Extension to your Slack

Install the Amazon Quick app in your Slack workspace to enable AI-powered assistance. This one-time setup makes Quick accessible throughout your Slack environment.

Add a Slack Extension to your Slack

1. Open and login to the Slack workspace for your company.
2. Choose **More** in the left navigation, then select **Automations**.
3. Choose **Apps**.

4. Choose **+ Add apps**.
5. Search for **Quick** and choose Quick.
6. Select your Slack profile picture in the bottom left of Slack.
7. Navigate to **Preferences > Navigation > AI Apps and Agents** > select **Show app agents** > and select **Quick**.
8. Quick is now available to access anywhere in Slack through an icon in the top right of your Slack window.

Note

For more information, see [Understand AI apps in Slack](#) in the Slack help center.

Access Quick in your Slack side panel at any time

Once you've added Quick to your Slack workspace, you can access it conveniently through the side panel for quick assistance without interrupting your workflow. The side panel provides persistent access to Quick while you work in Slack channels and direct messages.

Access Quick in your Slack side panel at any time

1. Click on your Slack profile picture in the bottom left of Slack.
2. Navigate to **Preferences > Navigation > AI Apps and Agents** and select **Amazon Quick**.
3. Quick will now be available to access anywhere in Slack through an icon in the top right of your Slack window.

Slack extension use cases

With Quick integrated into Slack, you can search and access your organization's knowledge bases directly from your conversations. This allows you to find relevant information, get answers to questions, and enhance your communications without leaving Slack.

Search your organization's knowledge wherever you are

1. Open the Quick side panel from the top right of your Slack window or start a DM with Quick under **Apps**.

2. Ask Quick a question about its knowledge from your spaces and connected knowledge bases.
3. To personalize your conversation using your data, use the gear icon (visible after sending your first message to Quick) within your conversation to select an agent or a space to respond from.

Get Quick's in-context help in Slack conversation threads

1. Navigate to a Slack conversation thread of your choice.
2. Type **@Amazon Quick** and ask any question about the messages in that thread or its knowledge from your spaces and Quick knowledge bases.
3. If Quick is not already added to the channel, you will be prompted to add it before receiving a response.

Perform actions in external applications

1. Start a direct message (DM) with Quick.
2. Ask it to perform an action of your choice in an external application using [connectors](#) configured by your organization.

Upload and analyze images

1. In any Slack channel or direct message, upload an image by dragging and dropping it or using the attachment button.
2. Mention **@Amazon Quick** and ask questions about the uploaded image, such as requesting analysis, descriptions, or insights.
3. Quick will analyze the image and provide relevant information based on your request.

Amazon Quick Slack extension usage guidelines

As a user, you are responsible for keeping company information safe. The following guidance helps you use Amazon Quick apps securely while maintaining data privacy and compliance.

When using the Slack extension

To start fresh, begin a new conversation by selecting **New chat** in direct messages. Closing the side panel ends your current conversation. You can access conversation history through Slack message history or the Amazon Quick chat instance, which includes conversations from all channels. You can

view complete conversation details, including attachment names, and access the same knowledge base available in your Amazon Quick chat instance.

Note

Users can access conversation history in Slack. Deleting the conversation in Slack will not delete from conversation history in Amazon Quick. However, users need to visit the Amazon Quick chat instance to manage their conversations.

Conversation retention policy and accuracy

Amazon Quick automatically deletes conversations after 30 days of inactivity. Slack conversation retention follows your company's specific history rules, and Slack retention periods may exceed Amazon Quick's 30-day limit.

Users can access conversation history in Slack through the AI App History tab. Deleting the conversation in Slack will not delete from conversation history in Amazon Quick. However, users need to visit the Amazon Quick chat instance to manage their conversations.

Security considerations

When you use Amazon Quick in public channels, remember that responses reflect individual user permissions and content may include information not accessible to all channel members. It may generate responses that contain sensitive data that can't be publicly shared.

To protect your organization's data, carefully evaluate public channel usage, consider the security implications, and plan deployment with data privacy in mind. Amazon Quick maintains strict data privacy by not using customer data for service improvements, not using customer data to enhance language models, and not indexing Slack conversations into your company's Amazon Quick instance.

Slack extension known limitations

The following are known limitations of the Amazon Quick Slack extension:

- The Slack extension doesn't have access to all your Slack conversations. It only has access to the messages in Slack conversation threads where it is mentioned.
- The Slack extension doesn't have access to previous messages when mentioned in a Slack channel or in group message.

- The Slack extension isn't accessible in group direct messages or in direct messages with teammates unless it is explicitly added to the conversation as a member.
- You can filter Amazon Quick agents and spaces only in direct messages with the Slack extension. The Slack extension will use the default assistant and all spaces available to you when invoked in public such as in channels or group messages.
- The Slack extension can't render visuals for prompts about your structured data.
- Web search isn't supported in the Slack extension.
- The Slack extension can't be configured to automatically reply to messages in channels or posts.
- The Slack extension will not respond when invoked by Slack's workflow bot as it is not able to authenticate the user who made the query in these situations.
- The Slack extension isn't available in huddles.
- [Actions](#) (using your action integrations) can only be performed in direct messages with the Slack extension.
- Actions that require file uploads as inputs are not supported by the Slack extension.
- [Flows](#) are not supported in the Slack extension at this time.
- File upload limitations are the same within Amazon Quick chat. For more information, see [Upload files and chat](#).

Amazon Quick Microsoft Teams extension

Note

Before you deploy a Microsoft Teams extension as an author, your Quick admin must [configure Amazon Quick access to Microsoft Teams](#).

The Amazon Quick Microsoft Teams extension brings AI-powered assistance directly into team conversations, enabling access to organizational knowledge and document analysis without leaving Microsoft Teams.

Key capabilities include:

- Seamless integration within Microsoft Teams allowing you to access information while staying in your conversations.

- Collaborative assistance through **@Amazon Quick** mentions in thread discussions for thread-specific information.
- Action item extraction and summary generation from conversations.
- File upload and processing capabilities for enhanced productivity.

- [Delete Microsoft Teams extension](#)

Deploy Microsoft Teams extension

Deploy a new Microsoft Teams extension instance in the Amazon Quick console. This process establishes the foundation for connecting AI-powered assistance to your Microsoft Teams workspace.

Note

This action requires full author permissions.

Use this procedure to create and configure a new Microsoft Teams extension for your organization.

1. Sign in to the Amazon Quick console.
2. In the left navigation, under **CONNECTIONS**, select **Extensions**.
3. Select **Create extension**.
4. Select **Microsoft Teams**. Then, select **Next**.
5. Configure the following fields:
 - **Name** - A name for your extension is pre-filled for you. You can edit this and enter a descriptive name for the Microsoft Teams extension.
 - **Description** (optional) - A description for your extension is pre-filled for you. You can edit this and enter a new description to provide additional context about this extension configuration.
 - **Installation** type - Your Microsoft Teams extension supports OAuth installation by default.
6. Select **Next** to save your configuration.
7. From the **Extension** summary page, navigate to the extension you just configured.
8. Then, from the **Actions** menu, navigate to the extension you just configured.
9. Select **Install**. Then, from the **Complete installation for Teams assistant** dialog box that opens, select **Install**.

A success message will open up on the top right of your screen.

10. From the success message, select **Install extension** to finish installing your extension.

 Note

You can also navigate to the extensions summary page and deploy your extension from the **Actions** menu.

11. Open the link and login as Global Admin or someone with administrative permissions can add the Amazon Quick App to the Microsoft Teams admin center for your organization.
12. Choose **Teams apps** in the left navigation.
13. Choose **Amazon Quick** from the list of available apps.
14. Review and grant admin consent by choosing the **Permissions** tab and reviewing the permissions and choose **Grant admin consent**.

 Note

If permissions are already granted, proceed to the end of the procedure, there is no further action required.

15. Authenticate and choose **Accept** for Amazon Quick app.
16. Confirm that an app titled Amazon Quick **Permissions** tab now says **Admin consent granted for all required permissions**.
17. All users assigned to the app from the Teams admin center can now find the app in the **Built for your org** section of the **Apps** page of their Teams app.

Your Microsoft Teams extension has now been successfully deployed and is available for users.

Edit Microsoft Teams extension

 Note

This action requires full author permissions.

As an author, you can edit the extensions you deploy to your users. Modify extension settings to update names, descriptions, or configuration options. Changes take effect immediately and apply to all users with access to the extension.

Use this procedure to modify settings and configuration for an existing Microsoft Teams extension.

1. Sign in to the Amazon Quick console.
2. In the left navigation, under **CONNECTIONS**, select **Extensions**.
3. Select the three dot menu icon for the Microsoft Teams extension you need to edit.
4. Select **Edit**.
5. Edit the configuration as required and select **Save** to confirm the changes.

Your changes are now applied and will be reflected in the extension configuration for all users.

Share Microsoft Teams extension

Share ownership and management permissions with specific users and groups, enabling multiple users to manage extensions and assist with installation. You can assign different permission levels and manage access as needed.

Use this procedure to share your Microsoft Teams extension with other users and manage their access permissions.

1. Sign in to the Amazon Quick console.
2. In the left navigation, under **CONNECTIONS**, select **Extensions**.
3. Select the three dot menu icon for the Microsoft Teams extension you need to share.
4. Select **Share**.
5. Enter the users and groups you would like to share the extension with.
6. Select **Share** to send the access email to each group and user.
7. From the drop-down next to each name, you can edit their access levels (**Viewer** or **Owner**).
8. **Optional:** You could select **Remove access** to delete the access for the selected group or user.

The specified users and groups now have access to your Microsoft Teams extension with the permissions you assigned.

Delete Microsoft Teams extension

As an author, you can delete the extensions you deploy to your users. Permanently remove an extension from your Quick console and revoke access for all users. This action cannot be undone and requires confirmation.

Use this procedure to permanently remove a Microsoft Teams extension from your organization.

1. Sign in to Amazon Quick console.
2. In the left navigation, under **CONNECTIONS**, select **Extensions**.
3. Select the three dot menu icon for the Microsoft Teams extension you need to delete.
4. Select **Delete**.
5. Enter the word, "confirm", and select **DELETE**.

The Microsoft Teams extension has been permanently removed and is no longer accessible to users in your organization.

Amazon Quick Microsoft Teams extension user guide

As a user, you can access Quick directly within Microsoft Teams to get AI-powered assistance without leaving your workspace. The extension integrates seamlessly into your Microsoft Teams environment, providing instant access to knowledge bases and intelligent responses.

Topics

Add a Microsoft Teams Extension to your Microsoft Teams

Install the Quick app in your Microsoft Teams workspace to enable AI-powered assistance. This one-time setup makes Quick accessible throughout your Microsoft Teams environment.

Add a Microsoft Teams Extension to your Microsoft Teams

1. Open and login to the Microsoft Teams workspace for your company.

2. Choose **Apps** in the left navigation and search for **Quick**.
3. Choose **Quick**.
4. On the top bar, Quick icon is now available. You can select it to access and chat with Quick.

Note

For more information, see [Chat with a bot in Microsoft Teams](#) from Microsoft support.

Microsoft Teams extension use cases

With Amazon Quick integrated into Microsoft Teams, you can search and access your organization's knowledge bases directly from your conversations. This allows you to find relevant information, get answers to questions, and enhance your communications without leaving Team.

Search your organization's knowledge without leaving Teams

1. Start a chat with Quick after adding it from the **Apps** section.
2. Ask Quick a question about its knowledge from your spaces and connected knowledge bases.
3. To personalize your conversation using your data, use the gear icon (visible after sending your first message to Quick) within your conversation to select an agent or a space to respond from.

Get Quick's in-context help in Teams posts

1. Navigate to a Teams post of your choice.
2. Type **@Amazon Quick** and ask any question about the messages in that thread or its knowledge from your spaces and your organization's knowledge bases.
3. If Quick is not already added to the channel, you will be prompted to add it before receiving a response.

Perform actions in external applications

1. Start a direct message (DM) with Quick.
2. Ask it to perform an action of your choice in an external application using [connectors](#) configured by your organization.

Amazon Quick Microsoft Teams extension usage guidelines

As a user, you are responsible for keeping company information safe. The following guidance helps you use Amazon Quick apps securely while maintaining data privacy and compliance.

Conversation retention policy and accuracy

Amazon Quick automatically deletes conversations after 30 days of inactivity. Teams conversation retention follows your company's specific history rules. Teams retention periods may exceed Amazon Quick's 30-day limit. To start fresh, begin a new conversation by using the `/new_conv` command

Users can review past conversations in Teams or all conversations from all channels (Teams, browser extensions, etc.) in your Amazon Quick chat instance.

Note

Deleting conversations or messages in Teams does not remove them from Amazon Quick. To manage your conversation history, use the Amazon Quick chat instance.

Security considerations

When Amazon Quick is invoked by a user in a public Teams channel, it generates responses based on the invoking user's permissions, which may include content that other channel members aren't authorized to access. To prevent unintended exposure of sensitive information, carefully evaluate the use of Amazon Quick in public channels.

File upload behavior in Amazon Quick Teams Extension:

- Responses will be limited to the uploaded file content.
- General knowledge access depends on admin settings.
- Start a new chat to access company knowledge again.

Data privacy and conversation behavior

Amazon Quick does not use customer data for service improvement or for improving its underlying large language models (LLMs). Also, none of the data you include in your Teams conversations will be indexed into your company's Amazon Quick instance.

The Amazon Quick Teams app will have access to the same knowledge available in the corresponding Amazon Quick web experience.

Closing the Amazon Quick bot for Teams side panel will end the current conversation. Users can review past conversations in Teams or all conversations from all channels (Teams, browser extensions, etc.) in your Amazon Quick web experience. You can access all the history of previous conversations including, the names of the attachments in those conversations.

Microsoft Teams extension known limitations

The following are known limitations of the Amazon Quick Microsoft Teams extension:

- The Microsoft Teams extension doesn't have access to all your Microsoft Teams conversations. It only has access to the messages in Microsoft Teams posts where it is mentioned.
- The Microsoft Teams extension isn't accessible in group direct messages or in direct messages with other teammates.
- You can filter Amazon Quick agents and spaces only in direct messages with the Microsoft Teams extension. The Microsoft Teams extension will use the default assistant and all spaces available to you when invoked in public, such as in channels and Microsoft Teams posts.
- The Microsoft Teams extension can't render visuals for prompts about your structured data.
- Web search is not supported in the Microsoft Teams extension.
- The Microsoft Teams extension can't be configured to automatically reply to messages in channels or posts.
- The Microsoft Teams extension isn't available for your Microsoft Teams meetings.
- You cannot review your conversation history in Microsoft Teams. To review and manage your conversation history, go to your Amazon Quick chat instance.
- [Actions](#) (using your action integrations) can only be performed in direct messages with the Microsoft Teams extension.
- Actions that require file uploads as inputs are not supported by the Microsoft Teams extension at this time.
- [Flows](#) are not supported in the Microsoft Teams extension at this time.
- File upload limitations are the same as those in the web experience. For more information see [Upload files and chat](#).

Amazon Quick on desktop

Amazon Quick on desktop is an agentic AI teammate that connects to your local files and the tools you use every day. It builds an understanding of your work that deepens over time, so it provides relevant, personalized assistance. Agents take on work you delegate, follow through independently, and bring you the results.

For the plans that include Amazon Quick on desktop and pricing details, see [Amazon Quick pricing](#).

What is Amazon Quick on desktop?

Amazon Quick on desktop is a native application that extends Amazon Quick to your machine. It gives Quick direct, persistent access to your files, your connected services, and the context of how your work fits together.

What you can do with Quick on desktop

Quick on desktop works with the files already on your machine. You grant access to the folders you choose, and Quick reads, writes, searches, and indexes them directly.

Amazon Quick runs in the cloud. Your conversations, memory, knowledge graph, agent-produced files, and the index of content you make searchable are kept for you in your Amazon Quick account, so they are available across the web, mobile, and desktop. What the desktop application adds is access to your machine: the files in the folders you grant, browser automation in your own browser, local code execution, and MCP servers and coding agents you configure locally. The desktop keeps only what it needs to work locally: your folder permissions, local connector configuration, and sign-in credentials.

Quick connects to the services you use every day: email, calendar, chat, customer relationship management (CRM) tools, and more. Once connected, Quick pulls information from these services, takes actions in them, and combines data across them in a single conversation.

As you work with Quick, it builds a knowledge graph of the people, projects, and decisions relevant to you, and it retains your preferences and workflows in long-term memory. Together, these let Quick understand your work context and provide personalized responses that improve over time. You review and manage both from My context.

You create agents with their own instructions and knowledge, and pair them with schedules that run at intervals you define. Agents prepare for your meetings, summarize what changed in your channels, generate reports, and deliver results through an activity feed.

Quick on desktop is extensible. You connect MCP servers to add custom tools and integrations, delegate development tasks to coding agents, use browser automation to interact with web applications, and create skills that teach Quick new workflows.

Next steps

To get started, see [Getting started](#). If your organization uses an Enterprise account, see [Setting up Amazon Quick on desktop for enterprise deployments](#) first.

Setting up Amazon Quick on desktop for enterprise deployments

Applies to: Enterprise Edition

Intended audience: System administrators

To use Amazon Quick on desktop for enterprise deployments, administrators must configure enterprise single sign-on (SSO) so that users in the organization can sign in with their corporate credentials. This setup connects your organization's OpenID Connect (OIDC) compatible identity provider (IdP) to Amazon Quick.

Note

If you are using a Free or Plus account, this section does not apply to you. Continue to [Getting started](#).

How enterprise sign-in works

The Amazon Quick desktop application uses the OIDC protocol to authenticate users. When you choose **Continue with SSO**, a browser window opens to Amazon Quick. Amazon Quick identifies your configured identity provider and redirects to your IdP's authorization endpoint. The application then exchanges the resulting authorization code for tokens using Proof Key for Code Exchange (PKCE).

To identify the configured identity provider, your browser must have an active Amazon Quick web session. If no session exists, the browser prompts you to sign in to Amazon Quick before the application redirects to your IdP.

Amazon Quick validates the token and maps the user to an identity in your account. The email address in your IdP must exactly match the email address of the user in Amazon Quick.

 Note

If you sign in for the first time, the browser checks for an active Amazon Quick web session. If no session exists, the browser opens the Amazon Quick sign-in page instead of redirecting to your IdP. Sign in to Amazon Quick in the browser to continue. The desktop application then completes sign-in through your configured identity provider.

Supported token signing algorithms

Amazon Quick verifies the signature on each ID token against the public keys published at your identity provider's JWKS URI. Your IdP must sign ID tokens with one of the following asymmetric algorithms.

Key type	Supported alg values
RSA	RS256, RS384, RS512, PS256, PS384, PS512
ECDSA	ES256, ES384, ES512

 Symmetric signing is not supported

Amazon Quick does not accept ID tokens signed with HMAC (HS256, HS384, or HS512). These algorithms sign the token with the client secret rather than with a key that can be published in a JWKS, so the signature cannot be verified against your IdP's JWKS URI. Unsecured tokens (an alg value of none) are also rejected. If your IdP is configured to use one of these, sign-in fails with a token validation error.

You do not select the algorithm in Amazon Quick. Your IdP chooses it when it issues the token, and Amazon Quick accepts any of the algorithms in the preceding table. Most identity providers use RS256 by default.

Prerequisites

Before you begin, verify that you have the following:

- An AWS account with an active Amazon Quick subscription. The Amazon Quick account's home region (identity region) must be in a supported AWS Region. For a list of supported Regions, see [Supported AWS Regions for Amazon Quick](#). All identity types are supported, including IAM Identity Center, IAM federation, and native Amazon Quick (username/password) users.
- Administrator access to your Amazon Quick account.
- Access to your IdP with permissions to create OIDC application registrations.
- In restricted network environments, the ability to reach the required Amazon Quick and identity provider domains. For the list of domains to add to your allow list, see [Network access and required domains](#).

Important

Amazon Quick on desktop is available for Enterprise accounts in AWS Regions that support the full Amazon Quick feature set. Regions that support Amazon Quick Sigh capabilities only do not include desktop. For the full list, see [Supported AWS Regions for Amazon Quick](#).

Setup process

Setting up enterprise sign-in involves the same four steps regardless of which identity provider you use:

1. **Create an OIDC application in your identity provider.** Register a public OIDC client and record its Client ID and OIDC endpoints. The steps and endpoint formats are specific to your identity provider.
2. **Add the extension access in the Amazon Quick administration console.** In the Amazon Quick administration console, add an extension access using the Client ID and OIDC endpoints from Step 1.
3. **Create the extension in the Amazon Quick console.** On the **Extensions** page in the Amazon Quick console, create the extension from the extension access you added in Step 2.

4. **Download, verify, and distribute the desktop application.** Download and install the application, choose **Continue with SSO** to confirm that authentication succeeds, and then direct your users to download and sign in.

The complete procedure for each of these steps is documented on the page for your identity provider. Choose your identity provider to get started:

- [Microsoft Entra ID](#) – Microsoft Entra ID
- [Google Workspace](#) – Google Workspace
- [Okta](#) – Okta
- [Ping Identity](#) – Ping Identity (PingFederate and PingOne)

If you encounter problems during setup or sign-in, see [Troubleshooting enterprise sign-in for Amazon Quick on desktop](#).

Managed deployment configuration

Administrators can configure and deploy Amazon Quick on desktop across an enterprise fleet using the following options.

Managed policies

Amazon Quick reads policies from vendor-neutral OS-managed locations. Any mobile device management (MDM) tool that can deliver a configuration profile (macOS) or registry policy (Windows) works without vendor-specific integration.

Policy	macOS location	Windows location	Effect
DisableSocialLogin	Preference domain com.aws.Q uickWork.mac	HKLM\SOFTWARE \Policies \Amazon\Quick (REG_DWORD)	Hides social sign-in, blocks it server-side, and hides "Sign up for free." This policy enforces enterprise SSO as the only authentication path.

Policy	macOS location	Windows location	Effect
DisableAutoUpdates	Preference domain com.aws.QuickWork.mac	HKLM\SOFTWARE\Policies\Amazon\Quick (REG_SZ)	Stops the application from updating itself, so that your organization controls when new versions reach the fleet. Accepts patch, minor, or major. The value is the smallest update size that the policy disables. patch disables all automatic updates, including patch, minor, and major updates. minor disables minor and major updates. major disables major updates only.

Amazon Quick reads policy values at application startup.

macOS

Deploy a configuration profile with preference domain com.aws.QuickWork.mac. The profile supports device scope (/Library/Managed Preferences/com.aws.QuickWork.mac.plist) or user scope.

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plist PUBLIC "-//Apple//DTD PLIST 1.0//EN"
    "http://www.apple.com/DTDs/PropertyList-1.0.dtd">
<plist version="1.0">
<dict>
    <key>DisableSocialLogin</key>
    <true/>
    <key>DisableAutoUpdates</key>
    <string>major</string>
</dict>
</plist>
```

Windows

Set the registry values at HKLM\SOFTWARE\Policies\Amazon\Quick. The Policies hive is not user-editable and survives application updates.

The following example shows both policies configured in the registry:

```
HKLM\SOFTWARE\Policies\Amazon\Quick
  DisableSocialLogin (REG_DWORD) = 1
  DisableAutoUpdates (REG_SZ) = major
```

For MDM-specific deployment steps, see your provider's documentation:

- [macOS preference file profiles](#) on the Microsoft Intune website
- [Application & Custom Settings](#) on the Jamf Pro website

Proxy support

Amazon Quick respects the operating system's proxy configuration (system proxy on Windows, Proxy Auto-Configuration on macOS). All application network traffic, including child processes, routes through the configured enterprise proxy automatically. You don't need to configure the proxy separately.

Application data paths

The following table lists the application data paths for each operating system.

OS	Path
macOS	~/ .quickwork/
Windows	%USERPROFILE%\ .quickwork\

This directory contains local user-specific settings and configurations.

Silent installation and fleet deployment

To distribute the application silently to a managed fleet with a mobile device management (MDM) solution – including per-machine packaging for Microsoft Intune and other MDM tools, certificate

authority trust, and troubleshooting – see [Deploying Amazon Quick on desktop to a managed fleet with MDM](#).

For a single-user silent installation on Windows, the installer also supports silent mode. This installs Amazon Quick for the current user in %LOCALAPPDATA% and creates desktop and Start menu shortcuts.

```
.\Amazon-Quick-Setup.exe /S
```

Application updates

By default, Amazon Quick delivers updates automatically over HTTPS. Updates are code-signed and apply for each user on the next restart. On macOS, updates use Apple notarization. On Windows, updates use Authenticode signing.

To take control of update delivery, set the `DisableAutoUpdates` policy described in [Managed policies](#). When you block updates, you become responsible for delivering new versions to the fleet, using the same tools you use to deploy other managed applications.

Even when you block updates, Amazon Quick can still notify your users of a required update and restrict functionality remotely if a critical issue is found.

Important

We strongly recommend that you continue to allow patch updates. Patch updates deliver security fixes, performance improvements, and bug fixes. To control larger updates while your fleet still receives patches, set `DisableAutoUpdates` to `minor` or `major` instead of `patch`.

Set up enterprise sign-in with Microsoft Entra ID for Amazon Quick on desktop

Applies to: Enterprise Edition

Intended audience: System administrators

This page walks you through all four steps to set up enterprise sign-in with Microsoft Entra ID:

1. Create an OIDC application in Microsoft Entra ID and record its values.
2. Add the extension access in the Amazon Quick administration console.
3. Create the extension in the Amazon Quick console.
4. Download, verify, and distribute the desktop application.

Note

Before you begin, review the prerequisites in [Setting up Amazon Quick on desktop for enterprise deployments](#).

Step 1: Create an OIDC application in Microsoft Entra ID

Register a public OIDC client application in Microsoft Entra ID. The Amazon Quick desktop application uses this client to authenticate users through the authorization code flow with PKCE. This client requires no client secret. Grant the `offline_access` scope so that the application can issue refresh tokens. Without it, users must re-authenticate frequently.

For more information, see [Register an application](#) in the Microsoft Entra documentation.

To create the Entra ID app registration

1. In the Azure portal, navigate to **Microsoft Entra ID** → **App registrations** → **New registration**.

2. Configure the following settings:

Setting	Value
Name	Amazon Quick Desktop
Supported account types	Accounts in this organizational directory only (Single tenant)
Redirect URI platform	Public client/native (mobile & desktop)
Redirect URI	http://localhost:18080

3. Choose **Register**.
4. On the **Overview** page, note the **Application (client) ID** and **Directory (tenant) ID**. You need these values in later steps.

This is a public client registration. Entra ID enforces PKCE automatically for public clients.

To configure API permissions

1. In the app registration, navigate to **API permissions** → **Add a permission** → **Microsoft Graph** → **Delegated permissions**.
2. Add the following permissions: openid, email, profile, offline_access.
3. Choose **Add permissions**.
4. If your organization requires it, choose **Grant admin consent for [your organization]**.

To configure authentication settings

1. In the app registration, navigate to **Authentication**.
2. Under **Advanced settings**, leave **Allow public client flows** set to **No**.
3. Verify that http://localhost:18080 is listed under **Mobile and desktop applications**.
4. Choose **Save**.

To configure token claims

1. In the app registration, navigate to **Token configuration**.

- 2. Choose **Add optional claim**.
- 3. Select token type: **ID**.
- 4. Select the email claim and choose **Add**.

 Important

This step is required. Without the email optional claim, Microsoft Entra ID does not include the user's email address in the ID token, and Amazon Quick cannot map the token to a user. Additionally, each user who signs in must have their **Mail** attribute populated in their Entra ID profile (under **Contact Information**). The User Principal Name (UPN) alone is not sufficient — the Mail attribute must contain a value.

Record the following OIDC endpoints. You enter these values, together with the **Application (client) ID** you noted earlier, in Step 2. Replace <TENANT_ID> with your Directory (tenant) ID.

 Important

The Issuer URL must include the /v2.0 path suffix. Do not use the **Authority URL** shown in the Entra ID Endpoints panel, which omits this suffix. If the /v2.0 suffix is missing, token validation fails with an "Invalid issuer" error at sign-in time.

Field	Value
Client ID	The Application (client) ID from the app registration Overview page
Issuer URL	https://login.microsoftonline.com/<TENANT_ID>/v2.0
Authorization endpoint	https://login.microsoftonline.com/<TENANT_ID>/oauth2/v2.0/authorize
Token endpoint	https://login.microsoftonline.com/<TENANT_ID>/oauth2/v2.0/token

Field	Value
JWKS URI	<code>https://login.microsoftonline.com/<TENANT_ID>/discovery/v2.0/keys</code>

 Tip

The JWKS URI is not displayed in the Microsoft Entra ID **Endpoints** panel. You can find it by opening the **OpenID Connect metadata document** URL from the Endpoints panel and locating the `jwks_uri` field in the JSON response. Alternatively, construct it using the format shown in the preceding table.

 Important

If your application has custom signing keys because of the claims-mapping feature, you must append an `appid` query parameter containing the **Application (client) ID** to the JWKS URI. Otherwise, token validation fails because the default keys endpoint does not return the application's custom signing key. For example:

`https://login.microsoftonline.com/<TENANT_ID>/discovery/v2.0/keys?appid=<CLIENT_ID>`

To confirm the correct value, open the OpenID Connect metadata document with the same `appid` parameter appended (`https://login.microsoftonline.com/<TENANT_ID>/.well-known/openid-configuration?appid=<CLIENT_ID>`) and use the `jwks_uri` it returns. For more information, see [Validate the signature](#) in the Microsoft Entra documentation.

Step 2: Add the extension access in the Amazon Quick administration console

In the Amazon Quick administration console, add an extension access using the OIDC endpoint values and Client ID that you recorded in Step 1.

To add the extension access

1. Sign in to the Amazon Quick administration console and choose **Manage account**.
2. In the left navigation pane, under **Permissions**, choose **Extension access**.

3. Choose **Add extension access**.
4. Under **Select Service**, select **Amazon Quick (Desktop application for Quick)**, and then choose **Next**.
5. Enter the extension details using the values you recorded in Step 1:

Field	Value
Name	A name for this extension access (for example, QuickDesktop-access). This is an internal reference only and is not configured in your IdP. Use alphanumeric characters and hyphens only, with no spaces.
Description	(Optional) A description of this extension access, for your reference only.
Issuer URL	The exact OIDC issuer URL from Step 1, including any required path suffix.
Authorization Endpoint	The OIDC authorization endpoint URL from Step 1
Token Endpoint	The OIDC token endpoint URL from Step 1
JWKS URI	The JSON Web Key Set URI from Step 1
Client ID	The OIDC client identifier (Client ID or Application (client) ID) that you recorded in Step 1. Required.

6. Choose **Add**.

 Important

Verify that all values are correct before you choose **Add**. The extension access configuration cannot be edited after creation. If any value is incorrect, you must delete the extension access and create a new one.

Step 3: Create the extension in the Amazon Quick console

After you add the extension access in the Amazon Quick administration console, create the extension on the **Extensions** page in the Amazon Quick console.

To create the extension

1. In the Amazon Quick console, in the left navigation pane, choose **Extensions**. If you don't see **Extensions**, choose **More** to find it.
2. Choose **Add extension**.
3. Select the **Desktop application for Quick** extension access that you created in Step 2, and then choose **Next**.
4. Choose **Create**.

Important

Both Step 2 and Step 3 are required. If you add the extension access but do not create the extension, enterprise sign-in is not available and users see the error: "Enterprise sign-in for Quick Desktop has not been configured for this account."

Note

Creating the extension is a one-time, account-level action. After an administrator creates the extension, enterprise sign-in is available for all users in the account. Individual users do not need to enable the extension themselves — they only need to download the desktop application and sign in.

Step 4: Download, verify, and distribute the desktop application

In this step, you download and install the desktop application, verify that enterprise sign-in works, and then distribute the application to your users.

First, download the application from the Amazon Quick console.

To download the desktop application

1. In the Amazon Quick console, in the left navigation pane, choose **Extensions**. If you don't see **Extensions**, choose **More** to find it.
2. Select the Quick Desktop extension that you created in Step 3.
3. Choose the more options icon (...) for the extension.
4. Choose **Download for Windows** or **Download for Mac**, depending on your operating system.

Then, install the application. For installation instructions, see [Getting started](#).

After you install the application, verify that enterprise sign-in works.

To verify enterprise sign-in

1. Open the Amazon Quick desktop application.
2. On the sign-in screen, choose **Continue with SSO**.
3. (Optional) Select your AWS Region from the list, or choose **Dynamic** to have the application detect your Region automatically.
4. Authenticate with your corporate credentials. The application redirects to your identity provider, and then returns to the Home screen after authentication succeeds.

Tip

If sign-in fails, verify the values you entered in Step 2 against the OIDC endpoints and Client ID from Step 1. If any value is incorrect, delete the extension access under **Permissions** → **Extension access** in the Amazon Quick administration console, and repeat Step 2 with the correct values. For more help, see [Troubleshooting enterprise sign-in for Amazon Quick on desktop](#).

Finally, after you verify the setup, distribute the application to your users. Direct them to [Getting started](#) for download, installation, and sign-in instructions. Users choose **Continue with SSO** and sign in with their corporate credentials — no additional per-user configuration is required.

Set up enterprise sign-in with Google Workspace for Amazon Quick on desktop

Applies to: Enterprise Edition

Intended audience: System administrators

This page walks you through all four steps to set up enterprise sign-in with Google Workspace:

1. Create an OIDC application in Google Workspace and record its values.
2. Add the extension access in the Amazon Quick administration console.
3. Create the extension in the Amazon Quick console.
4. Download, verify, and distribute the desktop application.

Note

Before you begin, review the prerequisites in [Setting up Amazon Quick on desktop for enterprise deployments](#).

Step 1: Create an OIDC application in Google Workspace

Register an OAuth client in the Google Cloud Console. The Amazon Quick desktop application uses this client to authenticate users through the authorization code flow with PKCE. Google issues a refresh token automatically when the authorization request includes the `access_type=offline` parameter. Quick includes this parameter automatically. No additional scope or grant type configuration is required.

For more information, see [OAuth 2.0 for Mobile & Desktop Apps](#) in the Google for Developers documentation.

To create the Google OAuth client

1. In the Google Cloud Console, navigate to **APIs & Services** → **Credentials** → **Create Credentials** → **OAuth client ID**.

2. Configure the following settings:

Setting	Value
Application type	Desktop app
Name	Amazon Quick Desktop

3. Choose **Create**.

4. Note the **Client ID** and **Client secret**. You need these values in later steps.

To configure the OAuth consent screen

1. In the Google Cloud Console, navigate to **Google Auth Platform** → **Branding**.
2. Set the **User type** to **Internal**. This restricts sign-in to users in your Google Workspace organization.
3. Fill in the required app information and choose **Save**.

To configure scopes

1. In the Google Cloud Console, navigate to **Google Auth Platform** → **Data Access**.
2. Add the following scopes: openid, email, profile.
3. Choose **Save**.

Record the following OIDC endpoints. You enter these values, together with the **Client ID** you noted earlier, in Step 2.

Field	Value
Client ID	The Client ID from your OAuth client
Issuer URL	<code>https://accounts.google.com</code>
Authorization endpoint	<code>https://accounts.google.com/o/oauth2/v2/auth</code>

Field	Value
Token endpoint	<code>https://oauth2.googleapis.com/token?client_secret=<CLIENT_SECRET></code>
JWKS URI	<code>https://www.googleapis.com/oauth2/v3/certs</code>

 Note

Append your client secret to the token endpoint as a `client_secret` query parameter so that token exchange succeeds—for example, `https://oauth2.googleapis.com/token?client_secret=<CLIENT_SECRET>`. Replace `<CLIENT_SECRET>` with the client secret generated for your OAuth client.

Step 2: Add the extension access in the Amazon Quick administration console

In the Amazon Quick administration console, add an extension access using the OIDC endpoint values and Client ID that you recorded in Step 1.

To add the extension access

1. Sign in to the Amazon Quick administration console and choose **Manage account**.
2. In the left navigation pane, under **Permissions**, choose **Extension access**.
3. Choose **Add extension access**.
4. Under **Select Service**, select **Amazon Quick (Desktop application for Quick)**, and then choose **Next**.
5. Enter the extension details using the values you recorded in Step 1:

Field	Value
Name	A name for this extension access (for example, QuickDesktop-access). This is an internal reference only and is not configured in your IdP. Use alphanumeric characters and hyphens only, with no spaces.

Field	Value
Description	(Optional) A description of this extension access, for your reference only.
Issuer URL	The exact OIDC issuer URL from Step 1, including any required path suffix.
Authorization Endpoint	The OIDC authorization endpoint URL from Step 1
Token Endpoint	The OIDC token endpoint URL from Step 1
JWKS URI	The JSON Web Key Set URI from Step 1
Client ID	The OIDC client identifier (Client ID or Application (client) ID) that you recorded in Step 1. Required.

6. Choose **Add**.

 Important

Verify that all values are correct before you choose **Add**. The extension access configuration cannot be edited after creation. If any value is incorrect, you must delete the extension access and create a new one.

Step 3: Create the extension in the Amazon Quick console

After you add the extension access in the Amazon Quick administration console, create the extension on the **Extensions** page in the Amazon Quick console.

To create the extension

1. In the Amazon Quick console, in the left navigation pane, choose **Extensions**. If you don't see **Extensions**, choose **More** to find it.
2. Choose **Add extension**.
3. Select the **Desktop application for Quick** extension access that you created in Step 2, and then choose **Next**.
4. Choose **Create**.

 Important

Both Step 2 and Step 3 are required. If you add the extension access but do not create the extension, enterprise sign-in is not available and users see the error: "Enterprise sign-in for Quick Desktop has not been configured for this account."

 Note

Creating the extension is a one-time, account-level action. After an administrator creates the extension, enterprise sign-in is available for all users in the account. Individual users do not need to enable the extension themselves — they only need to download the desktop application and sign in.

Step 4: Download, verify, and distribute the desktop application

In this step, you download and install the desktop application, verify that enterprise sign-in works, and then distribute the application to your users.

First, download the application from the Amazon Quick console.

To download the desktop application

1. In the Amazon Quick console, in the left navigation pane, choose **Extensions**. If you don't see **Extensions**, choose **More** to find it.
2. Select the Quick Desktop extension that you created in Step 3.
3. Choose the more options icon (...) for the extension.
4. Choose **Download for Windows** or **Download for Mac**, depending on your operating system.

Then, install the application. For installation instructions, see [Getting started](#).

After you install the application, verify that enterprise sign-in works.

To verify enterprise sign-in

1. Open the Amazon Quick desktop application.
2. On the sign-in screen, choose **Continue with SSO**.

3. (Optional) Select your AWS Region from the list, or choose **Dynamic** to have the application detect your Region automatically.
4. Authenticate with your corporate credentials. The application redirects to your identity provider, and then returns to the Home screen after authentication succeeds.

Tip

If sign-in fails, verify the values you entered in Step 2 against the OIDC endpoints and Client ID from Step 1. If any value is incorrect, delete the extension access under **Permissions** → **Extension access** in the Amazon Quick administration console, and repeat Step 2 with the correct values. For more help, see [Troubleshooting enterprise sign-in for Amazon Quick on desktop](#).

Finally, after you verify the setup, distribute the application to your users. Direct them to [Getting started](#) for download, installation, and sign-in instructions. Users choose **Continue with SSO** and sign in with their corporate credentials — no additional per-user configuration is required.

Set up enterprise sign-in with Okta for Amazon Quick on desktop

Applies to: Enterprise Edition

Intended audience: System administrators

This page walks you through all four steps to set up enterprise sign-in with Okta:

1. Create an OIDC application in Okta and record its values.
2. Add the extension access in the Amazon Quick administration console.
3. Create the extension in the Amazon Quick console.
4. Download, verify, and distribute the desktop application.

Note

Before you begin, review the prerequisites in [Setting up Amazon Quick on desktop for enterprise deployments](#).

Step 1: Create an OIDC application in Okta

Register an OIDC native application in Okta. The Amazon Quick desktop application uses this client to authenticate users through the authorization code flow with PKCE, and requests the `openid`, `profile`, `email`, and `offline_access` scopes at sign-in.

For more information, see [Create OpenID Connect app integrations](#) in the Okta documentation.

To create the Okta OIDC Native Application

1. In the Okta Admin Console, navigate to **Applications** → **Applications** → **Create App Integration**.
2. Select **OIDC - OpenID Connect** as the sign-in method.
3. Select **Native Application** as the application type, then choose **Next**.
4. Configure the following settings:

Setting	Value
App integration name	Amazon Quick Desktop
Grant type	Authorization Code and Refresh Token
Sign-in redirect URIs	<code>http://localhost:18080</code>
Assignments	Assign to the appropriate users or groups

5. Choose **Save**.
6. On the **General** tab, note the **Client ID**.

Okta enforces PKCE (S256) automatically for native applications.

To verify authentication settings

1. In the app integration, go to the **General** tab.
2. Under **General Settings**, confirm that the application type is **Native**, client authentication is **None** (public client), and PKCE is **Required**.
3. Under **LOGIN**, confirm that `http://localhost:18080` is listed as a redirect URI.
4. Choose **Save** if you made any changes.

Record the following OIDC endpoints. You enter these values, together with the **Client ID** you noted earlier, in Step 2. Replace `<OKTA_DOMAIN>` with your Okta domain (for example, `your-org.okta.com`). For the endpoint reference, see [Authorization Code with PKCE](#) in the Okta documentation.

Field	Value
Client ID	The Client ID from the General tab
Issuer URL	<code>https://<OKTA_DOMAIN></code>
Authorization endpoint	<code>https://<OKTA_DOMAIN>/oauth2/v1/authorize</code>
Token endpoint	<code>https://<OKTA_DOMAIN>/oauth2/v1/token</code>
JWKS URI	<code>https://<OKTA_DOMAIN>/oauth2/v1/keys</code>

Use the standard Okta domain, not the admin subdomain

Use your standard Okta domain (for example, `your-org.okta.com`) in these endpoints, not the `-admin` subdomain (`your-org-admin.okta.com`) shown in the address bar of the admin console. The `-admin` subdomain does not host the OAuth endpoints, so using it causes sign-in to fail with an HTTP 404 error.

Step 2: Add the extension access in the Amazon Quick administration console

In the Amazon Quick administration console, add an extension access using the OIDC endpoint values and Client ID that you recorded in Step 1.

To add the extension access

1. Sign in to the Amazon Quick administration console and choose **Manage account**.
2. In the left navigation pane, under **Permissions**, choose **Extension access**.
3. Choose **Add extension access**.
4. Under **Select Service**, select **Amazon Quick (Desktop application for Quick)**, and then choose **Next**.
5. Enter the extension details using the values you recorded in Step 1:

Field	Value
Name	A name for this extension access (for example, QuickDesktop-access). This is an internal reference only and is not configured in your IdP. Use alphanumeric characters and hyphens only, with no spaces.
Description	(Optional) A description of this extension access, for your reference only.
Issuer URL	The exact OIDC issuer URL from Step 1, including any required path suffix.
Authorization Endpoint	The OIDC authorization endpoint URL from Step 1
Token Endpoint	The OIDC token endpoint URL from Step 1
JWKS URI	The JSON Web Key Set URI from Step 1
Client ID	The OIDC client identifier (Client ID or Application (client) ID) that you recorded in Step 1. Required.

6. Choose **Add**.

Important

Verify that all values are correct before you choose **Add**. The extension access configuration cannot be edited after creation. If any value is incorrect, you must delete the extension access and create a new one.

Step 3: Create the extension in the Amazon Quick console

After you add the extension access in the Amazon Quick administration console, create the extension on the **Extensions** page in the Amazon Quick console.

To create the extension

1. In the Amazon Quick console, in the left navigation pane, choose **Extensions**. If you don't see **Extensions**, choose **More** to find it.
2. Choose **Add extension**.
3. Select the **Desktop application for Quick** extension access that you created in Step 2, and then choose **Next**.
4. Choose **Create**.

Important

Both Step 2 and Step 3 are required. If you add the extension access but do not create the extension, enterprise sign-in is not available and users see the error: "Enterprise sign-in for Quick Desktop has not been configured for this account."

Note

Creating the extension is a one-time, account-level action. After an administrator creates the extension, enterprise sign-in is available for all users in the account. Individual users do not need to enable the extension themselves — they only need to download the desktop application and sign in.

Step 4: Download, verify, and distribute the desktop application

In this step, you download and install the desktop application, verify that enterprise sign-in works, and then distribute the application to your users.

First, download the application from the Amazon Quick console.

To download the desktop application

1. In the Amazon Quick console, in the left navigation pane, choose **Extensions**. If you don't see **Extensions**, choose **More** to find it.
2. Select the Quick Desktop extension that you created in Step 3.
3. Choose the more options icon (...) for the extension.
4. Choose **Download for Windows** or **Download for Mac**, depending on your operating system.

Then, install the application. For installation instructions, see [Getting started](#).

After you install the application, verify that enterprise sign-in works.

To verify enterprise sign-in

1. Open the Amazon Quick desktop application.
2. On the sign-in screen, choose **Continue with SSO**.
3. (Optional) Select your AWS Region from the list, or choose **Dynamic** to have the application detect your Region automatically.
4. Authenticate with your corporate credentials. The application redirects to your identity provider, and then returns to the Home screen after authentication succeeds.

Tip

If sign-in fails, verify the values you entered in Step 2 against the OIDC endpoints and Client ID from Step 1. If any value is incorrect, delete the extension access under **Permissions** → **Extension access** in the Amazon Quick administration console, and repeat Step 2 with the correct values. For more help, see [Troubleshooting enterprise sign-in for Amazon Quick on desktop](#).

Finally, after you verify the setup, distribute the application to your users. Direct them to [Getting started](#) for download, installation, and sign-in instructions. Users choose **Continue with SSO** and sign in with their corporate credentials — no additional per-user configuration is required.

Set up enterprise sign-in with Ping Identity for Amazon Quick on desktop

Applies to: Enterprise Edition

Intended audience: System administrators

This page walks you through all four steps to set up enterprise sign-in with Ping Identity:

1. Create an OIDC application in your Ping Identity product (PingFederate or PingOne) and record its values.
2. Add the extension access in the Amazon Quick administration console.
3. Create the extension in the Amazon Quick console.
4. Download, verify, and distribute the desktop application.

Note

Before you begin, review the prerequisites in [Setting up Amazon Quick on desktop for enterprise deployments](#).

Step 1: Create an OIDC application in Ping Identity

Register a public OIDC client in your Ping Identity product. The Amazon Quick desktop application uses this client to authenticate users through the authorization code flow with PKCE. This client requires no client secret. Enable the Refresh Token grant type and grant the `offline_access` scope. Choose the instructions for your Ping Identity product.

PingFederate

For more information, see [Setting up an OIDC application in PingFederate](#) in the Ping Identity documentation.

To create the PingFederate OIDC client

1. In the PingFederate administrative console, go to **Applications** → **OAuth** → **Clients**, and choose **Add Client**.
2. In the **Client ID** field, enter a unique identifier for this client.
3. In the **Name** field, enter Amazon Quick Desktop.
4. For **Client Authentication**, select **None**.
5. In the **Redirection URI** section, enter `http://localhost:18080` and choose **Add**.
6. In the **Allowed Grant Types** list, select **Authorization Code** and **Refresh Token**.
7. Select the **Require Proof Key for Code Exchange (PKCE)** checkbox.
8. Under **Common Scopes**, grant the following: `openid`, `email`, `profile`, `offline_access`.
9. Choose **Save**.
10. Note the **Client ID**. You need this value in later steps.

To configure the OIDC policy

1. In the PingFederate administrative console, go to **Applications** → **OAuth** → **OpenID Connect Policy Management**.
2. Select the OIDC policy associated with this client, or choose **Add Policy** to create one.
3. Select the **Return ID Token On Refresh Grant** checkbox. This ensures that the desktop application receives a fresh ID token with current claims when refreshing the session.
4. Under **Attribute Contract**, verify that the `email` claim is included and mapped to the corresponding user attribute in your authentication source. The `email` claim must be present in tokens issued during both initial authentication and refresh token grants.
5. Choose **Save**.

Record the following OIDC endpoints. You enter these values, together with the **Client ID** you noted earlier, in Step 2. Replace `<PINGFEDERATE_HOST>` with your PingFederate server hostname.

Field	Value
Client ID	The Client ID you entered when you created the client
Issuer URL	<code>https://<PINGFEDERATE_HOST></code>

Field	Value
Authorization endpoint	https://<PINGFEDERATE_HOST>/as/authorization.oauth2
Token endpoint	https://<PINGFEDERATE_HOST>/as/token.oauth2
JWKS URI	https://<PINGFEDERATE_HOST>/pf/JWKS

PingOne

For more information, see [Editing an application – Native](#) in the Ping Identity documentation.

To create the PingOne OIDC native application

1. In the PingOne admin console, go to **Applications** → **Applications** and choose the **+** icon.
2. Enter Amazon Quick Desktop as the application name.
3. In the **Application Type** section, select **Native**, then choose **Save**.
4. On the **Configuration** tab, choose **Edit** and configure the following settings:

Setting	Value
Response Type	Code
Grant Type	Authorization Code and Refresh Token
PKCE Enforcement	S256
Redirect URIs	http://localhost:18080
Token Endpoint Authentication Method	None

5. Choose **Save**.
6. On the **Resources** tab, add the following scopes: openid, email, profile, offline_access.

⚠ Add scopes on the Resources tab, not the Configuration tab

This is a separate step from the **Configuration** tab. PingOne grants only the `openid` scope by default, so you must explicitly add `email`, `profile`, and `offline_access` on the **Resources** tab. If you skip this step, sign-in fails with "User info request failed (HTTP 401)". This error occurs because sign-in requires tokens issued with these scopes, and PingOne does not grant them unless you add them on this tab.

7. On the **Attribute Mappings** tab, verify that the `email` attribute is mapped to the user's email address.
8. Toggle the application to **Enabled**.
9. Note the **Client ID** and **Environment ID** from the **Configuration** tab.

Note

The PingOne domain varies by region. The following examples use `.com`. Replace the domain with the one for your environment (for example, `.ca`, `.eu`, or `.asia`).

Record the following OIDC endpoints. You enter these values, together with the **Client ID** you noted earlier, in Step 2. Replace `<ENV_ID>` with your PingOne environment ID.

Field	Value
Client ID	The Client ID from the Configuration tab
Issuer URL	<code>https://auth.pingone.com/<ENV_ID>/as</code>
Authorization endpoint	<code>https://auth.pingone.com/<ENV_ID>/as/authorize</code>
Token endpoint	<code>https://auth.pingone.com/<ENV_ID>/as/token</code>
JWKS URI	<code>https://auth.pingone.com/<ENV_ID>/as/jwks</code>

⚠ Use the correct JWKS URI path for PingOne

For the JSON Web Key Set (JWKS) URI, use the `/as/jwks` path shown in the preceding table. Do not use `/.well-known/jwks.json`, which can appear as a placeholder in some PingOne forms. PingOne does not use this path, and sign-in token validation fails if you enter it.

Step 2: Add the extension access in the Amazon Quick administration console

In the Amazon Quick administration console, add an extension access using the OIDC endpoint values and Client ID that you recorded in Step 1.

To add the extension access

1. Sign in to the Amazon Quick administration console and choose **Manage account**.
2. In the left navigation pane, under **Permissions**, choose **Extension access**.
3. Choose **Add extension access**.
4. Under **Select Service**, select **Amazon Quick (Desktop application for Quick)**, and then choose **Next**.
5. Enter the extension details using the values you recorded in Step 1:

Field	Value
Name	A name for this extension access (for example, QuickDesktop-access). This is an internal reference only and is not configured in your IdP. Use alphanumeric characters and hyphens only, with no spaces.
Description	(Optional) A description of this extension access, for your reference only.
Issuer URL	The exact OIDC issuer URL from Step 1, including any required path suffix.
Authorization Endpoint	The OIDC authorization endpoint URL from Step 1

Field	Value
Token Endpoint	The OIDC token endpoint URL from Step 1
JWKS URI	The JSON Web Key Set URI from Step 1
Client ID	The OIDC client identifier (Client ID or Application (client) ID) that you recorded in Step 1. Required.

6. Choose **Add**.

 Important

Verify that all values are correct before you choose **Add**. The extension access configuration cannot be edited after creation. If any value is incorrect, you must delete the extension access and create a new one.

Step 3: Create the extension in the Amazon Quick console

After you add the extension access in the Amazon Quick administration console, create the extension on the **Extensions** page in the Amazon Quick console.

To create the extension

1. In the Amazon Quick console, in the left navigation pane, choose **Extensions**. If you don't see **Extensions**, choose **More** to find it.
2. Choose **Add extension**.
3. Select the **Desktop application for Quick** extension access that you created in Step 2, and then choose **Next**.
4. Choose **Create**.

 Important

Both Step 2 and Step 3 are required. If you add the extension access but do not create the extension, enterprise sign-in is not available and users see the error: "Enterprise sign-in for Quick Desktop has not been configured for this account."

Note

Creating the extension is a one-time, account-level action. After an administrator creates the extension, enterprise sign-in is available for all users in the account. Individual users do not need to enable the extension themselves — they only need to download the desktop application and sign in.

Step 4: Download, verify, and distribute the desktop application

In this step, you download and install the desktop application, verify that enterprise sign-in works, and then distribute the application to your users.

First, download the application from the Amazon Quick console.

To download the desktop application

1. In the Amazon Quick console, in the left navigation pane, choose **Extensions**. If you don't see **Extensions**, choose **More** to find it.
2. Select the Quick Desktop extension that you created in Step 3.
3. Choose the more options icon (...) for the extension.
4. Choose **Download for Windows** or **Download for Mac**, depending on your operating system.

Then, install the application. For installation instructions, see [Getting started](#).

After you install the application, verify that enterprise sign-in works.

To verify enterprise sign-in

1. Open the Amazon Quick desktop application.
2. On the sign-in screen, choose **Continue with SSO**.
3. (Optional) Select your AWS Region from the list, or choose **Dynamic** to have the application detect your Region automatically.
4. Authenticate with your corporate credentials. The application redirects to your identity provider, and then returns to the Home screen after authentication succeeds.

Tip

If sign-in fails, verify the values you entered in Step 2 against the OIDC endpoints and Client ID from Step 1. If any value is incorrect, delete the extension access under **Permissions** → **Extension access** in the Amazon Quick administration console, and repeat Step 2 with the correct values. For more help, see [Troubleshooting enterprise sign-in for Amazon Quick on desktop](#).

Finally, after you verify the setup, distribute the application to your users. Direct them to [Getting started](#) for download, installation, and sign-in instructions. Users choose **Continue with SSO** and sign in with their corporate credentials — no additional per-user configuration is required.

Troubleshooting enterprise sign-in for Amazon Quick on desktop

Applies to: Enterprise Edition

Intended audience: System administrators

Use the following guidance to resolve common enterprise sign-in issues, regardless of which identity provider you use.

Tip

To help diagnose a sign-in problem, you can export application logs from the sign-in screen. Include these logs when you contact your administrator or AWS Support.

Note

If the application cannot reach the sign-in page, complete authentication, or load content, the issue might be network related. In restricted environments, confirm that the required domains are on your allow list and that firewall and VPN settings are not blocking the connections. For the list of required domains, see [Network access and required domains](#).

redirect_mismatch error

Verify that the redirect URI in your IdP is exactly `http://localhost:18080` and is configured as a public client or native platform.

Access blocked: app not verified (Google Workspace)

This error means the OAuth consent screen is set to **External**. In the Google Cloud Console, navigate to **Google Auth Platform** → **Branding** and set the **User type** to **Internal**, which restricts sign-in to users in your Google Workspace organization.

User not found after sign-in

This error has two common causes:

1. **The email claim is not being returned in the token.** For Microsoft Entra ID, you must add the `email` optional claim to the ID token under Token configuration (see Step 1). Additionally, the user's **Mail** attribute must be populated in their Entra ID profile. The User Principal Name (UPN) alone is not sufficient.
2. **No matching user exists in Amazon Quick.** The email in the token must exactly match the email of a provisioned user. For IAM Identity Center accounts, verify the user's email in Identity Center matches. Email matching is case-sensitive.

Token validation failure

This error has two common causes:

1. **The issuer URL does not match.** Verify that the issuer URL in the extension access configuration matches the issuer URL in your IdP's OIDC configuration exactly.
2. **The ID token is signed with an unsupported algorithm.** Amazon Quick accepts asymmetric signatures only. If your IdP signs ID tokens with HMAC (HS256, HS384, or HS512), validation fails regardless of the JWKS URI you configured, because the signing key is never published in a JWKS. Reconfigure your IdP to use a supported algorithm. For the list, see [Supported token signing algorithms](#).

Invalid issuer error (Microsoft Entra ID)

If sign-in fails with "Invalid issuer: `https://login.microsoftonline.com/TENANT_ID/v2.0`", verify that the Issuer URL in your extension access configuration includes the `/v2.0` path suffix. The Entra ID v2.0 endpoint issues tokens with an `iss` claim that includes `/v2.0`. If the suffix is missing, delete the extension access and recreate it with the correct Issuer URL.

Enterprise sign-in not configured for this account

This error means the extension access was created but the extension itself was not. In the Amazon Quick console, in the left navigation pane, choose **Extensions** (you might need to choose **More** to find it), and create the extension, selecting the extension access you previously configured.

User info request failed (HTTP 504)

This is a transient backend timeout. Sign in to your Amazon Quick account via the web browser first, then retry the desktop sign-in. If the error persists, verify network connectivity to the Amazon Quick service endpoint. For the list of required domains, see [Network access and required domains](#).

Consent or permission errors (Microsoft Entra ID)

Grant admin consent for the required API permissions in the Azure portal. Navigate to the app registration's **API permissions** page and choose **Grant admin consent for [your organization]**.

Session expires frequently

Verify that your IdP is configured to issue refresh tokens. For Microsoft Entra ID, the `offline_access` scope is required. For Google Workspace, include `access_type=offline` in the authorization request (handled automatically by Quick). For Okta, the Refresh Token grant type must be enabled and the `offline_access` scope must be granted. For Ping Identity, the Refresh Token grant type must be enabled and the `offline_access` scope must be granted. For PingFederate, also verify that **Return ID Token On Refresh Grant** is selected in the OIDC policy.

Application not enabled (PingOne)

If authentication fails immediately without reaching the PingOne login page, verify that the application toggle is set to **Enabled** in the PingOne admin console.

User info request failed (HTTP 401) (PingOne)

The required scopes are not enabled on the application's **Resources** tab. This is a separate step from the **Configuration** tab: PingOne grants only the `openid` scope by default. In the PingOne admin console, open the application's **Resources** tab and add the `email`, `profile`, and `offline_access` scopes.

Token validation failure with a PingOne JSON Web Key Set (JWKS) URI

Verify that the JWKS URI in your extension access configuration uses the `/as/jwks` path (for example, `https://auth.pingone.com/<ENV_ID>/as/jwks`). Do not use `/.well-known/jwks.json`, which can appear as a placeholder in some PingOne forms. PingOne does not use this path.

Missing email claim after refresh (PingFederate)

Verify that the `email` claim is included in the OIDC policy **Attribute Contract** and mapped to the correct user attribute. The mapping must produce the `email` claim for both initial authentication and refresh token grants.

Deploying Amazon Quick on desktop to a managed fleet with MDM

Applies to: Enterprise Edition

Intended audience: System administrators

As an administrator, you can distribute the Amazon Quick desktop application to a managed fleet with mobile device management (MDM), without any per-machine interaction. This page describes the deployment using Microsoft Intune for both macOS and Windows. The artifacts it describes – a signed macOS `.pkg` and a per-machine Windows `.exe` – also work with other MDM solutions, such as Jamf, Kandji, and VMware Workspace ONE. Only the upload mechanics differ between solutions.

This page describes how to complete the following tasks:

1. Get the per-machine installer artifacts from the download service.
2. Deploy the macOS application with Microsoft Intune.
3. Deploy the Windows application with Microsoft Intune.
4. (Optional) Trust a corporate certificate authority for networks that inspect encrypted traffic.

Note

This page covers distributing the application binary. To let users sign in with their corporate credentials, you must also configure enterprise single sign-on. For more information, see [Setting up Amazon Quick on desktop for enterprise deployments](#). To enforce enterprise SSO as the only sign-in method by disabling consumer social login across your fleet, see [Managed policies](#).

Prerequisites

Before you begin, verify that you have the following:

- Administrator access to your MDM solution, and a fleet of devices that are enrolled in it.
- Devices that meet the Amazon Quick desktop application system requirements. For the macOS and Windows requirements, see [Prerequisites](#).
- For Windows, devices that run Windows Pro, Enterprise, or Education. The application deployment method for Windows uses the Win32 app type, which Microsoft Intune does not support on Windows Home. MDM enrollment also requires a Windows client edition (Windows Server is not supported for MDM enrollment).
- For Windows, the Microsoft Win32 Content Prep Tool (IntuneWinAppUtil.exe), which packages the installer into the .intunewin format that the Win32 app type requires. For more information, see [Microsoft Win32 Content Prep Tool](#) on GitHub.

⚠ Use per-machine installers only

Use the per-machine installer variants described in this page, not the per-user installers that your users download individually. An MDM solution runs as the system account with no signed-in user, so a per-user installer does not deploy correctly in that context.

Get the installer artifacts

The Amazon Quick download service at `desktop.downloads.quick.aws.com` provides the desktop installers. For MDM deployment, use the per-machine installer for each platform. The per-machine installer differs from the per-user installer that individual users download from the standard download page:

- **macOS** – a signed, notarized component .pkg, named Amazon Quick-*version*-arm64.pkg, that installs Amazon Quick.app to the /Applications folder as the root user.
- **Windows** – a per-machine .exe, named Amazon Quick-Admin Setup *version*.exe, that installs the application for all users into C:\Program Files\Amazon Quick\.

Each platform publishes a channel manifest that lists the current version and a SHA-512 checksum. Fetch the manifest to find the version to deploy and the checksum to verify your download against.

```
# macOS manifest
curl -fsSL https://desktop.downloads.quick.aws.com/darwin/arm64/quick-external-cloud-mac.yml

# Windows per-machine manifest
curl -fsSL https://desktop.downloads.quick.aws.com/win32/x64/quick-external-cloud-admin.yml
```

The manifest includes two keys that you use for MDM deployment.

version

The version of the most recent build released externally. Use this value wherever a procedure in this topic asks you for *version*.

path

The version-specific artifact, relative to the platform base URL. On Windows, you append path to `https://desktop.downloads.quick.aws.com/win32/x64/` to download the per-machine installer. On macOS, path refers to the archive that the application auto-updater consumes rather than a deployable installer, so you use version with the .pkg URL pattern that follows.

Download the per-machine artifact for each platform. In the following URL patterns, replace *version* with the version from the manifest.

```
# macOS .pkg (per-machine, installs to /Applications)
https://desktop.downloads.quick.aws.com/darwin/arm64/quick-external-cloud/Amazon
Quick-version-arm64.pkg
```

```
# Windows per-machine .exe (installs for all users into Program Files)
https://desktop.downloads.quick.aws.com/win32/x64/quick-external-cloud-admin/Amazon
Quick-Admin Setup version.exe
```

A pre-production beta channel also exists for internal testing. It updates itself automatically and does not publish a public first-time installer, so it is not used for MDM deployment. For the standard download page that individual users use, see [Downloading and installing](#).

Static and version-specific download URLs

The Windows per-machine .exe also has a static download link that resolves to the most recent build released externally, so you do not need to fetch the manifest first. A static link can trail the version in the manifest while a release finishes rolling out. If you need a specific version, or you want to verify your download against the SHA-512 checksum, fetch the manifest and use the version-specific URL instead.

```
https://desktop.downloads.quick.aws.com/windows/x64/Amazon-Quick-Admin.exe
```

The macOS .pkg has no static link, because it is published only under its version-specific channel path. Get the current version from the manifest, and then build the .pkg URL with that version.

Deploying the macOS application with Microsoft Intune

The macOS installer is a signed, notarized component .pkg that installs Amazon Quick.app to the /Applications folder.

To add and assign the macOS application

1. In the Microsoft Intune admin center, go to **Apps** → **All apps** → **Add**, and then select the **macOS app (PKG)** app type.

Note

Use the **macOS app (PKG)** type, not the line-of-business app type.

2. Choose **Select app package file**, and then upload the .pkg that you downloaded.
3. In the **Included apps** detection list, keep only the main application bundle and remove the helper bundles.

Keep only the main application bundle

The macOS installer includes the main application plus four nested helper components inside Contents/Frameworks/. When you upload the .pkg, Microsoft Intune automatically populates the **Included apps** list with all five bundles. Delete the four helper rows (the ones whose IDs end in .e0 through .e3, such as **Amazon Quick Helper (GPU)**) so that exactly one entry remains, with the following values.

Field	Value
App bundle ID	com.aws.QuickWork.mac
Build number	The numeric part of the manifest version (for example, 1.0.3377). Use the value from the manifest rather than this example.

If you leave the helper rows in place, macOS might report installation failure code 0x87D13BA2 even when the application files are present.

Note

The app bundle ID (com.aws.QuickWork.mac) is the application's CFBundleIdentifier, which Microsoft Intune uses for detection. It is intentionally different from the installer's package receipt identifier (com.amazon.QuickWork.mac), which you use with `pkgutil --forget` when you clean a test device.

4. Set **Ignore app version** to **Yes**. The application includes a built-in updater that keeps it current from the channel manifest, so let the application manage its own version. With this setting, Microsoft Intune installs the application once if the bundle ID is absent, and then does not reinstall it when the version changes. Without it, Microsoft Intune repeatedly attempts to reinstall when it detects version drift between what it deployed and what the auto-updater has since applied.
5. On the **Assignments** tab, add a device or user group with the **Required** intent.

On each assigned device, the installation runs silently and the application is installed at /Applications/Amazon Quick.app. To verify the installation on a device, run the following command and confirm that it returns com.aws.QuickWork.mac.

```
defaults read "/Applications/Amazon Quick.app/Contents/Info" CFBundleIdentifier
```

Device-side deployment logs are in the /Library/Logs/Microsoft/Intune/ directory.

Deploying the Windows application with Microsoft Intune

The Windows installer is an NSIS .exe. The Microsoft Intune Win32 app type does not accept a raw .exe, so you first wrap the installer into a .intunewin package. Use the **Windows app (Win32)** app type. The line-of-business app type accepts only .msi, .appx, and .msix files, so it does not apply.

The following table lists the key facts for the per-machine Windows installer.

Item	Value
Silent install flag	/S (a capital S, not /silent)
Silent uninstall flag	/S
Install path	C:\Program Files\Amazon Quick\
Binary name	Amazon Quick.exe
Uninstaller name	Uninstall Amazon Quick.exe
Required edition	Windows Pro, Enterprise, or Education (not Home)

To wrap the installer into a .intunewin package

1. Place the .exe installer by itself in a source folder.
2. Run the Win32 Content Prep Tool, replacing *version* with the version you downloaded.

```
IntuneWinAppUtil.exe -c C:\IntuneSource -s "Amazon Quick-Admin Setup version.exe" -  
o C:\IntuneOutput -q
```

The tool creates C:\IntuneOutput\Amazon Quick-Admin Setup *version*.intunewin.

To create and assign the Win32 application

1. In the Microsoft Intune admin center, go to **Apps** → **All apps** → **Add**, select the **Windows app (Win32)** app type, and then upload the .intunewin package.
2. On the **Program** tab, configure the following settings. Replace *version* with the version you downloaded.
 - **Install command** – "Amazon Quick-Admin Setup *version*.exe" /S
 - **Uninstall command** – "C:\Program Files\Amazon Quick\Uninstall Amazon Quick.exe" /S
 - **Install behavior** – **System**
3. On the **Requirements** tab, set the operating system architecture to **x64** and set the minimum operating system to a supported Windows client version.
4. On the **Detection rules** tab, add a manually configured rule with the following settings.

Field	Value
Rule type	File
Path	C:\Program Files\Amazon Quick
File or folder	Amazon Quick.exe
Detection method	File or folder exists
Associated with a 32-bit app on 64-bit clients	No

5. On the **Assignments** tab, add a device group with the **Required** intent.

The Intune Management Extension installs on a device the first time you assign a Win32 application, which can take a few minutes and two device check-ins. To trigger a check-in on a

device, go to **Settings** → **Accounts** → **Access work or school**, select your account, and choose **Sync**. To watch the installation on a device, tail the log with the following PowerShell command.

```
Get-Content "C:\ProgramData\Microsoft\IntuneManagementExtension\Logs\AppWorkload.log" -  
Wait -Tail 50
```

Trusting a corporate certificate authority

If your network inspects encrypted traffic or uses a custom corporate certificate authority (CA), the Amazon Quick desktop application must trust that CA. Otherwise, sign-in and responses can fail on the corporate network. Examples of traffic-inspection proxies include Zscaler and Netskope.

Deploy the CA into the operating system trust store with an MDM certificate profile. The application reads the operating system trust store when it starts, so a CA that you install there is trusted for all of the application's outbound connections. This approach works on both platforms and requires no environment variables, scripts, or certificate file placement.

macOS

Deploy a configuration profile with a **Trusted certificate** payload that targets the **System keychain**.

Windows

Deploy a **Trusted certificate** configuration profile to the computer store under **Trusted Root**.

Note

The certificate profile is the reliable path for the application itself. Deploy environment variables such as REQUESTS_CA_BUNDLE, SSL_CERT_FILE, or NODE_EXTRA_CA_CERTS only if other, non-Amazon Quick tools on the device require the CA through those variables.

Advanced: environment variables for mixed toolchains on Windows

Do not use per-user path variables in scripts that run under Intune

Do not use %HOMEDRIVE%%HOMEPATH% in scripts that run under Intune. Intune runs scripts as the system account, where those variables resolve to a service profile path (for example, C:\Windows\system32\config\systemprofile), not the user's home directory. Place certificate files and environment-variable scripts at a machine-wide path such as C:\ProgramData\Amazon Quick\certs\ instead. Use SETX /M to write machine-scoped environment variables. New processes inherit these variables after the next sign-in or restart.

The following example install script places the CA bundle at a machine-wide path and sets the environment variables.

```
@echo off
mkdir "C:\ProgramData\Amazon Quick\certs" 2>nul
copy /Y "%~dp0tls-ca-bundle.pem" "C:\ProgramData\Amazon Quick\certs\tls-ca-bundle.pem"
SETX /M REQUESTS_CA_BUNDLE "C:\ProgramData\Amazon Quick\certs\tls-ca-bundle.pem"
SETX /M SSL_CERT_FILE "C:\ProgramData\Amazon Quick\certs\tls-ca-bundle.pem"
exit /b 0
```

The NODE_EXTRA_CA_CERTS variable is not consumed by the Amazon Quick agent, so the certificate profile remains the reliable path for the application itself. Use the environment-variable script only if other tooling on the device requires the CA through those variables.

Troubleshooting MDM deployment

The following table describes common issues you might encounter when you deploy the application with an MDM solution, and how to resolve them.

The Windows silent installation does nothing

Confirm that the install command uses the /S flag (a capital S), not /silent.

A device reports that the Win32 app is not supported

The device runs Windows Home, which does not support Win32 app deployment. Use a device that runs Windows Pro, Enterprise, or Education.

The IntuneManagementExtension folder or logs are missing

The Intune Management Extension bootstraps only after you assign a Win32 application and the device checks in. Assign the application, sync the device, and then wait a few minutes.

macOS reports a failure although the files installed

If macOS reports installation failure code 0x87D13BA2, the nested helper bundles were left in the **Included apps** list. Delete every helper row so that only the main application bundle (com.aws.QuickWork.mac) remains, and then reassign the application.

Microsoft Intune reports the macOS app as installed but the app is missing

A prior installation left an application bundle or a package receipt on the device. With version-independent detection, this reads as installed and the deployment is skipped. Test on a clean device. To fully clean a test device, remove the application bundle and forget the package receipt, and then test the deployment again.

```
sudo rm -rf "/Applications/Amazon Quick.app"  
sudo pkgutil --forget com.amazon.QuickWork.mac
```

Application binaries are removed after a restart, but profile data survives

This is caused by a version conflict between the MDM-deployed build and the built-in auto-updater, which happens when the software catalog pins an older version while the auto-updater has already applied a newer one. The installer reads the version mismatch as a broken installation and removes the binaries. To resolve it, set **Ignore app version** to **Yes** in the Intune application configuration, and do not pin a specific version while the auto-updater is active. Admin-controlled version pinning is not available at general availability.

A Windows Server or pooled virtual machine does not enroll

MDM enrollment requires a persistent Windows client edition (Windows 10 or 11). Windows Server is not supported for MDM enrollment.

Getting started

This section walks you through downloading, installing, and signing in to the Amazon Quick desktop application for macOS and Windows.

Prerequisites

Verify that your system meets the following requirements.

macOS

Requirement	Minimum
Operating system	macOS 12 (Monterey) or later
Processor	Apple Silicon (M1 or later)
Memory	8 GB RAM
Disk space	2 GB available for installation. 10 GB or more recommended for search indexing and knowledge graph features.
Internet	Required for sign-in, AI model access, and connected services

Windows

Requirement	Minimum
Operating system	Windows 10 (64-bit) or later
Processor	x86_64 compatible
Memory	8 GB RAM
Disk space	2 GB available for installation. 10 GB or more recommended for search indexing and knowledge graph features.
Internet	Required for sign-in, AI model access, and connected services

Downloading and installing

Important

If your organization uses an Enterprise account, complete the steps in [Setting up Amazon Quick on desktop for enterprise deployments](#) before downloading or distributing the application. Enterprise sign-in becomes available after an administrator configures it.

You can download the Amazon Quick desktop application from the following locations:

- **Amazon Quick web application** – Sign in to Amazon Quick on the web. In the left navigation, choose **Extensions**, find the desktop extension card, and choose the download for your platform.
- **Direct download** – Use the following links:

Platform	Download
macOS (Apple Silicon)	Amazon-Quick.dmg
Windows (x64)	Amazon-Quick.exe

To install on macOS

1. Download the .dmg installer file.
2. Open the .dmg file.
3. Drag **Amazon Quick** to the **Applications** folder.
4. Open **Amazon Quick** from the Applications folder or Launchpad.

Note

On first launch, macOS might report that the application is from an unidentified developer or was downloaded from the internet. Choose **Open** to continue. If macOS blocks the application, open **System Settings**, choose **Privacy & Security**, scroll to **Security**, and choose **Open Anyway**.

To install on Windows

1. Download the .exe installer file.
2. Run the installer and follow the on-screen prompts.
3. After installation, launch **Amazon Quick** from the Start menu or desktop shortcut.

Note

On first launch, Windows might display a SmartScreen prompt. Choose **More info**, then **Run anyway**, to continue.

Signing in

When you open the application, the sign-in screen shows the available options.

To sign in with a personal account

1. Open the application.
2. On the sign-in screen, choose **Continue with**, and select your provider (for example, email, Amazon, Apple, Google, or GitHub).
3. Enter your credentials on the provider's sign-in page.
4. Complete any multi-factor authentication prompts.
5. After authentication succeeds, the application loads the Home screen.

Enterprise sign-in becomes available after your organization's administrator configures it.

To sign in with an enterprise account

1. Open the application.
2. On the sign-in screen, choose **Continue with single sign-on (SSO)**.
3. (Optional) Select your AWS Region, or choose **Dynamic** to detect it automatically.
4. Enter your corporate credentials on your organization's identity provider page.
5. After authentication succeeds, the application loads the Home screen.

First-run setup

After you sign in for the first time, Quick guides you through connecting your data sources. The onboarding flow presents categories of connections:

Category	What it connects	Examples
Email	Calendar and email, for meeting prep and action items	A calendar or email connector
Messaging	Threads, direct messages, and channels	A messaging connector
Local files	Folders on your computer	Any folder on your machine

For each category, choose **Connect** to set it up, or **Dismiss** to skip it. You can connect data sources later from **Customize**, on the **Connectors** tab. For more information, see [the section called "Connectors"](#).

Understanding the desktop interface

The interface is organized into a left navigation rail, a main content area, a top bar, and overlay panels.

Home

When you open Quick, the Home screen shows a time-aware greeting and the chat composer as the main entry point. It also surfaces connection setup cards for data sources you have not connected, and Quick Briefs, a summary of your highest-priority feed items with a link to open the full feed.

From the composer you choose which agent handles the conversation, set the response mode (Fast, Balanced, or Smart), and set the thinking effort (Off, Low, Medium, or High). You can also start an Incognito chat, a private conversation that Quick does not save to your history.

Features

The navigation rail on the left provides access to the main areas of Amazon Quick.

Features	What you do there
Chat	Start and continue conversations with Quick. This is the primary way you work.
Feed	Review a prioritized activity feed, your calendar, and your to-dos, drawn from connected services.
Library	Browse, search, and reuse your content and Quick resources in one place.
Customize	Manage the agents, skills, connectors, and knowledge that power your agents.
Apps	Open and build interactive applications (Apps in Amazon Quick).
Spaces	Open curated collections your team maintains, and chat against them.
More	Reach additional areas, such as Research, Data, Dashboards, and Automations.

Choose **Edit navigation** to select and reorder the areas shown in the rail.

Recents

Below the navigation, the Recents area lists your previous conversations, organized into folders and by date. From Recents you can organize conversations into folders, each showing a count; pin a conversation; rename, move, archive, or delete a conversation from its menu; search across your conversations; and use Auto-clean up to sort chats into folders by topic.

Account menu

Selecting your profile at the bottom of the rail opens the account menu, which reaches My context, Settings, Help, and Sign out. Your profile is also where you view your current session usage.

Overlay panels and top bar

The overlay panels and top bar give you access to content and tooling without leaving your current chat view: session activity, the Feed, Mission Control, the All data and apps panel (the spaces, local

folders, and skills available to the current conversation), and Session tabs (an in-conversation reader where documents open beside the chat). The top bar contains a fixed ingress to Mission Control and a connection status indicator.

Working with chat

Chat is the primary way you interact with Amazon Quick on desktop. You can ask questions, get help with tasks, analyze files, create documents, generate visualizations, and work with your connected services through natural language. The following sections describe the chat features available in the desktop application.

Response preferences

Amazon Quick on desktop provides multiple response modes that you choose based on your task. To switch between modes, use the response preferences selector in the chat input area.

Mode	Description	Best for
Fast	Optimized for speed on everyday tasks. Responses are generated quickly with the lowest latency.	Quick questions and simple tasks where speed matters more than depth.
Balanced	Balances quality and speed. Provides high-quality responses with moderate latency.	Most tasks, including writing assistance, summarization, and general day-to-day work.
Smart	Highest-quality responses. Provides the most thorough reasoning, with longer response times.	Complex analysis, nuanced writing, detailed reasoning, and tasks that require high accuracy.

Thinking effort

You control the thinking effort independently from the response mode. Thinking effort determines how much reasoning Quick applies before it responds. Higher thinking effort enables deeper reasoning for complex code, strategic planning, and analysis.

Level	Description
Off	No extended reasoning. Quick responds directly.
Low	Minimal reasoning before responding.
Medium	Moderate reasoning. A good balance for most tasks.
High	Extended reasoning for complex problems.

You can set thinking effort on Balanced and Smart modes. Fast mode responds without extended reasoning. To change the thinking effort, choose the response preferences selector in the chat input area, and then adjust the thinking effort picker.

Chat input

You enter your messages in the chat input area at the bottom of the conversation. From the chat input area, you can attach files, add local folders, turn on web search, attach a space, run commands, and mention agents and items. To open the menu of context options, choose the + (Add context) icon.

Attachments and file uploads

You can attach files directly to your chat messages for Quick to analyze, summarize, or reference. The desktop application supports common file types, including documents, spreadsheets, presentations, images, PDF files, and code files.

To attach a file, use one of the following methods.

- Choose the + (Add context) icon in the chat input area, and then choose Upload files.
- Drag and drop a file directly into the chat window.

Each attachment can be up to 50 MB. When you attach a file, Quick can read, analyze, and reference the file contents in its responses.

Local folders

You can give the agent access to local folders for it to read, write, or search their contents. To add a folder or view the folders you have already granted access to, choose the + (Add context)

icon in the chat input area, choose Local folders, and then choose Manage folders. This opens the Knowledge tab in Customize, where adding a folder works the same as choosing **Customize > Knowledge** and adding a folder there. For more information, see [the section called "Knowledge"](#).

Web search

You can turn on web search to allow Quick to search the internet for up-to-date information when it responds to your messages. When web search is on, Quick can retrieve current information from the web to supplement its responses.

To turn web search on or off, choose the + (Add context) icon in the chat input area, and then choose Web search. When web search is on, Quick includes citations from the web sources it references in its responses.

Spaces

You can attach a space to your conversation to give Quick access to shared team knowledge. Spaces contain curated collections of information that your team maintains in Amazon Quick. While it is attached, Amazon Quick answers from the content in that space and does not reach outside it on its own, so the conversation works within a narrow, scoped context for confidentiality or data compliance. This applies to everything in the space, including its files, datasets, dashboards, topics, and actions.

This is useful when you need answers grounded in your team's shared context, such as the following.

- Project documentation
- Company policies and procedures
- Domain-specific knowledge bases
- Team wikis and reference materials

If the answer is not in the attached space, Quick tells you so rather than answering from somewhere else. Ask Quick to search more broadly and it will, for the rest of that conversation until you change it again. A space you attach applies to that conversation only. Starting a new conversation starts with nothing attached, so you never inherit context from work you have already finished.

To attach a space, choose the + (Add context) icon in the chat input area, choose Spaces, and then select the space you want to use.

Slash commands

You can run commands directly from the chat input area. To open the command menu, type a forward slash (/) at the start of your message, and then choose a command or continue typing to filter the list.

Command	Description
/clear	Start a new conversation with fresh context. Your current chat is saved separately, not lost.
/compact	Condense the current conversation to free up context.
/export	Export the conversation as Markdown or PDF.
/mode	Switch the response mode (Fast, Balanced, Smart) and thinking level (Off, Low, Medium, High).
/rename	Rename the current conversation.
/copy	Copy the most recent response.
/skills	View the available skills.
/connectors	View and manage your connectors.
/goal	Give the agent a job to finish rather than a single question to answer. In a normal chat, it replies once and waits for you. With /goal, it keeps working on its own until the job is complete, double-checks its own work, and only then hands it back.
/help	View the list of available commands.

Mentions

To reference a specific agent, an item in your message, or people from your knowledge graph, type an at sign (@), and then choose from the list that appears. Mentions let you direct your request to a particular agent or person, or point Quick to a specific item, without leaving the chat input area.

Citations and sources

When Quick uses information that is not part of model knowledge to answer a question, it cites where that information came from. Citations help you verify a response and explore the underlying sources.

- **Inline citations:** Quick adds citation markers within its response. Choose a citation to open its source, such as a web page, a file, context, or a connected application.
- **Sources:** Quick shows a Sources summary with the full set of sources that informed a response. Sources can include web pages, files, connected data, and the memories that shaped the response.

For responses informed by your memory, the Sources panel shows the memories that were used. You can boost the memories that were helpful or remove the ones that were not.

Managing messages

You can revise and rerun the messages in a conversation.

- **Edit and rerun:** edit one of your earlier messages and submit it again. Quick generates a new response from the edited message.
- **Retry:** ask Quick to generate a new response to your most recent message.
- **Branch navigation:** when you edit a message or retry a response, Quick keeps each version as a separate branch. Use the branch controls to move between the previous and next versions and compare responses.

Each message also supports inline actions. On a message you sent, you can copy it, edit it, or reply in a thread. Messages can carry emoji reactions, shown as a row of reaction pills. In a read-only transcript, copy remains available while edit and reply are hidden, and reply is not offered inside a thread.

Running work in the background

While Quick is responding, you can send the task to the background and keep working in another conversation. To send the current task to the background, choose the send-to-background control, or press Ctrl+B (Windows) or Cmd+B (macOS). The task continues to run, and Quick notifies you when it finishes.

You can also queue follow-up messages while Quick is working. Queued items show a count and can be sent immediately or removed.

Coding agent sessions

You can use coding agents such as Kiro, Claude, or other connected agents to accomplish coding tasks directly inside a conversation. The desktop application's local code execution runs in an isolated sandbox that blocks common coding commands, so you delegate those tasks to a coding agent. For information about connecting a coding agent, see [the section called “Connectors”](#).

Plan mode

For complex, multi-step tasks, you can use plan mode. When you turn on plan mode, Quick breaks your request into a structured plan with individual steps before it executes. You can review and modify the plan before Quick proceeds with each step. The plan appears in a panel next to your conversation and as a plan card in the chat.

Plan mode is useful for tasks such as the following.

- Multi-file document generation
- Complex data analysis workflows
- Multi-step research projects
- Large-scale code refactoring

Deep research

Deep research provides structured, multi-step investigation. When you start deep research, Quick investigates your question across multiple sources and compiles the results into a comprehensive deliverable. A research plan card appears in the conversation and shows live progress as Quick gathers information, generates figures, and finalizes the report.

Deep research is useful for the following tasks.

- Market research and competitive analysis
- Technical topic deep dives
- Strategic planning and investigation
- Multi-angle problem exploration

To start deep research, ask Quick to research a topic or perform a comprehensive investigation. To follow along while Quick works, choose View research progress on the research plan card.

Incognito mode

Use incognito mode when you want a private conversation that does not update your memory or history. In an incognito conversation, Quick does not read from or write to your long-term memory or knowledge graph, and your responses are not personalized from past conversations. The conversation does not appear in Recents, and it is discarded with nothing retained when you leave it.

Inside an incognito conversation, Quick still follows the current conversation from turn to turn, and it can still search files that you have already indexed. It does not remember anything after you leave the conversation.

To start an incognito conversation, choose the Incognito control at the top right of the chat surface. A private-mode indicator appears while incognito is active.

Note

Privacy is locked once a chat has messages. Turn on incognito before you begin. When you leave an incognito conversation, its contents are deleted and nothing is retained.

Managing conversation context

The Context used indicator shows how much of the conversation context window is in use. As the conversation grows, it fills. To free context during a long session, choose Summarize to compact the conversation history, or start a new conversation.

Away From Keyboard (AFK) recap

When you step away during a long-running task and return, Quick shows an away-from-keyboard (AFK) recap. The recap summarizes what happened while you were away, so you can catch up quickly without scrolling through the full conversation. This recap is specific to a task running in the current conversation. For a summary of activity across your connected services while you were away, see the feed catch-up in [the section called “Activity feed”](#).

Managing conversations

Quick keeps your conversation history in your Amazon Quick account, so it is available to you across the web, mobile, and desktop. You can organize, search, and manage your conversations with the following features.

- **Folders:** organize your conversations into folders. You can create, rename, and delete folders, and drag conversations between them. Auto-clean up sorts chats into folders by topic.
- **Pinning:** pin important conversations to keep them at the top of your chat history.
- **Search:** search across all of your conversations from the search control in the sidebar.
- **Archive:** archive conversations that you no longer need without deleting them.
- **Thread routing:** Quick can route related discussions into organized threads for structured conversations, and you can reply in a thread to branch a sub-conversation from a specific message.

Your conversation history appears in the Recents section of the sidebar, organized by date.

Creating documents and visuals

Quick generates documents directly from chat, including presentations (.pptx), Word documents (.docx), spreadsheets (.xlsx), PDF files, Markdown, and HTML, along with interactive data visualizations. Describe what you need. For example, "Create a presentation about our quarterly results." Generated items appear as artifacts that you can save locally or to your Library. For detailed information about supported formats, editing, visualizations, and best practices, see [Document and visual creation](#).

Quick can also generate and edit images from a text description. Generated images appear as artifacts you can save locally or add to a space.

Session tabs

Documents and artifacts open in session tabs alongside the conversation. In a session tab you view and edit a rendered document, turn on selection mode to select text, images, and tables and add them as context for your next prompt, and act on the open document (open, download, add to a space, share, or open in chat). Multiple documents can stay open as tabs at once.

All data and apps

The All data and apps panel shows the spaces, local folders, and skills available to the current conversation, so you can add or adjust the resources the agent draws on. Skills show a status indicator.

Exporting a conversation

You can export an entire conversation to share it or keep a record. To export the current conversation, use the `/export` command or the export action, and then choose Markdown or PDF.

Activity feed

The activity feed is your single place to catch what happened across your connected services, such as Slack, Outlook, and your calendar, without opening each app. Amazon Quick reads that activity, enriches it with your knowledge graph (the people, projects, and topics in your work), and surfaces only what is relevant to you. A feed agent processes items from your connected messaging, email, and calendar sources, assigns importance, and suggests actions. The feed is organized into Feed, Calendar, and To-dos tabs.

The feed has these characteristics.

- **Personalized every time:** items are ranked by what matters to you, not by what arrived most recently.
- **Burns down as you work:** the feed gets smaller as you handle items, not bigger. The goal is an empty feed, not an endless timeline.
- **Does not consume agent hours:** using the feed does not consume agent hours. Only scheduled tasks that post results to your feed use agent hours. For plan availability and pricing, see [Amazon Quick pricing](#).

On Home

Your activity feed surfaces directly on the desktop and mobile home page, so the items that need you are the first thing you see. From Home you can open the full feed to review everything in one place.

Feed

The Feed tab shows an aggregated activity stream. Each item shows its source service, an AI-generated summary, an importance level, and suggested actions, including a suggested draft when a reply is appropriate. Related items group into collapsible threads. A density control switches the cards between a comfortable and a compact layout.

Quick assigns one of the following importance levels.

Level	Description
Important	Requires immediate attention: direct mentions, urgent requests, time-sensitive updates.
Informational	Relevant but not immediately actionable: project updates, team announcements.
Low priority	Reviewable later: general channel activity and for-your-information messages.

Briefing

Quick on desktop delivers a daily briefing at the top of your activity feed to help you stay on top of your day. The briefing is a curated card that summarizes what you need to know: overnight activity in your connected services, your day plan and calendar, decisions that need your attention, and follow-ups that are due. Choose **Show briefing** on the card to expand it, or choose the card to open the full briefing view.

- **Delivered through the feed:** the briefing appears as a card at the top of your activity feed. You do not need to configure it separately.
- **Updated three times a day:** the briefing refreshes in the morning, midday, and afternoon, so it reflects the latest activity, not just what happened overnight.
- **Personalized over time:** Quick tailors the briefing based on the topics, people, and projects you engage with.
- **Actionable:** suggested actions on the briefing, for example review a draft response, open a document, or start a chat, are the same actions available on individual feed items.

A condensed view of your highest-priority feed items also appears on the chat Home screen, with a link to open the full feed.

Filters and search

Filters are visible by default at the top of the feed. Narrow the feed by label, project, person, or priority, and customize which filters appear for your workflow. A search bar at the top of the feed searches up to seven days of feed activity, so you can locate a specific notification or agent result in seconds. You can also sort the feed, for example ranked, most recent, by project, or by person.

Auto resolve

Quick automatically clears feed items that no longer need you, so your feed stays focused on what is still open. When an item has been handled, such as when you replied to the message elsewhere, the meeting passed, or a newer update supersedes it, Quick resolves it for you. Resolved items collapse behind a Resolved filter, so you can still review what was cleared. You can also give feedback on any item (Not relevant, Already handled, or Something else) to sharpen what surfaces over time.

Catch-up

When you return after being away, the feed offers a catch-up summary: a consolidated view of everything that happened while you were gone, organized by importance level, so you can get up to speed quickly. This summarizes activity across your connected services. For a recap of a single long-running task in a conversation, see the Away From Keyboard (AFK) recap in [the section called “Working with chat”](#).

Always on

Because Quick runs in the cloud, your feed continues to update while the desktop application is closed and your computer is off. Scheduled tasks, monitoring agents, and background workflows run overnight and post their results to your feed, so anything that happened while you were away is captured and waiting for you. You open your day to a feed and briefing that already reflect what is most important, instead of starting from an empty screen or a backlog to sort through.

Calendar

The Calendar tab shows your day on a time grid, today or tomorrow, alongside a Quick Suggests side panel of AI recommendations tied to your events and free time. Each suggestion is a card

you act on, copy, or mark done, and you can start a chat about it. For a free slot, Quick can block focus time directly on your calendar. Other suggestions start a chat with a prefilled prompt, such as preparing for a meeting.

To-dos

The To-dos tab tracks a personal task list alongside the feed. Tasks show due dates and importance, can originate from feed items, and you can create a new task directly.

Configuring the feed

Choose which connected sources surface items to your feed, grouped by function.

Category	Sources
Messaging	Direct messages, mentions, and thread replies from a connected messaging service.
Mail	New email from people who matter to you.
Calendar	Meeting reminders with join links and the day ahead.

You also set how often the feed agent checks for new activity. For feed settings, see Settings.

Library

Library is where you browse, search, and pick up where you left off on content and resources. You can search, filter it by content type, and switch between a table view and a thumbnail grid.

What Library holds

Library stores typed content, including documents, presentations, spreadsheets, PDF files, HTML, images, audio, video, and Markdown, along with Amazon Quick resources such as apps, spaces, agents, skills, research, datasets, dashboards, analyses, flows, automations, and topics.

Views and filters

Switch between list and grid views, with columns for type, owner, and last viewed. Filter by ownership, favorites, owned by you, or shared with you, and by content type. You can favorite items with a star.

Item actions

From an item's menu you open, download, add to a space, share, open in chat, or delete it. Opening an item shows it in a session tab, where you read it and select content to add as context.

Sharing files

Sharing gives view access to that file only. Recipients find the file in their own Library. Choose **Copy link** to get a link to the file that you can send in chat or email. The link works only for people you have already shared the file with.

Apps in Amazon Quick

Apps in Amazon Quick are interactive applications you build by describing what you want, and they are available directly in the desktop application. This section covers how to reach apps on desktop. For how to build, edit, publish, and share an app, see [Build web applications with apps in Quick](#).

There are three ways to get to apps on desktop.

- **From the left navigation:** choose **Apps**, to open the apps landing page, where you describe a new app or browse existing ones.
- **From the Library:** open your Library to see apps you already have access to, including apps shared with you, alongside your other saved items.
- **From chat:** ask Quick to build an app right in a conversation. Quick creates it and opens it for you, with no separate setup needed.

Once an app is open, you can interact with it in a session tab, including full-screen and side-by-side with chat.

Apps in Amazon Quick is available in a subset of AWS Regions. For the list, see [the section called "Regional availability"](#).

Spaces

Spaces are curated collections of documents and Amazon Quick resources that an agent uses as a source of information. On desktop you browse spaces, chat with them as context, and create new ones by navigating to **Spaces** in the left navigation or through chat.

Browsing spaces

Search spaces by name, filter them (Favorites, Owned by me, and Created by me), and switch between Card and List views. Each space offers a quick action to start a chat with it, plus a per-space menu.

Chatting with a space

Attach a space to a conversation to ground the responses from Quick in that shared context, for example project documentation, policies and procedures, or a team reference. You attach a space from the chat composer's data controls or from the All data and apps panel. To learn more about the chat boundary with spaces, see [the section called "Working with chat"](#).

Creating and organizing spaces

Choose **Create** to make a new space. Selecting a space opens it as a tab, so you keep chatting while viewing it. After you create a space, you can create a folder, upload files, upload a folder, or add assets (dashboards, knowledge bases, actions, or datasets).

Uploading your local files and folders makes them searchable in natural language. After your files are uploaded and reach a Ready status, you can query them in natural language.

Note

Adding documents to spaces consumes index cost. For details, see [Amazon Quick pricing](#).

Customize

Customize is the hub for managing everything that powers your agents. It has four tabs:

- **Agents:** build and manage agents. For more information, see [the section called "Agents"](#).
- **Skills:** create and manage skills. For more information, see [the section called "Skills"](#).

- **Connectors:** manage web and cloud connectors, MCP servers, and coding agents. For more information, see [the section called "Connectors"](#).
- **Knowledge:** give Quick access to folders on your computer and control how they are indexed. For more information, see [the section called "Knowledge"](#).

Across the Customize tabs you install additional agents, skills, and connectors from the Add to Quick catalog, which offers items shared with you and, for skills, an Official set published by Amazon that you filter by category.

Agents

Agents are configurable AIs in Amazon Quick. You give each one its own instructions, knowledge sources, and tools so it can answer questions and get work done for you. Quick is the built-in agent, and you can also build your own or install ones shared with you. Each agent can work with you in chat or run on its own on a routine. Agents can only access the same resources and services that you have access to, and you control what each agent is allowed to do.

Users can browse agents that are shared with them on the Agents page by choosing **Browse all**. This view presents available agents in a read-only detail view along with the description and knowledge sources each one uses. From this view, you can install an agent to add it to your agent list. Once installed, an agent is ready to use anywhere you work: you can chat with it, @ mention it inline in any conversation, and run it on a routine, and it appears in your agent switcher for quick access. From the Agents page, you can favorite an agent for easy access or set an agent as your default. A published agent can also be accessed from Quick on the web.

Creating an agent

You can create an agent through the interface or through natural language. To create an agent through natural language, enter "I want to create an agent" in the conversation.

To create an agent

1. Choose **Customize** in the navigation, and then choose the **Agents** tab.
2. Choose **Create**, and then choose **From chat** (or say "create an agent" in chat). To import an existing agent definition, choose **From file** instead.
3. Describe what you want the agent to do in natural language.
4. Quick generates a draft configuration including name, description, and instructions.

5. Review and refine the configuration through conversation or by editing fields directly.
6. Publish the agent when you are ready. Agents cannot be shared with other users until published. Agents are private unless shared explicitly.

You can attach reference documents during creation to provide additional context. You can also start editing an agent by mentioning it with an at-sign in chat, which opens the agent editor in a session tab.

Agent configuration

The agent editor organizes configuration into two tabs.

Instructions tab: set the agent's Name, Description, and Instructions. Instructions support rich formatting (headings, lists, emphasis, code, and quotes) and a welcome message with starter prompts. Instructions can be up to 50,000 characters.

The Capabilities tab has these fields.

Capability	Description
Web search	Toggle to allow the agent to search the web.
Skills	The skills the agent can use. By default an agent can use all skills; if you add specific skills, the agent is limited to those. Remove them to re-enable all skills.
Spaces	Connected data sources the agent reads from.
Connections	Connectors and the tools that the agent can be configured to use.

Using an agent

Use one of the following ways to use your agent.

- **Agent switcher:** choose an agent at the top of chat to start a conversation with it.
- **At-mention:** mention an agent by name in any chat to invoke it inline.
- **Chat button:** start a new conversation from an agent's landing page.

- **Run it on a routine:** pair the agent with a routine to run on a recurring basis without prompting. Routines run in the cloud, so they keep running even when your laptop is closed or offline. The agent stores deliverables in its **Agent Files** and surfaces results on its **Agent briefing** page (when briefing is turned on) and **Mission Control** activity page.

You ask questions and get responses shaped by the agent's instructions and connected data sources, applications, and skills. Have it perform tasks using its configured tools and connections.

Monitoring agents

You can monitor agent activity in two places.

- **Agent landing page:** the agent's overall page, with Overview (including an AI-generated agent briefing), Activities, Agent Files, and Settings tabs. View a specific agent's runs, approvals, routines, and deliverables.
- **Mission Control:** a centralized command center that gives you visibility across all your agents in one place. Monitor all agent activity, unblock agents that need input, view running agents, manage routines, and track KPIs, without switching between individual agent pages. For more information, see [the section called "Mission Control"](#). Access Mission Control from the icon in the top-right navigation bar.

Agent landing page

Each agent has a landing page with four tabs.

Tab	Description
Overview	Summary of the agent's purpose, items needing your input, and an AI-generated agent briefing.
Activities	Activity log with filter tabs: All, Needs input, Running, and Routines.
Agent Files	Persistent file storage: artifacts and deliverables the agent has produced across runs.
Settings	Agent preferences, such as automatic briefing updates. Instructions and capabilities are edited from Configuration, not here.

The Overview tab includes the following sections.

- **Needs input:** when the agent pauses on an action that requires your decision, an approval card appears. Each card shows a description of the proposed action with **Approve** and **Deny** buttons.
- **Agent briefing:** an AI-generated summary of the agent's work (for example, top findings, trend analysis, or status dashboards). It updates after each run and can be regenerated on demand.

The Activities tab shows past and current agent work. You can filter the view using the following sub-tabs.

- **All:** shows all activities in reverse chronological order. Each entry includes a title, summary, agent name, and timestamp.
- **Needs input:** items where the agent paused and is waiting for your decision. Each item shows **Approve** and **Deny** buttons.
- **Running:** tasks in progress.
- **Routines:** lists the agent's configured routines. Time-based routines (schedules), for example, "Every Monday at 9 AM" or "Every weekday at 8:30 AM," are supported on the desktop today. Each routine has a play button to trigger a run and a toggle to turn it on or off. Choose **Create** to add a new routine.

Activities can include file attachments (for example, drafted documents or reports) that you can open and review.

Run status

Each run shows its current status. A run is **Running** while it is in progress, and **Needs input** when it has finished or paused with one or more actions awaiting your decision. Once a run ends, it is **Completed** if it finished with no issues, **Interrupted** if it was stopped before completing, or **Failed** if it ended with an error. An agent that has not run yet shows **No runs yet**. On the Agents list, the Status column summarizes each agent's most recent run, so these finished states appear there as "Last run completed," "Last run interrupted," or "Last run failed."

Managing agents

Agents are versioned. You work on a draft, add release notes that are shown to your team on publish, and then publish. You can manage versions and discard a draft. Agents cannot be shared with other users until published, and a routine always runs the published version.

From an agent's menu you can **make it your default**, so Quick uses it for every new chat until you pick another, as well as **share** it, **export** its configuration to a JSON file, **duplicate** it, **manage its versions** (switch between the published and draft versions), **manage its routines** (the routines that run it on its own), **uninstall** it, or **delete** it. Uninstall removes the agent from your list only; it stays available to everyone else it is shared with. Delete removes an agent you own for everyone. The Agents list supports search, filtering (including by status and version), sorting (including by last run and last modified), favoriting, and list or grid views. The list shows each agent's description, last-modified time, and run status.

For others to use your agent's connected sources, you must share those with the intended recipients. Otherwise, they will only get responses from the sources they have access to. You do not need to share all underlying resources.

Skills

Skills are reusable sets of instructions that teach your agents how to do a specific task. Each skill packages the steps and know-how for that task. Instead of re-explaining how you want a task done every time, you capture it once as a skill, and Quick applies those instructions whenever the task comes up, for example writing a blog post that follows your brand guidelines, or preparing a weekly status update from your template. You can create your own skills, publish and share them, and install skills that other people in your organization share with you. You manage these from the **Skills** tab (**Customize > Skills**).

Skill definition

A skill is a folder with a `SKILL.md` file at its root. That file holds a description (a short summary of what the skill is for, which Quick uses to recognize when the skill applies to your request) and instructions (the steps and guidance Quick follows when the skill is active, which can define a multi-step process, not just a single prompt).

A skill can also reference tools and bundle reference files.

- **Referenced tools:** the tools the skill relies on. Tools are defined separately, as connectors or built-in capabilities. A skill points to the tools it needs rather than containing them, and Quick makes them available when the skill activates.
- **Reference files:** supporting files the instructions draw on, such as scripts, templates, or examples.

How agents load skills

Agents load skills in two stages.

1. Discovery: agents search skills by name and description to know when a skill is relevant.
2. Activation: when your request matches a skill's description, or you name the skill, the agent reads its full instructions into the conversation and then follows them, including the referenced tools and files.

Owner and viewer

What you can do with a skill you created or installed depends on your role for it.

- Owner: you created the skill or duplicated one into your own. You can edit, publish, share, export, and delete it.
- Viewer: someone shared the skill with you. You can add and use it, and it stays in sync with the owner's published version. You cannot edit, publish, re-share, or delete it. To make a version you can change, duplicate it. Duplicating creates a separate skill that you own.

System skills

Quick includes system skills, pre-installed skills for capabilities such as document creation, presentations, spreadsheets, web browsing, code execution, knowledge graph management, and transcription. They carry a System badge. You can try one and turn it on or off, but you cannot edit, duplicate, export, publish, share, or delete it.

Creating a skill

To create a skill, choose **Customize > Skills**, choose **Create**, and then choose a method.

To create a skill from chat

1. Choose **Create**, and then choose **From chat**.
2. Describe the skill you want. Quick drafts the instructions, selects the tools to reference, and creates the SKILL.md file.
3. Review and edit the skill, and then save it.

To create a skill from a file

1. Choose **Create**, and then choose **From file**.
2. Select a .md or .zip file from your computer.
3. Review and edit the skill, and then save it.

To create a skill from a folder

1. Choose **Create**, and then choose **From folder**.
2. Select a folder that contains a SKILL .md file at its root, along with any reference files the skill uses.
3. Review and edit the skill, and then save it.

Tip

When you finish a multi-step task in chat, Quick might offer to save those steps as a reusable skill.

Using a skill

You can use a skill in one of the following ways.

- By name: mention the skill in your message. For example, enter "use the Web Browser skill to check this page."
- Automatic activation: Quick detects when a skill matches your request and loads it without you asking. For example, when you ask Quick to build a presentation, the Presentations skill loads.
- Try it: on a skill's detail panel, choose Try it to start a conversation with the skill loaded. Use Try it to test a skill you created, imported, or have in draft before you publish it.

The skill detail panel

Choose a skill to open its detail panel. The panel shows the skill's description, its instructions, and its reference files. The available actions depend on whether it is a built-in skill or one of your own, your role for it, and whether it is published.

Action	Description
Try it	Start a conversation with the skill loaded.
Edit	Change the skill's instructions and files. Edits are saved to the draft. Owner only.
Publish	Make the draft the live published version, available when the skill has unpublished changes. Owner only.
Duplicate	Copy the skill as the starting point for a new one that you own.
Add to favorites	Pin the skill under the Favorites filter.
Share	Share the skill with people or groups, or with your entire account. Owner only.
Export	Download the skill as a file. Owner only.
Enable or disable	Turn the skill on or off. A disabled skill stays in your list but is not loaded until you turn it back on.
Uninstall or Delete	For a skill shared with you, Uninstall removes it from your list only. For a skill you own, Delete removes it permanently for everyone it is shared with, not just you.

Draft and published versions

A skill you own has two versions.

- **Draft:** the version you edit. Changes you make are saved to the draft and do not affect how the skill runs until you publish. A skill with unpublished changes shows an Unpublished changes indicator.
- **Published (live):** the live published version, which Quick uses when the skill runs.

To update a skill, edit the draft, choose Try it to test it, and then choose Publish. Publishing replaces what is live, and everyone you shared the skill with moves to the update. Because your

draft stays separate from what is published, a skill already in use keeps running the same way while you work on its next version.

Managing skills

The Skills tab lists every skill you can use.

- Search: find skills by name or description.
- Filter: narrow to Favorites, Owned by me, or Shared with me.
- Sort: order the list, for example by Last modified.
- View: switch between a list view and a grid of cards.
- Status: the Status column shows whether each skill is enabled.
- Version indicator: for a skill you own, the list shows a Draft or Unpublished changes label when the draft is ahead of the published version.

Browsing for more skills

To find skills beyond the ones in your list, choose **Browse all** on the Skills tab. This opens Add to Quick, scoped to skills, with two ways to find them: Official (curated, first-party skills provided by Amazon Quick) and Shared with me (skills that people or teams in your organization have shared with you). Search by name, filter by Owner and Category, and sort the results. Choose a skill to preview its description and details before you add it.

When you add a skill from Official or Shared with me, it enters your list as a reference to the owner's published version, not a copy. It stays in sync and updates automatically as the owner republishes. To make a version you can change, duplicate it.

Note

The Quick official skills span everyday productivity, role-based solutions for teams such as Sales, Marketing, and Legal, and industry depth in areas such as Finance, Healthcare and Life Sciences, and Energy and Utilities. New skills are added over time.

Sharing your skills

Publishing and sharing are separate steps. Publishing creates the live version of a skill but does not distribute it. Sharing is a separate action in which you choose who receives the skill. Publishing a skill does not share it with anyone.

To share a skill you own

1. Open the skill's detail panel.
2. Choose **Share**.
3. Choose who to share it with: specific people or groups, or your entire account with Share with all.

People you share the skill with find it in Add to Quick under Shared with me and add it to their own list. As viewers, their skill stays in sync with your published version and updates automatically as you republish.

Note

Your administrator can require approval before a skill is shared, and can control whether skills can be shared with your entire account. See Administrator controls (the next section).

Administrator controls

Administrators can restrict skills through custom permissions. Custom permissions is a scope-down policy that an administrator applies at the account, role, or user level to limit the capabilities people can use. It restricts capabilities; it does not grant them. The following capabilities apply to skills.

- **Skills:** restricts access to skills, including sharing them. This is the parent capability; denying it restricts the skill's full feature set.
- **Share skills with individuals:** a child of the Skills capability. When denied, users cannot share skills with individuals.
- **Share skills with all:** a child of the Skills capability. When denied, users cannot share skills with their entire account; they can still share with specific people or groups if that is allowed.

- Require approval to share skills: a child of the Skills capability. When enabled, a skill must be approved before it is shared.

For how administrators configure custom permissions profiles and how precedence is resolved across the account, role, and user levels, see [the section called “Custom permissions”](#).

Connectors

Connectors bring cloud connectors, system tools, local connectors, and coding agents together in one place, with a catalog to discover and add new ones. A connector links Amazon Quick to an external application or a native tool so agents can access data and act on your behalf. You manage them from Customize, on the Connectors tab, which supports four capabilities.

- Cloud connectors connect Quick to external services such as Outlook, SharePoint, OneDrive, Slack, Jira, Asana, Airtable, and Salesforce, as well as remotely hosted Model Context Protocol (MCP) servers. Once connected, they are reachable from any Quick device, including desktop, mobile, and web.
- System tools are the capabilities Quick provides out of the box, such as image generation, browser automation, and research. You do not install or sign in to them, but you can turn them on or off. Some run in the cloud; others, such as browser automation, are device specific. For the full list, see [the section called “System tools”](#).
- Local connectors run on your own machine, covering local MCP servers you host yourself. Their tools are available only when that machine is on and connected.
- Coding agents such as Kiro and Claude Code can be connected so you can delegate development work to them from chat. See the Coding agents section.

Discovering and adding connectors

On the Connectors tab, you can discover and add connectors that expand what Amazon Quick can do for you. To see the full catalog, choose **Browse all**. Each connector card shows its name and a short description of what it does.

Adding a cloud connector

Cloud connectors in the catalog are either connectors that have been shared with you or connectors that you can set up with a single click of Install followed by a sign-in. The Suggested for

your area contains cloud connectors that have already been set up and shared with you, along with the most popular cloud connectors for Quick users. When you install one of these connectors, by default Amazon Quick connects to the external service using an Amazon-hosted OAuth application for that service. OAuth applications are the standard way an application, such as Quick, makes calls to an external application, such as Outlook or Salesforce, on your behalf. An end-user sign-in is also required.

Some enterprises prefer to use their own OAuth application rather than the Amazon default. To do this, choose Create and then choose Cloud Connector. This Create option gives additional enterprise admin controls during setup, such as setting a connector's name, description, who it is shared with, and its tool permissions. Connectors that do not have an Amazon default OAuth application are also found in the Create section. Creating a custom connection to a remotely hosted MCP server also uses Create and then Cloud Connector.

Connectors you add appear automatically in the connectors table in the lower half of the Connectors tab.

Adding a local connector

Beyond the connectors in the catalog, you can add a local connector that runs on your own machine, such as a local MCP server. A local connector lets Amazon Quick use tools you host yourself, such as a database, an internal API, or a developer tool, so those tools become available to agents in chat and in scheduled tasks. To add one, choose Create and then choose Create local connector. Because a local connector runs on your machine, its tools are available only when that machine is on and connected. For the MCP server fields, see the MCP servers section.

Adding a coding agent

You can also connect a coding agent, an external AI coding tool such as Kiro or Claude Code, that Amazon Quick can hand development work to. Once a coding agent is connected and enabled, you can delegate tasks to it from chat, and it does the work and reports back. To add one, choose Create and then choose Coding agent. See the Coding agents section.

Managing your installed connectors

The Connectors tab has a table of all your installed connectors. Each connector shows its name and description, its Type (Cloud, Local, or System), its Owner, and its Status. To manage your connectors, you can do the following.

Action	Description
Search	Find a connector by name.
Filter	Narrow the list to Cloud, Local, or System connectors. Additional filters are available from the filter control next to the connector type filters.
Sort	Order the list, for example by Recommended.
Sign in	Complete the authentication flow for a connector that requires it before it can be used.
Enable or disable	Turn an individual connector on or off with its status toggle, without removing it.
Create	Add a new connector (an MCP server or a coding agent) using the Create button.
Browse all	Open Add to Quick to discover and install more connectors.

Each connector also has an actions menu with options that depend on its type. For all connectors, you can manage tool permissions (see the next section) and enable or disable the connector.

Connector type	Actions menu options
Cloud connectors	Try it (see example prompts in chat), About connector (view connector details), Sign out, and Uninstall.
Local connectors	Try it, Edit, and Delete.
System tools	Try it.

Some connectors are shared with you by your organization. A connector's Owner column shows whether you own it or it was shared with you. For a connector that supports more than one workspace, for example Slack, choose Set preferred workspace to pick which workspace Quick uses.

Managing tool permissions

Connectors provide tools that agents can use on your behalf. Because a tool can make changes in an external application, Amazon Quick can pause for a consent step before a tool runs, keeping a human in the loop on the changes an agent makes. Whether this consent step is needed is controlled with tool permissions, which are set at two levels: a connector owner level and a user preference level.

Connector owners, usually the application admins who share connectors with users, control one level of settings, and those settings are enforced for everyone who uses the connector. At the owner level, each tool can be set to one of three options.

Owner setting	Description
Let Users Choose	Hands the decision to each user, who then chooses how the tool behaves for them. This is the default.
Always Ask	The tool always pauses for a consent step before it runs, for every user.
Disable	The tool is turned off and is not available to users.

When a tool is set to Let Users Choose at the connector level, each user can set their own preference for the tools they use. The following options are available at the user level.

User setting	Description
Always Allow	The tool runs without a consent step.
Ask Each Time	The tool pauses for a consent step each time it runs.
Disable	The tool is turned off for you and does not run.

By default, tools are set to Let Users Choose at the connector level. The user-level default then depends on whether the tool performs a write task or a read task.

Task type	Connector-level default	User-level default
Write tasks	Let Users Choose	Ask Each Time (can be changed by the user)
Read tasks	Let Users Choose	Always Allow (can be changed by the user)

New tools discovered during an MCP sync are disabled by default, so a connector owner can review them before making them available.

MCP servers

Amazon Quick supports the Model Context Protocol (MCP), an open standard that extends Quick with custom tools and integrations. When you connect an MCP server, its tools become available in your chat conversations and scheduled runs, for example a server that provides database query tools.

To add one, choose Create and then MCP server. A dialog offers three connection types. You can also paste a standard MCP server JSON configuration to populate the form.

Local

Run an MCP server as a command on your machine, the most common option for development tools and locally installed servers.

Field	Required	Description
Name	Yes	A friendly name, for example "My Database MCP".
Command	Yes	The executable to run. Common values: python, npx, node, uvx.
Arguments	No	Command-line arguments, space-separated, for example <code>-m mcp_server --port 8080</code> .
Description	No	What the server does and what tools it provides, so Quick knows when to use it.

Field	Required	Description
Environment variables	No	Key-value pairs the server requires.
Startup timeout	No	Seconds to wait for the server to start, 5 to 300 (default 30).

Import

Load MCP server definitions from an existing configuration file, so you reuse configurations from other tools. Quick supports configuration files from Kiro, Claude Code, AIM, Antigravity, and QuickWork exports. Enter the configuration file path (for example, `~/.kiro/settings/mcp.json`). Quick scans the file and detects the servers defined in it, and also detects compatible tools installed on your system, showing them as chips under "Detected on this system". Choose Load file to import the servers.

Remote

Connect to an MCP server over HTTP, for shared team servers or hosted services.

Field	Required	Description
Name	Yes	A friendly name.
URL	Yes	The MCP endpoint URL. Must start with <code>http://</code> or <code>https://</code> .
Headers	No	HTTP request headers as key-value rows, for example an <code>Authorization</code> header. A header value can be stored as a secret in your operating system keychain.
Description	No	What the server does and what tools it provides.
Startup timeout	No	Seconds to wait for the server, 5 to 300 (default 30).

After you add servers, they appear in the MCP servers section, where you search, filter by status, toggle individual servers on or off, edit, and remove them. You can attach MCP servers to a schedule so automated runs use their tools.

Coding agents

Coding agents are external AI coding tools that Amazon Quick delegates development tasks to, using the Agent Client Protocol (ACP). When enabled, you ask Quick to send work to a coding agent, for example "refactor this module," and Quick reports the results back.

To add a coding agent

1. Choose Customize, and then choose the Connectors tab.
2. Choose Create, and then choose Coding agent.
3. Configure the agent, and then save.

You add a coding agent from a preset (a one-click add for a supported agent, which you edit afterward) or with a custom configuration. A custom agent is configured with a Name, the launch Command and Arguments, an optional Description, and optional advanced settings.

- Environment variables: values the agent needs at launch.
- Override path: where the agent runs. When empty, the agent runs in the current conversation's workspace. An absolute path supports mounted, external-volume, or remote setups.
- MCP server forwarding: which MCP servers are forwarded to the agent: None (the default), All enabled, or Choose specific servers.

For a supported preset agent, additional configuration is available: tool permissions with three states per tool (Off, Ask for Permission, or Auto-approve), write-path scoping, and model selection. You can test the connection before saving.

Add only coding agents your organization approves. You are responsible for the security and data-handling compliance of any coding agent you register.

Knowledge

The Knowledge tab in Customize is where you give Amazon Quick access to files on your computer and control how Quick indexes them. For each folder, choose whether Quick uploads its files for

full-content search, extracts information from them into your knowledge graph, both, or neither. Adding a folder grants access only; indexing stays off until you turn it on.

Indexing options

Open a folder's details pane and choose **Settings** to find these options under Indexing.

Option	Description
Allow full file context for enhanced searching	Uploads and indexes this folder's files so Quick can search across their full content, including in scheduled and background work. When this option is on, it shows estimated monthly usage as a percentage of the monthly indexing budget.
Always remember file information	Uploads this folder's files and extracts people, projects, and dates from them into your knowledge graph. When this option is on, it shows estimated monthly usage as a percentage of the monthly budget available for extraction.
Agent access	Lets Quick read files from this folder. A folder in your list always has agent access, so turning this off removes the folder. Quick asks you to confirm first.

Details

The Details tab reports Files, Size, and Entities extracted. Entities extracted shows a dash until you turn on Always remember file information. Choose **Files** to jump to the advanced settings. Choose **Sync** at the top of the pane to pick up changes immediately.

Advanced settings

Choose **Advanced** on the Settings tab to reach the per-folder indexing controls. Scan interval (every 30 minutes) and Max file size are read-only; files larger than the maximum are skipped. You can set Max file age to index only files modified within a window, restrict File extensions, add Exclude patterns as glob patterns that Quick never indexes, and give knowledge graph extraction instructions to guide entity extraction. Rescan folder picks up changes incrementally. Rebuild index rebuilds from scratch and shows a cost estimate first.

Search indexing limits

Global search-indexing limits apply across all indexed folders. Indexing stops automatically when free disk space falls below 8.0 GiB. You set a storage limit for the knowledge database, a maximum file size for indexing (larger files are skipped but remain available through direct search), and a maximum folder size for indexing.

Folder access permissions

To set what Quick can do with a folder, choose **Manage permissions** and set an access level: Full Access (read and write), Read Only, or Ask Each Time. You can adjust individual read and write operations independently.

Mission Control

Mission Control is a centralized command center in the Amazon Quick desktop application that gives you full visibility and management over all your agents in one place. You monitor agent activity, review outputs, manage routines, and track performance metrics, so you do not need to check on agents individually.

Why use Mission Control

As you scale your use of agents with background tasks and automated workflows, keeping track of everything becomes complex. Mission Control provides these benefits.

- Centralized visibility: view all agent activity without switching between conversations or agents.
- Faster unblocking: agents that need your input are surfaced clearly, so you respond quickly.
- Operational awareness: key performance indicators (KPIs) and run history confirm your agents are working correctly.
- Efficiency at scale: whether you have 2 agents or 20, Mission Control keeps you in control.

Capabilities

Mission Control provides these capabilities for managing your agents.

Capability	Description
Monitor all agent activity	View a unified list of what every agent has done across all runs.
Filter by agent name	Drill into a specific agent's history and access its outputs.
Unblock agents	Filter on agents that need your input and provide it directly.
View running agents	See which agents are currently active and monitor their progress.
Manage routines	View and edit routines for all agents in one place.
Track KPIs	Understand error rates, active agents, completed tasks, and total runs.
View creator analytics	See insights on how your shared agents and apps are being adopted.

Routines

The desktop application runs your agents automatically through routines. A schedule, an agent that runs at recurring times, is the first routine type. You define what the agent does, when it runs, its capabilities, and its response mode. Quick delivers each run to your feed or a connected app. Schedules are currently the available routine type.

You configure a routine in a modal with two tabs: Overview and Activity.

The Overview tab has these fields.

Field	Description
Repeats	How often the routine runs (for example, daily) and the time of day it runs.
Custom time range	Optionally set a start date and time, an end date and time, and a time zone that bound when the routine is active.
Triggers	Select the agent that you want to run when the routine starts.

Field	Description
Uses	The capabilities, such as MCP servers and tools, the routine can use. Choose + Add to attach more.
Instructions	What the agent should accomplish each time the routine runs.
Model details	Expand to configure the model, thinking effort, memory, and sub-task settings for the routine.

Expand Model details to configure these options.

- Model: choose Fast, Balanced, or Smart.
- Thinking effort: have the agent apply additional reasoning before responding.
- Include memory: allow the agent to use profile and search tools.
- Allow spawning sub-tasks: let the agent break work into parallel sub-tasks.

The Activity tab shows the run history for the routine. From the modal, you can also enable or disable the routine, run it immediately, edit it with chat, and choose Done to save.

Quick includes pre-configured routines, such as a feed agent that processes items from your connected services and populates the activity feed. You customize a built-in routine's cadence, capabilities, instructions, and model.

To create a routine

1. Open Mission Control from the top bar.
2. Choose Create to define a new routine.
3. Configure how often it repeats, its capabilities, instructions, and model.
4. Turn it on when you are ready for it to run.

You can also ask Quick in chat to create a routine. For example, "check my channels every morning at 9 AM and summarize what I missed."

Routines run in the cloud, so they run at their configured time even when the desktop application is closed or your computer is off. The exception is a run that needs a local tool, such as reading a

file on your machine, browser automation, or local code execution. For those steps, your computer must be on with the desktop application running and connected at that time. Otherwise the run proceeds but the local step is unavailable until the desktop reconnects.

Working with agent runs

Mission Control organizes agent activity into runs. Depending on the state of a run, you can take different actions.

For a completed run, you view what the agent did and access the artifacts it produced, get an in-depth summary, track events of all sub-tasks, and chat to follow up on results. For an ongoing run, you view live events as the agent works, pause the run, or cancel it. For a run that needs input, you approve or deny authorization requests for third-party applications, or chat with the agent to provide clarifications.

KPIs and metrics

Mission Control displays key performance indicators that help you understand agent health and productivity at a glance. These metrics are available.

Metric	Description
Failed runs	Number of agent runs that ended with an error.
Active now	Count of agents that are currently running.
Routines completed	Number of routines completed today.
Runs this week	Total agent runs and app visits in the selected period, showing how your deployed agents and apps are being adopted.

Viewing your runs and creator analytics

From the Mission Control landing page, choose the Runs this week KPI to open the activity page. The activity page has two views: Runs and Creator analytics.

The Runs view shows your agent and app run activity for the selected time range (this week, last week, this month, last month, or last 90 days). It displays:

- **Summary cards:** a Runs this week card (a total with a trend chart broken down by Agents and Apps) and an Agent hours card (the amount of agent runtime used, with the reset period).
- **Runs list:** a searchable, sortable list of runs that you can filter by all, agents, or apps. The list has the columns run name, run type (agent or app), uses, run status, and last run (shown as last visited for apps). Rows expand to show more detail.

The Creator analytics view shows activity across the assets you have published or have co-owner access to, for the selected time range (this week, last week, this month, last month, or past 12 months). You can filter by all, agents, or apps.

- **All:** summary cards for total assets shared and total assets used (each broken down by agents and apps), and a table with the columns asset name, type, usage, active users, and shared with.
- **Agents:** summary cards for total agents shared and total conversations, and a table with the columns agent name, total active users, total conversations, average queries per user, and shared with.
- **Apps:** summary cards for total apps shared and total app views, and a table with the columns app name, total active users, total app views, and shared with.

A Last updated timestamp shows when the analytics were refreshed. The creator analytics page refreshes every hour.

Accessing Mission Control

You can access Mission Control from anywhere in the desktop application. Choose the Mission Control icon in the top-right navigation bar. A quick-access popover appears showing agent runs, pending inputs, and routine management. To view the full Mission Control landing page, choose the Mission Control header or the View all button in the popover. Work from the lightweight popover for quick actions such as unblocking an agent, or open the full page for a comprehensive view of all agent activity.

Examples of routines

- **Morning brief:** every morning, summarize unread messages, new email, and today's calendar.
- **Inbox triage:** every 30 minutes, scan new email and flag anything urgent.
- **Project monitor:** daily, check a channel for updates on a project and compile a summary.
- **Meeting prep:** before each meeting, gather relevant context and prepare a brief.

- **Competitive monitor:** weekly, search the web for news about specified companies and produce a report.

My context

My context is where you review and manage what Amazon Quick knows about you and your work. You reach it from the account menu. It has two tabs: [the section called “Memories”](#) and [the section called “Knowledge graph”](#).

Memories

Memories are the facts, preferences, procedures, and patterns Amazon Quick learns from your conversations to personalize future responses. Each memory shows a confidence score, how many times it has been referenced, and its source.

Memories are kept per agent. The default assistant and each custom agent you create have their own memories, so a rule you set for one agent does not silently change how another agent behaves. Entities in your knowledge graph remain shared across agents.

Reviewing and organizing memories

Search memories, filter and sort them, and switch between list and grid views. A single Filters panel covers the following.

- **Agent:** use the Agent dropdown at the top of the tab to view memories for All agents, Default (chat), or a specific custom agent.
- **Type:** filter by memory category. The available categories are supplied at runtime, so they vary. Examples include procedures, preferences, and profile facts.
- **Provenance:** show only Told memories (you stated it explicitly to Quick), only Learned memories (Quick inferred it from your activity or conversations), or both.
- **Sort:** Date created, Accuracy confidence, or Times referenced.

Each memory card shows the agent it applies to. Knowledge graph entities in the memory panel are marked shared to indicate that they are visible to every agent.

A memory's detail view shows its text, an information section (created, updated, times referenced, confidence, type, and Applicable to), an attributes section (the Told or Learned badge, any tags,

and a global-behavior badge), and a step-by-step provenance timeline that traces what Quick used to form it. Each memory card provides the following actions.

- **Boost:** raise the confidence in the memory to the highest level so it is prioritized in future responses.
- **Forget:** remove the memory. When you forget a memory, you can optionally choose a reason (for example, Too specific, Never said this, or Outdated) or add free-form feedback. Quick uses the reason to avoid re-learning the same thing.
- **Edit:** update the memory's text. Use edit to correct a fact rather than delete and re-teach it.

Memory settings

The Memory section in Configuration includes a master switch and a Forget all memories action.

- **Enable memory:** a master toggle that controls whether Quick learns from your conversations and personalizes future responses. When memory is off, existing memories are not used and no new memories are recorded.
- **Forget all memories:** permanently deletes every memory Quick has saved. Type "forget" to confirm.

Forgetting all memories cannot be undone. It does not affect your knowledge graph. To clear entities and relationships, use Reset knowledge graph (see [the section called "Knowledge graph"](#)).

Knowledge graph

Amazon Quick builds a personal knowledge graph that captures entities and the relationships between them from your connected data sources and files. The graph gives Quick contextual understanding of the people, projects, organizations, and events in your work, so it provides more relevant, personalized responses. It is kept for you, per user, in your Amazon Quick account.

If you ask about a project, Quick uses the graph to identify related people, recent meetings, associated documents, and relevant channels.

Entity categories

Quick organizes graph entities into categories that span the people, organizations, projects, places, events, communications, documents, actions, decisions, and terminology in your work, along with

structured data types such as datasets, dashboards, and topics when relevant. The category set is supplied at runtime. Each entity has a count of edges, the relationships connecting it to other entities.

Data sources

The graph extracts entities from connected integrations and from local folders. When you enable auto-ingestion, Quick extracts entities from your connected apps. When you enable knowledge graph extraction for a folder on the Knowledge tab in Customize (see [the section called “Knowledge”](#)), Quick extracts entities from files in that folder, independently of keyword and semantic indexing.

Viewing the knowledge graph

Open My context and choose the Knowledge graph tab for an interactive, force-directed visualization where nodes are entities and edges are relationships.

- Node color: each category has a distinct color; a legend maps colors to categories and lets you highlight a category.
- Node size: scaled automatically by how connected an entity is; more-connected entities appear larger.
- Search entities: find an entity by name and jump to it.
- Interact: click a node to select it and view its details, double-click to focus on a node and see its direct connections, scroll to zoom, and drag to pan.
- View mode: switch between Top N connected (the most-connected entities) and Communities (clustered by community detection).
- Display limits: choose how many nodes (50 to 1,000) and edges (100 to 2,000) render, shown against the totals, to keep large graphs responsive.
- Node details: selecting an entity opens an entity details panel (see the next section).

Working with an entity

When you select an entity, the entity details panel shows the following.

- Name and category: the entity's display name and its category (for example, Person or Project). Choose Edit next to either to rename the entity or change its category.

- **AI-generated summary:** a short summary of what Quick knows about the entity. Choose **Regenerate** to rebuild the summary from the latest data.
- **Connected entities:** other entities that this entity is related to, grouped by relationship.
- **Source files:** the files and messages Quick used to extract this entity.
- **Ask:** start a new chat about the entity. Quick opens a conversation preloaded with the entity's context.
- **Delete:** remove the entity and its relationships from the knowledge graph. This permanently removes the entity and any relationships that connect to it, and cannot be undone.

Configuring and resetting the knowledge graph

The Knowledge graph settings include Auto-ingest from integrations, a single toggle that lets Quick learn from your connected apps and build the graph. Per-folder knowledge graph extraction is configured separately, on the Knowledge tab in Customize (see [the section called “Knowledge”](#)).

You can reset the knowledge graph to permanently remove all entities and relationships that Quick has built. Resetting removes all people, projects, organizations, events, and relationships. It does not affect your files, your memories, or your connected services. Quick can rebuild the graph from those sources over time if you leave auto-ingest and per-folder extraction enabled.

To reset the knowledge graph

1. From the account menu, choose **My context**.
2. Choose **Configuration** in the upper-right corner.
3. In the Knowledge graph section, choose **Reset knowledge graph**.
4. Type "reset" to confirm, and then choose **Reset**.

A reset is permanent. There is no undo. Consider narrowing auto-ingest or per-folder extraction first if you only want to remove a specific source of entities.

Settings

Open Settings from the account menu. Settings are organized into tabs: Account, Appearance and language, Chat, General, and Advanced.

Account

Manage account identity and view plan and usage. The Account tab shows your profile, and, for a managed account, an indicator that your organization manages it, a session-usage meter for agent hours, and an Account region selector that controls where account data is stored and processed.

Appearance and language

- Color mode: Light, Dark, or System.
- Language: the interface language.
- Timezone: used for schedules, timestamps, and calendar availability.

Chat

- Instructions: global instructions sent with every message across all agents, such as preferred language, format, and style.
- Default agent: the agent used for new chats.

General

- Desktop notifications: show operating-system notifications when Quick is in the background.
- Browser: choose the default browser Quick opens for web tasks and automation (System default, Chrome, Edge, Brave, or Firefox), and turn on Use my existing browser to connect Quick to your running browser, where your logins, cookies, and extensions are available.
- Keyboard shortcuts: a screenshot-capture shortcut and the key combination that sends a message, including a custom option you record.
- Maximum parallel tasks: a slider from 1 to 20 that controls how many background tasks run at once.
- Updates: install updates automatically, so Quick downloads new versions in the background and installs them on restart.

Use my existing browser

When you connect Quick to your running browser, follow the setup steps to enable remote debugging, then test the connection. Enabling remote debugging allows applications on your

computer to connect to the browser and access open pages, cookies, and authenticated sessions; turn it off when you are not using this feature. When this option is off, the agent launches a separate browser instance with a copy of your profile.

Advanced

- **Export diagnostics:** save diagnostic logs for troubleshooting; choose a time range and export.
- **Clear all data:** removes all Quick data, including conversations, cached messages, knowledge graph, saved credentials, and preferences. The application quits after cleanup. Clearing all data is irreversible.

System tools

Amazon Quick on desktop includes built-in system tools that provide core capabilities such as web search, file operations, browser automation, image generation, and code execution. You enable or disable each tool individually and configure granular permission controls. Manage system tools in **Customize**, on the **Connectors** tab.

Managing permissions

In the connectors table, each system tool has an enable/disable toggle and an actions menu. Choose the ellipsis (actions menu), and then choose **Manage permissions** to set the tool's access level and adjust its per-operation permissions. To turn a tool on or off, use its enable/disable toggle.

Access levels

You set one of three access levels:

Access level	Description
Always Allow	Quick has full read and write access to this tool. Operations run without prompting you for confirmation.
Ask Each Time	Quick asks for your confirmation before performing any operation with this tool.
Always Deny	Quick cannot perform any operation with this tool.

Below the access level, each tool lists its operations grouped into read and write, and you set each independently, for example Always Allow overall but a specific write operation set to Ask Each Time.

To manage permissions for a tool

1. Choose **Customize** in the navigation, and then choose the **Connectors** tab.
2. Find the system tool in the connectors table, choose the ellipsis (actions menu), and then choose **Manage permissions**.
3. Set the access level, and adjust individual operation permissions.
4. Close the panel. Changes take effect immediately.

Available system tools

The built-in system tools include:

- **Web Search:** find current information from the internet through search and fetch-URL operations, with citations.
- **File operations:** download files from URLs and open local files in their default applications.
- **Browser Automation:** launch a browser, navigate, interact with elements, fill forms, take screenshots, and extract text. It supports a default mode, which uses a separate browser instance with a copy of your profile, and a use-your-own-browser mode.
- **Image Generation:** generate and edit images with Amazon Nova Canvas, including remove background, variations, and outpaint (extending an image beyond its original boundaries).
- **Engram Builder:** analyze your writing across messages and conversations to build a personality profile (an engram), so Quick can write in your style. Operations: get, list, save, and delete engrams.
- **Knowledge and memory:** query and build the knowledge graph, and recall learned patterns.
- **Agent management:** create, update, delete, and trigger routines from chat.
- **Task management:** break complex requests into parallel background sub-tasks, organized into groups, with progress tracking.
- **Chat and notifications:** surface contextual suggestion pills, message reactions, desktop notifications for events such as task completion, and briefing summaries on the Home screen.
- **Transcription:** convert audio and video files to text so Quick can summarize, quote, or answer questions about their contents. The Transcribe media operation transcribes an audio or video

file (for example, .mp3, .mp4, .wav, .flac, .m4a, or .ogg) to text. Use it when you want Quick to work with recordings such as meeting captures, voice memos, screen recordings, podcast clips, or interview audio as if they were text.

- **Explainability:** produce a structured account of how Quick arrived at its answer. The `Emit` operation returns an explanation that includes assumptions (what Quick took as given), sources (which datasets, files, connectors, or memories were consulted), calculations (the steps that produced the result), and limitations (known caveats or places where the answer is uncertain). Use it when you want to see the reasoning behind an answer, share it, or check the assumptions before acting.
- **File indexing and search:** find and cite content across the folders you have granted access to. Operations include `Search files` (search across indexed files by keyword or meaning), `Read document` (return the full content of a specific file), `Check indexing` (report indexing status for a folder or file), and `Approve indexing` (approve or skip a pending indexing operation). For how folders are indexed, see [the section called “Knowledge”](#).
- **Working with your data:** answer questions in natural language about the datasets and dashboards you connect through Quick spaces. Quick can answer questions from datasets (run analytical queries and return an answer with the underlying data), read dashboards (interpret and summarize the data behind a dashboard visual), and discover data (browse the catalog of datasets and dashboards available to you). Which datasets and dashboards Quick can see depends on your organization's permissions.

All system tools are enabled by default with Always Allow permissions. You restrict or disable any tool at any time; changes take effect immediately for new conversations and agent runs. For the permission model and hardening guidance, see [the section called “Security and privacy”](#).

Code execution

The Code Execution tool writes and runs Python in a sandbox for data analysis, calculations, file processing, chart generation, and automation. A persistent namespace carries variables across runs within a conversation, and pre-installed packages are available. Sandbox file access follows your folder permissions, plus system temporary directories.

Security, privacy, and architecture

Amazon Quick on desktop is designed to keep your data private while providing full access to AI capabilities.

Your data is never used for AI model training. AWS does not use your conversations, files, or personal context to train or improve AI models.

How data is handled

Amazon Quick runs in the cloud. Your conversations, memory, knowledge graph, agent-produced files (your Library), and the index of content you make searchable are kept per user in your Amazon Quick account, isolated from other users. The desktop application stores only what it needs to operate locally: application configuration (settings, preferences, and connection state), the folders you have granted access to and their local settings, locally configured MCP and coding-agent servers, and your sign-in credentials (authentication tokens, held in your operating system's credential vault).

Data storage

Local application data, configuration, folder permissions, locally configured MCP and coding-agent servers, and sandbox settings, is stored in `~/ .quickwork/` on macOS or `%USERPROFILE% \ .quickwork\` on Windows. Your conversations, memory, and knowledge graph are not stored here; they are kept in your Amazon Quick account.

Folder permissions

Quick uses operating-system sandboxing to control file access. It accesses only folders you explicitly grant, and you revoke access at any time. Each folder supports independent controls for keyword search, semantic search, and knowledge graph extraction, plus granular per-operation permissions.

Quick also has access to system temporary directories regardless of folder permissions. On Windows these are `C:\TEMP`, `C:\TMP`, `\TEMP`, and `\TMP`. On macOS and Linux these are `/tmp`, `/var/tmp`, and `/usr/tmp`.

System tool permissions

Amazon Quick on desktop governs three kinds of capabilities with the same permission model: system tools that provide core capabilities, connectors to third-party services such as Slack, Outlook, and Gmail, and local tools that run on your device. You can turn each capability on or off. Each supports a three-tier permission model, Always Allow, Ask Each Time, or Always Deny, with granular per-operation controls (see [the section called "System tools"](#)).

Quick stores your permission choices and applies them consistently whenever an agent acts on your behalf, including scheduled agents. An agent can only take actions you have authorized, and you can review or change these permissions at any time.

Connection security

- OAuth 2.0: connected services authenticate with OAuth 2.0; Quick never sees or stores your third-party passwords.
- Independent connections: each service is managed independently; you disconnect and reconnect any service without affecting others.
- Minimal permissions: Quick requests only the permissions needed for each service.

Privacy controls

Quick provides controls for whether it learns from your conversations, searches your conversation history, and extracts entities from connected services. You view, edit, and delete individual memories (see [the section called “My context”](#)).

Network access and required domains

The application makes outbound connections for discovery and data-plane operations, remote configuration, application updates, and identity-provider authentication. In restricted networks, add the required Amazon Quick domains to your allow list.

Category	Domain	Wildcard meaning	Purpose
Amazon Quick console	*.quicksight.aws.amazon.com	* = AWS Region (for example, us-east-1)	Web console, resource discovery
Amazon Quick data plane	*.dp.integrations.*.prod.plato.ai.aws.dev	First * = per-account cell ID; second * = AWS Region	Inference, streaming, search

Category	Domain	Wildcard meaning	Purpose
Amazon Quick enterprise gateway	*.desktop .enterprise.quick. aws.dev	* = multi-level subdomain (<cell>.<stage>.<region>)	Enterprise account bidirectional communication
Remote configuration and updates	*.cloudfront.net	* = CloudFront distribution ID	Feature flags, application updates, Apps in Amazon Quick content
Telemetry	cognito-identity.* .amazonaws.com	* = AWS Region	Operational telemetry
Identity provider	Customer-specific (for example, login.microsoftonline.com)	Not applicable	Enterprise SSO authentication

For strict proxy environments that cannot use wildcards, you can determine the account-specific cell hostname after you first sign in. It follows the pattern <cell-id>.dp.appintegrations.<region>.prod.plato.ai.aws.dev, where <cell-id> is a stable per-account identifier and <region> is the account's home region. If your organization inspects encrypted traffic, the operating-system trust store must trust the inspection certificate authority, or the Quick domains must be excluded from inspection (see [the section called "Enterprise setup"](#)).

Clearing all data

To completely reset Quick, use Clear all data in Settings, on the Advanced tab. This is irreversible and removes all conversations, knowledge graph data, saved credentials, and preferences.

Troubleshooting

Installation and launch issues

- macOS reports an unidentified developer: open System Settings, choose Privacy & Security, and choose Open Anyway.
- The application does not launch: restart, verify the minimum requirements, and check disk space. As a last resort, delete ~/ .quickwork/ (macOS) or %USERPROFILE%\ .quickwork\ (Windows) and reinstall. Deleting this directory removes all local data.

Connection issues

- A messaging, email, or calendar connection fails: disconnect and reconnect in Customize, on the Connectors tab, verify your permissions in the third-party service, and check your internet connection.
- A connection shows Not synced: verify connectivity, then disconnect and reconnect; if it persists, the service might be having an outage.
- Sign-in or responses fail only on a corporate network or virtual private network (VPN): confirm the required Quick domains are reachable, and address Transport Layer Security (TLS) inspection with your network administrator (see [the section called “Security and privacy”](#)). If it persists, export logs and contact AWS Support.

Performance issues

- Slow responses: switch to Fast mode, reduce thinking effort to Off or Low, close unused applications, and check your connection.
- High memory usage: reduce the number of indexed folders, disable semantic search where you do not need it, lower Maximum parallel tasks, and restart to clear cache. Search indexing pauses automatically when free disk space falls below 8.0 GiB.

File access issues

- Quick cannot find a file: confirm the parent folder is added on the Knowledge tab in Customize. System temporary directories are always accessible. After you add a folder, Quick reads it immediately; indexing runs in the background.

- Search returns no results: confirm keyword search is on for the folder, check that indexing status is Ready, confirm the file is within the maximum index size, and enable semantic search for natural-language queries.

Browser automation issues

Verify Browser Automation is enabled in Customize, on the Connectors tab. If you use your own browser, complete the remote-debugging setup and test the connection; otherwise, confirm a supported browser is installed.

Schedule issues

- A schedule did not run: confirm the schedule is enabled in Mission Control. Schedules run in the cloud, so they run even when your computer is off; but a run that needs a local tool (file access, browser, or code execution) requires your computer to be on with the desktop running and connected at that time.
- Unexpected results: in Mission Control, review the schedule's instructions and capabilities, consider a higher model (Balanced or Smart), and run it manually to observe results.

Managing agent-hours consumption

- Reduce the number of background schedules; each run consumes agent hours.
- Match the model and thinking effort to task complexity: Fast with thinking Off for simple tasks; Balanced or Smart with higher thinking levels consume more agent hours.

Session usage

View current session usage by selecting your profile. The session limit is a service-protection limit that spreads your monthly agent-hours allocation over time. When you reach it, the application indicates the allocation has been used, and the limit recovers gradually.

MCP server issues

- Local: verify the command and that the executable is installed, check argument formatting, raise the timeout, and verify environment variables.

- Remote: verify the URL and that the server is running, verify any authentication header, and check network and firewall settings.
- Imported: verify the configuration file path and that the source application is installed.

Exporting diagnostics

Export logs from Settings, on the Advanced tab, by selecting a time range and choosing Export Diagnostics. If you cannot open the application, find logs at `~/Library/Application Support/QuickWork/` and `~/Library/Logs/QuickWork/` (macOS) or `%APPDATA%\QuickWork\` and `%APPDATA%\QuickWork\logs\` (Windows).

Getting additional help

Export diagnostics and share them with your support team, contact your organization's IT administrator for enterprise issues, and visit the Amazon Quick documentation for the latest guidance.

Amazon Quick on mobile

Amazon Quick is available as a companion app for iOS and Android that works alongside the desktop application. Use the mobile app to chat with Quick, review your activity feed, and open dashboards while you are away from your computer. You sign in with the same account, and your conversations stay in sync across your devices.

The mobile app focuses on the tasks you are most likely to do on a phone. Some capabilities that are available on desktop are limited or not available on mobile. This chapter describes what you can do on mobile and how the mobile experience differs from desktop.

Topics

- [Getting the app](#)
- [Signing in](#)
- [Feature availability at a glance](#)
- [Mobile-specific behaviors](#)
- [What is not available on mobile](#)
- [Differences between iOS and Android](#)

Getting the app

Download Amazon Quick from the [App Store](#) on iOS or from [Google Play](#) on Android. After you install the app, open it and sign in to get started.

Note

Some capabilities require a recent version of iOS or Android. To get the full mobile experience, keep the app and your operating system up to date.

Signing in

Sign in to the mobile app with your organization's Amazon Quick credentials. The app supports enterprise single sign-on (SSO), including IAM Identity Center federation.

For added security, you can turn on biometric app lock (Face ID, Touch ID, or fingerprint) so that Amazon Quick requires biometric verification each time you open it. You manage this in Settings, under Security. Your administrator can also require biometric lock for your organization.

Feature availability at a glance

The following tables summarize feature availability on mobile compared to desktop. Availability is one of the following.

- Available: works on mobile.
- Limited: partially available on mobile. See the note for details.
- Not available: not available on mobile. Use the desktop application for this capability.

Chat

Feature	Availability
Chatting with Quick	Available
Response modes (Fast, Balanced, Smart)	Available
Thinking effort	Available
Attachments and file uploads	Available
Web search	Available
Mentions (@)	Available
Citations and sources	Available
Editing and retrying messages	Available
Branching conversations	Available
Plan mode	Available
Deep research	Available

Feature	Availability
Managing conversations (folders, pinning, search, archive)	Available
Approvals	Available
Running work in the background	Available
Incognito mode	Not available
Slash commands	Not available
Attaching a space	Not available
Context meter	Not available

Note

Branching conversations is available on Android only. See [the section called “Differences between iOS and Android”](#). For how these chat capabilities work in detail, see [the section called “Working with chat”](#).

Creating documents and visuals

Feature	Availability
Document creation	Available
Data visualizations	Available
Image generation	Available
Exporting a conversation (Markdown, PDF)	Available

Your content and data

Feature	Availability	Notes
Dashboards	Available	Browse dashboards natively and open them in a viewer.
Activity feed	Available	Includes your calendar and to-dos.
Library (saved artifacts)	Available	Includes documents and visuals generated in Quick.
Knowledge graph (view and manage)	Not available	The knowledge graph is on by default, but viewing and managing it is not available on mobile.
Memory (view and manage)	Not available	Quick uses the same memories across desktop and mobile, but managing them on mobile is not yet available.

Connectors, agents, and skills

Feature	Availability	Notes
Agents	Available	Choose an agent and use agent templates.
Connectors	Limited	You can connect a service and re-authenticate an existing connection. Set up, manage, and remove connectors on desktop.
Skills	Limited	Skills run in your conversations. Manage skills on desktop.
Mission Control	Available	
Apps (Apps in Amazon Quick)	Not available	

Settings

Feature	Availability	Notes
Account, language, region, and appearance	Available	
Biometric app lock	Available	
Default agent and response preferences	Available	

Mobile-specific behaviors

Some capabilities work differently on mobile than on desktop.

- Dashboards open in a viewer: on mobile, you browse your dashboards in a native list and open a dashboard in an embedded viewer with mobile controls.
- On-device file access: Quick can read and write files on your device when you grant access. You approve each request, and you control which folders Quick can use.
- Approvals as cards: when an agent needs your permission to take an action, the request appears as a card in the conversation that you can allow or deny.
- Biometric app lock: when biometric lock is on, Amazon Quick requires Face ID, Touch ID, or a fingerprint each time you open the app.

What is not available on mobile

The following capabilities are available on desktop but not on mobile. Use the desktop application for these tasks.

- Apps (Apps in Amazon Quick): build and run apps on desktop.
- Memory management: view and manage your memories on desktop.
- Knowledge graph: view and manage your knowledge graph on desktop.
- Incognito mode: start a private chat on desktop.

- Connector management: set up, manage, and remove connectors on desktop. On mobile, you can connect a service and re-authenticate an existing connection.
- Skill management: manage your skills on desktop. On mobile, skills run in your conversations.

Differences between iOS and Android

The mobile experience is consistent across iOS and Android, with a few differences.

- Mission Control: available on iOS. Not available on Android.
- Branching conversations: available on Android. Not available on iOS.
- Attachments: on iOS, you can attach up to three files per message.
- Creating a connector: on iOS, creating a new connector requires iOS 17.4 or later. You can re-authenticate an existing connector on any supported version.

Document history for the Amazon Quick User Guide

This page describes changes to the *Quick User Guide*. For notifications about these documentation changes, subscribe to the RSS feed using the link near the top of this page.

To find out what's new in Quick, see [What's New with Analytics](#). To find out about changes to the Quick service, sign up for the [Quick newsletter](#).

New Amazon Quick releases appear in different AWS Regions over a period of time, beginning with the first Region on the initial release date. Documentation is released in coordination with this process. If you have questions, contact [AWS Support](#) or your technical account manager.

 **Note**

The following table describes important changes in each *Amazon Quick User Guide* release since March 4, 2019.

Change	Description	Date
Amazon Quick on desktop and mobile refresh	Refreshed the Amazon Quick on desktop chapter for the current interface and navigation model (Chat, Feed, Library, Customize, Apps, Spaces, More); added activity feed, Library, Apps in Amazon Quick, Spaces, My context, and Memories topics; reorganized agents, skills, connectors, and knowledge under the Customize hub; and added a new Amazon Quick on mobile chapter. The artifact library was renamed from "My stuff" to Library.	September 5, 2026

[AWS Agent Registry integration](#)

Added a new integration guide that describes how to connect an AWS Agent Registry to Amazon Quick and surface its remote MCP servers as connectors. For more information, see [AWS Agent Registry integration](#).

August 31, 2026

[Pricing and billing detail for standalone admin pages](#)

Expanded the standalone subscription admin pages with pricing and billing detail, including how collaborator billing works, annual subscription terms, billing cycles and proration, upgrade and downgrade billing, and how additional usage is billed. For more information, see [Upgrading your Amazon Quick plan](#), [Plan and billing for Amazon Quick Free, Plus, and Max accounts](#), and [Understanding usage on the Amazon Quick Plus and Max plans](#).

August 28, 2026

[DLP vended logs](#)

Added documentation for the DLP_LOGS vended log type, which captures data loss prevention (DLP) enforcement decisions and configuration changes. For more information, see [Monitoring Amazon Quick using CloudWatch Logs](#).

August 25, 2026

[Okta desktop enterprise sign-in uses the org authorization server](#)

Updated the Okta enterprise sign-in guide for Amazon Quick on desktop to use the Okta org authorization server, which every Okta org includes at no additional cost. This removes the dependency on the API Access Management add-on that a custom authorization server (for example, `/oauth2/default`) requires. Updated the OIDC endpoints, removed the scope configuration step, and added Okta reference links. For more information, see [Set up enterprise sign-in with Okta](#).

August 10, 2026

[New Limit profiles page](#)

Added a new page for Limits Management limit profiles, which let administrators cap per-user consumption of index storage and agent hours. For more information, see [Limit profiles](#).

August 10, 2026

Data loss prevention with Microsoft Purview	Added a new Governance section with a Data loss prevention page that describes how to connect Microsoft Purview and enforce data loss prevention policies on sensitive files in Amazon Quick. For more information, see Data loss prevention .	August 10, 2026
Added approval workflows documentation	Added documentation for approval workflows, which give administrators governance control over sharing actions for knowledge bases, spaces, and custom chat agents. For more information, see Approval workflows .	August 10, 2026
New custom permissions for browser extension and Office add-ins	Added five new custom permission features under the Extensions parent capability: Browser Extension, Excel Extension, Outlook Extension, PowerPoint Extension, and Word Extension. For more information, see Custom permissions .	July 6, 2026
Change email and social sign-up URL	Update links for Free/Plus/Max accounts to aws.com/quick .	June 24, 2026

[Public applications for Apps in Quick](#)

Free and Plus accounts can now create public-facing applications that are accessible to anyone with the URL. Public applications can be configured with access to in-app storage and AI inference . For more information, see [What you can build](#).

June 12, 2026

[Desktop documentation restructured with Capabilities section](#)

Reorganized the Amazon Quick on desktop documentation. Added a new Capabilities section with dedicated pages for Connections, Skills, Agents, Plugins, and Tools. Moved System tools and MCP server configuration under Capabilities. Added Agents documentation for creating, configuring, and managing agents. Added official catalog information to the Skills page.

June 12, 2026

[OneDrive knowledge base admin-managed setup](#)

Added admin-managed connection support for the Microsoft OneDrive knowledge base connector , including service credentials setup with AWS KMS signing, certificate-based authentication, and tenant-wide crawling of all users' OneDrive content. Admin-managed OneDrive knowledge bases always enforce document-level access control (ACL) with real-time verification at query time. For more information, see [Admin-managed setup](#).

June 1, 2026

[Web search processed in-Region for Sydney and Tokyo](#)

Updated cross-Region web search documentation to reflect that web search queries originating in Asia Pacific (Sydney) and Asia Pacific (Tokyo) are now processed in the originating Region and are no longer routed to US East (N. Virginia) . For more information, see [Cross-Region calls for web search](#).

May 29, 2026

[VPC support for MCP integration](#)

You can now connect Amazon Quick MCP integrations to private MCP servers that are reachable from a virtual private cloud (VPC) by selecting a Amazon Quick VPC connection during connector setup. The OAuth endpoints used by the MCP server must remain reachable over the public internet. Added troubleshooting guidance for connector creation, VPC connection issues, and Microsoft Entra ID errors. For more information, see [Model Context Protocol \(MCP\) integration](#).

May 29, 2026

[Updated HubSpot integration documentation](#)

Restructured the HubSpot integration topic to follow the built-in connector format. The topic now covers prerequisites, account verification, account configuration, Amazon Quick setup, and troubleshooting. The HubSpot action connector reads CRM data, including contacts, companies, deals, and tickets, and authenticates with a custom OAuth app. For more information, see [HubSpot integration](#).

May 28, 2026

[Clarified IAM permissions for DeleteAccountSubscription](#)

Clarified that the DeleteAccountSubscription Amazon Quick API requires both quicksight:Unsubscribe and quicksight:DeleteAccountSubscription IAM permissions. An explicit deny on either permission results in an AccessDeniedException. Updated the account termination permissions list and IAM policy examples accordingly. For more information, see [Closing your Amazon Quick account](#).

May 27, 2026

[Preview extensions for Microsoft 365](#)

Added preview extension documentation for Excel, Word, and PowerPoint with simplified deployment through the Microsoft 365 admin center. For more information, see [Connect Amazon Quick to your applications](#).

April 28, 2026

New connectors	Added connector documentation for Airtable, Dropbox, Google Analytics, Google Calendar, Google Docs, Google Drive, Google Meet, Google Sheets, Google Slides, Gmail, QuickBooks, and Zoom. Updated existing Slack and Outlook connectors. For more information, see Connectors .	April 28, 2026
Free and Plus account documentation	Added documentation for Amazon Quick Free and Plus accounts created at quick.aws.com, including signup, plans, user management, billing, and account administration. For more information, see Signing up at quick.aws.com and Administering Amazon Quick (Free and Plus) .	April 28, 2026
Document and visual creation	Added documentation for creating documents and visuals including Word, Excel, PowerPoint, PDF, and infographics directly from chat conversations. For more information, see Document and visual creation .	April 28, 2026

[Build web applications with apps in Amazon Quick](#)

Added documentation for apps in Amazon Quick, a feature that lets you build, publish, and share interactive web applications using natural language. For more information, see [Build web applications with apps in Amazon Quick](#).

April 28, 2026

[Amazon Quick on desktop](#)

Added documentation for the Amazon Quick desktop application for macOS and Windows, including local file access, activity feed, scheduled agents, system tools, MCP servers, knowledge graph, and settings. For more information, see [Amazon Quick on desktop](#).

April 28, 2026

[Visier integration](#)

Added documentation for the Visier people analytics integration, which connects to Visier through MCP server connectivity. You can query workforce data, analyze headcount trends, assess retention health, and generate workforce briefings. For more information, see [Visier integration](#).

April 22, 2026

[Spaces file size and storage limit increase](#)

Increased the file upload size limit for Spaces to 500 MB for PDF, Word, and PowerPoint files (50 MB for other file types), and increased the total space storage limit from 1 GB to 10 GB. For more information, see [Working with Spaces](#).

April 21, 2026

[Confluence knowledge base document-level access controls](#)

Added document-level access control (ACL) support for the Atlassian Confluence Cloud knowledge base connector. Includes Atlassian admin credentials setup, real-time permission verification at query time, and end-user sign-in flow. For more information, see [Document-level access controls](#).

April 21, 2026

[SharePoint knowledge base admin-managed setup](#)

Added admin-managed connection support for the SharePoint Online knowledge base connector, including service credentials setup (2LO) with AWS KMS signing, certificate-based authentication, document-level access control (ACL) with real-time verification, Sites.Selected least-privilege permissions, and specific SharePoint path support. For more information, see [Admin-managed setup](#).

April 16, 2026

[Knowledge base and data source sharing](#)

Added support for sharing admin-managed SharePoint and Google Drive knowledge bases with co-owners, and sharing data source connections with other users. For more information, see [Sharing knowledge bases and data sources](#).

April 16, 2026

[Index usage monitoring](#)

Added index usage logs (INDEX_USAGE_LOGS) to Amazon Quick vended logs for tracking storage consumption across knowledge bases and Spaces. Includes CloudWatch Log Insights queries for building dashboards. For more information, see [Monitor index storage usage](#).

April 16, 2026

[Incremental refresh support for datasets in the new data preparation experience](#)

You can now incrementally refresh SQL-based SPICE datasets that were created in the new data preparation experience. For more information, see [Incrementally refreshing a dataset](#).

April 15, 2026

[ServiceNow integration documentation update](#)

Rewrote the ServiceNow integration documentation with detailed setup instructions for both user authentication (OAuth authorization code) and service authentication (client credentials), a complete list of available actions derived from the ServiceNow REST API, and a new limitations and troubleshooting section. For more information, see [ServiceNow integration](#).

March 30, 2026

[Fine-grained ACL support for Google Drive knowledge base](#)

Added admin-managed connection support for the Google Drive knowledge base connector, including Google Workspace configuration with 2-legged OAuth (2LO) and document-level access control list (ACL) crawling. For more information, see [Google Drive knowledge base](#).

March 30, 2026

[Updated Quick Research documentation](#)

Updated Quick Research documentation to reflect current UI changes, including research mode options (Fast and Deep), updated research objective guidance, revised button labels, and added third-party data sources as a research material type. For more information, see [Using Amazon Quick Research](#).

March 26, 2026

[New Relic integration](#)

Added New Relic integration documentation with setup instructions, available actions, and troubleshooting. For more information, see [New Relic integration](#).

March 26, 2026

[Region expansion for Tokyo, Frankfurt, and London](#)

Updated regions documentation to reflect full Amazon Quick support in Tokyo (ap-northeast-1), Frankfurt (eu-central-1), and London (eu-west-2). Consolidated cross-Region inference (CRIS) documentation into the regions page with updated inference boundaries for AU-CRIS, JP-CRIS, EU-CRIS, and US-CRIS geographies, and added web search regional availability details. For more information, see [Supported Regions](#).

March 24, 2026

[New custom permissions for Spaces and Chat Agents](#)

Added three new custom permission features: Create Spaces, Share Spaces, and Share Chat Agents. For more information, see [Custom permissions](#).

March 24, 2026

[New Amazon CloudWatch metrics for Amazon Quick index capacity](#)

Added two new Amazon CloudWatch metrics for monitoring Amazon Quick index billing: QuickIndexCapacityConsumedRawFileSizeInGB and QuickIndexCapacityRawFileSizeLimitInGB. For more information, see [Monitoring data in Amazon QuickSight](#).

March 24, 2026

[Google Drive integration](#)

Refactored the Google Drive knowledge base integration documentation

March 20, 2026

[Embed custom chat agents](#)

Added documentation for embedding custom chat agents on external websites, including the process for allowing hosting domains and generating embed code. For more information, see [Create, customize, and deploy AI-powered chat agents](#).

March 19, 2026

[Custom permissions update](#)

Updated custom permissions documentation with new parent capabilities (Scenarios, Stories, Topics), new features (Edit Visual with AI, Build Calculation with AI, Create Executive Summary, Knowledge Base create/update and sharing), and an Action Connectors section documenting per-connector permissions. For more information, see [Custom permissions](#).

March 19, 2026

[Quick Automate actions update](#)

Updated Amazon Quick Automate documentation for the Data tables, Excel, Browser, Custom Agent, REST API, Code, and AWS Integrations action categories.

March 18, 2026

[Atlassian Jira Cloud integration](#)

Added dedicated Atlassian Jira Cloud integration documentation with validated OAuth scopes and a complete actions table. For more information, see [Atlassian Jira Cloud integration](#).

March 18, 2026

[Atlassian Confluence Cloud integration](#)

Refactored the Atlassian Confluence Cloud integration documentation with shared Atlassian OAuth modules for a consistent setup experience.

March 17, 2026

[Namespace isolation and administrative console clarification](#)

Clarified the difference in permission models between the Amazon Quick end-user console and the administrative console for namespace isolation. For more information, see [Supporting multitenancy with isolated namespaces](#).

March 16, 2026

[MCP integration documentation](#)

Rewrote the Model Context Protocol (MCP) integration topic with an MCP protocol overview, OAuth discovery flow documentation (RFC 9728), and shared Dynamic Client Registration (DCR) concepts. For more information, see [Model Context Protocol \(MCP\) integration](#).

March 16, 2026

[Web Crawler VPC support](#)

Added VPC support, sitemap discovery, and JavaScript navigation troubleshooting to the web crawler integration documentation. For more information, see [Web Crawler integration](#).

March 13, 2026

[Managing shared folders custom permission](#)

Added documentation for the managing shared folders custom permission. For more information, see [Custom permissions](#).

March 12, 2026

Chat user preferences	Added a user preferences section to the chat documentation for managing display and notification preferences in Amazon Quick. For more information, see Ask questions, explore data, and get insights with chat .	March 11, 2026
Microsoft 365 integration guides	Rewrote the Microsoft Outlook, SharePoint, and Teams integration guides with a consistent structure that includes full Microsoft Entra setup instructions, permission tables with descriptions, and correct OAuth scopes.	March 10, 2026
Conversation retention period update	Updated the chat conversation retention period from 30 days to 90 days. For more information, see Ask questions, explore data, and get insights with chat .	March 5, 2026
Amazon S3 ACL documentation	Added document-level access control list (ACL) documentation for the Amazon S3 integration and a best practices guide for managing ACLs in knowledge bases. For more information, see Document-level ACLs .	March 2, 2026

Asia Pacific (Malaysia) Region support	Added the Asia Pacific (Malaysia) ap-southeast-5 Region to the list of supported Amazon Quick Sight Regions, including the API endpoint and IP address range. For more information, see Supported Regions .	March 1, 2026
Quick Flows vs Quick Automate comparison	Added a comparison section to the automations landing page to help users choose between Amazon Quick Flows and Amazon Quick Automate based on their workflow needs. For more information, see Choosing between Quick Flows and Quick Automate .	February 27, 2026
TLS 1.2 MySQL version requirement	Documented the requirement for MySQL version 5.7.28 or later to support TLS 1.2 connections for MySQL data sources.	February 26, 2026
ApproveFlowShareRequests custom permission	Added the ApproveFlowShareRequests custom permission, which controls whether users can approve requests to share flows. For more information, see Custom permissions .	February 26, 2026
Space extracted text limits	Updated the extracted text limits for CSV and Excel files in spaces.	February 23, 2026

Knowledge base file size limit increase	Increased the file size limit for standard text documents in knowledge bases from 50 MB to 500 MB.	February 16, 2026
Automations usage metrics	Added a section for tracking Quick Flows, Quick Automate, and Amazon Quick Research usage hours in the usage metrics documentation.	February 6, 2026
SPICE capacity updates	Updated SPICE capacity and dataset size documentation to reflect increased limits.	February 2, 2026
Embedding and row-level security guidance	Added security guidance for embedded analytics to warn against AllowedEmbeddingDomains bypass vulnerabilities. Added guidance for using row-level security (RLS) in multi-tenant architectures.	January 27, 2026
CSV and Excel file size limits	Updated the file size limits for CSV and Excel uploads to 10 MB.	January 27, 2026
Extension access with Okta and IAM Identity Center	Updated extension setup instructions for Microsoft Word, Slack, and Teams to support Okta as an identity provider with IAM Identity Center. For more information, see Extension access .	January 26, 2026

AgentHours vended logs	Updated Quick vended logs documentation to include the AgentHours log type for tracking agent usage.	January 6, 2026
New integrations and PagerDuty advance	Added individual integration pages for 10 new MCP-based services and PagerDuty advance integration. Updated the supported integrations table and connector APIs. For more information, see Model Context Protocol (MCP) integration .	January 5, 2026
User-driven license upgrades	Added documentation for user-driven license upgrades, which allow end users to request license tier changes. For more information, see User-driven license upgrades .	December 29, 2025
Flows in browser extension	Added documentation for using Amazon Quick Flows in the browser extension. For more information, see Using Amazon Quick Flows in browser extension .	December 15, 2025

[Add IAM Identity Center support for extensions](#)

Added documentation for adding Amazon Quick extensions to Microsoft Word, Microsoft Office, Microsoft Teams, and Slack with accounts that use IAM Identity Center. For more information, see [Extension access](#).

November 19, 2025

[New data preparation experience](#)

Added documentation for the new visual data preparation experience in Amazon Quick Sight. For more information, see [Preparing data with the new data preparation experience](#).

October 20, 2025

[New Amazon Quick capabilities](#)

October 9, 2025

Amazon Quick provides an integrated suite of AI-powered analytics, automation, and research tools that transcend traditional business intelligence.

Chat and AI capabilities:

- Amazon Quick chat - Natural language interface for data exploration with contextual awareness, file uploads, web search, and artifact generation
- Quick chat agents - Customizable AI assistants with domain-specific expertise, configurable personas, and organizational context

Workflow automation:

- Amazon Quick Flows - Intelligent workflows combining generative AI with automated actions through no-code interface, supporting conversational and structured runtime modes
- Amazon Quick Automate - AI-powered automation platform that creates sophisticated workflows

from natural language
descriptions or process
documents

Research and analysis:

- Amazon Quick Research - Comprehensive research capability that analyzes multiple data sources and generates detailed reports with citations and source tracing for market research, competitive analysis, and business intelligence

Data and knowledge management:

- Amazon Quick Index - Data discovery and cataloging capabilities
- Spaces - Collaborative workspaces for organizing and sharing data, dashboards, topics, and files with team-specific knowledge bases

Integration and connectivity:

- Integrations - Connect to external applications for unstructured data access, including Google Drive,

Amazon S3, OneDrive, and MCP servers

- Connectors - Perform actions in third-party services like Microsoft Outlook, PagerDuty, and Slack with 15+ supported integrations
- Knowledge bases - Create AI-accessible content from third-party applications and data sources
- Extensions - Browser, Slack, Microsoft Teams, Outlook, and Word extensions for AI assistance within existing tools
- Bring Your Own Index (BYOI) - Connect existing Amazon Q Business indexes as data sources

[Amazon QuickSight rebrands to Amazon Quick](#)

Amazon QuickSight has been rebranded to Amazon Quick, expanding from a standalone business intelligence service to a comprehensive analytics and AI platform. QuickSight continues as Amazon QuickSight, a core component within the Quick ecosystem.

October 9, 2025

Amazon QuickSight retains existing functionality including interactive data visualization, SPICE in-memory analytics, embedded analytics, and dashboard sharing. All existing QuickSight APIs, SDKs, and integrations continue to work without changes.

[Font customization](#)

Authors can now customize fonts for data labels and axes in supported charts, in addition to the previously supported font customizations for visual titles, subtitles, and legends, as well as table and pivot table headers.

October 6, 2025

[Google Sheets data source](#)

You can now create datasets using a Google Sheets data source. Admins will need to perform a one-time setup to enable Google Sheets as a data source.

September 27, 2025

Q&A null support	Q&A now supports comprehensive support for null value handling, enabling users to create more sophisticated analyses and answer complex business questions.	September 18, 2025
Interactive Highchart features	Highchart visualizations now support custom actions, highlighting, and custom field color consistencies, allowing you to create interactive and visually cohesive charts that integrate seamlessly with other visuals.	September 2, 2025
Calculated fields limitation increase	The number of limits for calculated fields in an analysis has increased from 200 to 500. For more information, see Item limits for analyses .	August 15, 2025
Apache Impala data source	You can now create datasets using an Apache Impala data source.	August 1, 2025
Improve Q&A accuracy with custom instructions	Authors can now curate responses to questions by adding domain-specific knowledge that cannot be captured through a topic's metadata settings. This ensures more accurate, relevant, and tailored answers that are better suited for business needs.	July 18, 2025

New topic: Trusted identity propagation support with Athena data sources	Added information about using trusted identity propagation with QuickSight and Athena. For more information, see Using trusted identity propagation with Athena .	June 30, 2025
2 billion row SPICE datasets	QuickSight now supports SPICE datasets that contain up to 2 billion (2,000,000,000) rows. For more information, see SPICE quotas for imported data .	June 30, 2025
Topic Permissions	Authors can now manage permissions for dashboards and their linked topics from a single location. Control topic viewer access directly from a dashboard's sharing preferences, eliminating the need to manage permissions in multiple locations.	April 18, 2025
Sheet Highlighting	Added the ability to highlight specific data points across visuals in a sheet. When you select or hover over a data point on a visual, related data across other visuals will stand out, while unrelated data is dimmed.	April 11, 2025

Updated topic: Opting out of Amazon Q in Quick	Added additional information and guidance for opting out of Amazon Q in Quick. For more information, see Opting out of Amazon Q in Quick .	April 8, 2025
Enable Generative BI features in embedded dashboards and consoles	Added documentation for adding executive summaries to embedded dashboards, and adding executive summaries, data stories, authoring, and Q&A to embedded consoles. For more information, see Embedding with the Amazon QuickSight APIs .	March 31, 2025
Customize alert emails	Previously, the custom email template in your QuickSight account only affected dashboard report and pixel perfect report emails. Now, it also customizes alert emails. For more information, see Customizing report and alert emails .	March 31, 2025
Rules Dataset flag	A Rules Dataset flag has been implemented to distinguish permission datasets used for row-level security from regular datasets.	March 28, 2025

Publish a previous version of a dashboard	You can now revert back to a previous version of a dashboard by searching for it under the dashboard's Version History and publishing it. Each dashboard can store up to 1000 versions that are never deleted.	March 28, 2025
Scenarios general availability	Updated the scenarios documentation to support its general availability release. For more information, see Working with scenarios in Amazon QuickSight .	March 25, 2025
New Region	Amazon QuickSight is now available in the Europe (Spain) (eu-south-2) Region. For more information, see Supported AWS Regions for Amazon QuickSight .	March 11, 2025
Dashboard Q&A experience	Amazon QuickSight authors can now to turn on the Q&A experience directly from their dashboards in one click without the need to create a topic in QuickSight. For more information, see Turn on the Dashboard Q&A experience in Amazon QuickSight .	January 31, 2025

Unique key configuration	Amazon QuickSight authors can now configure a unique key column to a QuickSight dataset during data preparation. For more information, see Adding a unique key to an Amazon QuickSight dataset .	December 19, 2024
Amazon QuickSight scenarios	Amazon QuickSight Pro users can now use Amazon Q in Quick to create scenarios to analyze complex business problems with simple natural language. For more information, see Working with scenarios in Amazon QuickSight .	December 4, 2024
Augmenting Amazon QuickSight insights with Amazon Q Business	Amazon QuickSight account admins can now connect their QuickSight account to Amazon Q Business to augment insights with unstructured data sources. For more information, see Augmenting Amazon QuickSight insights with Amazon Q Business .	December 3, 2024
Prompted reports	Amazon QuickSight authors can now create prompts on pixel-perfect reports to allow dashboard users to filter data in on-demand and scheduled reports. For more information, see Setting up prompts for pixel perfect reports .	November 22, 2024

New visual type: layer map	Amazon QuickSight now supports layer map visuals. For more information, see Using layer maps .	November 22, 2024
New visual type: image component	You can now add images to QuickSight dashboards and analyses with image component visuals in Amazon QuickSight. For more information, see Using image components .	November 22, 2024
New visual type: Highcharts visual	Amazon QuickSight authors can now configure Highcharts visuals in QuickSight. For more information, see Using Highcharts .	November 22, 2024
Import visual public preview	(Public preview) Amazon QuickSight authors can now import QuickSight visuals from one dashboard or analysis to a new analysis that has access permissions. For more information, see Importing Amazon QuickSight visuals to an analysis .	November 22, 2024
Font customization	Amazon QuickSight dashboard viewers can now schedule their own dashboard reports for themselves. For more information, see Creating a reader generated report in Amazon QuickSight .	November 22, 2024

Font customization	Amazon QuickSight authors can now customize the font, font size, and font color of visual titles, subtitles, legends, headers, and cells. For more information, see Titles and subtitles on visual types in QuickSight .	November 22, 2024
Cross-Region inference with Amazon Q in Quick	Amazon Q in Quick now supports cross-Region inferencing. For more information, see Cross-Region inference with Amazon Q in Quick .	November 21, 2024
Create a custom brand in Amazon QuickSight	Amazon QuickSight account admins can now customize their application's branding and visual theme to align with their organization's guidelines. For more information, see Amazon QuickSight brand customization .	November 14, 2024
Connect to Starburst with OAuth client credentials	You can now use OAuth client credentials to connect your Amazon QuickSight account with Starburst through the QuickSight APIs. For more information, see Creating an Amazon QuickSight data source connection to Starburst with OAuth client credentials .	November 8, 2024

[Connect to Snowflake with OAuth client credentials](#)

You can now use OAuth client credentials to connect your Amazon QuickSight account with Snowflake through the QuickSight APIs. For more information, see [Creating an Amazon QuickSight data source connection to Snowflake with OAuth client credentials](#).

November 8, 2024

[Subfolders for restricted shared folders](#)

Assets that are located in a QuickSight restricted folder can now be moved within the restricted folder tree into one or more subfolders. For more information, see [Organizing assets into folders for Amazon QuickSight](#).

October 15, 2024

[Show an apply button](#)

QuickSight authors can now add an **Apply** button to a Calendar, Relative date picker, or Multiselect dropdown control that delays visual reload until the user chooses **Apply**. For more information, see [Adding filter controls to analysis sheets](#).

September 27, 2024

[Data story personalization](#)

Amazon Q in Quick now leverages user location and job-related information from your IAM Identity Center instance to generate personalized data stories that are more relevant to authors and readers. For more information, see [Personalize data stories in Amazon QuickSight](#).

September 27, 2024

[Shared view for embedded dashboards](#)

QuickSight developers can now use the Amazon QuickSight Embedding SDK (version 2.8.0 and higher) to allow readers of embedded dashboards to receive and distribute shareable links to their view of an embedded dashboard. For more information, see [Share an embedded view](#).

August 23, 2024

[5 new regions](#)

Amazon Q in Quick is now available in 5 new opt-in Regions: Asia Pacific (Mumbai), Canada (Central), Europe (Ireland), Europe (London), and South America (São Paulo). For more information, see [Supported AWS Regions for Amazon Q in Quick](#).

August 9, 2024

Nested filters	You can now apply nested filters to QuickSight analyses. For more information, see Adding nested filters .	August 1, 2024
Joined datasets in SPICE	The size limit for secondary tables of joins for datasets that are stored in SPICE have been updated. For more information, see Joining data .	July 10, 2024
Advanced options for paginated reports	You can now create repeating sections for pixel perfect reports in Amazon QuickSight. For more information, see Create repeating sections .	June 27, 2024
4 New Regions	QuickSight is now available in 4 new opt-in Regions: Europe (Milan), Europe (Zurich), Africa (Cape Town), and Asia Pacific (Jakarta). For more information, see AWS Regions, websites, IP address ranges, and endpoints .	May 28, 2024
New sorting options for tables in Amazon QuickSight	QuickSight Authors can now configure single column, multi column, and off-visual sorts for tables in Amazon QuickSight. For more information, see Sorting tables .	May 20, 2024

[Key management in
QuickSight: Updated IAM
policy conditions](#)

The required IAM policy permissions that grant access to AWS KMS keys in the QuickSight console and the QuickSight APIs have been updated. For more information, see [IAM identity-based policies for Amazon QuickSight: using the admin key management console](#).

May 16, 2024

[???](#)

QuickSight Admins can now update and manage CMKs that are registered to a QuickSight account with the QuickSight APIs. For more information about creating and managing CMKs with the QuickSight APIs, For more information, see [Key management operations](#).

May 16, 2024

[Hide SPICE capacity labels](#)

QuickSight Admins can now choose to hide the account-wide SPICE capacity usage and remaining size labels from QuickSight authors. For more information, see [Hiding SPICE capacity labels](#).

May 2, 2024

[Embed the Generative Q&A experience](#)

You can now set up an embedded Q&A that uses enhanced NLQ capabilities powered by LLMs. The Q&A is the recommended replacement for the embedded Q Search Bar and provides an updated BI experience for users. For more information, see [Embed the Amazon Q in Quick Generative Q&A experience](#).

April 30, 2024

[Amazon Q in Quick: New Pro roles](#)

Amazon Q integrates with Amazon QuickSight to give QuickSight users access to a suite of new generative BI capabilities. With Amazon Q in Quick, you can utilize the generative BI authoring experience, create executive summaries of your data, ask and answer questions of data, and generate data stories. To get started with Amazon Q in QuickSight Generative BI capabilities, upgrade your account's users to Admin Pro, Author Pro, or Reader Pro roles. For more information, see [Get started with Generative BI](#).

April 30, 2024

[VPC endpoint restrictions](#)

You can now create VPC endpoint restrictions in Amazon QuickSight to limit access to your QuickSight account. For more information, see [Turning on IP and VPC endpoint restrictions in Amazon QuickSight](#).

April 9, 2024

[Account instances of IAM Identity Center for account management](#)

Amazon QuickSight now supports account instances of IAM Identity Center for identity management. For more information, see [Managing user access inside Amazon QuickSight](#).

April 9, 2024

[Managed policy update](#)

Amazon QuickSight added a new managed policy to simplify Asset Bundle export operations. For more information, see [AWS managed policy: AWSQuickSightAssetBundleExportPolicy](#).

March 27, 2024

[Managed policy update](#)

Amazon QuickSight added a new managed policy to simplify Asset Bundle import operations. For more information, see [AWS managed policy: AWSQuickSightAssetBundleImportPolicy](#).

March 27, 2024

New Q pane	Amazon QuickSight users that are opted in to the Generative BI preview can now use the Q pane to access all relevant Generative BI features. For more information, see Using Generative BI with Amazon Q in Quick .	March 25, 2024
New Region: China (north)	Amazon QuickSight is now available in China (Beijing) (cn-north-1). For more information, see AWS Regions, websites, IP address ranges, and endpoints .	January 25, 2024
Amazon Q Business in Amazon QuickSight	Amazon Q Business integrates with Amazon QuickSight to give QuickSight users access to a suite of new generative BI capabilities. With Amazon Q in Quick, you can utilize the generative BI authoring experience, create executive summaries of your data, ask and answer questions of data, and generate data stories. For more information, see Using generative BI with Amazon Q in Quick .	November 28, 2023

[Trusted identity propagation in Amazon QuickSight](#)

QuickSight authors can now create data sources with trusted identity propagation, which allows database administrators to centrally manage data security in Amazon Redshift and automatically apply all data security rules to data consumers in QuickSight. For more information, see [Enabling trusted identity propagation with Amazon Redshift](#).

November 26, 2023

[Runtime filtering and theming for embedded dashboards and visuals](#)

QuickSight authors can now customize filters and themes for embedded dashboards and visuals. For more information, see [Customizing embedded assets](#).

November 17, 2023

[Custom time zones and week start days in Amazon QuickSight](#)

QuickSight authors can now restrict the functionality that people can access in Amazon QuickSight. For more information, see [Customizing access to the Amazon QuickSight console](#).

November 17, 2023

[Custom time zones and week start days in Amazon QuickSight](#)

QuickSight authors can now turn on SPICE auto capacity purchasing to allow Amazon QuickSight to automatically manage your QuickSight account's SPICE capacity. For more information, see [Turning SPICE auto capacity purchasing on](#).

November 17, 2023

[Amazon EventBridge integration](#)

You can now integrate your Amazon QuickSight account with Amazon EventBridge. For more information, see [Amazon QuickSight EventBridge integration](#).

November 17, 2023

[New look for the QuickSight analysis workspace](#)

We've redesigned the Amazon QuickSight analysis workspace. You might encounter screenshots or procedural text that doesn't reflect the new look in the QuickSight console. We're in the process of updating screenshots and procedural text. For more information on QuickSight's new look, see [Introducing new analysis experience on Amazon QuickSight](#).

November 16, 2023

[Custom time zones and week start days in Amazon QuickSight](#)

QuickSight authors can now set custom time zones and week start days for their analyses. For more information, see [Customize date and time values of an analysis](#).

November 14, 2023

[Float decimal type](#)

Decimal values in calculated fields of datasets that are stored in SPICE can now be assigned the Fixed or Float decimal data type. For more information, see [Supported data types and values](#).

November 8, 2023

[Custom total values in Amazon QuickSight](#)

QuickSight authors can now define the total and subtotal aggregations for their table or pivot table visuals from the field wells. For more information, see [Custom total values](#).

October 25, 2023

[Restricted and unrestricted shared folders in Amazon QuickSight](#)

QuickSight authors can now create restricted and unrestricted shared folders with the QuickSight CLI to help organize and manage the permissions of important QuickSight assets. For more information, see [Organizing assets into folders for Amazon QuickSight](#).

October 24, 2023

New data source	QuickSight now supports connecting to a Trino data source. For more information, see Using Trino with Amazon QuickSight .	October 20, 2023
New data source	QuickSight now supports connecting to a Starburst data source. For more information, see Using Starburst with Amazon QuickSight .	October 20, 2023
SageMaker AI Canvas integration	QuickSight authors can now export data into SageMaker AI Canvas to build ML models that can be sent back to QuickSight and applied to analyses and dashboards. For more information, see Build predictive models with SageMaker AI Canvas .	October 6, 2023
Managed policy update	The AWSQuickSightSageMakerPolicy is updated to reflect the Amazon QuickSight–SageMaker AI integration. For more information, see AWS managed policy: AWSQuickSightSageMakerPolicy .	October 6, 2023

Amazon Redshift run-as role	QuickSight authors can now connect Amazon Redshift data with run as role to enhance data security with fine grained access policies. For more information, see Run queries as an IAM role in Amazon QuickSight .	October 6, 2023
Generative BI public preview	The public preview for Generative BI is now available to users who have a QuickSight Q add-on subscription. For more information, see Working with Generative BI in QuickSight Q .	September 28, 2023
Freeze table columns in Amazon QuickSight	You can now freeze single or groups of table columns in Amazon QuickSight. For more information, see Freeze columns to table visuals .	September 26, 2023
Enhanced KPI options in Amazon QuickSight	New layouts and formatting options for KPIs are now available in Amazon QuickSight. For more information, see Using KPIs .	September 15, 2023
Scaled folders in Amazon QuickSight	You can create scaled folders that can be shared with thousands of namespaces at once with the Amazon QuickSight APIs. For more information, see Creating scaled folders with the AWS CLI .	August 30, 2023

[Excel format reports in Amazon QuickSight](#)

You can now create and schedule Excel snapshot reports of a dashboard in Amazon QuickSight. For more information, see [Scheduling and sending reports by email](#).

August 24, 2023

[Add contextual row subtitles to pivot tables in Amazon QuickSight](#)

You can now add contextual row subtitles to pivot tables in Amazon QuickSight. For more information, see [Totals and subtotals](#).

August 16, 2023

[New layouts for pivot tables in Amazon QuickSight](#)

Amazon QuickSight now supports two types of layout for pivot tables: tabular and hierarchy. For more information, see [Choosing a layout](#).

August 11, 2023

[Default column width Amazon QuickSight](#)

You can now set the default column width of your pivot table visuals in Amazon QuickSight. For more information, see [Row and column size in tables and pivot tables in Amazon QuickSight](#).

August 11, 2023

[Amazon QuickSight integration with IAM Identity Center](#)

You can now integrate your Amazon QuickSight Enterprise edition account with IAM Identity Center. For more information, see [Configure your Amazon QuickSight account with IAM Identity Center](#).

August 11, 2023

[Embedded callback actions at runtime](#)

You can now use embedded data point callback actions to build tighter integrations between your SaaS application and your Amazon QuickSight embedded dashboards and visuals. For more information, see [Add embedded callback actions to at runtime in Amazon QuickSight](#).

August 9, 2023

[Working with field level coloring in Amazon QuickSight](#)

You can now assign specific colors to specific field values across all visuals in a QuickSight analysis or dashboard. For more information, see [Working with field level coloring in Amazon QuickSight](#).

July 13, 2023

[Small multiples axis options in Amazon QuickSight](#)

You can now configure the x and y axes for each individual panel of a small multiples visual in Amazon QuickSight. For more information, see [Small multiples axis options](#).

July 13, 2023

[Use the analysis menu in Amazon QuickSight](#)

You can now use menu options to efficiently perform tasks without needing to manually navigate through your analysis in Amazon QuickSight. For more information, see [The analysis menu](#).

July 7, 2023

[Advanced report scheduling options in Amazon QuickSight](#)

You can now access more advanced PDF report scheduling options in Amazon QuickSight. For more information, see [Configuring email report settings for a dashboard in QuickSight Enterprise edition](#).

June 30, 2023

[Format visual language data based on language settings in Amazon QuickSight](#)

You can now choose how your numeric data values appear in visuals so that they align with the regional language that you have chosen in Amazon QuickSight. For more information, see [Formatting visual numeric data based on language settings in Amazon QuickSight](#).

May 26, 2023

[Create geospatial heatmaps in Amazon QuickSight](#)

You can now create geospatial heatmaps in Amazon QuickSight. For more information, see [Geospatial heatmaps in Amazon QuickSight](#).

May 26, 2023

[Work with Q topics using the QuickSight CLI in Amazon QuickSight](#)

You can now work with QuickSight Q topics using the Amazon QuickSight command line interface (CLI). For more information, see [Work with QuickSight Q topics using the Amazon QuickSight CLI](#).

May 4, 2023

[Use dataset parameters in Amazon QuickSight](#)

You can now use dataset parameters in direct query to dynamically customize their datasets and apply reusable logic to your datasets. For more information, see [Using dataset parameters in Amazon QuickSight](#).

May 4, 2023

[Enhanced options for scatter plots in Amazon QuickSight](#)

You can now plot unaggregated values on scatter plots in Amazon QuickSight. For more information, see [Using scatter plots](#).

May 4, 2023

[Create and update VPC connections Amazon QuickSight](#)

You can now create and update VPC connections in Amazon QuickSight. For more information, see [Using dataset parameters in Amazon QuickSight](#).

May 4, 2023

[Create tag-based RLS rules using the OR condition in Amazon QuickSight](#)

You can now add the OR condition to your tag-based rules to further customize the way data is presented to your QuickSight account users. For more information, see [Using row-level security \(RLS\) with tag-based rules to restrict access to a dataset when embedding dashboards for anonymous users](#).

April 7, 2023

[Threshold alerts on Table and Pivot table visuals in Amazon QuickSight](#)

You can now create threshold alerts for Table and Pivot table visuals in Amazon QuickSight. For more information, see [Working with threshold alerts in Amazon QuickSight](#).

March 17, 2023

[Hide collapsed columns in Amazon QuickSight table visuals](#)

You can now customize the way Amazon QuickSight readers view pivot tables to make them easier to read and understand at a glance. For more information, see [Pivot table layout options](#).

March 9, 2023

[Enhanced embedding capabilities in Amazon QuickSight](#)

You can now use QuickSight's Embedding SDK (v2.0) to improve developer experience when embedding QuickSight in your application or website. For more information, see [Embedding with the QuickSight APIs](#).

March 9, 2023

[Run queries with Amazon S3 data sources in Amazon QuickSight](#)

You can now enhance data security by using fine-grained access policies rather than broader permissions for data sources connected to Amazon S3 in Amazon QuickSight. For more information, see [Run queries with Amazon S3 data sources](#).

February 21, 2023

[Radar charts in Amazon QuickSight](#)

You can now create radar charts in Amazon QuickSight. For more information, see [Using radar charts in Amazon QuickSight](#).

January 30, 2023

[Data bars for tables and pivot tables in Amazon QuickSight](#)

You can now use data bars to add visual context to your table visuals in Amazon QuickSight. For more information, see [Adding data bars to tables in Amazon QuickSight](#).

January 24, 2023

[New question types: Boolean, Forecast, and Why](#)

You can now enter boolean, forecast, and why questions into the QuickSight Q search bar. For more information, see [Asking questions with Amazon QuickSight Q](#).

November 29, 2022

[Automated data prep for QuickSight Q](#)

Amazon QuickSight Q now uses AI-enhanced data preparation to automatically create topics that are relevant to your end users. For more information, see [Working with Amazon QuickSight Q topics](#).

November 29, 2022

[Pixel perfect reporting](#)

You can now create, schedule, and share highly formatted multi-page reports in Amazon QuickSight. For more information, see [Working with pixel perfect reports in Amazon QuickSight](#).

November 28, 2022

[Embedding the Q search bar for anonymous \(unregistered\) users](#)

You can now embed the QuickSight Q search bar for anonymous (unregistered) users. For more information, see [Embedding the Amazon QuickSight Q search bar for anonymous \(unregistered\) users](#).

November 19, 2022

[Asset management](#)

You can now manage all of the assets on your Amazon QuickSight account in one unified view. For more information, see [Amazon QuickSight asset management](#).

November 19, 2022

[Text boxes](#)

You can now add static and dynamic textual content using text boxes in Amazon QuickSight. For more information, see [Using text boxes](#).

November 18, 2022

[Small multiples](#)

You can now create small multiples in line, bar, and pie chart visuals. For more information, see [Using small multiples](#).

November 18, 2022

[Set a reserved value in QuickSight datasets](#)

You can now set a reserved value to determine the value of the **Select all** value of a dataset in Amazon QuickSight. For more information, see [Setting up parameters in Amazon QuickSight](#).

November 18, 2022

[Run queries as an IAM role in Amazon QuickSight](#)

You can now enhance data security by using fine-grained access policies rather than broader permissions for data sources connected to Athena. For more information, see [Run queries as an IAM role in Amazon QuickSight](#).

November 18, 2022

[Pin Amazon QuickSight Q answers to your pinboard](#)

You can now pin visuals from Q for easy access to frequently asked questions. For more information, see [Pinning visuals in Amazon QuickSight Q](#).

November 18, 2022

[Marker clustering on geospatial map visuals](#)

You can now use marker clustering to improve readability of co-located points on a map. For more information, see [Marker clustering on geospatial point maps in QuickSight](#).

November 18, 2022

[Line chart customization](#)

You can now add customizations to line chart visuals to emphasize what you want readers to focus on: color, line style, and markers. For more information, see [Line and marker styling on line charts in QuickSight](#).

November 18, 2022

[Connecting Amazon QuickSight accounts to Databricks](#)

You can now use Amazon QuickSight to connect to Databricks on AWS. For more information, see [Using Databricks in QuickSight](#).

November 18, 2022

[Account termination protection](#) [n](#)

You can now use account termination protection to prevent someone from deleting a QuickSight user account accidentally or maliciously. For more information, see [Deleting your Amazon QuickSight subscription and closing your account.](#)

November 18, 2022

[1 billion row SPICE datasets](#)

Amazon QuickSight now supports SPICE datasets that contain up to 1 billion (1,000,000,000) rows or 1 terabyte (TB) of data. For more information, see [SPICE quotas for imported data.](#)

November 18, 2022

[Monitor SPICE consumption metrics in Amazon CloudWatc](#) [h](#)

You can now monitor your QuickSight account's SPICE consumption metrics in Amazon CloudWatch. For more information, see [Aggregate SPICE metrics.](#)

November 8, 2022

[Use AWS KMS to encrypt your SPICE datasets in Amazon QuickSight](#)

You can now encrypt your SPICE datasets using the keys that you have stored in AWS KMS. This provides you with the tools to audit access to data and satisfy regulatory security requirements. For more information, see [Key management.](#)

October 27, 2022

[Add datasets that contain row-level security \(RLS\) to Q topics](#)

QuickSight Q now supports questions for access restricted datasets that use Row level Security (RLS) with user based rules. Readers can now ask questions about Topics that contain restricted access datasets and instantly receive accurate and pertinent answers based on access control rules defined by authors in RLS settings. For more information, see [Adding datasets with row-level security \(RLS\) to a topic](#).

October 10, 2022

[Use AWS Secrets Manager secrets instead of database credentials in Amazon QuickSight](#)

Amazon QuickSight administrators can grant QuickSight read-only access to secrets they create in AWS Secrets Manager. These secrets can be used in place of database credentials when creating and editing data sources using the QuickSight API. For more information, see [Using AWS Secrets Manager secrets instead of database credentials in Amazon QuickSight](#).

October 6, 2022

[Visual Embedding](#)

You can now embed visuals using a 1-click embed code or with the Amazon QuickSight API. For more information, see [Embedding visuals with the Amazon QuickSight API](#).

August 25, 2022

Undo and redo changes in Q answers	You can now undo or redo any changes you make to a Q answer by choosing the undo or redo arrows in the Q search bar. For more information, see step six in Asking questions with Q .	August 22, 2022
Updates to the sign in experience	The sign in experience in QuickSight has been updated. For more information about how to sign in, see Signing in to QuickSight .	July 21, 2022
Bookmarks	You can now bookmark views of a dashboard. For more information, see Bookmarking views of a dashboard .	July 21, 2022
Base Maps	When creating map visuals in QuickSight, you can now change map base. For more information, see Changing base maps .	July 21, 2022
Q updates	You can now try QuickSight Q out for free before getting the Q add-on. For more information, see Trying QuickSight Q .	July 7, 2022
Rolling dates in filters and parameters	You can now set a rolling date on date range filters and relative date parameters in analyses. For more information, see Creating range date filters in analyses and Setting up parameters .	July 5, 2022

[Calculations update](#)

You can now create level-aware calculations in QuickSight. You can specify at what level to group computations using level-aware calculation - aggregation (LAC-A) functions. You can also specify the window or partition to compute a calculation using level-aware calculation - window (LAC-W) functions (previously known as level-aware aggregations). For more information, see [Using level-aware calculations](#).

July 5, 2022

[Allowed domains](#)

Developers can now add a domain at run-time to an allow list with the `AllowedDomains` parameter of a `GenerateEmbedUrlForAnonymousUser` or a `GenerateEmbedUrlForRegisteredUser` API call. For more information, see [Allow listing domains at run-time with the QuickSight API](#).

July 5, 2022

[Account provisioning](#)

You can now sign up for an Amazon QuickSight account with the Amazon QuickSight API. For more information, see [CreateAccountSubscription](#).

July 5, 2022

[Monitoring data with Amazon CloudWatch](#)

You can now monitor metrics for Amazon QuickSight dashboards, visuals, and dataset ingestions on Amazon CloudWatch to provide your readers with a consistent, high-performing, and uninterrupted experience on QuickSight. For more information, see [Monitoring data in Amazon QuickSight](#).

June 22, 2022

[Forecast boundaries](#)

Authors can now set a minimum and maximum for forecasted values. For more information, see [Forecasting and creating what-if scenarios](#).

June 16, 2022

[Table and pivot table enhancements](#)

Authors and Readers can now resize rows and columns in a table or pivot table visual. For more information, see [Resizing rows and columns in tables and pivot tables](#).

June 14, 2022

[Hiding fields in pivot tables](#)

You can now hide fields in pivot table visuals. For more information, see [Showing and hiding pivot table columns](#).

June 14, 2022

[ML insights and forecasting for Q](#)

Readers can now see key data insights and add forecasts to Q answers. For more information, see [Asking questions with QuickSight Q](#).

June 2, 2022

What's New in QuickSight	To find out what's new in QuickSight, see the What's New page. What's New posts provide a brief overview of all QuickSight feature announcements as they are released.	June 1, 2022
Line chart updates	QuickSight now supports 10,000 data points for line charts. For more information, see Using line charts .	May 22, 2022
1-click public embedding	You can now embed dashboards for anyone on the internet in your public applications with a 1-click static embed code. For more information, see Enabling public access to dashboards with a 1-click embed code .	May 18, 2022
Creating and managing groups	You can now create and manage groups in the QuickSight console. For more information, see Creating and managing groups in Amazon QuickSight .	March 21, 2022
Automatic refresh controls for direct query	In QuickSight, filter controls are now refreshed every 24 hours for direct query. For more information, see Refreshing data .	March 8, 2022

Updating files in a dataset	You can now update files in a dataset to get the latest version of those files. For more information, see Updating files in a dataset .	January 27, 2022
Rich text formatting for titles and subtitles	QuickSight now offers rich text formatting for titles and subtitles, and the ability to add hyperlinks and parameters in titles. For more information, see Formatting a visual title and subtitle .	January 27, 2022
Comparative and cumulative date/time calculations	Comparative and cumulative period functions, such as year-over-year and year-to-date, are now supported in QuickSight. For more information, see Add comparative and cumulative date/time calculations in QuickSight .	January 27, 2022
Sharing dashboards	You now have the option to grant everyone in your QuickSight account access to a dashboard. You can also share a link to the dashboard with anyone who has access to it. For more information, see Sharing dashboards .	November 23, 2021

Customizing email report templates	You can now customize how dashboard email reports appear and behave for QuickSight account users. For more information, see Customizing email report templates .	November 23, 2021
1-click enterprise embedding	You can now embed dashboards for registered users in your internal applications with a 1-click static embed code. For more information, see Embedding dashboards for registered users with a 1-Click embed code .	November 23, 2021
New data source	QuickSight now supports connecting to an Exasol data source. For more information, see Supported data sources .	November 22, 2021
Dataset versioning	QuickSight now supports dataset versioning. For more information, see Reverting datasets back to previous published versions .	November 22, 2021
Adding datasets with RLS to Q topics	QuickSight Q topics now support datasets with row-level security (RLS). For more information, see Adding datasets with RLS to a Q topic .	November 19, 2021

Sheet change performance operations	QuickSight now only refreshes visuals when switching sheets if required. For more information, see Refreshing visuals .	November 12, 2021
Incrementally refresh a SQL-based dataset	In QuickSight Enterprise Edition, you can now refresh your SQL-based SPICE datasets incrementally within a look-back window of time. For more information, see Refreshing data .	October 25, 2021
Embedding the Q search bar	You can now embed the Q search bar in your application for registered users of QuickSight. For more information, see Embedding the QuickSight Q search bar for registered users .	October 22, 2021
Email syncing for federated users	In Enterprise Edition, QuickSight administrators can now restrict new users from using personal email addresses when provisioning through their identity provider (IdP) to QuickSight. For more information, see Configuring email syncing for federated users .	October 22, 2021

Adding RLS tags to a dataset	You can now add tag-based rules to a dataset in QuickSight when applying row-level security (RLS). For more information, see Using row-level security (RLS) with tag-based rules to restrict access to a dataset when embedding dashboards for anonymous users .	October 19, 2021
IP restrictions	You can now limit access to your organization's QuickSight account to a predefined list of Internet Protocol (IP) ranges. For more information, see Turning on Internet Protocol (IP) restrictions in Amazon QuickSight .	October 18, 2021
New table and pivot table styling options	You can now customize the look of tables and pivot tables. For more information, see Formatting tables and pivot tables .	October 12, 2021
New SPICE quota for imported data	In QuickSight Enterprise edition, you can now import up to 500 million rows into a SPICE dataset. For more information, see Data source quotas .	October 12, 2021

Links and images in tables	You can now add links to tables. You can also render links as images in tables. For more information, see Field styling .	October 12, 2021
Custom date formats	You can now customize how dates are formatted in your filter and parameter controls. For more information, see Customizing date formats .	October 8, 2021
QuickSight q	You can now ask questions about your data in the Q bar and get answers in the form of visuals. For more information, see Working with QuickSight q .	September 24, 2021
New geospatial region	QuickSight now supports creating geospatial charts for India. For more information about creating geospatial charts, see Using geospatial charts (maps) .	September 22, 2021
Free-form layouts	You can now place visuals anywhere in your dashboard using precise coordinates. For more information, see Customizing dashboards and visuals .	September 22, 2021
Passing IAM roles to QuickSight	You can now pass IAM roles to QuickSight. For more information, see Using QuickSight with IAM .	September 15, 2021

Create datasets from existing datasets	You can now create datasets from existing datasets. For more information, see Creating a dataset using an existing dataset .	September 15, 2021
Updated AWS managed policy	QuickSight updated an existing AWS managed policy. For more information, see Amazon QuickSight updates to AWS managed policies .	September 8, 2021
New AWS managed policy	QuickSight added a new AWS managed policy. For more information, see Amazon QuickSight updates to AWS managed policies .	September 8, 2021
Forecast multiple measures	You can now forecast up to three measures in the same chart. For more information, see Forecasting and creating what-if scenarios .	August 30, 2021
Share your view of a dashboard	You can now share your view of a dashboard. For more information, see Sharing dashboards .	August 20, 2021
Hide the data zoom on a chart	You can now choose to show or hide the data zoom for your charts in Amazon QuickSight. For more information, see Formatting axes and Grid lines .	August 16, 2021

[Row-level security with tags](#)

You can now use row-level security (RLS) with tags to specify which data your (unauthenticated) users can see in an embedded Amazon QuickSight dashboard depending on who they are. For more information, see [Using RLS with tags to restrict access to a dataset when embedding dashboards for anonymous users](#).

July 29, 2021

[New embedding API operations](#)

Amazon QuickSight has the following new API operations for embedding analytics: `GenerateEmbedUrlForAnonymousUser` and `GenerateEmbedUrlForRegisteredUser`. You can still use the `GetDashboardEmbedUrl` and `GetSessionEmbedUrl` API operations to embed dashboards and the QuickSight console, but they don't contain the latest embedding capabilities. For more information about using the new API operations, see [Embedding overview](#). For more information on using the old API operations, see [Embedding analytics using the old API operations](#).

July 29, 2021

Customizing charts	You can now hide the sort icon and the axis or field title in charts in Amazon QuickSight. For more information, see Formatting axes and Grid lines .	July 16, 2021
Threshold alert updates	You can now choose to be notified when there is no data to check your alert rule against in Amazon QuickSight. For more information, see Working with threshold alerts .	July 9, 2021
New chart type: Custom visual content	You can now embed webpages and online videos, forms, and images in your QuickSight dashboards using the custom visual content chart type. For more information, see Using custom visual content in QuickSight .	June 29, 2021
Feature improvements	You can now show totals for stacked bar charts. For more information, see Using bar charts .	June 29, 2021
Threshold alert updates	Dataset owners can now set a threshold alert evaluation schedule for a dataset in Amazon QuickSight. For more information, see Working with threshold alerts .	June 17, 2021

Duplicating analyses	You can now duplicate an analysis in Amazon QuickSight. For more information, see Duplicating an analysis .	June 17, 2021
Threshold alert updates	You can now choose how often you want to receive threshold alerts in Amazon QuickSight. For more information, see Working with threshold alerts .	May 25, 2021
Wildcard search	Amazon QuickSight now supports wildcard search. For more information, see Using wildcard search .	May 1, 2021
Threshold alerts	Amazon QuickSight now supports creating threshold alerts using KPI and Gauge visuals in dashboards. For more information, see Working with threshold alerts .	May 1, 2021
Service control policies	Amazon QuickSight now supports using service control policies (SCPs) to restrict how individuals in your organization can sign up for QuickSight. For more information, see Using service control policies to restrict QuickSight signup options .	April 26, 2021

Parameter improvements	Amazon QuickSight now supports dynamically displaying parameter values in titles and descriptions throughout charts and analyses. For more information, see Using parameters in titles and descriptions .	April 12, 2021
Feature improvements	QuickSight now supports selecting a time granularity for date and time range filters and datetime parameters. For more information, see Adding a date filter and Setting up parameters .	April 1, 2021
Export to PDF	QuickSight now supports PDF exports of the current sheet in dashboards and analyses. In Enterprise edition, you can now attach a PDF to email reports. For more information, see Exporting an analysis or dashboard as a PDF .	April 1, 2021
Seconds support for date fields	QuickSight now supports aggregating date fields at the second level. For more information, see Changing date field granularity .	March 30, 2021

[Pivot table sorting improvements](#)

QuickSight now supports sorting values in pivots tables by fields in the **Rows** and **Columns** field wells or by column headers. For more information, see [Sorting pivot tables](#).

March 30, 2021

[New feature](#)

Amazon QuickSight now supports customizing tooltips in visuals. For more information, see [Customizing tooltips in a visual](#).

March 16, 2021

[Feature improvements](#)

In Enterprise edition, QuickSight now supports computing anomalies for a time and measure field only, and computing the exact combination of fields in the Category field well. For more information, see [Adding an ML insight to detect outliers and key drivers](#).

March 16, 2021

[Line chart improvements](#)

Amazon QuickSight now supports creating line charts with dual axes. For more information, see [Creating a dual-axis line chart](#).

March 1, 2021

[New formatting options for charts](#)

Amazon QuickSight now supports hiding axis lines, axis labels, and grid lines, and also customizing the how axis labels appear in a chart. For more information, see [Formatting axis lines, axis labels, and Grid lines](#).

February 5, 2021

[New chart type: Sankey diagrams](#)

Amazon QuickSight now supports creating Sankey diagrams. For more information, see [Using sankey diagrams](#).

February 5, 2021

[Field mapping improvements](#)

Amazon QuickSight now supports updating field mapping between mismatched and missing fields when replacing a dataset in an analysis. For more information, see [Replacing datasets](#).

February 5, 2021

[Data prep enhancements](#)

Amazon QuickSight now supports organizing fields into folders and subfolders when preparing or editing datasets. For more information see, [Organizing fields into folders](#).

February 5, 2021

New features

In Enterprise edition, QuickSight now supports displaying anomaly ranges and multiple anomalies when exploring anomalies. Line charts now display notifications when QuickSight detects an anomaly, key driver, or forecasting opportunity. For more information, see [Detecting outliers with ML-powered anomaly detection](#).

February 3, 2021

New region: South America (São Paulo)

Amazon QuickSight is now available in South America (São Paulo) (sa-east-1). For more information, see [AWS Regions, websites, IP address ranges, and endpoints](#).

December 23, 2020

New region: Canada (central)

Amazon QuickSight is now available in Canada (Central) (ca-central-1). For more information, see [AWS Regions, websites, IP address ranges, and endpoints](#).

December 23, 2020

Define an action to open a different sheet

QuickSight now supports navigation actions to enable you to open a different sheet with the included parameter values. For more information, see [Using custom actions for filtering and navigating](#).

December 21, 2020

Data source enhancement: Athena federated query	QuickSight now supports connecting to Athena Federated Query. For more information, see Creating a dataset using Amazon Athena data .	December 21, 2020
New list items sheet control type	Amazon QuickSight now supports single and multi-select list control on dashboards. For more information, see Parameter controls .	December 18, 2020
New formatting options for tables	In QuickSight, you can now reorder columns in table charts. For more information, see Using tables as visuals .	December 17, 2020
Row-level security (RLS) now supports GRANT option only	To streamline and simplify RLS setup, QuickSight no longer supports using RLS in deny-access mode. To create a new RLS configurations, use the explicit grant-access model. Current RLS datasets and deny-access configurations should continue to work as expected. For more information, see Using row-level security (RLS) to restrict access to a dataset .	December 6, 2020

[New percentile functions](#)

QuickSight now supports variations on percentile calculations, including aggregate functions `percentileCont` and `percentileDisc` and `OVER` functions `percentileContOver` and `percentileDiscOver`. You can use all of these functions in the calculations editor in analysis mode. For more information, see [Functions by category](#).

December 6, 2020

[Dynamic queries, plus dataset editor improvements](#)

QuickSight now enables you to improve performance for visuals based on direct queries by specifying unique keys for joined tables. There are also multiple interface improvements, such as settings for optional autopreviews, zoom in and out of data diagrams, join recommendations, and more. For more information, see [Joining data](#).

December 6, 2020

[Developer portal for embedding](#)

The Dev Portal helps you learn how to use embedding by example in your web site or application. For more information, see [Using the dev portal](#).

November 30, 2020

New data source: Amazon OpenSearch	QuickSight now supports connecting to Amazon OpenSearch. For more information, see Using Amazon OpenSearch with QuickSight .	November 25, 2020
Format metrics on pie charts	QuickSight now supports formatting metrics on pie charts to display values, percentages, or both. For more information, see Customizing data labels .	November 25, 2020
New formatting options for tables	In QuickSight, you can now vertically align and wrap the text for headers in table charts. For more information, see Using tables as visuals .	November 24, 2020
New chart type: Box plots	QuickSight now supports using box plots so you can visualize how your data is distributed across an axis or over time. For more information, see Box plots .	November 24, 2020
Filled maps	QuickSight now supports filled maps so you can visualize your data over a geographical area. For more information, see Filled maps .	November 24, 2020

Favorite folders	In QuickSight, you can now favorite your folders for easy access. For more information, see Organizing assets into folders .	November 24, 2020
Change in display limits	For parameter controls and filters, Amazon QuickSight now displays up to 1,000 sample values. When you have more than that, you use the search box to locate a value. For more information, see Using a control with a parameter .	November 16, 2020
Null rendering	QuickSight now allows null values to be updated to a custom string. For more information, see Changing a field format .	November 9, 2020
New chart type: Waterfall charts	QuickSight now supports using waterfall charts so you can view your data sequentially. For more information, see Waterfall charts .	November 9, 2020

Embedding for everyone	QuickSight Enterprise edition now supports embedding for everyone. When you purchase session packs with capacity pricing, you can enable visitors to use embedded dashboards without registering them as QuickSight users. For more information, see Embedded analytics .	November 9, 2020
Column-level security	QuickSight now supports using column-level security to restrict access to a dataset. For more information, see Using column-level security .	November 9, 2020
Service provider initiated federation	QuickSight Enterprise edition now supports service provider initiated federation, so you can sign on directly to QuickSight using your IAM Identity Center login and password. For more information, see Setting up service provider–Initiated federation with QuickSight enterprise edition .	October 30, 2020
New chart type: Funnel charts	QuickSight now supports using funnel charts so you can display your data in a linear process. For more information, see Funnel charts .	October 29, 2020

Custom sorting	QuickSight now enables you to apply sort options on fields outside the field wells. This feature is available for all charts that support sorting. For more information, see Describing data .	October 29, 2020
New region: AWS GovCloud (US-West)	Amazon QuickSight is now available in AWS GovCloud (US-West) (gov-west-1). For more information, see QuickSight - AWS GovCloud (US) .	October 28, 2020
New data source: Oracle	QuickSight now supports connecting to Oracle. For more information, see Supported data sources .	October 23, 2020
Filter across datasets	In QuickSight, you can now create filters that apply to multiple datasets in an analysis. For more information, see Filtering data .	October 23, 2020
Add field descriptions to datasets	QuickSight now enables you to add column or field descriptions to datasets. This metadata is visible in both datasets and analyses, helping you make your data self-explanatory. For more information, see Describing data .	October 23, 2020

Filter controls on analysis sheets	QuickSight now offers a filter control that you can add to your analysis with a single click. You can put filters beside dashboard visuals and resize them to fit. For more information, see Using filter controls .	October 5, 2020
New data source: Amazon Timestream	QuickSight now supports Amazon Timestream as a data source. For more information, see Using Amazon Timestream data with QuickSight .	October 1, 2020
Export to excel	QuickSight now supports exporting data from pivot tables and table charts to Microsoft Excel (.xlsx) format. For more information, see Exporting data .	September 14, 2020
Duplicate sheets	QuickSight now supports duplicating sheets. For more information, see Working with multiple sheets in an QuickSight analysis .	September 14, 2020
Customize labels of totals and subtotals	In QuickSight, you can now add custom text to display beside totals and subtotals for pivot tables and table charts. For more information, see Table and pivot table formatting options in QuickSight .	September 14, 2020

Skipped row details	When you import data into QuickSight, you now get better error messages and row-by-row information on what caused rows to be skipped during ingestion into SPICE. For more information, see Troubleshooting skipped rows .	September 12, 2020
New configuration option for multivalue lists	QuickSight now supports a configuration option for multivalue lists to start with no values selected. For more information, see Setting up parameters in Amazon QuickSight .	September 11, 2020
Reference lines	QuickSight now supports using reference lines in bar, line, and combo charts. For more information, see Reference lines .	September 3, 2020
New table calculations	QuickSight now supports using window functions <code>firstValue</code> and <code>lastValue</code> in analyses. For more information, see Table calculations .	August 25, 2020
Multivalue default parameters	QuickSight now supports dynamic default values for multi-valued parameters. For more information, see Creating parameter defaults in QuickSight .	August 25, 2020

Last active status for users	QuickSight administrators can now see the last date and time that people accessed QuickSight. For more information, see Viewing user details .	August 25, 2020
Join SQL queries, tables, and files	QuickSight now supports using custom SQL queries in joins with other queries, tables, and files. For more information, see Joining data .	August 25, 2020
Calculated expressions editor	The enhanced editor adds ease-of-use features to help you more easily create calculated expressions in QuickSight. With the new full-screen editor, you can add functions and values directly from the menu. For more information, see Adding a calculated field to an analysis .	August 25, 2020
Personal and shared folders	QuickSight Enterprise edition now offers personal and shared folders to make it easier to discover, organize, share, and explore your available assets. For more information, see Organizing QuickSight assets into folders .	August 5, 2020

[QuickSight support for multitenancy](#)

In Enterprise edition, QuickSight now offers an additional layer of security to support multitenancy. By creating users and groups in a QuickSight namespace, you can isolate them from users and groups in other namespaces. For more information, see [Supporting multitenancy with isolated namespaces](#).

July 23, 2020

[Embed the QuickSight console](#)

In QuickSight Enterprise edition, you can now provide the full dashboard authoring experience of the QuickSight console in your own custom-branded authoring portal. For more information, see [Embedding the QuickSight console](#).

July 23, 2020

[Datasets with 2,000 columns](#)

QuickSight now supports datasets that have up to 2,000 columns. For more information, see [Data source limits](#).

July 23, 2020

[Customized permissions](#)

In QuickSight Enterprise edition, you can now create custom roles to restrict a person from using specific functionality in the QuickSight console, for example to control who can manage data sources and datasets or who can manage or subscribe to email reports. For more information, see [Customizing access to the QuickSight console](#).

July 23, 2020

[Customize the console](#)

In QuickSight Enterprise edition, you can now choose whether to show or hide QuickSight startup samples and videos. You can also create and specify a default theme to add branding to your experience of the QuickSight console. For more information, see [Customizing the QuickSight console](#).

July 23, 2020

[Larger SPICE datasets](#)

QuickSight Enterprise edition now supports SPICE datasets with up to 250 million (250,000,000) rows or 500 GB. For more information, see [Data source limits](#).

July 9, 2020

[Display width settings](#)

In QuickSight, you can now choose between responsive and fixed layouts for your analyses and dashboards. You can also temporarily change your current view from the menu bar. For more information, see [Display settings](#).

July 9, 2020

[Data refresh notifications](#)

QuickSight now supports sending email to notify SPICE dataset owners when data refresh fails. For more information, see [Refreshing data](#).

July 9, 2020

[Color settings for heat maps and tree maps](#)

You can now customize gradient colors for your heat maps and tree maps in QuickSight. For more information, see [Changing colors on heat maps and tree maps](#).

July 9, 2020

[Font choice](#)

You can now customize your theme with a font. Choose from a selection of fonts supported by QuickSight. For more information, see [Using themes in QuickSight](#).

July 8, 2020

[AWS Lake Formation](#)

If you use QuickSight Enterprise edition to query Amazon Athena, you can simplify data access management by using AWS Lake Formation to control permissions to Athena. For more information, see [Authorizing connections through AWS Lake Formation](#).

June 29, 2020

[New chart type](#)

QuickSight now supports using histograms so you can display the distribution of values in your data. For more information, see [Histogram charts](#).

June 12, 2020

[Gauge chart update](#)

You can now add conditional formatting to gauge charts in QuickSight. For more information, see [Adding conditional formatting to visuals](#).

June 12, 2020

[Five new languages](#)

QuickSight now supports Danish, Dutch, Finnish, Norwegian, and Swedish. These languages expand upon the existing 15 languages already available in QuickSight. For more information, see [Choosing a language in Amazon QuickSight](#).

June 12, 2020

[New region: Mumbai](#)

Amazon QuickSight is now available in Asia Pacific (Mumbai) (ap-south-1). For more information, see [AWS Regions, websites, IP address ranges, and endpoints](#).

June 3, 2020

[New SQL editor](#)

QuickSight enhanced the SQL editor that you use to create datasets from SQL queries. The new SQL editor supports syntax highlighting, basic autocomplete, autoindent, and line numbering. Also, you can use the new schema explorer to interactively explore schemas, tables, fields, and data types. For more information, see [Using a SQL query](#).

May 20, 2020

[Amazon SageMaker AI integration now generally available](#)

The integration of SageMaker AI with QuickSight launched in preview just before AWS re:Invent 2019. Now, this feature is generally available in all AWS Regions that are supported by QuickSight. Amazon QuickSight and SageMaker AI together make it faster, easier, and more cost-effective for customers to make use of their machine learning models for visualization and predictions. For more information, see [Amazon QuickSight integration with SageMaker](#).

May 19, 2020

[Update to presto data sources](#)

You can now use nonauthenticated private Presto as a data source. For more information, see [Creating a data source using presto](#).

May 18, 2020

[Rewrite of Amazon QuickSight VPC connection section](#)

Based on your feedback, we completely rewrote this documentation to better explain using Amazon VPC with QuickSight. It includes examples and AWS CLI commands to help you establish the path from Amazon QuickSight to your data source, even if you're using on-premises sources. For more information, see [QuickSight VPC connections](#).

May 18, 2020

[Use logarithmic scale with QuickSight](#)

You can now format visuals using log scale. For more information, see [Changing the visual scale](#).

May 1, 2020

[Severity levels for QuickSight anomaly detection insights](#)

You can now choose the level of severity for anomalies that display in your insight widgets. For more information, see [Using anomaly detection](#).

April 17, 2020

[QuickSight adds a new visual type](#)

The new visual type, stacked area line charts, is similar to area charts except that the stacked values indicate the relationship that each value contributes to the whole. Using stacked area charts, you can display cumulative totals over time while displaying the breakdown by the chosen category. For more information, see [Line charts](#).

April 17, 2020

[QuickSight activates legends by adding menus for quick feature access](#)

QuickSight now supports clicking on legend items to quickly access features like filtering, drilling, chart colors, and custom actions for filtering and URLs. For more information, see [Focusing on visual elements](#) and [Custom actions in QuickSight](#).

April 17, 2020

[Improvements to visual controls in QuickSight](#)

The on-visual menu can now float at the upper-right corner of the visual, moving inside or outside the border of the visual. Plus, you can make your visuals smaller and have more of them, as many as 36 across. For smaller visuals, the new visual controls have more viewing area for charts and insights. To see the new menu, choose one of your visuals. For more information, see [Working with visuals](#).

April 17, 2020

[QuickSight adds cascading filters](#)

You can now create cascading filters by adding them to custom actions in your analyses and dashboards. Each custom filter action can target one or more visuals in the same sheet, creating a cascading filter effect. For more information, see [Custom actions in QuickSight](#).

April 2, 2020

[Modulo operation available in Amazon QuickSight](#)

You can now use modulo operation to find the remainder after dividing one number into another. For more information, see [mod](#).

March 8, 2020

[Images in Amazon QuickSight narratives](#)

You can now insert images from URLs to be rendered as part of a narrative. Images can be resized, conditionally shown within an IF block, and also hyperlinked with the URL feature. For more information, see [Expression editor screen and menus](#).

March 8, 2020

[Amazon QuickSight adds minimum and maximum dates](#)

You can now use minimum and maximum date aggregations in tables and pivot tables. For more information, see [max](#) and [min](#).

March 8, 2020

[Now you can customize minimum delta values to enhance QuickSight ML-powered anomaly detection](#)

Now you can control the minimum delta value that QuickSight uses to detect anomalies (also known as outliers). You can change this setting when you are configuring or exploring anomalies. For more information, see [Detecting outliers with ML-powered anomaly detection](#).

February 4, 2020

[Improvements in the QuickSight narrative expression editor](#)

QuickSight now provides a much more spacious interface for editing narrative expressions. The interface now has instant feedback in a preview of your evaluated narrative before you save any changes. Plus, narratives now support both static and dynamic URLs in your custom narratives for links to searches, apps, other dashboards, other sheets in the same dashboard, and more. For more information, see [Using autonarratives](#).

February 4, 2020

[SageMaker AI integration now available in more AWS Regions](#)

The public preview for integrating SageMaker AI with QuickSight is now available in all of the AWS Regions that are supported by QuickSight. For more information, see [Amazon QuickSight integration with SageMaker](#).

January 10, 2020

[QuickSight now enables you to choose an Amazon Athena workgroup](#)

By choosing an Athena workgroup, you can better manage your Athena datasets. Using this option, you can also allocate Athena costs to the workgroup that QuickSight is using, for better cost reporting. For more information, see [Creating a dataset using Amazon Athena](#).

December 10, 2019

[Private VPC support for presto in QuickSight](#)

Now Presto can use a VPC connection. For more information, see [Supported data sources for VPC](#).

December 10, 2019

[New mathematical functions in QuickSight](#)

Amazon QuickSight now supports functions for base 10 logarithms (log), natural logarithm (ln), absolute value (abs), square root (sqrt), and base of natural log e raised to the power of (exp). For more information, see [Functions and operators](#).

December 10, 2019

[New LAA functions in QuickSight](#)

Now you can use rank, denseRank , and percentileRank for level-aware aggregations. For more information, see [Using level-aware aggregations](#).

December 10, 2019

[Integrate SageMaker AI ML models into your QuickSight analyses and dashboards](#)

In this public preview, QuickSight launches the ability to integrate machine learning (ML) models created and trained in SageMaker AI. This new feature makes it easier to augment your business data with ML predictions. Add your data scientists' prebuilt inferences and predictions to your analysts' dashboards, and let the collaboration and decision-making begin. For more information, see [Amazon QuickSight integration with SageMaker](#).

November 26, 2019

[New formatting options for visuals in QuickSight](#)

Amazon QuickSight launches more formatting for visuals and visuals titles, including font sizes from extra small to extra large. In key performance indicators (KPIs), you can set font sizes for primary and comparison values. In pivot tables and tables, you can see font sizes for table headers, cells, totals, and subtotals. Now your visuals render better even when smaller and with less padding between charts. For combo charts, you can now synchronize the Y-axes for both bars and lines into a single axis. For more information, see [Formatting a visual](#).

November 23, 2019

[QuickSight supports the now function in SPICE](#)

For more information, see [now](#).

November 22, 2019

[QuickSight now supports seconds in SPICE](#)

Seconds are now supported in SPICE datasets. Datetime fields are no longer truncated to minutes. Now you can use the SS option for the period parameter in date functions including `addDateTime`, `dateDiff`, `extract`, and `truncDate`. For more information, see [Date functions](#).

November 22, 2019

[QuickSight now has themes](#)

You can now create a collection of themes, and apply a theme to an analysis and all its dashboards. For more information, see [Using themes in QuickSight](#).

November 22, 2019

[New QuickSight API operations](#)

Amazon QuickSight launches new API operations to programmatically manage your data, dashboards, and fine-grained access control capabilities linked with AWS Identity and Access Management (IAM). With new data API operations, you can create, update, and delete Amazon QuickSight data sources and datasets programmatically. You can also manage data refreshes on your SPICE datasets with API operations. Amazon QuickSight also introduces templates, which store the visual configuration and data schemas required for a dashboard. You can transfer templates across accounts or use them to instantiate dashboards with the same visual presentation but different data. For more information, see the [Amazon QuickSight API reference](#).

November 22, 2019

[QuickSight now supports conditional formatting for tables, pivot tables, and key performance indicators \(KPIs\).](#)

For tables and pivot tables, you can set multiple conditions for fields or supported aggregations, along with format options to apply to a target cell. For KPIs, you can format the primary value based on conditions that are applied to any dimension in the dataset. The conditional formatting options now supported are text color, background color, and placement of supported icons. You can use icons from the provided set, or you can use Unicode icons instead. For more information, see [Adding conditional formatting to visuals](#).

November 18, 2019

[View history for SPICE ingestion on your Amazon QuickSight datasets](#)

You can now view the ingestion history for SPICE datasets in Amazon QuickSight. See information like when the latest ingestion started, how long it took, and what its status is. For more information, see [View SPICE ingestion history](#).

November 7, 2019

[Add your own functionality to visuals with Amazon QuickSight actions](#)

Amazon QuickSight enables you to add to the basic functionality for visuals by creating your own custom actions for filtering or opening URLs. For more information, see [Custom actions in Amazon QuickSight](#).

November 7, 2019

[Amazon QuickSight now supports dynamic sheet titles](#)

You can now use parameters in sheet titles to make the context of a dashboard clearer to the reader. For more information, see [Formatting a visual](#).

November 6, 2019

[Use Amazon QuickSight to join data from multiple data sources](#)

Amazon QuickSight now supports creating datasets that join multiple data sources. For more information, see [Joining data](#).

November 5, 2019

[Amazon QuickSight mobile iOS update and a new Android app](#)

Get access to insights from your data on the fly. Download the updated iOS app or the new Android app. You can browse, favorite, and interact with your dashboards and explore your data with drilldowns and filters. You can stay ahead of the curve by using forecasting. You can get email alerts when unexpected changes happen in your data, and you can share those insights with colleagues. For more information, see [Amazon QuickSight mobile](#).

November 5, 2019

[Amazon QuickSight supports printing](#)

Now you can print a dashboard or an analysis. For more information, see [Printing](#).

October 17, 2019

[Amazon QuickSight supports a new AWS Region](#)

Amazon QuickSight is now available in Asia Pacific (Seoul) (ap-northeast-2). For more information, see [AWS Regions, websites, IP address ranges, and endpoints](#).

October 17, 2019

[Amazon QuickSight now supports visual-level formatting](#)

Now, any formatting you apply from the field wells is applied only to the selected visual. For more information, see [Formatting a visual](#).

October 17, 2019

Transpose tables	In table visuals, you can now transpose columns and rows. For more information, see Tables .	October 10, 2019
Shared data sources	Share data sources with other users and groups. For more information, see Shared data sources .	October 10, 2019
SPICE enhancements	SPICE dashboards now support new wildcard filters on dimensions. You can now filter your data using any of the available wildcard filters: 'contains', 'starts with', 'end with', 'equals'. Additionally, SPICE dashboards now support new string functions (toString and parseDecimal) and two new date functions (parseDate and formatDate). For more information, see Calculated fields .	October 10, 2019
New publishing options for dashboards	Control your user experience with more publishing options for your dashboards. These options include ability to toggle the filter pane, tooltips, drill up/down, and more. For more information, see Publish a dashboard .	October 10, 2019

New median function	Amazon QuickSight supports median as a new aggregation. For more information, see median .	October 10, 2019
New filter functionality	Amazon QuickSight now supports additional relative date filter options. For more information, see Date filters .	October 10, 2019
New aggregations for fields	You can now use Nth percentile, median, standard deviation, and variance in field wells, filters, and ML Insights. For more information, see Field aggregations .	October 10, 2019
Filter for context	You can now filter text using the following wildcard comparison types: contains, does not contain, begins with, and ends with. For more information, see Text filters .	October 10, 2019
Use the power operator (^) in SPICE	QuickSight now supports using the power operator (^) on SPICE datasets. You can use the power operator with any numeric field, with any valid exponent. For example, "revenue ^ 0.5 " computes the square root of the revenue field. For more information, see Arithmetic and comparison operators .	September 11, 2019

[Use string functions in SPICE](#)

Now you can use string functions for calculated fields in your analyses based on SPICE datasets. For more information, see [Functions by category](#).

September 11, 2019

[Use level-aware aggregations to control your calculations](#)

QuickSight now supports level-aware aggregation calculations. Using this feature, you can perform aggregations at prefilter and preaggregation levels, before aggregations that happen in the display. This helps you explore more advanced query-building strategies than ever before. For more information, see [Level-aware aggregations](#).

September 11, 2019

[Sort your anomalies](#)

Now you can choose how to sort anomalies on the insight widget and in the anomaly exploration page. Choosing how to prioritize anomalies can help you identify the anomalies that are the most important to you. For more information, see [Using ML-powered anomaly detection](#).

September 11, 2019

[Put 100 million rows into a SPICE dataset](#)

We changed the SPICE dataset limit from 25GB to 100 million rows for Enterprise edition (and 25 million rows for Standard edition). For more information, see [SPICE data source limits](#).

September 11, 2019

[Rename your dashboard, keep your settings](#)

Amazon QuickSight now supports renaming your published dashboards in place. You can change the name and still keep your settings and subscribers. For more information, see [Publishing a dashboards](#).

September 6, 2019

[New visual type: Word clouds](#)

Amazon QuickSight supports word cloud visuals that are based on different aggregations over any dimension in your dataset. You can drill down, focus on specific data points, and apply specific colors to data points on the word cloud. For more information, see [Word clouds](#).

September 5, 2019

[Filter out the last \$n\$ time periods](#)

Amazon QuickSight lets you exclude a specific number and type of time periods from a time range (after) filter. For more information, see [Adding a date filter](#).

September 5, 2019

[Amazon QuickSight new feature to mark favorites](#)

Mark your favorite dashboards and analyses so you can come back to them quickly. For more information, see [Using the QuickSight start page](#).

September 5, 2019

[Amazon QuickSight Enterprise edition adds anomaly alerts](#)

Your readers can subscribe themselves to anomaly alerts on dashboards to get the latest ML-powered anomaly detection and contribution analysis by email. For more information, see [Using data dashboards](#).

September 5, 2019

[QuickSight adds custom colors for charts](#)

With the QuickSight enhanced color picker, you can choose custom colors for charts where color customization is supported. The enhanced color picker also retains the eight most recently used custom colors for easy selection across multiple charts. For more information, see [Changing visual colors](#).

August 1, 2019

[Detect anomalies with less data](#)

In Amazon QuickSight Enterprise edition, we lowered the required minimum data points to 15 for training anomaly detection. For more information, see [Dataset requirements for using ML insights with QuickSight](#).

August 1, 2019

[Amazon QuickSight supports new AWS Regions](#)

Amazon QuickSight is available in Europe (London) and Europe (Frankfurt). Also, you can now connect to Active Directory in any AWS Region supported by Amazon QuickSight, except Asia Pacific (Singapore) and Asia Pacific (Sydney). For more information, see [AWS Regions and IP address ranges](#).

August 1, 2019

[Embedding for Active Directory](#)

In Amazon QuickSight Enterprise edition, you can now embed dashboards for users authenticated through Active Directory. For more information, see [Embedding dashboards](#).

July 11, 2019

[Granular access control for using AWS services from Amazon QuickSight](#)

In Amazon QuickSight Enterprise edition, you can scope down your security policies to allow specific people access to specific AWS resources. You can attach and detach IAM policies in the Amazon QuickSight interface, simplifying finer control over who can access your AWS data sources. For more information, see [Controlling access to AWS resources](#).

June 14, 2019

[Tabs for dashboards and analyses](#)

Amazon QuickSight now supports multiple sheets inside of analyses and dashboards. You can add multiple tabs to your dashboards, utilize URL actions and on-screen controls to simplify navigation, and filter across all of your sheets. For more information, see [Multiple sheets](#).

June 11, 2019

[New visual types](#)

You can now use Amazon QuickSight to chart your data on a customizable gauge and donut charts. For more information, see [Visual types](#).

June 11, 2019

[New functions](#)

Amazon QuickSight now supports functions Variance and Standard Deviations as both aggregation and table calculation. You can create Sample and Population variants for both the functions. You can create these calculations through the calculations editor in analysis mode. [Functions by category](#)

June 11, 2019

[Hide/Show columns in table visualizations](#)

In Amazon QuickSight, you can hide or show columns in visualizations that use the *table* visual type. For more information, see [Customizing a visual](#).

June 11, 2019

Conditional string functions on SPICE	We added support for <code>ifelse</code> in analyses that use SPICE. For more information, see ifelse	June 11, 2019
Choose period granularity for date differences	We added an optional parameter to <code>dateDiff</code> so you can show differences between dates in the period you choose (years, months, and so on). For more information, see dateDiff .	June 11, 2019
Duplicate visuals	In Amazon QuickSight, you can now duplicate visuals. For more information, see Duplicating a visual .	May 21, 2019
Angled data labels	In Amazon QuickSight, data labels that are too long are now angled by default on vertical bar, combo, and line charts. For more information, see Customizing data labels .	May 21, 2019
New languages added	Amazon QuickSight is now available in 10 languages: English, German, Spanish, French, Portuguese, Italian, Japanese, Korean, Simplified Chinese, and Traditional Chinese. For more information, see Choosing a language in Amazon QuickSight .	April 8, 2019

[New aggregation function](#)

Amazon QuickSight supports aggregating by percentile. This function helps you understand the distribution of your data. For more information, see [percentile](#).

April 8, 2019

[Customize how many data points to display](#)

You can now format your visuals to display a custom number of data points or groups before showing the "other" category. This feature is available for bar charts, combo charts, line charts, pie charts, heat maps, and tree maps. For more information, see [Customizing a visual](#).

April 8, 2019

[ML-powered forecasting](#)

With forecasting powered by machine learning and what-if analyses in Amazon QuickSight, nontechnical users can now easily forecast their key business metrics. No ML expertise or Microsoft Excel data modeling is required. The built-in ML algorithm in Amazon QuickSight is designed to handle complex real-world scenarios. Amazon QuickSight uses ML to provide more reliable forecasts than traditional means. For more information, see [Forecasts and what-ifs](#).

March 14, 2019

[ML-powered anomaly detection](#)

Amazon QuickSight uses proven Amazon technology to continuously run ML-powered anomaly detection on millions of metrics and billions of data points. This anomaly detection enables you to get deep insights that are often buried in the aggregates, not visible in plain sight, and not scalable with manual analysis.

With ML-powered anomaly detection, there's no need for manual analysis, custom development, or ML domain expertise. For more information, see [Anomaly detection](#).

March 14, 2019

[Automatic narratives](#)

Automatic narratives provide key insights in everyday language, embedded contextually in your dashboard, saving hours on manual analysis. With automatic narratives, Amazon QuickSight interprets the charts and tables in your dashboard and provides a number of suggested insights in natural language. Depending on the shape and form of your data, you might get different suggestions. For example, you might see what the day-over-day changes look like, what was the highest sales date, or what the growth rate is. Or you might see what the forecast looks like for the next seven days. As the author of the dashboard, you can customize the computations and business language for your needs. You can use automatic narratives to effectively tell the story of your data in plain language. For more information, see [Narrative insights](#).

March 14, 2019

Previous updates

The following table describes the important changes in each release of the *Amazon Quick User Guide* before March 4, 2019.

Change	Description	Date changed
New features	Using custom window functions, you can calculate any aggregation for a defined window at the point of selection. You can define the window interval before and after any point in time. You can also do calculations for that window using the sum, average, minimum, maximum, and count functions. Doing this enables a moving window aggregation as you progress through your data points. For more information, see Table calculation functions. Send email reports with data tailored to each of your users and groups. You can now create email reports for datasets that use row-level security. Amazon QuickSight generates a custom email snapshot for each user or group based on their data permission that is defined in the dashboard. RLS for email reports works for both scheduled and ad hoc emails. For more information, see Scheduling and sending QuickSight reports by email. Amazon QuickSight now supports unbounded cardinality. That means you can have more than 10,000 values in your control or filter. For more information, see Using a control with a parameter in Amazon QuickSight. You can create a datetime parameter that has no static default value. Filters on these parameters become active after you choose a value. For more information, see Adding date filters.	March 4, 2019

Change	Description	Date changed
New features	There are new table calculations available: • percentileOver • runningAvg • runningCount • runningMax • runningMin	February 7, 2019
New features	Amazon QuickSight supports emailing reports that use row-level security, using controls with unbounded cardinality, and creating datetime parameters with no default values. For more information, see the following: • Scheduling and sending QuickSight reports by email • Using a control with a parameter in Amazon QuickSight • Adding date filters	January 22, 2019

Change	Description	Date changed
New features	We added conditional aggregations, including <code>sumIf</code>, <code>countIf</code>, <code>minIf</code>, <code>maxIf</code>, <code>avgIf</code>, and <code>distinct_countIf</code> . Pivot tables now support infinite scrolling through millions of rows. You can add up to 20 fields for columns, and 20 fields for rows. Plus, you can add subtotals and totals to rows and columns. For more information, see the following: • Aggregate functions • Using pivot tables	January 10, 2019
New feature	We enhanced the join editor to increase usability and functionality. You can now add tables from one or more schemas on the same data source, or add the same table twice. For more information, see Joining data.	January 3, 2019
New SDK	You can embed dashboards and manage users or groups by using the Amazon QuickSight SDKs. For more information, see Developing with QuickSight.	November 27, 2018
New features	You can use groups with row-level security (RLS), and you can add cascading controls for parameters. For more information, see the following: • Using row-level security with user-based rules to restrict access to a dataset • Using a control with a parameter in Amazon QuickSight	November 20, 2018

Change	Description	Date changed
Function renamed	We renamed the percentile function to make it more intuitive. Its new name is <code>percentileRank</code> . For more information, see percentileRank .	November 12, 2018
New features	Use a top and bottom filter to show the top or bottom <code>n</code> for the field you choose, based on values in another field. For example, you could choose to show the top five sales people based on revenue. For more information, see Adding text filters. Use cascading controls to limit the values displayed in the controls, so they only show values that are relevant to what is selected in other controls. For more information, see Setting up parameters in Amazon QuickSight.	November 1, 2018
New feature	Use JSON native data types with <code>parseJson</code> . For more information see, parseJson .	October 30, 2018
New features	Use date functions to find out what quarter a date is in: • addDateTime • Extract • truncDate Add parameters to URLs. For more information see, Using parameters in a URL.	September 10, 2018
New features	You can sort strings in SPICE datasets. For more information on these features, see Sorting visual data in Amazon QuickSight	August 20, 2018

Change	Description	Date changed
New features	You can schedule emailed reports, and add data labels to your visuals. For more information on these features, see the following sections: • Scheduling and sending QuickSight reports by email • Subscribing to email reports in QuickSight • Data labels on visual types in QuickSight	August 15, 2018
New features	You can create table calculations, using aggregated measures to discover how dimensions influence measures or each other. Also, you can visualize time data at granularities as low as one minute. For more information on these features, see the following sections: • Table calculations • Changing date field granularity	August 8, 2018

Change	Description	Date changed
New features	You can replace datasets, customize labels, and format dimensions that are aggregated with count and count distinct. Also, new visuals start out smaller in size. For more information on these features, see the following sections: • Replacing datasets • Labels on visual types in QuickSight • Customizing a field format • Visualizing data in QuickSight	June 21, 2018

Change	Description	Date changed
New features and a new AWS Region	You can upgrade your Amazon QuickSight subscription from Standard edition to Enterprise edition. In Enterprise edition, Amazon QuickSight supports usage-based pricing for users in the reader role, sharing dashboards with all users in the reader role, and hourly refresh of datasets. Amazon QuickSight also supports private connections to data in a VPC with a private subnet in Enterprise edition. In both editions, Amazon QuickSight supports parameters with on-sheet controls, dashboard co-ownership, custom URL actions, and 25-GB SPICE datasets. Also, Amazon QuickSight is available in Asia Pacific (Tokyo). For more information on these features, see the following sections: • Upgrading your Amazon QuickSight subscription from Standard edition to Enterprise edition • Self-provisioning an Amazon QuickSight read-only user • Inviting users to access Amazon QuickSight • Sharing QuickSight dashboards • Connecting to a VPC with QuickSight • Refreshing a dataset on a schedule • Parameters in Amazon QuickSight •	May 30, 2018

Change	Description	Date changed
	Exploring interactive dashboards in QuickSight (newly updated for read-only users) Using custom actions for filtering and navigating Data source quotas AWS Regions, websites, IP address ranges, and endpoints	
New feature	Amazon QuickSight supports quick sorting from axis labels, duplicating datasets, and showing or hiding totals on tabular reports. Also, you can add custom SQL to a dataset earlier in the creation workflow. For more information on these features, see the following sections: Sorting visual data in Amazon QuickSight Duplicating datasets Totals and subtotals Creating a basic SQL query	May 25, 2018
New features	You can use Amazon QuickSight to connect to Software as a Service (SaaS) providers. For more information, see Software as a service (SaaS) data. You can import JSON files to Amazon QuickSight. For more information, see JSON data. You can also parse JSON fields in a CSV file. For more information, see parseJson.	April 9, 2018

Change	Description	Date changed
New feature	You can use Amazon QuickSight with Amazon S3 files that are in a different AWS account. For more information, see Datasets using S3 files in another AWS account .	November 20, 2017
New visual types	You can create visuals using maps. You can also view tabular data in a visual. For more information on preparing geospatial data for use in a visual, see Adding geospatial data . For more information on creating a geospatial visual, see Creating maps and geospatial charts . For more information on using tabular reports, see Using tables as visuals .	November 20, 2017
New features	Amazon QuickSight can support 1000 columns in a dataset. For more information, see Data source quotas . Calculated fields are supported in SPICE datasets. For more information, see Adding calculated fields . Also, high cardinality values, which often display as a long tail on a visual, are placed into a category called other . For more information, see Visual types in Amazon QuickSight .	November 20, 2017
New feature	In Enterprise edition, you can restrict access to a dataset by adding row-level security. To learn more, see Using row-level security with user-based rules to restrict access to a dataset .	October 20, 2017
New visual type	You can create visuals using combo charts. To learn more about combo charts, see Using combo charts .	October 20, 2017

Change	Description	Date changed
New features	Amazon QuickSight supports creating custom aggregations for calculated fields in analyses, custom date formats, and copies of dashboards. For more information on aggregating calculated fields, see Aggregate functions . For more information on using unsupported dates by creating a custom date format, see Using unsupported or custom dates . For more information on duplicating dashboards, see Copying an QuickSight dashboard .	September 25, 2017

CC0 1.0 Universal

CREATIVE COMMONS CORPORATION IS NOT A LAW FIRM AND DOES NOT PROVIDE LEGAL SERVICES. DISTRIBUTION OF THIS DOCUMENT DOES NOT CREATE AN ATTORNEY-CLIENT RELATIONSHIP. CREATIVE COMMONS PROVIDES THIS INFORMATION ON AN "AS-IS" BASIS. CREATIVE COMMONS MAKES NO WARRANTIES REGARDING THE USE OF THIS DOCUMENT OR THE INFORMATION OR WORKS PROVIDED HEREUNDER, AND DISCLAIMS LIABILITY FOR DAMAGES RESULTING FROM THE USE OF THIS DOCUMENT OR THE INFORMATION OR WORKS PROVIDED HEREUNDER.

Statement of Purpose

The laws of most jurisdictions throughout the world automatically confer exclusive Copyright and Related Rights (defined below) upon the creator and subsequent owner(s) (each and all, an "owner") of an original work of authorship and/or a database (each, a "Work").

Certain owners wish to permanently relinquish those rights to a Work for the purpose of contributing to a commons of creative, cultural and scientific works ("Commons") that the public can reliably and without fear of later claims of infringement build upon, modify, incorporate in other works, reuse and redistribute as freely as possible in any form whatsoever and for any purposes, including without limitation commercial purposes. These owners may contribute to the Commons to promote the ideal of a free culture and the further production of creative, cultural and scientific works, or to gain reputation or greater distribution for their Work in part through the use and efforts of others.

For these and/or other purposes and motivations, and without any expectation of additional consideration or compensation, the person associating CC0 with a Work (the "Affirmer"), to the extent that he or she is an owner of Copyright and Related Rights in the Work, voluntarily elects to

apply CC0 to the Work and publicly distribute the Work under its terms, with knowledge of his or her Copyright and Related Rights in the Work and the meaning and intended legal effect of CC0 on those rights.

1. Copyright and Related Rights. A Work made available under CC0 may be protected by copyright and related or neighboring rights ("Copyright and Related Rights"). Copyright and Related Rights include, but are not limited to, the following:

- i. the right to reproduce, adapt, distribute, perform, display, communicate, and translate a Work;
- ii. moral rights retained by the original author(s) and/or performer(s);
- iii. publicity and privacy rights pertaining to a person's image or likeness depicted in a Work;
- iv. rights protecting against unfair competition in regards to a Work, subject to the limitations in paragraph 4(a), below;
- v. rights protecting the extraction, dissemination, use and reuse of data in a Work;
- vi. database rights (such as those arising under Directive 96/9/EC of the European Parliament and of the Council of 11 March 1996 on the legal protection of databases, and under any national implementation thereof, including any amended or successor version of such directive); and
- vii. other similar, equivalent or corresponding rights throughout the world based on applicable law or treaty, and any national implementations thereof.

2. Waiver. To the greatest extent permitted by, but not in contravention of, applicable law, Affirmer hereby overtly, fully, permanently, irrevocably and unconditionally waives, abandons, and surrenders all of Affirmer's Copyright and Related Rights and associated claims and causes of action, whether now known or unknown (including existing as well as future claims and causes of action), in the Work (i) in all territories worldwide, (ii) for the maximum duration provided by applicable law or treaty (including future time extensions), (iii) in any current or future medium and for any number of copies, and (iv) for any purpose whatsoever, including without limitation commercial, advertising or promotional purposes (the "Waiver"). Affirmer makes the Waiver for the benefit of each member of the public at large and to the detriment of Affirmer's heirs and successors, fully intending that such Waiver shall not be subject to revocation, rescission, cancellation, termination, or any other legal or equitable action to disrupt the quiet enjoyment of the Work by the public as contemplated by Affirmer's express Statement of Purpose.

3. Public License Fallback. Should any part of the Waiver for any reason be judged legally invalid or ineffective under applicable law, then the Waiver shall be preserved to the maximum extent

permitted taking into account Affirmer's express Statement of Purpose. In addition, to the extent the Waiver is so judged Affirmer hereby grants to each affected person a royalty-free, non transferable, non sublicensable, non exclusive, irrevocable and unconditional license to exercise Affirmer's Copyright and Related Rights in the Work (i) in all territories worldwide, (ii) for the maximum duration provided by applicable law or treaty (including future time extensions), (iii) in any current or future medium and for any number of copies, and (iv) for any purpose whatsoever, including without limitation commercial, advertising or promotional purposes (the "License"). The License shall be deemed effective as of the date CC0 was applied by Affirmer to the Work. Should any part of the License for any reason be judged legally invalid or ineffective under applicable law, such partial invalidity or ineffectiveness shall not invalidate the remainder of the License, and in such case Affirmer hereby affirms that he or she will not (i) exercise any of his or her remaining Copyright and Related Rights in the Work or (ii) assert any associated claims and causes of action with respect to the Work, in either case contrary to Affirmer's express Statement of Purpose.

4. Limitations and Disclaimers.

a. No trademark or patent rights held by Affirmer are waived, abandoned, surrendered, licensed or otherwise affected by this document.

b. Affirmer offers the Work as-is and makes no representations or warranties of any kind concerning the Work, express, implied, statutory or otherwise, including without limitation warranties of title, merchantability, fitness for a particular purpose, non infringement, or the absence of latent or other defects, accuracy, or the present or absence of errors, whether or not discoverable, all to the greatest extent permissible under applicable law.

c. Affirmer disclaims responsibility for clearing rights of other persons that may apply to the Work or any use thereof, including without limitation any person's Copyright and Related Rights in the Work. Further, Affirmer disclaims responsibility for obtaining any necessary consents, permissions or other rights required for any use of the Work.

d. Affirmer understands and acknowledges that Creative Commons is not a party to this document and has no duty or obligation with respect to this CC0 or use of the Work.

CREATIVE COMMONS CORPORATION IS NOT A LAW FIRM AND DOES NOT PROVIDE LEGAL SERVICES. DISTRIBUTION OF THIS LICENSE DOES NOT CREATE AN ATTORNEY-CLIENT RELATIONSHIP. CREATIVE COMMONS PROVIDES THIS INFORMATION ON AN "AS-IS" BASIS. CREATIVE COMMONS MAKES NO WARRANTIES REGARDING THE INFORMATION PROVIDED, AND DISCLAIMS LIABILITY FOR DAMAGES RESULTING FROM ITS USE.

License

THE WORK (AS DEFINED BELOW) IS PROVIDED UNDER THE TERMS OF THIS CREATIVE COMMONS PUBLIC LICENSE ("CCPL" OR "LICENSE"). THE WORK IS PROTECTED BY COPYRIGHT AND/OR OTHER APPLICABLE LAW. ANY USE OF THE WORK OTHER THAN AS AUTHORIZED UNDER THIS LICENSE OR COPYRIGHT LAW IS PROHIBITED.

BY EXERCISING ANY RIGHTS TO THE WORK PROVIDED HERE, YOU ACCEPT AND AGREE TO BE BOUND BY THE TERMS OF THIS LICENSE. THE LICENSOR GRANTS YOU THE RIGHTS CONTAINED HERE IN CONSIDERATION OF YOUR ACCEPTANCE OF SUCH TERMS AND CONDITIONS.

1. Definitions

a. "Collective Work" means a work, such as a periodical issue, anthology or encyclopedia, in which the Work in its entirety in unmodified form, along with a number of other contributions, constituting separate and independent works in themselves, are assembled into a collective whole. A work that constitutes a Collective Work will not be considered a Derivative Work (as defined below) for the purposes of this License.

b. "Derivative Work" means a work based upon the Work or upon the Work and other pre-existing works, such as a translation, musical arrangement, dramatization, fictionalization, motion picture version, sound recording, art reproduction, abridgment, condensation, or any other form in which the Work may be recast, transformed, or adapted, except that a work that constitutes a Collective Work will not be considered a Derivative Work for the purpose of this License. For the avoidance of doubt, where the Work is a musical composition or sound recording, the synchronization of the

Work in timed-relation with a moving image ("synching") will be considered a Derivative Work for the purpose of this License.

c. "Licensor" means the individual or entity that offers the Work under the terms of this License.

d. "Original Author" means the individual or entity who created the Work.

e. "Work" means the copyrightable work of authorship offered under the terms of this License.

f. "You" means an individual or entity exercising rights under this License who has not previously violated the terms of this License with respect to the Work, or who has received express permission from the Licensor to exercise rights under this License despite a previous violation.

2. Fair Use Rights. Nothing in this license is intended to reduce, limit, or restrict any rights arising from fair use, first sale or other limitations on the exclusive rights of the copyright owner under copyright law or other applicable laws.

3. License Grant. Subject to the terms and conditions of this License, Licensor hereby grants You a worldwide, royalty-free, non-exclusive, perpetual (for the duration of the applicable copyright) license to exercise the rights in the Work as stated below:

a. to reproduce the Work, to incorporate the Work into one or more Collective Works, and to reproduce the Work as incorporated in the Collective Works;

b. to create and reproduce Derivative Works;

c. to distribute copies or phonorecords of, display publicly, perform publicly, and perform publicly by means of a digital audio transmission the Work including as incorporated in Collective Works;

d. to distribute copies or phonorecords of, display publicly, perform publicly, and perform publicly by means of a digital audio transmission Derivative Works.

e. For the avoidance of doubt, where the work is a musical composition:

i. Performance Royalties Under Blanket Licenses. Licensor waives the exclusive right to collect, whether individually or via a performance rights society (e.g. ASCAP, BMI, SESAC), royalties for the public performance or public digital performance (e.g. webcast) of the Work.

ii. Mechanical Rights and Statutory Royalties. Licensor waives the exclusive right to collect, whether individually or via a music rights agency or designated agent (e.g. Harry Fox Agency), royalties for any phonorecord You create from the Work ("cover version") and distribute, subject to the

compulsory license created by 17 USC Section 115 of the US Copyright Act (or the equivalent in other jurisdictions).

f. Webcasting Rights and Statutory Royalties. For the avoidance of doubt, where the Work is a sound recording, Licensors waive the exclusive right to collect, whether individually or via a performance-rights society (e.g. SoundExchange), royalties for the public digital performance (e.g. webcast) of the Work, subject to the compulsory license created by 17 USC Section 114 of the US Copyright Act (or the equivalent in other jurisdictions).

The above rights may be exercised in all media and formats whether now known or hereafter devised. The above rights include the right to make such modifications as are technically necessary to exercise the rights in other media and formats. All rights not expressly granted by Licensors are hereby reserved.

4. Restrictions. The license granted in Section 3 above is expressly made subject to and limited by the following restrictions:

a. You may distribute, publicly display, publicly perform, or publicly digitally perform the Work only under the terms of this License, and You must include a copy of, or the Uniform Resource Identifier for, this License with every copy or phonorecord of the Work You distribute, publicly display, publicly perform, or publicly digitally perform. You may not offer or impose any terms on the Work that alter or restrict the terms of this License or the recipients' exercise of the rights granted hereunder. You may not sublicense the Work. You must keep intact all notices that refer to this License and to the disclaimer of warranties. You may not distribute, publicly display, publicly perform, or publicly digitally perform the Work with any technological measures that control access or use of the Work in a manner inconsistent with the terms of this License Agreement. The above applies to the Work as incorporated in a Collective Work, but this does not require the Collective Work apart from the Work itself to be made subject to the terms of this License. If You create a Collective Work, upon notice from any Licensors You must, to the extent practicable, remove from the Collective Work any reference to such Licensors or the Original Author, as requested. If You create a Derivative Work, upon notice from any Licensors You must, to the extent practicable, remove from the Derivative Work any reference to such Licensors or the Original Author, as requested.

b. If you distribute, publicly display, publicly perform, or publicly digitally perform the Work or any Derivative Works or Collective Works, You must keep intact all copyright notices for the Work and give the Original Author credit reasonable to the medium or means You are utilizing by conveying the name (or pseudonym if applicable) of the Original Author if supplied; the title of the Work if supplied; to the extent reasonably practicable, the Uniform Resource Identifier, if any, that Licensors

specifies to be associated with the Work, unless such URI does not refer to the copyright notice or licensing information for the Work; and in the case of a Derivative Work, a credit identifying the use of the Work in the Derivative Work (e.g., "French translation of the Work by Original Author," or "Screenplay based on original Work by Original Author"). Such credit may be implemented in any reasonable manner; provided, however, that in the case of a Derivative Work or Collective Work, at a minimum such credit will appear where any other comparable authorship credit appears and in a manner at least as prominent as such other comparable authorship credit.

5. Representations, Warranties and Disclaimer

UNLESS OTHERWISE MUTUALLY AGREED TO BY THE PARTIES IN WRITING, LICENSOR OFFERS THE WORK AS-IS AND MAKES NO REPRESENTATIONS OR WARRANTIES OF ANY KIND CONCERNING THE WORK, EXPRESS, IMPLIED, STATUTORY OR OTHERWISE, INCLUDING, WITHOUT LIMITATION, WARRANTIES OF TITLE, MERCHANTIBILITY, FITNESS FOR A PARTICULAR PURPOSE, NONINFRINGEMENT, OR THE ABSENCE OF LATENT OR OTHER DEFECTS, ACCURACY, OR THE PRESENCE OF ABSENCE OF ERRORS, WHETHER OR NOT DISCOVERABLE. SOME JURISDICTIONS DO NOT ALLOW THE EXCLUSION OF IMPLIED WARRANTIES, SO SUCH EXCLUSION MAY NOT APPLY TO YOU.

6. Limitation on Liability. EXCEPT TO THE EXTENT REQUIRED BY APPLICABLE LAW, IN NO EVENT WILL LICENSOR BE LIABLE TO YOU ON ANY LEGAL THEORY FOR ANY SPECIAL, INCIDENTAL, CONSEQUENTIAL, PUNITIVE OR EXEMPLARY DAMAGES ARISING OUT OF THIS LICENSE OR THE USE OF THE WORK, EVEN IF LICENSOR HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

7. Termination

a. This License and the rights granted hereunder will terminate automatically upon any breach by You of the terms of this License. Individuals or entities who have received Derivative Works or Collective Works from You under this License, however, will not have their licenses terminated provided such individuals or entities remain in full compliance with those licenses. Sections 1, 2, 5, 6, 7, and 8 will survive any termination of this License.

b. Subject to the above terms and conditions, the license granted here is perpetual (for the duration of the applicable copyright in the Work). Notwithstanding the above, Licensor reserves the right to release the Work under different license terms or to stop distributing the Work at any time; provided, however that any such election will not serve to withdraw this License (or any other license that has been, or is required to be, granted under the terms of this License), and this License will continue in full force and effect unless terminated as stated above.

8. Miscellaneous

- a. Each time You distribute or publicly digitally perform the Work or a Collective Work, the Licensor offers to the recipient a license to the Work on the same terms and conditions as the license granted to You under this License.
- b. Each time You distribute or publicly digitally perform a Derivative Work, Licensor offers to the recipient a license to the original Work on the same terms and conditions as the license granted to You under this License.
- c. If any provision of this License is invalid or unenforceable under applicable law, it shall not affect the validity or enforceability of the remainder of the terms of this License, and without further action by the parties to this agreement, such provision shall be reformed to the minimum extent necessary to make such provision valid and enforceable.
- d. No term or provision of this License shall be deemed waived and no breach consented to unless such waiver or consent shall be in writing and signed by the party to be charged with such waiver or consent.
- e. This License constitutes the entire agreement between the parties with respect to the Work licensed here. There are no understandings, agreements or representations with respect to the Work not specified here. Licensor shall not be bound by any additional provisions that may appear in any communication from You. This License may not be modified without the mutual written agreement of the Licensor and You.

THE WORK (AS DEFINED BELOW) IS PROVIDED UNDER THE TERMS OF THIS CREATIVE COMMONS PUBLIC LICENSE ("CCPL" OR "LICENSE"). THE WORK IS PROTECTED BY COPYRIGHT AND/OR OTHER

APPLICABLE LAW. ANY USE OF THE WORK OTHER THAN AS AUTHORIZED UNDER THIS LICENSE OR COPYRIGHT LAW IS PROHIBITED.

BY EXERCISING ANY RIGHTS TO THE WORK PROVIDED HERE, YOU ACCEPT AND AGREE TO BE BOUND BY THE TERMS OF THIS LICENSE. TO THE EXTENT THIS LICENSE MAY BE CONSIDERED TO BE A CONTRACT, THE LICENSOR GRANTS YOU THE RIGHTS CONTAINED HERE IN CONSIDERATION OF YOUR ACCEPTANCE OF SUCH TERMS AND CONDITIONS.

1. Definitions

"Adaptation" means a work based upon the Work, or upon the Work and other pre-existing works, such as a translation, adaptation, derivative work, arrangement of music or other alterations of a literary or artistic work, or phonogram or performance and includes cinematographic adaptations or any other form in which the Work may be recast, transformed, or adapted including in any form recognizably derived from the original, except that a work that constitutes a Collection will not be considered an Adaptation for the purpose of this License. For the avoidance of doubt, where the Work is a musical work, performance or phonogram, the synchronization of the Work in timed-relation with a moving image ("synching") will be considered an Adaptation for the purpose of this License.

"Collection" means a collection of literary or artistic works, such as encyclopedias and anthologies, or performances, phonograms or broadcasts, or other works or subject matter other than works listed in Section 1(f) below, which, by reason of the selection and arrangement of their contents, constitute intellectual creations, in which the Work is included in its entirety in unmodified form along with one or more other contributions, each constituting separate and independent works in themselves, which together are assembled into a collective whole. A work that constitutes a Collection will not be considered an Adaptation (as defined above) for the purposes of this License.

"Distribute" means to make available to the public the original and copies of the Work or Adaptation, as appropriate, through sale or other transfer of ownership.

"Licensor" means the individual, individuals, entity or entities that offer(s) the Work under the terms of this License.

"Original Author" means, in the case of a literary or artistic work, the individual, individuals, entity or entities who created the Work or if no individual or entity can be identified, the publisher; and in addition (i) in the case of a performance the actors, singers, musicians, dancers, and other persons who act, sing, deliver, declaim, play in, interpret or otherwise perform literary or artistic

works or expressions of folklore; (ii) in the case of a phonogram the producer being the person or legal entity who first fixes the sounds of a performance or other sounds; and, (iii) in the case of broadcasts, the organization that transmits the broadcast.

"Work" means the literary and/or artistic work offered under the terms of this License including without limitation any production in the literary, scientific and artistic domain, whatever may be the mode or form of its expression including digital form, such as a book, pamphlet and other writing; a lecture, address, sermon or other work of the same nature; a dramatic or dramatico-musical work; a choreographic work or entertainment in dumb show; a musical composition with or without words; a cinematographic work to which are assimilated works expressed by a process analogous to cinematography; a work of drawing, painting, architecture, sculpture, engraving or lithography; a photographic work to which are assimilated works expressed by a process analogous to photography; a work of applied art; an illustration, map, plan, sketch or three-dimensional work relative to geography, topography, architecture or science; a performance; a broadcast; a phonogram; a compilation of data to the extent it is protected as a copyrightable work; or a work performed by a variety or circus performer to the extent it is not otherwise considered a literary or artistic work.

"You" means an individual or entity exercising rights under this License who has not previously violated the terms of this License with respect to the Work, or who has received express permission from the Licensor to exercise rights under this License despite a previous violation.

"Publicly Perform" means to perform public recitations of the Work and to communicate to the public those public recitations, by any means or process, including by wire or wireless means or public digital performances; to make available to the public Works in such a way that members of the public may access these Works from a place and at a place individually chosen by them; to perform the Work to the public by any means or process and the communication to the public of the performances of the Work, including by public digital performance; to broadcast and rebroadcast the Work by any means including signs, sounds or images.

"Reproduce" means to make copies of the Work by any means including without limitation by sound or visual recordings and the right of fixation and reproducing fixations of the Work, including storage of a protected performance or phonogram in digital form or other electronic medium.

2. Fair Dealing Rights. Nothing in this License is intended to reduce, limit, or restrict any uses free from copyright or rights arising from limitations or exceptions that are provided for in connection with the copyright protection under copyright law or other applicable laws.

3. License Grant. Subject to the terms and conditions of this License, Licensor hereby grants You a worldwide, royalty-free, non-exclusive, perpetual (for the duration of the applicable copyright) license to exercise the rights in the Work as stated below:

to Reproduce the Work, to incorporate the Work into one or more Collections, and to Reproduce the Work as incorporated in the Collections;

to create and Reproduce Adaptations provided that any such Adaptation, including any translation in any medium, takes reasonable steps to clearly label, demarcate or otherwise identify that changes were made to the original Work. For example, a translation could be marked "The original work was translated from English to Spanish," or a modification could indicate "The original work has been modified.";

to Distribute and Publicly Perform the Work including as incorporated in Collections; and,

to Distribute and Publicly Perform Adaptations.

For the avoidance of doubt:

Non-waivable Compulsory License Schemes. In those jurisdictions in which the right to collect royalties through any statutory or compulsory licensing scheme cannot be waived, the Licensor reserves the exclusive right to collect such royalties for any exercise by You of the rights granted under this License;

Waivable Compulsory License Schemes. In those jurisdictions in which the right to collect royalties through any statutory or compulsory licensing scheme can be waived, the Licensor waives the exclusive right to collect such royalties for any exercise by You of the rights granted under this License; and,

Voluntary License Schemes. The Licensor waives the right to collect royalties, whether individually or, in the event that the Licensor is a member of a collecting society that administers voluntary licensing schemes, via that society, from any exercise by You of the rights granted under this License.

The above rights may be exercised in all media and formats whether now known or hereafter devised. The above rights include the right to make such modifications as are technically necessary

to exercise the rights in other media and formats. Subject to Section 8(f), all rights not expressly granted by Licensor are hereby reserved.

4. Restrictions. The license granted in Section 3 above is expressly made subject to and limited by the following restrictions:

You may Distribute or Publicly Perform the Work only under the terms of this License. You must include a copy of, or the Uniform Resource Identifier (URI) for, this License with every copy of the Work You Distribute or Publicly Perform. You may not offer or impose any terms on the Work that restrict the terms of this License or the ability of the recipient of the Work to exercise the rights granted to that recipient under the terms of the License. You may not sublicense the Work. You must keep intact all notices that refer to this License and to the disclaimer of warranties with every copy of the Work You Distribute or Publicly Perform. When You Distribute or Publicly Perform the Work, You may not impose any effective technological measures on the Work that restrict the ability of a recipient of the Work from You to exercise the rights granted to that recipient under the terms of the License. This Section 4(a) applies to the Work as incorporated in a Collection, but this does not require the Collection apart from the Work itself to be made subject to the terms of this License. If You create a Collection, upon notice from any Licensor You must, to the extent practicable, remove from the Collection any credit as required by Section 4(b), as requested. If You create an Adaptation, upon notice from any Licensor You must, to the extent practicable, remove from the Adaptation any credit as required by Section 4(b), as requested.

If You Distribute, or Publicly Perform the Work or any Adaptations or Collections, You must, unless a request has been made pursuant to Section 4(a), keep intact all copyright notices for the Work and provide, reasonable to the medium or means You are utilizing: (i) the name of the Original Author (or pseudonym, if applicable) if supplied, and/or if the Original Author and/or Licensor designate another party or parties (e.g., a sponsor institute, publishing entity, journal) for attribution ("Attribution Parties") in Licensor's copyright notice, terms of service or by other reasonable means, the name of such party or parties; (ii) the title of the Work if supplied; (iii) to the extent reasonably practicable, the URI, if any, that Licensor specifies to be associated with the Work, unless such URI does not refer to the copyright notice or licensing information for the Work; and (iv) , consistent with Section 3(b), in the case of an Adaptation, a credit identifying the use of the Work in the Adaptation (e.g., "French translation of the Work by Original Author," or "Screenplay based on original Work by Original Author"). The credit required by this Section 4 (b) may be implemented in any reasonable manner; provided, however, that in the case of a Adaptation or Collection, at a minimum such credit will appear, if a credit for all contributing authors of the Adaptation or Collection appears, then as part of these credits and in a manner at

least as prominent as the credits for the other contributing authors. For the avoidance of doubt, You may only use the credit required by this Section for the purpose of attribution in the manner set out above and, by exercising Your rights under this License, You may not implicitly or explicitly assert or imply any connection with, sponsorship or endorsement by the Original Author, Licensor and/or Attribution Parties, as appropriate, of You or Your use of the Work, without the separate, express prior written permission of the Original Author, Licensor and/or Attribution Parties.

Except as otherwise agreed in writing by the Licensor or as may be otherwise permitted by applicable law, if You Reproduce, Distribute or Publicly Perform the Work either by itself or as part of any Adaptations or Collections, You must not distort, mutilate, modify or take other derogatory action in relation to the Work which would be prejudicial to the Original Author's honor or reputation. Licensor agrees that in those jurisdictions (e.g. Japan), in which any exercise of the right granted in Section 3(b) of this License (the right to make Adaptations) would be deemed to be a distortion, mutilation, modification or other derogatory action prejudicial to the Original Author's honor and reputation, the Licensor will waive or not assert, as appropriate, this Section, to the fullest extent permitted by the applicable national law, to enable You to reasonably exercise Your right under Section 3(b) of this License (right to make Adaptations) but not otherwise.

5. Representations, Warranties and Disclaimer

UNLESS OTHERWISE MUTUALLY AGREED TO BY THE PARTIES IN WRITING, LICENSOR OFFERS THE WORK AS-IS AND MAKES NO REPRESENTATIONS OR WARRANTIES OF ANY KIND CONCERNING THE WORK, EXPRESS, IMPLIED, STATUTORY OR OTHERWISE, INCLUDING, WITHOUT LIMITATION, WARRANTIES OF TITLE, MERCHANTIBILITY, FITNESS FOR A PARTICULAR PURPOSE, NONINFRINGEMENT, OR THE ABSENCE OF LATENT OR OTHER DEFECTS, ACCURACY, OR THE PRESENCE OF ABSENCE OF ERRORS, WHETHER OR NOT DISCOVERABLE. SOME JURISDICTIONS DO NOT ALLOW THE EXCLUSION OF IMPLIED WARRANTIES, SO SUCH EXCLUSION MAY NOT APPLY TO YOU.

6. Limitation on Liability. EXCEPT TO THE EXTENT REQUIRED BY APPLICABLE LAW, IN NO EVENT WILL LICENSOR BE LIABLE TO YOU ON ANY LEGAL THEORY FOR ANY SPECIAL, INCIDENTAL, CONSEQUENTIAL, PUNITIVE OR EXEMPLARY DAMAGES ARISING OUT OF THIS LICENSE OR THE USE OF THE WORK, EVEN IF LICENSOR HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

7. Termination

This License and the rights granted hereunder will terminate automatically upon any breach by You of the terms of this License. Individuals or entities who have received Adaptations or Collections from You under this License, however, will not have their licenses terminated provided such individuals or entities remain in full compliance with those licenses. Sections 1, 2, 5, 6, 7, and 8 will survive any termination of this License.

Subject to the above terms and conditions, the license granted here is perpetual (for the duration of the applicable copyright in the Work). Notwithstanding the above, Licensor reserves the right to release the Work under different license terms or to stop distributing the Work at any time; provided, however that any such election will not serve to withdraw this License (or any other license that has been, or is required to be, granted under the terms of this License), and this License will continue in full force and effect unless terminated as stated above.

8. Miscellaneous

Each time You Distribute or Publicly Perform the Work or a Collection, the Licensor offers to the recipient a license to the Work on the same terms and conditions as the license granted to You under this License.

Each time You Distribute or Publicly Perform an Adaptation, Licensor offers to the recipient a license to the original Work on the same terms and conditions as the license granted to You under this License.

If any provision of this License is invalid or unenforceable under applicable law, it shall not affect the validity or enforceability of the remainder of the terms of this License, and without further action by the parties to this agreement, such provision shall be reformed to the minimum extent necessary to make such provision valid and enforceable.

No term or provision of this License shall be deemed waived and no breach consented to unless such waiver or consent shall be in writing and signed by the party to be charged with such waiver or consent.

This License constitutes the entire agreement between the parties with respect to the Work licensed here. There are no understandings, agreements or representations with respect to the Work not specified here. Licensor shall not be bound by any additional provisions that may appear in any communication from You. This License may not be modified without the mutual written agreement of the Licensor and You.

The rights granted under, and the subject matter referenced, in this License were drafted utilizing the terminology of the Berne Convention for the Protection of Literary and Artistic Works (as amended on September 28, 1979), the Rome Convention of 1961, the WIPO Copyright Treaty of 1996, the WIPO Performances and Phonograms Treaty of 1996 and the Universal Copyright Convention (as revised on July 24, 1971). These rights and subject matter take effect in the relevant jurisdiction in which the License terms are sought to be enforced according to the corresponding provisions of the implementation of those treaty provisions in the applicable national law. If the standard suite of rights granted under applicable copyright law includes additional rights not granted under this License, such additional rights are deemed to be included in the License; this License is not intended to restrict the license of any rights under applicable law.

Creative Commons Attribution 4.0 International Public License

By exercising the Licensed Rights (defined below), You accept and agree to be bound by the terms and conditions of this Creative Commons Attribution 4.0 International Public License ("Public License"). To the extent this Public License may be interpreted as a contract, You are granted the Licensed Rights in consideration of Your acceptance of these terms and conditions, and the Licensor grants You such rights in consideration of benefits the Licensor receives from making the Licensed Material available under these terms and conditions.

Section 1 – Definitions.

a. Adapted Material means material subject to Copyright and Similar Rights that is derived from or based upon the Licensed Material and in which the Licensed Material is translated, altered,

arranged, transformed, or otherwise modified in a manner requiring permission under the Copyright and Similar Rights held by the Licensor. For purposes of this Public License, where the Licensed Material is a musical work, performance, or sound recording, Adapted Material is always produced where the Licensed Material is synched in timed relation with a moving image.

b. Adapter's License means the license You apply to Your Copyright and Similar Rights in Your contributions to Adapted Material in accordance with the terms and conditions of this Public License.

c. Copyright and Similar Rights means copyright and/or similar rights closely related to copyright including, without limitation, performance, broadcast, sound recording, and Sui Generis Database Rights, without regard to how the rights are labeled or categorized. For purposes of this Public License, the rights specified in Section 2(b)(1)-(2) are not Copyright and Similar Rights.

d. Effective Technological Measures means those measures that, in the absence of proper authority, may not be circumvented under laws fulfilling obligations under Article 11 of the WIPO Copyright Treaty adopted on December 20, 1996, and/or similar international agreements.

e. Exceptions and Limitations means fair use, fair dealing, and/or any other exception or limitation to Copyright and Similar Rights that applies to Your use of the Licensed Material.

f. Licensed Material means the artistic or literary work, database, or other material to which the Licensor applied this Public License.

g. Licensed Rights means the rights granted to You subject to the terms and conditions of this Public License, which are limited to all Copyright and Similar Rights that apply to Your use of the Licensed Material and that the Licensor has authority to license.

h. Licensor means the individual(s) or entity(ies) granting rights under this Public License.

i. Share means to provide material to the public by any means or process that requires permission under the Licensed Rights, such as reproduction, public display, public performance, distribution, dissemination, communication, or importation, and to make material available to the public including in ways that members of the public may access the material from a place and at a time individually chosen by them.

j. Sui Generis Database Rights means rights other than copyright resulting from Directive 96/9/EC of the European Parliament and of the Council of 11 March 1996 on the legal protection of databases, as amended and/or succeeded, as well as other essentially equivalent rights anywhere in the world.

k. You means the individual or entity exercising the Licensed Rights under this Public License. Your has a corresponding meaning.

Section 2 – Scope.

a. License grant.

1. Subject to the terms and conditions of this Public License, the Licensor hereby grants You a worldwide, royalty-free, non-sublicensable, non-exclusive, irrevocable license to exercise the Licensed Rights in the Licensed Material to:

A. reproduce and Share the Licensed Material, in whole or in part; and

B. produce, reproduce, and Share Adapted Material.

2. Exceptions and Limitations. For the avoidance of doubt, where Exceptions and Limitations apply to Your use, this Public License does not apply, and You do not need to comply with its terms and conditions.

3. Term. The term of this Public License is specified in Section 6(a).

4. Media and formats; technical modifications allowed. The Licensor authorizes You to exercise the Licensed Rights in all media and formats whether now known or hereafter created, and to make technical modifications necessary to do so. The Licensor waives and/or agrees not to assert any right or authority to forbid You from making technical modifications necessary to exercise the Licensed Rights, including technical modifications necessary to circumvent Effective Technological Measures. For purposes of this Public License, simply making modifications authorized by this Section 2(a)(4) never produces Adapted Material.

5. Downstream recipients.

A. Offer from the Licensor – Licensed Material. Every recipient of the Licensed Material automatically receives an offer from the Licensor to exercise the Licensed Rights under the terms and conditions of this Public License.

B. No downstream restrictions. You may not offer or impose any additional or different terms or conditions on, or apply any Effective Technological Measures to, the Licensed Material if doing so restricts exercise of the Licensed Rights by any recipient of the Licensed Material.

6. No endorsement. Nothing in this Public License constitutes or may be construed as permission to assert or imply that You are, or that Your use of the Licensed Material is, connected with, or

sponsored, endorsed, or granted official status by, the Licensor or others designated to receive attribution as provided in Section 3(a)(1)(A)(i).

b. Other rights.

1. Moral rights, such as the right of integrity, are not licensed under this Public License, nor are publicity, privacy, and/or other similar personality rights; however, to the extent possible, the Licensor waives and/or agrees not to assert any such rights held by the Licensor to the limited extent necessary to allow You to exercise the Licensed Rights, but not otherwise.

2. Patent and trademark rights are not licensed under this Public License.

3. To the extent possible, the Licensor waives any right to collect royalties from You for the exercise of the Licensed Rights, whether directly or through a collecting society under any voluntary or waivable statutory or compulsory licensing scheme. In all other cases the Licensor expressly reserves any right to collect such royalties.

Section 3 – License Conditions.

Your exercise of the Licensed Rights is expressly made subject to the following conditions.

a. Attribution.

1. If You Share the Licensed Material (including in modified form), You must:

A. retain the following if it is supplied by the Licensor with the Licensed Material:

i. identification of the creator(s) of the Licensed Material and any others designated to receive attribution, in any reasonable manner requested by the Licensor (including by pseudonym if designated);

ii. a copyright notice;

iii. a notice that refers to this Public License;

iv. a notice that refers to the disclaimer of warranties;

v. a URI or hyperlink to the Licensed Material to the extent reasonably practicable;

B. indicate if You modified the Licensed Material and retain an indication of any previous modifications; and

C. indicate the Licensed Material is licensed under this Public License, and include the text of, or the URI or hyperlink to, this Public License.

2. You may satisfy the conditions in Section 3(a)(1) in any reasonable manner based on the medium, means, and context in which You Share the Licensed Material. For example, it may be reasonable to satisfy the conditions by providing a URI or hyperlink to a resource that includes the required information.

3. If requested by the Licensor, You must remove any of the information required by Section 3(a)(1) (A) to the extent reasonably practicable.

4. If You Share Adapted Material You produce, the Adapter's License You apply must not prevent recipients of the Adapted Material from complying with this Public License.

Section 4 – Sui Generis Database Rights.

Where the Licensed Rights include Sui Generis Database Rights that apply to Your use of the Licensed Material:

- a. for the avoidance of doubt, Section 2(a)(1) grants You the right to extract, reuse, reproduce, and Share all or a substantial portion of the contents of the database;
- b. if You include all or a substantial portion of the database contents in a database in which You have Sui Generis Database Rights, then the database in which You have Sui Generis Database Rights (but not its individual contents) is Adapted Material; and
- c. You must comply with the conditions in Section 3(a) if You Share all or a substantial portion of the contents of the database.

For the avoidance of doubt, this Section 4 supplements and does not replace Your obligations under this Public License where the Licensed Rights include other Copyright and Similar Rights.

Section 5 – Disclaimer of Warranties and Limitation of Liability.

a. Unless otherwise separately undertaken by the Licensor, to the extent possible, the Licensor offers the Licensed Material as-is and as-available, and makes no representations or warranties of any kind concerning the Licensed Material, whether express, implied, statutory, or other. This includes, without limitation, warranties of title, merchantability, fitness for a particular purpose, non-infringement, absence of latent or other defects, accuracy, or the presence or absence of errors, whether or not known or discoverable. Where disclaimers of warranties are not allowed in full or in part, this disclaimer may not apply to You.

b. To the extent possible, in no event will the Licensor be liable to You on any legal theory (including, without limitation, negligence) or otherwise for any direct, special, indirect, incidental, consequential, punitive, exemplary, or other losses, costs, expenses, or damages arising out of this Public License or use of the Licensed Material, even if the Licensor has been advised of the possibility of such losses, costs, expenses, or damages. Where a limitation of liability is not allowed in full or in part, this limitation may not apply to You.

c. The disclaimer of warranties and limitation of liability provided above shall be interpreted in a manner that, to the extent possible, most closely approximates an absolute disclaimer and waiver of all liability.

Section 6 – Term and Termination.

a. This Public License applies for the term of the Copyright and Similar Rights licensed here. However, if You fail to comply with this Public License, then Your rights under this Public License terminate automatically.

b. Where Your right to use the Licensed Material has terminated under Section 6(a), it reinstates:

1. automatically as of the date the violation is cured, provided it is cured within 30 days of Your discovery of the violation; or
2. upon express reinstatement by the Licensor.

For the avoidance of doubt, this Section 6(b) does not affect any right the Licensor may have to seek remedies for Your violations of this Public License.

c. For the avoidance of doubt, the Licensor may also offer the Licensed Material under separate terms or conditions or stop distributing the Licensed Material at any time; however, doing so will not terminate this Public License.

d. Sections 1, 5, 6, 7, and 8 survive termination of this Public License.

Section 7 – Other Terms and Conditions.

a. The Licensor shall not be bound by any additional or different terms or conditions communicated by You unless expressly agreed.

b. Any arrangements, understandings, or agreements regarding the Licensed Material not stated herein are separate from and independent of the terms and conditions of this Public License.

Section 8 – Interpretation.

- a. For the avoidance of doubt, this Public License does not, and shall not be interpreted to, reduce, limit, restrict, or impose conditions on any use of the Licensed Material that could lawfully be made without permission under this Public License.
- b. To the extent possible, if any provision of this Public License is deemed unenforceable, it shall be automatically reformed to the minimum extent necessary to make it enforceable. If the provision cannot be reformed, it shall be severed from this Public License without affecting the enforceability of the remaining terms and conditions.
- c. No term or condition of this Public License will be waived and no failure to comply consented to unless expressly agreed to by the Licensor.
- d. Nothing in this Public License constitutes or may be interpreted as a limitation upon, or waiver of, any privileges and immunities that apply to the Licensor or You, including from the legal processes of any jurisdiction or authority.

Copyright (c) Microsoft Corporation

All rights reserved.

Microsoft Public License (Ms-PL)

This license governs use of the accompanying software. If you use the software, you accept this license. If you do not accept the license, do not use the software.

1. Definitions

The terms "reproduce," "reproduction," "derivative works," and "distribution" have the same meaning here as under U.S. copyright law.

A "contribution" is the original software, or any additions or changes to the software.

A "contributor" is any person that distributes its contribution under this license.

"Licensed patents" are a contributor's patent claims that read directly on its contribution.

2. Grant of Rights

(A) Copyright Grant- Subject to the terms of this license, including the license conditions and limitations in section 3, each contributor grants you a non-exclusive, worldwide, royalty-free copyright license to reproduce its contribution, prepare derivative works of its contribution, and distribute its contribution or any derivative works that you create.

(B) Patent Grant- Subject to the terms of this license, including the license conditions and limitations in section 3, each contributor grants you a non-exclusive, worldwide, royalty-free license under its licensed patents to make, have made, use, sell, offer for sale, import, and/or otherwise dispose of its contribution in the software or derivative works of the contribution in the software.

3. Conditions and Limitations

(A) No Trademark License- This license does not grant you rights to use any contributors' name, logo, or trademarks.

(B) If you bring a patent claim against any contributor over patents that you claim are infringed by the software, your patent license from such contributor to the software ends automatically.

(C) If you distribute any portion of the software, you must retain all copyright, patent, trademark, and attribution notices that are present in the software.

(D) If you distribute any portion of the software in source code form, you may do so only under this license by including a complete copy of this license with your distribution. If you distribute any portion of the software in compiled or object code form, you may only do so under a license that complies with this license.

(E) The software is licensed "as-is." You bear the risk of using it. The contributors give no express warranties, guarantees or conditions. You may have additional consumer rights under your local laws which this license cannot change. To the extent permitted under your local laws, the contributors exclude the implied warranties of merchantability, fitness for a particular purpose and non-infringement.
