What is Amazon Quick?

Amazon Quick is an AI-powered service for automating tasks, analyzing data, building web applications, and conducting research. You interact with Quick through natural language chat, and Quick uses AI agents to process your requests against connected data sources and applications.

Quick includes the following features:

- **Amazon Quick Sight** – Interactive data visualization and business intelligence. Connect to data sources, build dashboards, and embed analytics in applications.
- **Amazon Quick Flows** – Automate repetitive tasks with AI-powered workflows that use your data and take actions in connected applications.
- **Amazon Quick Automate** – Build business process automations with AI agents that make contextual decisions and execute actions across applications.
- **Amazon Quick Index** – Connect your organization's documents and data sources so AI responses are grounded in your information.
- **Amazon Quick Research** – Conduct in-depth research across the web and your data, delivered as a cited report.
- **Apps in Amazon Quick** – Build interactive web applications by describing what you need in natural language.

Note

Amazon Quick evolved from Amazon QuickSight. QuickSight continues as Amazon Quick Sight, a feature within Quick. All existing QuickSight APIs, SDKs, and integrations continue to work without changes.

Benefits of Quick

Everything in one place

Agents, research, automation, analytics, and app building are all built in. You don't need separate products for each capability.

Fully managed

No infrastructure to provision, no models to host, no ML expertise required.

Connects to your tools and data

Quick integrates with the apps, databases, and systems your organization already uses through knowledge bases, action connectors, extensions, and structured data connections. Open standards including Model Context Protocol (MCP) and OpenAPI let you connect any system.

Meets you where you work

Use Quick from the web, the desktop application, or directly inside Chrome, Slack, Microsoft Teams, and Microsoft 365 applications.

AI you can trust

Quick runs on AWS with the same identity, network, and compliance controls your security team already approved. Your data stays in your control.

Accessing Quick

To start using Amazon Quick, you have two options:

1. **Sign up at aws.com/quick** – Use your email or social credentials (Google, Apple, Amazon, GitHub). No AWS account required. Free and Plus plans available.
2. **Provision through the AWS Management Console** – Configure Quick for your organization with IAM Identity Center or IAM Federation. Per-user subscriptions with standard AWS billing.

Getting started

To start using Quick immediately, sign up at aws.com/quick.

If your organization uses AWS:

1. [How Amazon Quick works](#) – Learn how Quick components work together.
2. [Setting up and signing into Amazon Quick](#) – Configure Quick for your organization.
3. [Getting started with Amazon Quick](#) – Start a conversation, explore features, and see what Quick can do.

How Amazon Quick works

When you use Quick, the following components work together to process your requests.

You start in chat

Chat is the primary interface for Quick. You type a question, give an instruction, or describe what you need. Quick interprets your request and determines how to respond: answering from connected data, generating content, running a workflow, conducting research, or taking action in an external application. For more information, see [Ask questions, explore data, and get insights with chat in Amazon Quick](#).

Agents process your requests

Behind every interaction is an agent. Agents are configured with instructions that define their behavior, knowledge sources that ground their responses, and tools that let them take action. Quick provides a default agent, and you can create custom agents for specific domains. For more information, see [Create, customize, and deploy AI-powered chat agents in Amazon Quick](#).

Spaces organize context

Spaces bring together the resources an agent needs: documents, dashboards, datasets, knowledge bases, and connectors. When you assign a space to an agent, it draws on everything in that space to answer questions and complete tasks. You share spaces with your team so everyone benefits from the same context. For more information, see [Organize, collaborate, and share resources with spaces in Amazon Quick](#).

Integrations connect Quick to your world

Integrations give Quick access to external information and the ability to act on your behalf:

Knowledge bases

Bring external content into Quick for AI retrieval. Sources include Amazon S3, SharePoint, OneDrive, Confluence, Google Drive, and web crawlers. Quick keeps the index in sync as sources update.

Connectors

Let Quick read data, trigger workflows, and update records in external services. You create connectors from OpenAPI specifications or Model Context Protocol (MCP) servers.

Extensions

Embed Quick inside Chrome, Slack, Microsoft Teams, and Microsoft 365 applications so you interact with agents without leaving the app you're working in.

Structured data connections

Connect Quick Sight to databases, data warehouses, and data lakes for analytics and visualization.

For more information, see [Work with integrations in Amazon Quick](#).

Features use those building blocks

Each Quick feature combines the components above in different ways:

Feature	What it does	What it uses
Quick Sight	Interactive dashboards and analytics	Structured data connections, SPICE, datasets
Quick Flows	Task automation	Connectors, spaces, agent logic
Quick Automate	End-to-end process automation	Connectors, agents, human-in-the-loop
Quick Research	In-depth cited reports	Spaces, knowledge bases, web
Apps in Quick	Interactive web applications	Structured data, connectors, Quick Sight visuals
Desktop application	Personalized AI on your machine	Local files, email, calendar, MCP servers

Build an app	Build web applications with apps in Amazon Quick
Connect Quick to my tools	Work with integrations in Amazon Quick
Use Quick on my desktop	What is Amazon Quick on desktop?

Setting up and signing into Amazon Quick

Amazon Quick offers two ways to get started, depending on your needs:

- **Get started quickly** – If you're an individual or small team and don't have an AWS account, see [Signing up at aws.com/quick](https://aws.com/quick).
- **Use Quick with your organization's AWS account** – If your organization already uses AWS services, see [Signing up through the AWS Console](#).

Free and Plus accounts: Sign up at <https://aws.com/quick> using an email address. Amazon Quick creates an account for you automatically using your email or social login credentials. Choose from Free, Free Trial Plus, or Paid Plus plan tiers. No AWS account or technical configuration is required.

AWS Console accounts: If your organization uses AWS, you can provision Amazon Quick through the AWS Management Console. This path uses IAM Identity Center for authentication and integrates with your existing AWS billing and governance.

If your IAM Identity Center instance is replicated to multiple AWS Regions, you can create your Quick Enterprise subscription in an active additional Region. For more information, see [Set up Amazon Quick with IAM Identity Center multi-Region](#).

For a comparison of features available with each account type, see [Pricing and availability](#).

For more information on administering your account after setup, see [Administering Amazon Quick \(Free/Plus/Max\)](#) or [Administering Amazon Quick](#) for accounts provisioned through the AWS Management Console.

Topics

- [Complete initial configuration tasks](#)

- [Signing up through the AWS Console](#)
- [Signing in to Amazon Quick](#)

Complete initial configuration tasks

Note

The following configuration tasks apply to AWS Console accounts only. If you are signing up for Free/Plus/Max with email at aws.com/quick, these steps are handled automatically. See [Signing up at aws.com/quick](https://aws.com/quick) instead.

To use Amazon Quick you must first complete the following tasks:

Topics

- [Sign up for an AWS account](#)

Sign up for an AWS account

To get started with AWS, you need an AWS account. For information about creating an AWS account, see [Getting started with an AWS account](#) in the *AWS Account Management Reference Guide*.

Signing up at aws.com/quick

Amazon Quick is available directly at <https://aws.com/quick> – no existing AWS account required. This page walks you through creating a Amazon Quick Free or Plus account using your email address or social login credentials.

Note

If your organization already uses AWS and you want to access Amazon Quick through the AWS Management Console, see [Signing up through the AWS Console](#) instead. For a comparison of features available with each account type, see [Pricing and availability](#).

Topics

- [Who is this for?](#)
- [Sign-in options](#)
- [Step-by-step signup procedure](#)

- [What happens behind the scenes](#)

Who is this for?

The direct signup at aws.com/quick is designed for:

- **Individuals** who want to explore Amazon Quick without creating an AWS account.
- **Small teams** who need a fast way to get started with AI-powered productivity tools.
- **Anyone** who wants to try Amazon Quick with a few clicks.

You can sign up with an email address or use an existing Google, Apple, GitHub, or Amazon account. An AWS account is created and managed automatically behind the scenes – you never need to interact with it directly.

Sign-in options

When you sign up at aws.com/quick, you can create your account using:

- **Email address** – Create an account with any email (covered in this guide).
- **Google** – Sign in with your Google account.
- **Apple** – Sign in with your Apple ID.
- **GitHub** – Sign in with your GitHub account.
- **Amazon** – Sign in with your Amazon account.

This guide covers the email-based signup flow. Social login options follow a similar process but use your existing credentials from the selected provider.

Step-by-step signup procedure

To sign up for a Amazon Quick Free or Plus account

1. **Navigate to aws.com/quick.**

Open your web browser and go to <https://aws.com/quick>. You see the Amazon Quick landing page with an option to **Sign up for free**.

2. **Choose Sign up for free.**

Choose **Sign up for free** to begin the account creation process. You are redirected to the AWS signup page.

3. Enter your email address.

In the email field, type the email address you want to use for your Amazon Quick account. This email becomes your sign-in identity for Amazon Quick.

After entering your email, choose **Continue**.

Tip

Use an email address you check regularly. You need to verify it in the next step, and Amazon Quick sends important account notifications to this address.

4. Enter your name.

On the next screen, enter your name. This is the display name that other users in your Amazon Quick account see.

Your email address is shown for confirmation. If you need to change it, choose **Change** to go back.

Choose **Continue** to proceed.

5. Verify your email address.

Amazon Quick sends a 6-digit verification code to the email address you provided. Check your inbox (and spam/junk folder if needed) for an email from AWS.

Enter the 6-digit code in the verification field and choose **Continue**.

Note

If you don't receive the code, choose **Resend code** to send a new one. The resend option becomes available after a brief countdown.

6. Create a password.

Create a password for your account. Your password must meet standard AWS security requirements:

- At least 8 characters
- At least one uppercase letter
- At least one lowercase letter
- At least one number
- At least one special character

Enter your password, then re-enter it to confirm. Choose **Continue**.

7. Wait for account provisioning.

After setting your password, Amazon Quick provisions your account. You see a "Setting up" screen with a brief message. This process typically takes less than one minute.

Note

During this step, Amazon Quick automatically creates and configures an AWS account on your behalf. You don't need to manage this account – it's handled entirely by the service.

8. Choose how to access Amazon Quick.

Once provisioning completes, the Welcome page appears. You have two options:

- **Download for macOS** – Download the Amazon Quick desktop application for your computer.
- **Continue on web for now** – Start using Amazon Quick immediately in your web browser.

Choose the option that works best for you. You can always download the desktop app later from the **Quick anywhere** menu in your profile settings.

9. Choose your work focus (Getting Started wizard).

Amazon Quick presents a Getting Started wizard that helps personalize your experience. You can select one or more work focus topics, or skip this step entirely.

The available work focus topics are:

Topic	Description
Communicate with stakeholders	Tools and templates for stakeholder communication
Grow my sales pipeline	Sales pipeline management and analysis
Improve my business performance	Business performance analytics and insights
Organize my team's knowledge	Knowledge management and documentation
Plan and prioritize my work	Project planning and task prioritization
Build and ship my product	Product development and delivery workflows
Improve my marketing reach	Marketing analytics and content creation
Hire and develop my team	HR, recruiting, and team development
Manage risk and compliance	Risk assessment, compliance, and governance

Select a topic that matches your primary use case, then choose **Let's go**. Alternatively, choose **Skip and start chatting** to go directly to the chat interface.

10. Start using Amazon Quick.

The Amazon Quick chat interface loads. If you selected a work focus topic, you see personalized suggestion cards tailored to your selection. The interface includes:

- **Left navigation** – Access New chat, Search, Spaces, Research, Chat agents, and More.
- **Chat input** – Type questions or requests in the **Ask me anything** field.
- **Attach files** – Upload documents for analysis (up to 20 files, under 50 MB each).
- **Suggestion cards** – Pre-built prompts based on your selected work focus.

You're now ready to start using Amazon Quick. For information about features and capabilities, see [Getting started with Amazon Quick](#).

What happens behind the scenes

When you sign up at aws.com/quick, Amazon Quick automatically:

1. Creates a **sign-in identity** linked to your email address – this is what you use to sign in to Amazon Quick.
2. Provisions an **AWS account** that hosts your Quick resources – you don't need to access or manage this account.
3. Sets up your Quick environment with default settings and built-in AI agents.

Signing up through the AWS Console

Note

This section covers signing up for Amazon Quick through the AWS Management Console for organizations that already use AWS. If you want to sign up without an AWS account, see [Signing up at aws.com/quick](https://aws.com/quick) for a faster setup process using email or social login. For a comparison of features available with each account type, see [Pricing and availability](#).

When you first sign up for Amazon Quick, you get a free trial subscription for twenty-five users for 30 days. During the process of signing up, you may set options for your identity provider.

Before you begin, make sure that you can connect to an existing AWS account. If you don't have an AWS account, see [Complete initial configuration tasks](#). The person who signs up for Quick needs to have the correct AWS Identity and Access Management (IAM) permissions. For more information, see [IAM policy examples for Quick](#).

To test your permissions, you can use the IAM policy simulator; for more information, see [Testing IAM policies with the IAM policy simulator](#). Also, check whether your AWS account is part of an organization based on the AWS Organizations service. If so and you sign in as an IAM user, make sure that you didn't inherit any IAM permissions that deny access to the required permissions. For more information on Organizations, see [What is AWS Organizations?](#)

 Note

Your data is encrypted by default using AWS-managed keys. Admins can adjust settings for custom encryption in the admin portal after signing up.

To subscribe to Quick

1. Sign in to your AWS account and open Quick from the AWS Management Console. You can find it under **Analytics** or by searching for *Quick*.

Your AWS account number is displayed for verification purposes.

2. Enter a unique account name for Quick.
 - Enter a notification email address for the Quick account owner or group. This email address receives service and usage notifications.
3. Choose the AWS Region that you want to use for your initial data storage capacity, called SPICE.
4. Choose an authentication method that you want to connect to Quick with. Select from one of the following:
 - **(Recommended) Password-based or Single-Sign On**
 - **IAM Identity Center**
 - **Single-Sign On Only**
 - **Active Directory**
5. Review the choices that you made, then choose **Create account**.
6. Upon completion, your Quick account is created. To open Quick, choose **Go to Quick**.

Non-admin sign-up process

If you are not an administrator, you can sign up for Quick using a link provided by your admin. This process allows you to create your account and configure your Quick environment.

To sign up as a non-admin user

1. **Getting your sign-up link**

Sign up for Amazon Quick with the link provided by your admin.

2. Account creation and Quick access

After you've created your account, from within Quick, search for Amazon Quick.

3. Account configuration

Enter your Account name, Email, Region, and Authentication method.

- For authentication, Amazon Quick supports Pro license integration with start URL format:
`https://amzn.awsapps.com/start`
- Default Region is us-east-1

4. Plan selection

Select the plan and storage options you are using for your instance of Amazon Quick.

Signing in to Amazon Quick

You can sign in to Amazon Quick multiple ways, depending on what your Quick administrator has set up. You can sign in to Quick using AWS root, AWS Identity and Access Management (IAM), corporate Active Directory, or your native Quick credentials. If your Quick account is integrated with an identity provider such as Okta, the following procedures don't apply to you.

If you're a Quick administrator, make sure to allow-list the following domains within your organization's network.

User type	Domain or domains to allow-list
Users who sign in directly through Quick and Active Directory users	<code>signin.aws</code> and <code>awsapps.com</code>
AWS root user	<code>signin.aws.amazon.com</code> and <code>amazon.com</code>
IAM users	<code>signin.aws.amazon.com</code>

Signing in to a Amazon Quick Free or Plus account

If you created your Amazon Quick account at aws.com/quick, follow these steps to sign in.

To sign in to a Amazon Quick Free or Plus account

1. Navigate to the [sign-in page](#).
2. Choose **Sign in**.
3. Enter the email address associated with your account.
4. Enter your password.
5. Choose **Sign in**.

If you have multiple Amazon Quick accounts associated with your email, you may be prompted to select which account to access. Choose the account you want to sign in to.

Tip

You can also sign in using the social login option you used during signup (Google, Apple, GitHub, or Amazon) if you linked your account during registration.

Note

If you signed up through the AWS Management Console instead, see the next section for console sign-in instructions.

Post-setup configuration

After signing in to Quick, you can customize your environment by configuring agent settings and other preferences.

To complete post-setup configuration

1. **Agent customization access**

From the left navigation menu, under Customization, select Agent customization.

2. **Environment settings**

Enter the settings you require for your environment. These settings will customize Amazon Q's behavior for your specific use case.

Important

We strongly recommend that you don't use the AWS root user for your everyday tasks, even the administrative ones. Instead, adhere to the best practice of using the root user only to create your first IAM user. Then securely lock away the root user credentials and use them to perform only a few account and service management tasks. For more information, see [AWS account root user](#) in the *IAM User Guide*.

Signing in through the AWS Console

Use the following procedure to sign in to Quick through the AWS Management Console.

To sign in to Quick

1. Go to <https://quicksight.aws.amazon.com/>.
2. For **Quick account name**, enter your account name. This is the name that was created when the Quick account was created in AWS.

If you were invited to the Quick account by email, you can find the account name inside of that email. If you don't have the email that invited you to Quick, ask the Quick administrator in your organization for the information that you need.

You can also find your Quick account name by choosing the profile icon on the Quick console menu. In some cases, you might not have access to your Quick account or have an administrator who can provide this information, or both. If so, contact AWS Support and open a ticket that includes your AWS customer ID.

3. For **Username**, enter your Quick user name. User names that contain a semicolon (;) aren't supported. Choose one of the following:
 - For organizational users – The user name is provided by your administrator.

Your account can be based on IAM credentials or your email address if it's a root email address. Or it can be used as the user name to invite you into the Quick account. If you

received an invitation email from another Quick user, it indicates what type of credentials to use.

- For individual users – The user name that you created for yourself.

This is usually the IAM credentials that you created.

The remaining steps vary depending on the user type you sign in as (directly through Quick or as an Active Directory user, AWS root user, or IAM user). For more information, see the following sections.

Finishing Quick sign-in as a Quick or Active Directory user

If you're signing in directly through Quick or are using your corporate Active Directory credentials, you're redirected to `signin.aws` after you enter your account name and user name. Use the following procedure to finish signing in.

To finish signing in to Quick if you sign in directly through Quick or use Active Directory credentials

1. For **Password**, enter your password.

Passwords are case-sensitive and must be 8–64 characters in length. They must also contain each of the following:

- Lowercase letters (a–z)
- Uppercase letters (A–Z)
- Numbers (0–9)
- Nonalphanumeric characters (~!@#\$\$%^&* _-+= `| \(){}[];:"'<>.,?/)

2. If your account is multi-factor authentication enabled, enter the multi-factor authentication code that you receive for **MFA code**.
3. Choose **Sign in**.

Finishing Quick sign-in as an AWS root user

If you're signing in as an AWS root user, you're redirected to `signin.aws.amazon.com` (or `amazon.com`) to complete the sign-in process. Your user name is prefilled. Use the following procedure to finish signing in.

To finish signing in as an AWS root user

1. Choose **Next**.
2. For **password**, enter your password. For more information about root user passwords, see [Changing the AWS account root user password](#) in the *IAM User Guide*.
3. Choose **Sign in**.

Finishing Quick sign-in as an IAM user

If you're signing in as an IAM user, you're redirected to signin.aws.amazon.com (or amazon.com) to complete the sign-in process. Your user name is prefilled. Use the following procedure to finish signing in.

To finish signing in as an IAM user

1. For **Password**, enter your password. For more information about IAM user passwords, see [Default password policy](#) in the *IAM User Guide*.
2. Choose **Sign in**.

Signing in with multiple accounts

You can sign in to Amazon Quick with multiple accounts at the same time and switch between them as necessary.

To sign in to multiple accounts

1. Follow the steps at [Signing in to Amazon Quick](#) to sign in to Amazon Quick.
2. From the navigation bar, choose your account name to reveal a dropdown menu.
3. Hover over **Switch accounts**. A list of accounts that you've signed in to before appears. Do one of the following:
 - To switch to an account, select that account and provide sign-in credentials.
 - To sign in to a new account, choose **Add another account**. You are prompted to provide sign-in credentials for the account.

To sign out of an account or all accounts

1. From the navigation bar, choose your account name to reveal a dropdown menu.
2. Hover over **Sign out**. You can choose to sign out of your current account or to **Sign out of all accounts**.

URL structure

When using multiple accounts, Amazon Quick URLs include the account name to identify which account you're accessing.

Application URLs

Application URLs follow this structure:

```
https://us-east-1.quicksight.aws.amazon.com/sn/account/ACCOUNT-NAME/...
```

Examples:

```
https://us-east-1.quicksight.aws.amazon.com/sn/account/my-account/start/home  
https://us-east-1.quicksight.aws.amazon.com/sn/account/my-account/dashboards/1234
```

Console URLs

Console URLs follow this structure.

Standard accounts (account alias is the account ID)

```
https://us-east-1.quicksight.aws.amazon.com/sn/console/account/123456789012/...
```

Examples:

```
https://us-east-1.quicksight.aws.amazon.com/sn/console/account/123456789012/admin  
https://us-east-1.quicksight.aws.amazon.com/sn/console/account/123456789012/asset-  
management
```

Accounts with IAM multi-account access (account alias is the session differentiator)

```
https://us-east-1.quicksight.aws.amazon.com/sn/console/account/123456789012-abc123/...
```

Examples:

```
https://us-east-1.quicksight.aws.amazon.com/sn/console/account/123456789012-abc123/admin
https://us-east-1.quicksight.aws.amazon.com/sn/console/account/123456789012-abc123/asset-management
```

Key considerations and limitations

- The URL structures above enable bookmarking of resources within the Amazon Quick account.
- You can simultaneously be signed in to different accounts in different tabs or windows in your browser.
- The Amazon Quick URL contains your account name. If you change it to another account name, you are prompted to sign in if you aren't already.
- You can sign in to up to five accounts. If you try to sign in to a sixth account, the system automatically signs out and forgets the least recently signed in account.
- Multi-account sign-in is not supported for IAM users who access Amazon Quick through IAM-based multi-account federation.

IAM SSO federation with multi-account

For more information about setting up identity federation, see [Initiating sign-on from Quick](#).

Service Provider (SP) initiated federation

If your account has SSO configuration established in Quick, all login attempts or links that include the account alias provide seamless login. There is no change in behavior for these logins.

Identity Provider (IdP) initiated federation

Scenarios with no change in behavior:

- If you have enabled IAM multi-account access, all federation links provide seamless login, regardless of whether they include the account alias.
- If you have SSO configuration enabled in Quick, all IdP initiated federation or IdP deep links that include the account alias provide seamless login.
- If you have never used Quick before or have only ever used one account with Quick and you use IdP federation to access that one account, there is no change in experience.

Scenarios with change in behavior: When you have one or more saved Quick accounts and access any IdP federation link without an account alias, instead of being taken directly to your account, you land on the Quick saved account login page where you can select your session and be taken to your account.

Recommended configuration: To ensure seamless IdP federation, include the account alias in all IdP federation links. If you are unable to ensure the account alias in your deep links or you do not have SSO configuration enabled in Quick, include the `sso_login=true` query parameter in your links.

Recommended example start federation URL:

```
https://us-east-1.quicksight.aws.amazon.com/sn/account/ACCOUNT-NAME/start/home?  
sso_login=true
```

If your sign-in process happens automatically and you need to use a different account, use a private or incognito browser window. Doing this prevents the browser from reusing cached settings.

 Note

If you're not sure which type of account you have: if you signed up at aws.com/quick and use an email/password to sign in, you have a Free or Plus account. If you sign in through the AWS Management Console or your organization's single sign-on portal, you have an AWS Console account.

Getting started with Amazon Quick

Amazon Quick is an AI-powered workspace that combines business intelligence, AI-assisted chat, workflow automation, and research capabilities in a single service. Use the topics in this section to get started with the core capabilities of Quick, including AI agents for natural language conversations, Amazon Quick Sight for data visualization, Spaces for team collaboration, Quick Flows for workflow automation, and Research for comprehensive analysis.

You can begin by exploring the platform's features through AI chat, using sample data for visualizations, or connecting to your own data sources to start building real-world solutions.

Topics

- [Using the Amazon Quick console](#)
- [Getting started with Amazon Quick Sight](#)

Using the Amazon Quick console

In the following topic, you can find a brief introduction to using the Amazon Quick user interface.

Topics

- [Using the Amazon Quick menu and landing page](#)
- [Searching Amazon Quick](#)
- [Choosing a language in Amazon Quick](#)

Using the Amazon Quick menu and landing page

After you sign in to Amazon Quick, you see the Amazon Quick landing page. This page provides tabs for your analyses, dashboards, folders, data, and more. It also provides a menu bar at the top, with options for the following:

- Searching Amazon Quick
- Accessing your user profile (managing Quick, language selection, and help)
- Interacting with the Quick chat agent
- Choosing the AWS Region that you want to work in

- Discovering helpful resources (documentation, how-to videos, community forum, blogs, and more)

Note

Consult your administrator before changing your AWS Region. Your default AWS Region is configured by your Amazon Quick administrator. Changing the AWS Region changes where your work is stored.

Navigating the homepage

Using the navigation menu on the left, you can explore how to work with dashboards, build powerful analyses, manage your data sources, organize content with folders, leverage advanced analytics capabilities, and more.

The following are all the available Amazon Quick capabilities:

- **Agents** – Build AI agents that intelligently analyze, plan, and work with your data to help complete tasks.
- **Spaces** – Work with Amazon Q using specific files, data, and information to complete projects or organize teams.
- **Scenarios** – Elevate your data exploration in the AI-driven workbook canvas that is enhanced with generative analysis capabilities. Allow AI to suggest relevant data to enrich your insight discovery.
- **Stories** – Use Amazon Q prompts and visuals to produce a story that incorporates the details that you provide.
- **Topics** – Create a new generative topic to introduce the generative Q&A experience for users.
- **Dashboards** – Share interactive data visualizations with your audience. You can explore and filter visualizations according to your specific needs and generate snapshots for easy sharing.
- **Analyses** – Dive deep into your data with robust visualization and analysis tools. Create charts and graphs to uncover insights before publishing to a wider audience.
- **Favorites** – Favorite the dashboards and analyses you want to easily find later.
- **Folders** – Organize your analyses and dashboards in folders.
- **Automations** – Create automated processes that reduce manual intervention and save valuable time.

- **Flows** – Create and share intelligent workflows to accomplish goals quickly and predictably.
- **Data** – Connect to data and visualize, create specialized chat assistants, or mix both.
- **Actions** – Perform tasks such as creating and updating tickets, managing incidents, and accessing project information directly.

Customizing the homepage layout

The Quick homepage provides a customizable workspace where you can add widgets that enhance your analytics experience. The homepage features three key widget types:

- **Quick use cases** – Offers quick access to tutorial videos and onboarding resources.
- **Recents** – Displays recently viewed resources for faster navigation.
- **Business Metrics** – Allows you to pin important visualizations and metrics directly from your dashboards.

You can easily add, remove, and rearrange these widgets to create a personalized homepage that suits your workflow.

To add a widget

1. From the Quick homepage, choose **Add widget**.
2. You can choose to add either **Quick use cases**, **Recents**, or **Business metrics**.
 - a. If **Quick use cases** is already added to the homepage, this option will be unavailable. If you previously deleted the widget, choose **Add widget** then **Quick use cases** to add it back to the homepage. **Quick use cases** always appears at the top of the homepage to ensure easy access to learning resources, even if previously dismissed.
 - b. If you choose **Recents**, a widget containing recently viewed resources is added to the homepage. Choose a resource to quickly pick up where you left off.
 - c. If you choose **Business metrics**, you will be redirected to the **Dashboards** page. From there, you can open a dashboard and choose which visual you would like to pin to the homepage by selecting the home + icon.

To delete a widget

1. Navigate to the widget you would like to delete.

2. Choose the three-dot menu on the top right of the widget.
3. Choose **Delete**.
4. The selected widget should be removed from the homepage.

To reorder a widget

1. Select the widget you would like to reorder.
2. When the widget is selected, the handle icon appears on the top left of the widget.
3. Choose the handle icon and drag the widget to swap its place with another widget.

To resize a widget

1. Select the widget you would like to resize.
2. When the widget is selected, a resize icon appears on the bottom right.
3. Choose the resize icon and drag the widget up or down to reach your desired size.

Accessing user profiles

To access the user profile menu, choose the user icon at the upper right of any page in Amazon Quick. Use this menu to manage Amazon Quick features, choose a language, change your AWS Region, get help from the documentation, or sign out of Amazon Quick.

The following options are available from the user profile menu:

- **Manage Quick** – If you have appropriate permissions, you can access administrative functions such as managing users, subscriptions, [SPICE](#) capacity, and account settings.
- **Language setting** – Choose the language you want to use in the Amazon Quick user interface.
- **Region setting** – Choose the AWS Region that you want to work in.

Note

Consult your administrator before changing your AWS Region. Your default AWS Region is configured by your Amazon Quick administrator. Changing the AWS Region changes where your work is stored.

- **Help** – This will open the official Quick documentation, which you can view online, in Kindle, or as a PDF.
- **Sign out** – Choose this option to sign out of Amazon Quick and your AWS session.

Searching Amazon Quick

From the search bar, you can search for analyses and dashboards. To use the search tool, go to the **Start Page** and choose the search box at the top-left of the page. Then enter the name, or part of the name, of the data set, analyses, or dashboard you want to find. The search is not case-sensitive.

After you locate the item that you're looking for, you can open it directly from the search results. You can modify a dataset, create an analysis from a dataset, or access an analysis or dashboard. Choose an item from the search results to open it.

Choosing a language in Amazon Quick

You can choose the language that you want to use in the Amazon Quick user interface. This option is set separately for each individual user. The first time a user signs in, Amazon Quick detects and selects a suitable language. This choice is based on the user's browser preferences and interactions with localized AWS websites.

Quick supports the following languages:

Languages available in the Amazon Quick user interface

Official name	Language code	Localized name
Dansk	da-DK	Danish
Deutsch (Deutschland)	de-DE	German
English (US)	en-US	English
Español (España)	es-ES	Spanish
Français (France)	fr-FR	French

Official name	Language code	Localized name
Italiano (Italia)	it-IT	Italian
Nederlands (Nederland)	nl-NL	Dutch
Norsk bokmål	nb-NO	Norwegian
Português (Brasil)	pt-BR	Portuguese
Suomi	fi-FI	Finnish
Svenska (Sverige)	sv-SE	Swedish
日本語	ja-JP	Japanese
한국어	ko-KR	Korean
中文 (中国)	zh-CN	Simplified Chinese
中文 (台灣)	zh-TW	Traditional Chinese

Choosing a language translates only user interface elements. It doesn't translate the following:

- Amazon Quick reserved keywords
- User input
- Data
- Date or number formats
- ML Insights, suggested insights, or computations in narratives (including text)

Use the following procedure to change the language in the Amazon Quick interface.

1. Choose your account name at the top right.

2. Choose **Preferences**.
3. Choose the language that you want to use from the **Preferred Language** dropdown list.

Getting started with Amazon Quick Sight

Amazon Quick Sight is the data visualization and analysis component of Amazon Quick. This section walks you through creating your first analysis using sample data, including uploading datasets, creating visualizations with AutoGraph, and sharing your results through dashboards.

Topics

- [Quick start: Create an Amazon Quick Sight analysis with a single visual using sample data](#)
- [Tutorial: Create an Amazon Quick Sight dashboard using sample data](#)
- [Sample data](#)

Quick start: Create an Amazon Quick Sight analysis with a single visual using sample data

Before you create your first analysis, make sure to complete the steps in [Setting up and signing into Amazon Quick](#).

With the following procedure, you use the Web and Social Media Analytics sample dataset to create an analysis containing a line chart visual. This visual shows the count by month of people that have added themselves to the mailing list.

To create an analysis containing a line chart visual using a sample dataset

1. From the Amazon Quick homepage, from Amazon Quick Sight, choose **Analyses** from the left navigation menu. If you don't have sample data, you can download it from [web-and-social-analytics.csv.zip](#). Unzip the file so you can use the .csv file.

To upload the sample data, do the following:

- a. Choose **Data** from the left navigation menu. Under the **Dataset** tab, select **New** then **Dataset**.
- b. Choose **Upload file**.

- c. Choose the sample file, `web-and-social-analytics.csv`, from your drive. If you don't see it, check that you unzipped the `web-and-social-analytics.csv.zip` file.
 - d. Confirm file upload settings by choosing **Next** on the **Confirm file upload settings** screen.
 - e. Choose **Visualize** on the **Data source details** screen.
 - f. Skip the next step. Choosing **Visualize** brings you to the same screen as the process in Step 2.
2. On the **Datasets** page, choose the **Web and Social Media Analytics** dataset, and then choose **Use in Analysis**.
3. In the **Data** pane, choose **Date**, and then choose **Mailing list adds**.

Amazon Quick Sight uses AutoGraph to create the visual, selecting the visual type that it determines is most compatible with those fields. In this case, it selects a line chart that shows mailing list adds by day, which is the date granularity default.

4. Navigate to the **Field wells** at the bottom of the **Visuals** pane.
5. Choose the **X axis** field well. Select the three-dot menu, choose **Aggregate**, and then choose **Month**.

The line chart updates to show mailing list adds by month, rather than by the default of by year.

Tutorial: Create an Amazon Quick Sight dashboard using sample data

Use the procedures in the following sections to complete these tasks:

- Create and prepare a Marketing dataset using the Web and Social Media Analytics sample data.
- Create a Marketing analysis and add several visuals to it.
- Modify the visuals in the analysis, including the following:
 - Adding another measure to an existing visual
 - Changing chart colors
 - Changing date granularity
 - Changing the size and layout of the visuals
 - Applying a filter
- Publish a dashboard based on the analysis.

Topics

- [Tutorial: Modify Amazon Quick Sight visuals](#)
- [Tutorial: Create an Amazon Quick Sight dashboard](#)

Tutorial: Create a prepared Amazon Quick Sight dataset

Use the following procedure to prepare the Marketing dataset and create an analysis. If you don't see the Web and Social Media Analytics sample data already in Amazon Quick Sight, you can download it: [web-and-social-analytics.csv.zip](#).

To prepare the Marketing dataset and create an analysis

1. From the Amazon Quick homepage, choose **Data** in the navigation pane.
2. In the **Datasets** tab, choose **New** then **Dataset**.
3. From the existing data sources, choose the **Web and Social Media Analytics** Amazon S3 data source. Choose your table and then choose **Edit/Preview data**.

Amazon Quick opens the data preparation page.

4. For **Dataset Name**, enter **Marketing Sample** to replace *Web and Social Media Analytics* for the dataset name.
5. Exclude some fields from the dataset.

In the **Fields** pane, choose the three-dot menu for the **Twitter followers cumulative** and **Mailing list cumulative** fields, and then choose **Exclude field**. To select more than one field at a time, press the Ctrl key while you select (Command key on Mac).

6. Rename a field.

In the **Dataset** preview pane, scroll to the **Website Pageviews** field and choose the pencil icon to edit.

In the **Edit field** page that opens, for **Name**, enter **Website page views**, and then choose **Apply**.

7. Add a calculated field that substitutes a text string for any 0-length string value in the **Events** field:

- a. On the data preparation page, scroll to the top of the **Fields** pane, and then choose **Add calculated field**.
- b. In the **Add calculated field** page that opens, for **Add name**, enter **populated_event**.
- c. In the **Functions** pane at right, double-click the **ifelse** function from the list of functions. This adds the function to the calculated field formula.
- d. Expand the **Field list** pane by choosing the drop-down arrow, and then double-click the **Events** field. This adds the field to the calculated field formula.
- e. In formula editor, enter the following additional functions and parameters required, in bold in the following: `ifelse(strlen({Events})=0, 'Unknown', {Events})`.

The final formula should be as follows: `ifelse(strlen({Events})=0, 'Unknown', {Events})`.

- f. Choose **Save**.

The new calculated field is created, and appears at the top of the **Fields** pane.

8. Choose **Save**.

Next steps

Create an analysis by using the procedure in [Tutorial: Create an Amazon Quick Sight analysis](#).

Tutorial: Create an Amazon Quick Sight analysis

In the following short tutorial, you create an analysis, add a visual using AutoGraph, and add another visual by choosing a specific visual type. This procedure builds on the dataset that you create and prepare in [Tutorial: Create a prepared Amazon Quick Sight dataset](#).

Create your analysis

Use the following procedure to create your analysis.

To create your analysis

1. On the Amazon Quick Sight homepage, choose **Analyses**.
2. Choose **Create analysis** and select the dataset to use.

Create a visual by using AutoGraph

Create a visual by using AutoGraph, which is selected by default.

On the analysis page, choose **Date** and **Return visitors** in the **Fields list** pane.

Amazon Quick Sight creates a line chart using this data.

Create a scatter plot visual

Create a visual by choosing a visual type and dragging fields to the field wells.

To create a scatter plot visual

1. On the analysis page, choose **Insert** and then **Add visual** on the application bar. A new, blank visual is created, and AutoGraph is selected by default.
2. In the **Visual types** pane, choose the scatter plot icon.
3. Choose fields in the **Fields list** pane to add to the **Field wells** pane:
 - Choose **Desktop Uniques** to populate the **X axis** field well.
 - Choose **Mobile Uniques** to populate the **Y axis** field well.
 - Choose **Date** to populate the **Group/Color** field well.

A scatter plot is created using these fields.

Next steps

Modify the visuals in your analysis by using the procedure in [Tutorial: Modify Amazon Quick Sight visuals](#).

Tutorial: Modify Amazon Quick Sight visuals

Use the following procedures to modify the visuals that you created using the procedures in [Tutorial: Create an Amazon Quick Sight analysis](#).

Modify the line chart visual

Modify your line chart visual by making it show an additional measure by date, and also by changing the chart color.

To modify your line chart visual

1. In your analysis, select the line chart visual.
2. Add another measure to the visual.

Select the **New visitors SEO** field in the **Fields list** pane. This measure is added to the **Value** field well, and the line chart updates with a line to represent it. The visual title also updates.

3. Change the color of the line used to represent the **Return visitors** measure.

Choose the line on the chart that represents **Return visitors**. To do this, choose the end of the line, not the middle of the line.

Choose **Color Return visitors**, and then choose the red icon from the color selector.

4. Choose the **Date** field in the **X axis** field well, choose **Aggregate**, and then choose **Month**.

Modify the scatter plot visual

Modify your scatter plot visual by changing the data granularity.

To modify your scatter chart visual

1. In the analysis, select the scatter plot visual.
2. Choose the **Group/Color** field well, choose **Aggregate**, and then choose **Month**.

The scatter plot updates to show the measures by month, rather than by the default of by year.

Modify both visuals by changing visual layout and adding a filter

Modify both visuals by changing visual size and location, and by adding a filter and applying it to both of them.

Change the visual layout

Modify both visuals by changing visual size and location.

To modify both visuals

1. In your analysis, select the line chart visual.

2. Choose the resize handle in the lower right corner of the visual and drag up and to the left, until the visual is half its former size both horizontally and vertically.
3. Repeat this procedure on the scatter plot visual.
4. Choose the move handle on the scatter plot visual, and drag it up to the right of the line chart visual so that they are side by side.

Modify both visuals by adding a filter

Modify both visuals by adding a filter and applying it to both of them.

To add a filter to both visuals

1. In the analysis, choose the scatter plot visual.
2. Choose **Insert** then **Add Filter** on the application bar.
3. Choose the **Date** field to filter on.
4. Select the new filter to expand it.
5. In the **Edit filter** pane, for **Condition**, choose the **After** comparison type.
6. Enter a start date value of 1/1/2014.

Choose **Date**, choose **2014** for the year, **January** for the month, and then choose **1** on the calendar.

7. In the **Edit filter** pane, choose **Apply** to apply the filter to the visual.

The filter is applied to the scatter plot visual. This is indicated with a filter icon on the visual drop-down menu.

8. Apply the filter to the line chart visual.

In the **Filter** pane, choose the **Date** filter again and choose **Single visual**, and then choose **All visuals of this dataset**.

The filter is applied to the line chart visual as well.

Next steps

Create a dashboard from your analysis by using the procedure in [Tutorial: Create an Amazon Quick Sight dashboard](#).

Tutorial: Create an Amazon Quick Sight dashboard

Use the following procedure to create a dashboard from the analysis that you created using the procedure in [Tutorial: Create an Amazon Quick Sight analysis](#).

To create a dashboard from your analysis

1. In your analysis, choose **Publish**, then choose **Publish dashboard**.
2. Choose **Publish as a new dashboard** or **Replace existing dashboard**.
3. For a new dashboard, enter **Marketing Dashboard** in **Dashboard name**. Optionally, add notes.
4. Under **Select sheets**, choose **All sheets** or **Specific sheets**.
5. Configure the following options as needed:
 - **Dashboard options - Enable Quick Actions** to allow dashboard users to take actions in connected services from visuals and alerts.
 - **Generative capabilities - Allow executive summary** to leverage generative capabilities to build precise summary for each sheet of the dashboard.
 - **Allow Data Q&A** to enable generative Q&A for this dashboard. This setting enables Amazon Q in QuickSight.
 - **Allow sharing data stories** to allow viewers of this dashboard to share data stories, that include snapshots of the dashboards visuals, with other users.
 - **Data snapshot options - Allow sharing scenarios** to allow viewers of this dashboard to share scenarios, that include snapshots of the dashboard's visuals, with other users.
6. Choose **Publish**.

The dashboard is now published.

7. On the **Share dashboard** page that opens, choose the **X** icon to close it. You can share the dashboard later by using the sharing option on the dashboard page.

Sample data

To get a first look at how Amazon Quick Sight works, you can explore Amazon Quick Sight using the following sample data:

- [B2b sales data](#)

- [Business overview data](#) (revenue)
- [ML insights data](#)
- [People overview data](#) (human resources)
- [Sales pipeline data](#)
- [Web and social media analytics data](#) (marketing)

Also, a variety of datasets are available free online that you can use with Amazon Quick Sight, for example the [AWS public datasets](#). These datasets come in a variety of formats.

Administering Amazon Quick

The administration experience for Amazon Quick depends on how your account was created. Choose the guide that matches your account type:

- **Free, Plus, and Max accounts** – For accounts created with email or social on aws.com/quick. See [the section called “Free, Plus, and Max accounts”](#).
- **Enterprise accounts** – For accounts provisioned through the AWS Management Console or AWS CLI. These accounts provide governance controls and the full range of enterprise capabilities, including connections to additional enterprise applications, data sources, and knowledge bases. Access is managed through IAM permissions, and customers can connect to Amazon Quick using their enterprise SSO and identity provider. See [the section called “Enterprise accounts”](#).

Administering Amazon Quick (Free/Plus/Max)

This section covers administration for Amazon Quick Free, Plus, and Max accounts that you create at aws.com/quick. Free, Plus, and Max accounts use email or social login for authentication and don't require an AWS account. You can manage users, assets, billing, and account settings directly from the Amazon Quick web interface.

Topics

- [Amazon Quick plans and pricing](#)

Amazon Quick plans and pricing

Amazon Quick accounts created at aws.com/quick are available in three plans: **Free**, **Plus**, and **Max**. New accounts receive 30 days of Plus at no cost. For current pricing details, plan limits, and feature comparisons, see [Amazon Quick pricing](#).

Note

This page covers pricing for Amazon Quick Free, Plus, and Max accounts created at aws.com/quick. For pricing information about Amazon Quick accessed through the AWS Management Console, see [Amazon Quick pricing](#).

Topics

- [Compare plans](#)
- [Viewing your current plan](#)

Compare plans

Amazon Quick has two account types: accounts created at aws.com/quick (available in the Free, Plus, and Max plans), and Enterprise accounts provisioned through the AWS Management Console, AWS Command Line Interface, or the Amazon Quick API. Most features, including chat with AI agents, spaces, Amazon Quick Flows, Amazon Quick Research, Apps in Amazon Quick, extensions, and integrations, are available to both account types.

Some features are available only to Enterprise accounts. These include Amazon Quick Sight dashboards and analytics, Amazon Quick Automate, and API access.

For a detailed comparison of features, limits, and pricing across all plans, see [Amazon Quick pricing](#).

Viewing your current plan

To view your current plan:

1. In the Amazon Quick navigation bar, choose your username.
2. Choose **Manage account**.
3. In the left navigation, choose **Plan and billing**.

The **Plan & Billing** page displays your current plan name, estimated charges, days remaining (for trial plans), and payment method (for paid plans).

Alternatively, you can choose **Upgrade plan** from the profile menu, which takes you directly to the plan management page.

Upgrading your Amazon Quick plan

You can upgrade your Amazon Quick plan to the Plus or Max plan at any time. This page walks you through the full upgrade process, including entering contact information, verifying your phone number, and adding a payment method.

Note

This page applies to Amazon Quick accounts created with email or social at aws.com/quick. For information about subscription management for Amazon Quick accessed through the AWS Management Console, see [Administering Amazon Quick](#).

Topics

- [Accessing plan management](#)
- [Step-by-step upgrade procedure](#)
- [How upgrade billing works](#)
- [Downgrading your plan](#)

Accessing plan management

You can access the plan management page in two ways.

Option 1: Through the profile menu

1. In the Amazon Quick navigation bar, choose your username.
2. Choose **Upgrade plan**. The plan management page opens in a new browser tab.

Option 2: Through Manage Account

1. In the Amazon Quick navigation bar, choose your username.
2. Choose **Manage account**.

3. In the left navigation of the Manage Account page, choose **Plan and billing**.
4. On the Plan & Billing page, choose **Manage plan**.

Step-by-step upgrade procedure

To upgrade to the Plus or Max plan

1. **Review available plans.**

On the **Manage plan** page, you see the available plans.

Your current plan is indicated with a "Current plan" badge and the number of days remaining (for trial plans).

To see a detailed feature comparison, expand the **Compare plans** section at the bottom of the page.

2. **Select your new plan.**

Under the plan you want to upgrade to, choose **Choose plan**. A **Continue** button appears at the bottom of the page.

Choose **Continue** to proceed.

3. **Enter your contact information.**

You are redirected to a contact information form.

Choose **Continue** after completing all required fields.

4. **Verify your phone number.**

Amazon Quick needs to verify your phone number for security purposes.

Note

If you don't receive the code, choose **Resend code** after the countdown timer completes. Make sure your phone can receive SMS messages from short codes.

- a. On the **Verify your phone number** page, confirm that the displayed phone number is correct. If not, choose **Edit** to change it.

- b. Choose **Send text message**. Amazon Quick sends a 4-digit verification code to your phone via SMS.
 - c. Enter the 4-digit verification code in the **Verification code** field.
 - d. Choose **Continue**.
5. **Enter payment information.**

 Note

You might be redirected to your bank's website to authorize a verification charge. This is a temporary hold and is not an actual charge.

6. **Complete the upgrade.**

After entering your payment information, choose **Upgrade plan**.

Amazon Quick processes your payment method and activates your new plan. You are redirected to the **Plan & Billing** page.

Your upgrade takes effect immediately. All team collaboration features are now available.

How upgrade billing works

When you upgrade your plan, the change takes effect immediately.

 Note

The prices in the following examples are for illustration only. For current rates, see [Amazon Quick plans and pricing](#).

Monthly plan upgrades

- You receive a full credit for your current plan's monthly charge.
- You are then billed the full rate of your new plan for the entire month.
- You receive the full usage allocation of your new plan (agent hours and storage) right away for the entire billing cycle – not prorated for the remaining days.

Example: In this example, assume the Plus plan costs USD \$25 per user per month, and you have 3 users (USD \$75 per month). On August 16, you upgrade. You receive a USD \$75 credit for the Plus charge, and are billed the full rate of your new plan for the entire month. Your usage allocation resets to the new plan's limits immediately.

First-month exception

If you upgrade during your first billing month, both the credit and the new charge are prorated. The proration is based on the days remaining in the month. Starting the following month, the standard full-credit/full-charge model applies.

Example: In this example, assume you subscribe to Plus on July 15, with a prorated charge of approximately USD \$13.71 for 17 remaining days. On July 22, you upgrade. Your credit is USD \$13.71 (the prorated Plus charge), and your new charge is prorated for the same 17-day period. Starting August 1, you are billed the full monthly rate.

Annual plan upgrades

If you are on an annual plan and upgrade mid-term:

- You receive a credit for the unused portion of your annual subscription (the time remaining on your current plan).
- You are charged the new plan's annual rate for the remaining term.
- The time already used on your previous plan is not adjusted.
- You receive the full usage allocation of your new plan immediately.

Example: In this example, assume you are on the annual Plus plan at USD \$240 per year. On day 120 of your term (245 days remaining), you upgrade to a higher annual plan. You receive a credit of approximately USD \$161.10 ($245/365$ of USD \$240) for unused Plus time. You are charged the new plan's annual rate prorated for the remaining 245 days. Your usage allocation increases immediately.

Upgrading from the free trial

- When you upgrade from the Free plan to a paid plan during your free trial, you immediately gain access to the full features and usage allocation of the paid plan.
- Your free trial ends at the point of upgrade and cannot be resumed or restarted.
- Your first charge is prorated for the remaining days in the month. Your next full billing cycle starts on the 1st of the following month.

Example: In this example, assume the Plus plan costs USD \$25 per user per month. You start a free trial on July 1. On July 5, you upgrade to Plus. You are charged approximately USD \$21.77 (USD \$25 multiplied by 27 of 31 days remaining in July). You immediately receive the full Plus allocation. Your free trial cannot be reactivated. Starting August 1, you are billed the full monthly rate.

Downgrading your plan

How to downgrade

To downgrade from Plus or Max to Free:

1. Navigate to **Plan and billing** → **Manage plan**.
2. Under **Free**, choose **Choose plan**.
3. Follow the confirmation prompts.

How downgrade billing works

- Downgrades take effect at the **start of your next billing cycle**, not immediately.
- You continue to have access to your current plan's features and usage allocation through the end of your current billing cycle.
- No refund is issued for the current billing period.
- Starting the next billing cycle, you are billed at the lower plan's rate.

Example: You are on the Plus plan with a billing cycle of August 1–31. On August 10, you request a downgrade to Free. You keep Plus-level access through August 31. Starting September 1, your account reverts to the Free plan.

Annual plan downgrades

- If you are on an annual plan, downgrades take effect at the **end of your annual term**.
- Annual subscriptions cannot be canceled mid-term. There is no refund for the remaining period.

Important

Downgrading to the Free plan reduces your account to a single user and removes access to team collaboration features. All data and configurations are preserved, but only the account owner retains access.

Managing a Amazon Quick Free or Plus account

Amazon Quick Free and Plus accounts – created through the direct signup process at aws.com/quick – include a built-in administration interface for managing your account, users, assets, billing, and support. This interface is accessible directly within the Amazon Quick web application, without requiring access to the AWS Management Console.

Note

This section applies to Amazon Quick Free and Plus accounts only. If your organization accesses Amazon Quick through the AWS Management Console, see [Administering Amazon Quick](#) for information about managing your account using IAM, IAM Identity Center, and other AWS services.

Topics

- [Account administration overview](#)
- [Accessing the Manage Account page](#)
- [Manage Account page layout](#)
- [Free and Plus vs. AWS Console administration](#)

Account administration overview

When you create a Amazon Quick Free or Plus account at aws.com/quick, the person who completes the signup process is automatically assigned the **administrator** role. As the account administrator, you have full access to all account management capabilities, including user management, asset oversight, plan and billing configuration, and support resources.

Free and Plus account administration is organized into the following sections:

Section	Description
Users	Invite team members, manage active users, view usage statistics, and manage pending invitations. For more information, see Managing users in a Amazon Quick Free or Plus account .
Assets	View and manage all account resources including chat agents, spaces, automations, and built-in tools. For more information, see Managing assets in a Amazon Quick Free or Plus account .
Plan and billing	View your current plan, estimated charges, payment methods, and billing history. Upgrade or change your plan. For more information, see Plan and billing for Amazon Quick Free and Plus accounts .
Support	Access AWS Support resources for help with your Amazon Quick account.

Accessing the Manage Account page

To access account administration

1. Sign in to Amazon Quick at aws.com/quick.
2. From the navigation panel, choose your username (displayed with your initials and name).
3. From the profile menu, choose **Manage account**.

The Manage Account page opens, displaying an overview dashboard with a summary of your account sections.

Manage Account page layout

The Manage Account page uses a left-side navigation panel with the following sections:

- **Manage account** – The overview dashboard. Displays a summary card for each section, including a user count and a **Manage** link that navigates directly to the Users page.
- **Users** – Manage active users and pending invitations. See [Managing users](#).
- **Assets** – View and manage account resources. See [Managing assets](#).

- **Plan and billing** – Opens the plan and billing settings page in a new browser tab. See [Plan and billing](#).
- **Support** – Opens the AWS Support portal in a new browser tab for submitting support requests.

Free and Plus vs. AWS Console administration

The following table summarizes the key differences between Free and Plus account administration and AWS Console–based administration.

Feature	Free or Plus account (aws.com/quick)	AWS Console account
Identity provider	Email or social login	IAM Identity Center, IAM, or federated identity
Admin interface	Built-in Quick web UI (Manage Account page)	AWS Management Console
User management	Email-based invitations	IAM Identity Center groups, IAM users
Billing	Billing portal (account.global.app.aws)	AWS Billing and Cost Management console
Plans	Free, Plus	Standard AWS subscription pricing
Account creation	Automatic (AWS account created behind the scenes)	Manual AWS account setup required

Note

Regardless of how your Amazon Quick account was created, all product features – including chat, chat agents, spaces, research, automations, Amazon Quick Sight, integrations, and extensions – function identically. The differences are limited to account setup, identity management, and billing.

Managing users in a Amazon Quick Free or Plus account

In a Amazon Quick Free or Plus account, the account administrator can invite team members by email, monitor user activity, and manage pending invitations. User management is handled directly within the Amazon Quick web application through the Manage Account page.

Note

This section applies to Amazon Quick Free and Plus accounts created at aws.com/quick. For information about managing users in AWS Console–based accounts, see [Managing user access inside Amazon Quick](#).

Topics

- [User limits by plan](#)
- [Navigating to user management](#)
- [Managing active users](#)
- [Inviting new users](#)
- [Managing invited users](#)

User limits by plan

The number of users you can have in your account depends on your plan. For specific user limits for each plan, see [Amazon Quick pricing](#).

For more information about plans, see [Amazon Quick plans and pricing](#).

Navigating to user management

To access the Users page

1. Sign in to Amazon Quick at aws.com/quick.
2. From the navigation panel, choose your username.
3. Choose **Manage account**.
4. In the left navigation, choose **Users**.

The Users page displays two tabs: **Active** and **Invited**.

Managing active users

The **Active** tab displays all users who have accepted their invitation and are currently active in your Amazon Quick account.

Topics

- [Active users table](#)
- [Viewing user usage](#)

Active users table

The Active users table includes the following columns:

- **Name** – The user's display name, as set in their AWS Builder ID profile.
- **Email** – The email address associated with the user's AWS Builder ID.

You can sort the table by either column by choosing the column header. Use the **Search users** field to filter the list by name or email.

Viewing user usage

You can view usage statistics for any active user.

To view a user's usage

1. On the **Active** tab, locate the user in the table.
2. In the row for that user, choose the **More options** menu.
3. Choose **See usage**.

A dialog opens displaying the user's usage statistics.

4. Review the usage information. When finished, choose **Close** to dismiss the dialog.

Inviting new users

You can invite team members to join your Amazon Quick account by sending them an email invitation. Invited users receive an email with instructions to create an AWS Builder ID (if they don't already have one) and join your Quick account.

Note

You can only invite users up to the maximum allowed by your plan. If you need to invite more users than your plan allows, consider [upgrading your plan](#).

To invite new users

1. On the Users page, choose **Invite**.

The Invite dialog opens.

2. In the **Enter email addresses** field, type the email address of the person you want to invite.
3. Press **Enter**. The email address appears as a chip (bubble) in the field, confirming it has been accepted.
4. (Optional) Repeat the previous steps to add additional email addresses. You can also enter multiple email addresses separated by commas.
5. Choose **Send invitations**.

Amazon Quick sends an invitation email to each address. The invitations appear in the **Invited** tab.

Tip

You can invite multiple users at once by entering several email addresses before choosing **Send invitations**. Each email address must be confirmed as a chip in the field before sending.

Managing invited users

The **Invited** tab displays all pending invitations that have not yet been accepted.

Topics

- [Invited users table](#)
- [Resending or canceling invitations](#)

Invited users table

The Invited users table includes the following columns:

- **Email** – The email address the invitation was sent to.
- **Invitation Status** – The current status of the invitation (for example, *Pending*).

You can sort the table by either column. Use the **Search invitations** field to filter the list.

Resending or canceling invitations

You can resend an invitation if the original email was not received, or cancel an invitation to revoke access before it is accepted.

To resend an invitation

1. On the **Invited** tab, locate the invitation in the table.
2. In the row for that invitation, choose the **More options** menu.
3. Choose **Resend**.

Amazon Quick sends a new invitation email to the address.

To cancel an invitation

1. On the **Invited** tab, locate the invitation in the table.
2. In the row for that invitation, choose the **More options** menu.
3. Choose **Cancel**.

The invitation is revoked. The recipient will no longer be able to use the invitation link to join your account.

Important

Canceling an invitation does not affect users who have already accepted and are active in your account. To remove an active user, use the options available on the **Active** tab.

Managing assets in a Amazon Quick Free or Plus account

In a Amazon Quick Free or Plus account, assets represent the resources created and used within your account – including chat agents, spaces, automations, and other AI-powered tools. The Assets page in the Manage Account interface lets administrators view, search, filter, and manage all assets across the account.

Note

This section applies to Amazon Quick Free and Plus accounts created at aws.com/quick. For information about managing resources in AWS Console–based accounts, see [Administering Amazon Quick](#).

Topics

- [Navigating to asset management](#)
- [Viewing assets by name](#)
- [Viewing assets by user](#)
- [Using bulk actions](#)
- [Built-in assets](#)
- [Managing individual assets](#)

Navigating to asset management

To access the Assets page

1. Sign in to Amazon Quick at aws.com/quick.
2. From the navigation panel, choose your username.
3. Choose **Manage account**.
4. In the left navigation, choose **Assets**.

The Assets page opens, displaying all resources in your account.

Viewing assets by name

The default view on the Assets page is **By asset name**, which lists all assets in a single table.

Topics

- [Assets table columns](#)
- [Sorting and searching](#)

Assets table columns

- **Name** – The display name of the asset (for example, *My Assistant* or *RFP Response Generator*).
- **Type** – The asset type (for example, *Chat agent*, *Space*, or *Automation*).

Each row includes:

- A **checkbox** for selecting the asset (used with bulk actions).
- A **More options** menu for asset-specific actions.

Sorting and searching

- Choose a column header to sort the table by that column.
- Use the **Search by asset name** field to filter the list by asset name.
- Use the **All types** dropdown to filter by a specific asset type.

Viewing assets by user

Choose the **By user** tab to view assets grouped by the user who created them.

In this view:

- Use the **Search by user name** combobox to find a specific user and view their assets.
- Use the **All types** dropdown to filter results by asset type.

This view is useful for understanding how assets are distributed across team members and for auditing resource ownership.

Using bulk actions

You can perform actions on multiple assets at once using the bulk action feature.

To use bulk actions

1. On the Assets page, select the checkboxes next to the assets you want to act on. To select all assets, choose the **Select all** checkbox in the table header.

After selecting one or more assets, the **Bulk action** button becomes active.

2. Choose **Bulk action** and select the desired action from the dropdown menu.

Note

The **Bulk action** button is disabled until at least one asset is selected.

Built-in assets

Every new Amazon Quick account includes a set of built-in assets that provide ready-to-use AI-powered tools for common business tasks. These assets are available immediately after account creation and do not count against any resource limits.

Asset name	Description
My Assistant	The default chat agent for your account. Provides general-purpose AI assistance for questions, analysis, and document creation.
Whiteboard Notes Generator	Generates structured notes from whiteboard images or meeting discussions.
Flows Idea Generator	Suggests automation workflow ideas based on your described business processes.
5-Why Root Cause Analysis	Guides you through a structured root cause analysis using the 5-Why methodology.
Marketing Video Analyzer	Analyzes marketing video content and provides insights on messaging, audience, and effectiveness.

Asset name	Description
Social Media Content Creator	Creates social media posts, captions, and content plans tailored to your brand and goals.
Job Description Generator	Drafts professional job descriptions based on role requirements and company context.
Product Launch Email Generator	Creates email campaigns for product launches, including subject lines and body content.
Customer Interest Optimizer	Analyzes customer data to identify interest patterns and suggest optimization strategies.
Flows Prompt Helper	Assists with writing effective prompts for Amazon Quick automations and flows.
RFP Response Generator	Drafts responses to Requests for Proposal (RFPs) based on your organization's capabilities and the RFP requirements.

 Tip

Built-in assets serve as starting points. You can customize these assets or create new ones tailored to your organization's specific needs. For more information about creating custom chat agents, see [Create and deploy AI assistants using Amazon Quick chat agents](#).

Managing individual assets

To manage a specific asset, choose the **More options** menu in the asset's row. The available actions depend on the asset type and may include options such as viewing details, editing, sharing, or deleting the asset.

Plan and billing for Amazon Quick Free, Plus, and Max accounts

This topic describes how to view and manage your plan and billing information for Amazon Quick Free, Plus, and Max accounts created at aws.com/quick.

 Note

This section applies to Amazon Quick Free, Plus, and Max accounts. If your organization manages Amazon Quick through the AWS Management Console, billing is handled through your AWS account. For more information, see [AWS Billing and Cost Management](#).

Topics

- [Accessing Plan & Billing](#)
- [Viewing your current plan](#)
- [Billing history](#)
- [Billing preferences](#)
- [How collaborator billing works](#)
- [Annual subscription terms](#)
- [Billing cycle and proration](#)
- [Changing your plan](#)

Accessing Plan & Billing

The Plan & Billing page is located in the Amazon Quick account settings portal.

To access Plan & Billing

1. In Amazon Quick, from the navigation bar, choose your username.
2. Choose **Manage account**.
3. In the left navigation of the Manage Account page, choose **Plan and billing**.

The Plan & Billing settings page opens in a new browser tab at `account.global.app.aws`.

The settings page has its own navigation panel with the following sections:

- **Plan & Billing** – View your current plan, estimated charges, and billing history.
- **My account** – View your account profile and account details. For more information, see [Account settings for Amazon Quick Free and Plus accounts](#).
- **Support** – Access AWS Support (opens externally).

Viewing your current plan

The Plan & Billing page displays the following information about your current subscription:

- **Current plan** – The name and type of your active plan. For example, **FREE**, **PLUS**, or **MAX**.
- **Manage plan** – Choose this button to view available plans and change your subscription. For more information, see [Upgrading your Amazon Quick plan](#).
- **Current estimated charges** – The estimated cost for your current billing period, displayed in USD.
- **Days remaining** – For trial plans, the number of days remaining in the trial period along with the expiration date.
- **Payment method** – The card type and last four digits of the payment method on file. A **Change** link is available to update your payment method.
- **Estimated charges breakdown** – An expandable section that provides a detailed breakdown of the charges for the current billing period.

Billing history

The **Billing history** section displays a table of past billing records with the following columns:

Column	Description
ID	A unique identifier for the billing record.
Type	The type of charge (for example, subscription).
Status	The payment status (for example, paid, pending).
Due date	The date the payment is due.
Payment method	The payment method used for the charge.
Amount	The total amount charged.
Charge type	The category of the charge.
Action	Available actions for the billing record, such as downloading an invoice.

 Note

New accounts will not have any billing records until the first billing cycle completes. The table displays "No billing records to display" until charges are processed.

Billing preferences

Choose the **Preferences** button on the Plan & Billing page to configure your billing notification preferences.

How collaborator billing works

When you add a collaborator to your Amazon Quick Plus or Max account, billing for their seat begins when the collaborator **accepts the invitation** – not when the invitation is sent.

When billing starts

- You incur no charges for a pending invitation. You are charged only for collaborators who accept.
- When a collaborator accepts, billing begins for their seat at a prorated rate for the remainder of your current billing cycle.
- The prorated charge appears on your next invoice. It is not charged to your payment method on the day the invitation is accepted.

Removing a collaborator

- Removing a collaborator does not result in a refund for the current billing period.
- The seat charge applies through the end of your current billing cycle, regardless of when the collaborator is removed.
- This applies even if the collaborator is removed shortly after accepting the invitation.

Canceling a pending invitation

- If a collaborator never accepts the invitation, your account incurs no charge for that seat.
- You can cancel a pending invitation at any time at no cost.

Annual subscription terms

When you commit to an annual plan, your subscription is billed for the full annual term.

- Annual subscriptions cannot be canceled mid-term.
- Cancellations and downgrades take effect at the end of your annual term. You receive no refund for the remaining period.
- Upgrades to a higher plan during your annual term apply a credit for the unused portion of your current annual subscription, and you are charged the new plan's annual rate for the remainder of your term.

Billing cycle and proration

Amazon Quick bills on a calendar-month basis.

- Your billing month starts at 12:00 AM (UTC) on the first day of the month and ends at 11:59 PM (UTC) on the last day.
- If you subscribe partway through a month, your first charge is prorated for the remaining days in that month. Your next full billing cycle starts on the 1st of the following month.
- If you upgrade mid-month, you are billed immediately for the full new plan rate minus a full credit for your previous plan's monthly charge. Overage charges, if applicable, appear as a separate line item at the end of the billing cycle.

Changing your plan

To upgrade, downgrade, or change your Amazon Quick plan, choose **Manage plan** on the Plan & Billing page. For detailed instructions on the upgrade process, including entering contact information and payment details, see [Upgrading your Amazon Quick plan](#).

For information about the available plans and their features, see [Amazon Quick plans and pricing](#).

Understanding usage on the Amazon Quick Plus and Max plans

Amazon Quick uses limits to keep your usage predictable and to spread heavy activity evenly across your billing month. Understanding how these limits work helps you avoid interruptions, decide when to enable more usage, and get the most from your plan.

 Note

This page applies to Amazon Quick Free, Plus, and Max accounts created with email or social login at aws.com/quick. It does not apply to Amazon Quick Professional or Enterprise plans managed through the AWS Management Console, which handle usage differently.

Topics

- [How usage limits work](#)
- [Usage does not roll over](#)
- [How to get more usage](#)
- [Best practices to conserve usage](#)

How usage limits work

Your usage is governed by two limits that work together: a monthly limit and a session limit.

- **Monthly limit** – The total amount of work you can do with Quick in a billing month. This limit resets at the start of each billing cycle.
- **Session limit** – A shorter, rolling window that limits activity in any single stretch. The session limit is a percentage of your monthly limit. It refreshes continuously as time passes, so you no longer need to wait until the next billing month. When you reach a session limit, Quick pauses your session briefly. It does not block you for the rest of the month.

 Note

Reaching a session limit is temporary. It clears on its own as the rolling window moves forward, so you can keep working after a short pause.

Quick measures your usage by the length and complexity of your work, the features you use, the model selected, and the thinking level. Heavier tasks use more; lighter tasks use less. Because usage depends on these factors, the same activity can consume different amounts on different days.

What to do when you hit a limit

Limit	Free plan	Plus and Max plans
Session limit	Wait for the session window to refresh, or upgrade to Plus or Max for more usage.	Wait for the session window to refresh, or enable additional usage to keep working.
Monthly limit	Upgrade to Plus or Max, or wait for the reset at the start of the next billing cycle.	Enable additional usage, or wait for the reset at the start of the next billing cycle.

Usage does not roll over

Your usage allocation resets at the start of each billing cycle. Unused usage from the previous cycle does not carry over, and no credit is issued for unused capacity. Make the most of your allocation each month.

How to get more usage

If you need more usage, you can enable additional usage and set a maximum monthly limit—a spend cap that you control.

- **You control the cost** – You only pay for what you actually use, up to the cap you set. The cap is a ceiling, not a charge.
- **What changes** – Once enabled, your monthly capacity expands up to your cap, and your session windows adjust accordingly, so you're less likely to be paused mid-task.

To enable additional usage

1. In Amazon Quick, from the navigation bar, choose your username, and then choose **Manage account**.
2. Enable additional usage.
3. Set your maximum monthly limit (spend cap).

How additional usage billing works

- Additional usage is **off by default**. You must manually enable it in your account settings.
- When you enable additional usage, you are required to set a **maximum monthly limit** (spending cap). This prevents unexpected charges.
- When additional usage is enabled and your cap has not been reached, your work continues uninterrupted beyond your plan's included allocation.
- Additional usage is billed at the end of your billing cycle as a separate line item on your invoice.
- **When your spending cap is reached:** Usage pauses until your next billing cycle resets your allocation. You can also raise your cap or upgrade your plan to continue.

What happens when you upgrade with additional usage charges

If you have accumulated additional usage charges and then upgrade to a higher plan mid-cycle, your usage is **recalculated against the new plan's higher allocation**.

- The higher plan includes more capacity. If your total usage for the month now falls within the new plan's included allocation, your additional usage charges are reduced or eliminated.
- You are only billed for usage that exceeds the new plan's allocation.

Example: You are on the Plus plan and have used more than your plan's included allocation this month, so you have additional usage charges pending. You upgrade to a higher plan with a larger included allocation. Your month-to-date usage now falls within the new plan's allocation, so your additional usage charges are eliminated.

Tip

If your additional usage charges are approaching the price difference between your current plan and a higher plan, upgrading might lower your total bill and increase your included allocation.

Additional usage and downgrades

- If you downgrade your plan, your current allocation remains in effect through the end of your billing cycle.

- Downgrading does not recalculate your additional usage charges for the current cycle.
- Your new, lower allocation takes effect at the start of your next billing cycle.

Best practices to conserve usage

Use the following practices to make your usage go further before you need to enable additional usage:

- **Start fresh for new tasks** – Start a new chat for a new topic. Long, growing conversations carry their whole history with each turn and consume more usage. A fresh chat is lighter.
- **Match the thinking level to the task** – Use a lower thinking level for routine tasks, and reserve the highest thinking level for genuinely complex work. Higher thinking levels consume more usage.
- **Be concise and specific** – Clear, scoped prompts avoid long back-and-forth and re-work, which saves usage.

Account settings for Amazon Quick Free and Plus accounts

This topic describes how to view and manage account-level settings for Amazon Quick Free and Plus accounts created at aws.com/quick. Account settings include your profile information, account details, and support access.

Note

This section applies to Amazon Quick Free and Plus accounts. If your organization manages Amazon Quick through the AWS Management Console, account settings are managed through your AWS account and IAM Identity Center. For more information, see [Administering Amazon Quick](#).

Topics

- [Accessing account settings](#)
- [My account](#)
- [Support](#)

Accessing account settings

The account settings are located in the Amazon Quick account settings portal, alongside Plan & Billing.

To access account settings

1. In Amazon Quick, from the navigation bar, choose your username.
2. Choose **Manage account**.
3. In the left navigation of the Manage Account page, choose **Plan and billing**.

The settings portal opens in a new browser tab at `account.global.app.aws`.

4. In the left navigation of the settings portal, choose **My account**.

My account

The My account page displays your profile information and account details.

Topics

- [Profile & security](#)
- [Account details](#)
- [Account closure and reopening](#)

Profile & security

The Profile & security section displays the following information:

- **Name** – Your display name. This is the name associated with your AWS Builder ID.
- **Email** – Your email address. This is the email associated with your AWS Builder ID.
- **Manage profile & security** – Choose this link to open the AWS Builder ID profile management page in a new browser tab. From there, you can update your name, nickname, email, password, multi-factor authentication settings, and privacy preferences.

Note

Your name and email address in Amazon Quick are managed through your AWS Builder ID. To change these details, choose **Manage profile & security** to open the Builder ID profile

page, or choose **Edit profile** from the Amazon Quick profile menu. For more information, see [User profile and preferences in Amazon Quick](#).

Account details

The Account details section displays the following information:

- **Account ID** – A unique numeric identifier for your Amazon Quick account. You may need this ID when contacting AWS Support.
- **Copy Account ID** – Choose this button to copy your Account ID to the clipboard.
- **Close account** – Choose this button to close your Amazon Quick account. For more information, see [Account closure and reopening](#).

Account closure and reopening

You can close your Amazon Quick account at any time. After closure, you have 90 days to reopen it before it is permanently closed and AWS deletes your content.

To close your account

- Go to **Manage account** → **Plan & Billing** → **My account** → **Close account**.

To reopen your account, contact AWS Support within the 90-day post-closure period.

Before closing, note the following:

- All content and resources are permanently deleted after the 90-day post-closure period, including chat history, agents, spaces, automations, and uploaded files.
- All users lose access immediately.
- You remain responsible for outstanding charges and will receive a final bill the following month.

Support

To access AWS Support for Amazon Quick:

- In the left navigation of the settings portal, choose **Support**.

The AWS Support portal opens in a new browser tab at `support.aws.amazon.com`.

From the AWS Support portal, you can:

- Create a new support case for Amazon Quick.
- View the status of existing support cases.
- Access self-service troubleshooting resources.

 Tip

You can also access support resources from within Amazon Quick by choosing your username, then choosing **Help** in the profile menu. The Help submenu includes links to Getting Started guides, Quick Documentation, the Quick Community forum, and How to Videos.

User profile and preferences in Amazon Quick

This topic describes how to access and configure your personal profile settings, preferences, and related options in Amazon Quick. These settings apply to your individual user experience and are separate from account-level administration settings.

Topics

- [Accessing the profile menu](#)
- [Edit profile](#)
- [Preferences](#)
- [Help](#)
- [Quick anywhere](#)
- [Private Mode](#)

Accessing the profile menu

To access the profile menu, from the Amazon Quick navigation bar, choose your name or avatar. The profile menu displays your name, email address, and current plan information.

The profile menu contains the following options:

Menu option	Description
Upgrade plan	Opens the plan management page in a new browser tab where you can change your subscription tier.
Manage account	Opens the Manage Account page within Amazon Quick. Available to account owners and administrators. For more information, see Managing a Amazon Quick Free or Plus account .
Switch accounts	Allows you to switch between multiple Amazon Quick accounts if you are a member of more than one.
Edit profile	Opens the AWS Builder ID profile management page in a new browser tab.
Preferences	Opens the Preferences dialog where you can configure personalization, chat, and language settings.
Help	Expands a submenu with links to help resources.
Quick anywhere	Expands a submenu with options for accessing Quick on other platforms.
Sign out	Signs you out of your Amazon Quick account.

Edit profile

When you choose **Edit profile** from the profile menu, the AWS Builder ID profile management page opens in a new browser tab. Your AWS Builder ID is the identity you use to sign in to your Amazon Quick Free or Plus account. From this page, you can manage your personal information, security settings, and privacy preferences.

Topics

- [My details](#)
- [Security](#)
- [Privacy & data](#)

My details

The My details tab displays and allows you to edit your personal information.

- **Name** – Your full name. Choose **Edit** to update.
- **Nickname** – An optional display name. Choose **Edit** to update.
- **Email address** – The email address associated with your AWS Builder ID. Choose **Edit** to change your email address. A verification step is required for email changes.

Security

The Security tab provides options for managing your account security.

- **Change password** – Choose this button to update your AWS Builder ID password.
- **Multi-factor authentication (MFA)** – Manage MFA devices for additional sign-in security. The MFA devices table displays the following columns: Name, Type, Make and Model, and Registered Date.
 - **Register device** – Add a new MFA device (authenticator app or security key).
 - **Rename** – Change the display name of a registered MFA device.
 - **Delete** – Remove a registered MFA device.
- **Active sessions** – View all currently active sign-in sessions.
 - The sessions table displays the following columns: Device, IP address, and Sign-in date.
 - **Delete all active sessions** – Choose this button to immediately terminate all active sessions. You will be signed out of all devices.

Privacy & data

The Privacy & data tab provides options for managing your data and privacy.

- **AWS Privacy Notice** – A link to the AWS Privacy Notice for information about how AWS handles your data.
- **Request your Builder ID data** – Choose this button to request a copy of the data associated with your AWS Builder ID.
- **Request your AWS data** – A link to request a copy of all your AWS data through the AWS Data Subject Access Request process.
- **Delete AWS Builder ID** – Choose this button to permanently delete your AWS Builder ID.

Warning

Deleting your AWS Builder ID is permanent and cannot be undone. You will lose access to all AWS services and applications that use your Builder ID for authentication, including Amazon Quick.

Preferences

When you choose **Preferences** from the profile menu, a dialog opens with three tabs for configuring your personal Amazon Quick experience. Choose **Save** to apply changes or **Cancel** to discard them.

Topics

- [Personalization](#)
- [Chat](#)
- [Language and time](#)

Personalization

The Personalization tab allows you to customize how Amazon Quick tailors its responses to your needs.

- **Your current work focus** – A text field where you can describe what you are currently working on (for example, "Q3 financial planning" or "Product launch preparation"). Amazon Quick uses this context to provide more relevant suggestions and responses.
- **Manage memories** – Choose this button to view and manage the information that Amazon Quick has learned about you through your conversations. You can review, edit, or delete individual memories.

Chat

The Chat tab allows you to configure default behaviors for the Amazon Quick chat experience.

- **Assistant data access** – A toggle that controls whether My Assistant can access all your connected data sources by default. When enabled, My Assistant can query your connected

data, documents, and integrations without you needing to specify the data source for each conversation. You can override this setting on a per-conversation basis.

- **Choose default data** – A dropdown selector that sets the default data scope for new conversations. You can override the default data scope within any individual conversation by using the data source selector in the chat footer. Options include:
 - **All data** – My Assistant can access all connected data sources and applications.
 - Other options may appear based on your connected integrations and data sources.

Language and time

The Language and time tab allows you to configure regional and display preferences.

- **Timezone** – Choose your preferred timezone from the dropdown selector. This setting affects how dates and times are displayed throughout Amazon Quick.
- **Language** – Choose your preferred display language from the dropdown selector. This setting controls the language of the Amazon Quick user interface.
- **Use browser time zone** – Select this checkbox to automatically use your web browser's detected timezone instead of the manually selected timezone above. When enabled, the timezone selector is overridden by your browser setting.

Help

When you choose **Help** from the profile menu, a submenu expands with the following resources:

Resource	Description
Getting Started	Opens an interactive guide that walks you through the key features of Amazon Quick.
Quick Documentation	Opens the official Amazon Quick documentation at docs.aws.amazon.com.
Ask the Quick Community	Opens the Amazon Quick community forum where you can ask questions and share knowledge with other users.
How to Videos	Opens a collection of tutorial videos demonstrating Amazon Quick features and workflows.

Quick anywhere

When you choose **Quick anywhere** from the profile menu, a submenu expands with options for accessing Amazon Quick on other platforms:

Platform	Description
Desktop	Download the Amazon Quick desktop application for macOS or Windows. The desktop app provides a native experience with system-level integrations.
Mobile	Access Amazon Quick on your mobile device.
Browser extensions	Install browser extensions that integrate Amazon Quick directly into your web browsing experience.

Private Mode

Amazon Quick includes a **Private Mode** toggle, accessible from the top area of the navigation bar. When Private Mode is enabled:

- Your conversations are not saved to your chat history.
- Amazon Quick does not learn from or retain information from private conversations.
- Private conversations do not appear in the Recents section of the navigation.

To enable or disable Private Mode, choose the **Private Mode** button in the navigation bar.

Administration for Amazon Quick

As an administrator, you decide who can access your Amazon Quick account and what those users can do in it. You also configure the security and encryption settings that protect your data. You do this work in the Amazon Quick administration console. Some sections require AWS Identity and Access Management (IAM) permissions, and you can perform some tasks programmatically with the Amazon Quick API.

If you created your account with email or social on aws.com/quick, see [Administering Amazon Quick \(Free/Plus/Max\)](#) instead.

Use this section to do the following:

- Set up identity and access, including IAM Identity Center, IAM federation, Active Directory, external identity providers, and multi-factor authentication.
- Manage users, groups, and subscriptions.
- Provision SPICE capacity and index capacity for unstructured data.
- Connect to your data through VPC connections and AWS data sources.
- Secure your account with domain allowlisting, namespaces, IP and VPC restrictions, and AWS Key Management Service customer managed keys.
- Control permissions with default access settings, custom permissions, IAM policy assignments, and limit profiles.
- Govern usage with approval workflows and data loss prevention.
- Customize branding and agent settings, and monitor usage metrics.

Getting started with Amazon Quick

This chapter provides you an overview of the key Amazon Quick concepts you need to understand before you dive in and start using Quick.

Topics

- [Amazon Quick user types](#)
- [Plan your Quick account structure and AWS Regions](#)
- [AWS Regions, websites, IP address ranges, and endpoints](#)
- [Supported browsers](#)

Amazon Quick user types

Amazon Quick has three distinct user personas based on permission levels and use cases: administrator, author, and reader. Within these personas, there are six specific user roles that can be assigned, including Pro versions that provide access to advanced Amazon Quick capabilities. The following sections describe the role and task boundaries of each type.

Topics

- [Understanding Amazon Quick subscriptions and roles](#)
- [Understanding reader capabilities](#)
- [Understanding author capabilities](#)
- [Understanding admin capabilities](#)

Understanding Amazon Quick subscriptions and roles

The new capabilities for Amazon Quick are available via the following monthly user subscriptions:

- **Amazon Quick Professional** (or Amazon Quick Sight Reader Pro role)
- **Amazon Quick Enterprise** (or Amazon Quick Sight Author Pro role)

To manage Amazon Quick users, billing and services, you need the Admin Pro role, which is the same as Amazon Quick Enterprise user subscription.

Amazon Quick also provides the following monthly user subscriptions to support business only (BI) only use cases:

- **Amazon Quick Sight Reader** – For users who need to view and interact with dashboards and reports.
- **Amazon Quick Sight Author** – For users who need to create and manage BI content.

To manage Amazon Quick Sight users, billing and services, you need Admin role, which is the same as Amazon Quick Sight Author user subscription.

Note

For pricing information, see [Amazon Quick pricing](#)

Understanding reader capabilities

Readers can use Quick to access company data and find answers through chat interactions with AI agents. They can upload files, run automations, create visualizations, and share spaces via direct links. Reader Pro users additionally have access to advanced Amazon Quick features including AI chat agents, collaborative spaces, flows, and extensions. For detailed information about reader capabilities and subscription types, see [Amazon Quick pricing](#).

Understanding author capabilities

Authors are domain experts who build and manage Quick resources. In addition to reader capabilities, they can create datasets, dashboards, automations, and agents. They have expanded sharing permissions for spaces and can use AI to create visualizations. Author Pro users can additionally create content using natural language, build knowledge bases, configure actions, and access advanced automation capabilities. For detailed information about author capabilities and subscription types, see [Amazon Quick pricing](#).

Understanding admin capabilities

Administrators manage user access, monitor costs, and maintain data sources with full reader and author capabilities. There are two types of administrators: system administrators oversee the broader AWS environment including Amazon Quick signup, system health, and security; Amazon Quick administrators manage users and resources within Amazon Quick.

When your Amazon Quick account is integrated with IAM Identity Center, admin capabilities are divided between IAM permissions and Amazon Quick admin role permissions. Access to some sections of the Amazon Quick administration console is restricted by IAM permissions. The

following table summarizes the admin actions that you can perform in Amazon Quick based on the access type that you choose.

Admin action	IAM permissions	Amazon Quick admin role permissions
Manage assets	✔ Yes	✘ No
Security & permissions	✔ Yes	✘ No
Manage VPC connections	✔ Yes	✘ No
KMS keys	✔ Yes	✘ No
Account settings	✔ Yes	✘ No
Account customization	✘ No	✔ Yes
Manage users	✔ Yes (IAM Identity Center users)	✔ Yes (Amazon Quick and IAM users)
Your subscriptions	✘ No	✔ Yes
Mobile settings	✘ No	✔ Yes
Domains and embedding	✘ No	✔ Yes
SPICE capacity	✘ No	✔ Yes

Admin and Admin Pro users have full reader and author capabilities but focus primarily on system administration to ensure efficient and secure operations for all users. For detailed information about author capabilities and subscription types, see [Amazon Quick pricing](#).

Plan your Quick account structure and AWS Regions

This topic describes the recommended way to structure Amazon Quick for your organization, how a single account operates across AWS Regions, and the role of your home Region.

Topics

- [Recommended account structure](#)

- [How a single account works across AWS Regions](#)
- [Your home Region](#)

Recommended account structure

We recommend that you use a single Amazon Quick account for your organization. A single account gives you one place to connect all of your apps and data, one place to manage users, and one place to manage fine-grained permissions. This makes it easier to apply consistent governance, share assets, and audit access across your organization.

To keep teams, projects, or business units separate within a single account, use namespaces. Namespaces provide logical isolation of users and resources while you maintain centralized account management. For more information, see [Supporting multitenancy with isolated namespaces](#).

To keep Quick subscription creation centralized on your approved account, you can use service control policies in AWS Organizations. For more information, see [Using service control policies to restrict Amazon Quick sign-up options](#).

How a single account works across AWS Regions

Amazon Quick is available in multiple AWS Regions. A single Amazon Quick account spans all available Amazon Quick Regions. After you sign up, you can create and use assets in any available Amazon Quick Region, and those assets live in the Region where you create them. These assets include datasets, knowledge bases, agents, spaces, flows, and dashboards. Each AWS account can have one Amazon Quick subscription, and that subscription can be used in multiple AWS Regions.

Capacity is managed separately in each Region. SPICE capacity and Quick Index capacity are allocated per AWS Region, so you provision capacity in each Region where you work with data.

Your home Region

Your home Region is the AWS Region that you select when you set up your Amazon Quick subscription. It is also called your account's identity Region, the Region that anchors your Amazon Quick account identity and user sign-in. Your home Region must be a supported Amazon Quick Region.

Your home Region also sets your default capacity behavior. Amazon Quick automatically creates your index in your home Region with auto-scaling, and your Index capacity allocation is billed against your home Region. If you provision Index capacity in Regions beyond your home Region, that capacity is billed as overage.

For the list of supported Regions, and for how Amazon Q in Quick processes AI inference across Regions within your geography, see [AWS Regions, websites, IP address ranges, and endpoints](#) and [Cross-Region inference for Australia, Japan, Europe, and the United States](#).

AWS Regions, websites, IP address ranges, and endpoints

AWS cloud-computing resources are housed in highly available facilities in different areas of the world (for example, North America, Europe, and Asia). These facilities are each part of an AWS Region. For more information about AWS Regions and Availability Zones (AZs), see [Global infrastructure](#).

The IP addresses listed in the sections below are the ranges where Amazon Quick traffic originates from when making outbound connections to databases. They are not the IP address ranges that you use to connect to the Amazon Quick website or service API. For more information about authorizing Amazon Quick, [Authorizing connections to AWS data sources](#).

Topics

- [Supported AWS Regions for Amazon Quick](#)
- [Cross-Region calls for web search](#)
- [Cross-Region inference for Australia, Japan, Europe, and the United States](#)

Supported AWS Regions for Amazon Quick

Amazon Quick is currently supported in the following AWS Regions. The following list provides websites, IP address ranges, and endpoints for Amazon Quick in each AWS Region.

Region name	Region code	Agentic Features	Website for user access	API endpoints (HTTPS)	IP address range for data source connectivity
US East (Ohio)	us-east-2	No	https://us-east-2.quick sigh	quicksigh t.us-east	52.15.247 .160/27

Region name	Region code	Agentic Features	Website for user access	API endpoints (HTTPS)	IP address range for data source connectivity
			t.aws.amazon.com	-2.amazonaws.com	
US East (N. Virginia)	us-east-1	Yes	https://us-east-1.quicksight.aws.amazon.com	quicksight.us-east-1.amazonaws.com	52.23.63.224/27
US West (Oregon)	us-west-2	Yes	https://us-west-2.quicksight.aws.amazon.com	quicksight.us-west-2.amazonaws.com	54.70.204.128/27
Africa (Cape Town)	af-south-1	No	https://af-south-1.quicksight.aws.amazon.com	quicksight.af-south-1.amazonaws.com	13.246.220.192/27
Asia Pacific (Jakarta)	ap-southeast-3	No	https://ap-southeast-3.quicksight.aws.amazon.com	quicksight.ap-southeast-3.amazonaws.com	43.218.71.192/27

Region name	Region code	Agentic Features	Website for user access	API endpoints (HTTPS)	IP address range for data source connectivity
Asia Pacific (Malaysia)	ap-southeast-5	No	<code>https://ap-southeast-5.quicksight.aws.amazon.com</code>	<code>quicksight.ap-southeast-5.amazonaws.com</code>	56.68.33.0/27

If your IAM Identity Center instance is replicated to multiple Regions, you can create your Quick Enterprise subscription in an active additional Region. For more information, see [Set up Amazon Quick with IAM Identity Center multi-Region](#).

Cross-Region calls for web search

Amazon Quick makes cross-Region calls for web search functionality in Chat, Agents, and Research features. When using web search, requests originating in US West (Oregon) are processed in the US East (N. Virginia) Region. For customers in EMEA Regions, web search queries are processed in the Europe (Ireland) Region.

Web search regional availability

Region name and code	Web search processing region
US East (N. Virginia) (us-east-1)	US East (N. Virginia) (us-east-1)
US West (Oregon) (us-west-2)	US East (N. Virginia) (us-east-1)
Europe (Ireland) (eu-west-1)	Europe (Ireland) (eu-west-1)
Europe (Frankfurt) (eu-central-1)	Europe (Ireland) (eu-west-1)

Region name and code	Web search processing region
Europe (London) (eu-west-2)	Europe (Ireland) (eu-west-1)
Asia Pacific (Sydney) (ap-southeast-2)	Asia Pacific (Sydney) (ap-southeast-2)
Asia Pacific (Tokyo) (ap-northeast-1)	Asia Pacific (Tokyo) (ap-northeast-1)

Cross-Region inference for Australia, Japan, Europe, and the United States

With cross-Region inference, Amazon Quick automatically selects the optimal Region within your geography to process your inference request. This approach maximizes available compute resources and model availability. With cross-Region inference, you get:

- Complete access to the most advanced Amazon Quick AI capabilities and features
- Access to a variety of models suitable for different tasks
- Improved performance for all your applications

Cross-Region inference requests stay within the AWS Regions in the geography where your data originally resides. For example, a request made in the US stays within the AWS Regions in the US. Although data is stored only in your primary Region, your input prompts and output results might move outside of that Region when you use cross-Region inference. Amazon transmits all data encrypted across its secure network.

Note

There is no additional cost for using cross-Region inference. Amazon CloudWatch and AWS CloudTrail logs do not specify the AWS Region in which data inference occurs.

Supported Regions for cross-Region inference

For a list of Region codes and endpoints supported in Amazon Quick AI capabilities and features, see [Supported AWS Regions for Amazon Quick](#).

The following table summarizes the supported geographies and their inference Regions for Amazon Quick cross-Region inference.

Supported Amazon Quick geography	Inference Regions
United States	US East (N. Virginia) (us-east-1)
	US East (Ohio) (us-east-2)
	US West (Oregon) (us-west-2)
Europe	Europe (Frankfurt) (eu-central-1)
	Europe (Ireland) (eu-west-1)
	Europe (Paris) (eu-west-3)
	Europe (Stockholm) (eu-north-1)
	Europe (Milan) (eu-south-1)
	Europe (Spain) (eu-south-2)
Australia	Asia Pacific (Sydney) (ap-southeast-2)
	Asia Pacific (Melbourne) (ap-southeast-4)
Japan	Asia Pacific (Tokyo) (ap-northeast-1)
	Asia Pacific (Osaka) (ap-northeast-3)

Note

Amazon Quick follows the Amazon Bedrock Europe geographic cross-Region inference profile. For the Europe geography:

- Amazon Quick processes a request that originates in a Europe Region other than Europe (London) (eu-west-2) only in the Europe Regions listed in the preceding table. For

example, this applies to requests from Europe (Frankfurt) (eu-central-1) or Europe (Ireland) (eu-west-1).

- Amazon Quick never processes those requests in Europe (London) (eu-west-2) or Europe (Zurich) (eu-central-2).
- Amazon Quick can process a request that originates in Europe (London) (eu-west-2) in the listed Europe Regions or in Europe (London) itself.

 Note

Amazon Quick manages this cross-Region inference routing for you. You can't configure it, and Amazon Bedrock controls such as service control policies (SCPs) and IAM inference-profile permissions aren't available in Amazon Quick.

AWS Regions for Amazon Q in Quick

Topics

- [Supported AWS Regions for Amazon Q in Quick](#)

Supported AWS Regions for Amazon Q in Quick

Amazon Q in Quick Generative BI features including scenarios are currently supported in the following AWS Regions:

Region	Scenarios
US East (N. Virginia) (us-east-1)	✓ Yes
US East (Ohio) (us-east-2)	✓ Yes
US West (Oregon) (us-west-2)	✓ Yes
Asia Pacific (Mumbai) (ap-south-1)	✓ Yes

Region	Scenarios
Asia Pacific (Seoul) (ap-north-east-2)	✓ Yes
Asia Pacific (Singapore) (ap-southeast-1)	✓ Yes
Asia Pacific (Tokyo) (ap-north-east-1)	✓ Yes
Asia Pacific (Sydney) (ap-southeast-2)	✓ Yes
Canada (Central) (ca-central-1)	Not Available
Europe (Frankfurt) (eu-central-1)	✓ Yes
Europe (Ireland) (eu-west-1)	✓ Yes
Europe (London) (eu-west-2)	✓ Yes
Europe (Paris) (eu-west-3)	✓ Yes
Europe (Stockholm) (eu-north-1)	Not Available
Europe (Zurich) (eu-central-2)	Not Available
South America (São Paulo) (sa-east-1)	Not Available

For the AWS Regions where Amazon Quick processes cross-Region inference requests, see [Supported Regions for cross-Region inference](#).

Supported browsers

Before you start working with Amazon Quick, use the following table to verify that your browser is supported for Quick access.

Note

Amazon Quick ended support for Microsoft Internet Explorer 11 on July 31, 2022. We can no longer ensure that the features and web pages of Quick will function properly on IE 11. Please use one of our supported browsers: Microsoft Edge (Chromium), Google Chrome, or Mozilla Firefox.

Browser	Version	Check your version
Apple Safari	13 or later	Open Safari. On the menu, choose Safari , and then choose About Safari . The version number is shown in the dialog box that displays.
Google Chrome	Last three versions	Open Chrome and type chrome://version in your address bar. The version is in the Google Chrome field at the top of the results.
Microsoft Edge (Chromium)	Latest version	Not applicable.
Mozilla Firefox	Last three versions	Open Firefox. On the menu, choose the Help icon, and then choose About Firefox . The version number is listed underneath the Firefox name.

Setting up for Quick

This section helps you understand how to configure identity and access management, and control sign-up for users when you set up an Amazon Quick instance.

Note

For information about how to set up your Amazon Quick instance, including creating an AWS account, signing up for an Amazon Quick subscription, and signing in to Amazon Quick, see [Setting up and signing into Amazon Quick](#).

Topics

- [Using service control policies to restrict Amazon Quick sign-up options](#)
- [Identity and access management in Quick](#)
- [Allowlisting Amazon Quick domains](#)

Using service control policies to restrict Amazon Quick sign-up options

If you're an administrator in AWS Organizations, you can use service control policies (SCPs) to restrict how individuals in your organization can sign up for Amazon Quick. You can restrict the edition of Quick they can sign up for, and also the type of user that they can sign up for.

AWS Organizations is a user account management service that you can use to consolidate multiple AWS accounts into an organization that you create and centrally manage. You can use SCPs in AWS Organizations to manage the permissions in your organization. For more information, see [What is AWS Organizations?](#) and [Service control policies](#) in the *AWS Organizations User Guide*.

In the following topic, you can learn about two ways to restrict Quick sign-up options using SCPs in AWS Organizations. The topic includes an example SCP. To learn more about creating SCPs, see the following topics in the *AWS Organizations User Guide*:

- [Creating, updating, and deleting service control policies](#)
- [SCP syntax](#)
- [Strategies for using SCPs](#)

Topics

- [Restricting the Quick edition](#)
- [Restricting user management options](#)
- [Example SCP](#)
- [Restricting which accounts can create Quick subscriptions](#)

Restricting the Quick edition

To restrict the edition of Quick that your managed accounts can sign up for, use the `quicksight:Edition` condition key in your SCP. The values for this key are listed and described in the following table.

Key Name	Key Value	Description
<code>quicksight:Edition</code>	<code>standard</code>	Amazon Quick Standard Edition
	<code>enterprise</code>	Amazon Quick Enterprise Edition

Restricting user management options

To restrict the user management options that individuals in your organization can use to sign up for Quick, use the `quicksight:DirectoryType` condition key in your SCP. The values for this key are listed and described in the following table.

Key Name	Key Value	Description
<code>quicksight:DirectoryType</code>	<code>quicksight</code>	IAM federated identities and Amazon Quick-managed users
	<code>iam</code>	Only IAM federated identities
	<code>microsoft_ad</code>	Users managed in Microsoft Active Directory on AWS Directory Service for Microsoft Active Directory

Key Name	Key Value	Description
	ad_connector	Users managed in on-premises Active Directory and connected through AD_Connector to AWS Directory Service for Microsoft Active Directory
	iam_identity_center	Users managed in a Amazon Quick account that is integrated with IAM Identity Center.

Example SCP

The following example for Quick shows a service control policy that denies signing up for a Amazon Quick Standard Edition and prevents the ability to sign up using IAM Identity Center authentication. This policy uses the `quicksight:Subscribe` action, in addition to the condition keys previously described. For a list of Amazon Quick-specific keys for use in IAM permission policies, see [Actions, resources, and condition keys for Quick](#) in the *Service Authorization Reference*.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Statement1",
      "Effect": "Deny",
      "Action": [
        "quicksight:Subscribe"
      ],
      "Resource": [
        "*"
      ],
      "Condition": {
        "ForAnyValue:StringEquals": {
          "quicksight:DirectoryType": [
            "iam_identity_center"
          ]
        }
      }
    }
  ]
}
```

```

    }
  },
  {
    "Sid": "Statement2",
    "Effect": "Deny",
    "Action": [
      "quicksight:Subscribe"
    ],
    "Resource": [
      "*"
    ],
    "Condition": {
      "StringEquals": {
        "quicksight:Edition": "standard"
      }
    }
  }
]
}

```

With this policy in effect, individuals in an organization can sign up only for Amazon Quick Enterprise Edition, and they must use authentication methods other than IAM Identity Center. If they try to sign up for Amazon Quick Standard Edition or attempt to use IAM Identity Center authentication, they will be restricted from signing up and receive a message explaining that they don't have the right permissions.

Restricting which accounts can create Quick subscriptions

In addition to restricting the edition and the user management options that individuals can sign up for, you can use an SCP to control *which* AWS accounts in your organization are allowed to create a Amazon Quick subscription. This helps you centralize Quick on a set of approved accounts and prevent individuals from starting new subscriptions in other accounts.

Two actions can create a Amazon Quick subscription: `quicksight:Subscribe` and `quicksight:CreateAccountSubscription`. If a policy denies either action, the deny takes effect and the attempt to create a subscription fails. To restrict subscription creation, include both actions in your Deny statement.

The following example SCP denies both actions in every account except the approved accounts that you list. The policy uses the `aws:PrincipalAccount` global condition key to compare the

account of the principal making the request against your approved accounts. Replace the example account IDs with the IDs of the accounts where you allow Quick subscriptions.

```
{
  "Version": "2012-10-17"      ,
  "Statement": [
    {
      "Sid": "Statement1",
      "Effect": "Deny",
      "Action": [
        "quicksight:Subscribe",
        "quicksight:CreateAccountSubscription"
      ],
      "Resource": [
        "*"
      ],
      "Condition": {
        "StringNotEquals": {
          "aws:PrincipalAccount": [
            "111111111111",
            "222222222222"
          ]
        }
      }
    }
  ]
}
```

With this policy in effect, only principals in the listed accounts can create a Amazon Quick subscription. Principals in any other account in your organization are prevented from signing up, and they receive a message explaining that they don't have the right permissions.

To allow subscription creation only through a specific provisioning identity – for example, a role that your infrastructure-as-code pipeline uses – use the `aws:PrincipalArn` global condition key instead of `aws:PrincipalAccount`. The following example denies all three actions unless the caller is the approved provisioning role. Replace the example role ARN with the ARN of your provisioning role.

```
{
  "Version": "2012-10-17"      ,
  "Statement": [
    {
```

```

    "Sid": "Statement1",
    "Effect": "Deny",
    "Action": [
        "quicksight:Subscribe",
        "quicksight:CreateAccountSubscription",
        "quicksight:CreateAdmin"
    ],
    "Resource": [
        "*"
    ],
    "Condition": {
        "ArnNotLike": {
            "aws:PrincipalArn": [
                "arn:aws:iam::*:role/QuickAccountProvisioner"
            ]
        }
    }
}
]
}

```

With this policy in effect, only the approved provisioning role can create a Amazon Quick subscription, regardless of which account the request comes from. Because CloudFormation creates resources as the principal that runs the template, you can use this approach to allow subscription creation only through CloudFormation. Run your template with the approved provisioning role. Protect the provisioning role by controlling who can assume it and who can change its trust policy.

This example also includes `quicksight:CreateAdmin`, which covers the Amazon Quick Standard Edition sign-up path in addition to `quicksight:Subscribe` and `quicksight:CreateAccountSubscription`.

As an alternative to using the condition key, you can attach a Deny statement for the same two actions (without the `aws:PrincipalAccount` condition) to every organizational unit (OU) except the OU that contains your approved accounts. For more information about where to attach policies, see [Strategies for using SCPs](#) in the *AWS Organizations User Guide*.

Identity and access management in Quick

Applies to: Enterprise Edition and Standard Edition

Intended audience: System administrators and Amazon Quick administrators

The following topics describe how to set up identity and access for Quick.

- [Using IAM Identity Center](#)
- [IAM federation](#)
- [Using Active Directory with Amazon Quick Enterprise edition](#)
- [Setting up IdP federation using IAM and Amazon Quick](#)
- [Using multi-factor authentication \(MFA\) with Amazon Quick](#)

 Note

In the following AWS Regions, Amazon Quick accounts can only use [IAM Identity Center](#) for identity and access management:

- af-south-1 Africa (Cape Town)
- ap-southeast-3 Asia Pacific (Jakarta)
- ap-southeast-5 Asia Pacific (Malaysia)
- eu-south-1 Europe (Milan)
- eu-south-2 Europe (Spain)
- eu-central-2 Europe (Zurich)
- il-central-1 Israel (Tel Aviv)
- me-central-1 Middle East (UAE)

The following sections help you configure the identity management method of your choice for Quick.

IAM permissions control access to some sections of the Amazon Quick administration console. The following table lists admin actions and whether they require IAM permissions.

Admin action	IAM permissions required
Account settings	 Yes

Admin action	IAM permissions required
Manage assets	✔ Yes
Amazon Q	✔ Yes
Manage subscriptions	✘ No
SPICE capacity	✘ No
Index capacity	✔ Yes
Manage users (view)	✘ No
Manage users > Role groups	✔ Yes
Manage domains	✘ No
Mobile settings	✘ No
Manage IP/VPC restrictions	✔ Yes
Manage VPC connections	✔ Yes
Manage OAuth client applications	✔ Yes
KMS keys	✔ Yes
AWS resources	✔ Yes
Default access policy	✔ Yes
IAM policy assignments	✔ Yes
AWS actions	✔ Yes
Extension access	✔ Yes
Custom permissions	✔ Yes
Configure SageMaker	✔ Yes

Admin action	IAM permissions required
Brand customization	✔ Yes
Agent customization	✔ Yes
Email customization	✔ Yes
Quick Usage Metrics	✔ Yes

If you have the Amazon Quick admin role, you can perform actions that do not require IAM permissions. To perform actions that require IAM permissions, sign in to the AWS Management Console as an IAM principal with the appropriate `quicksight:*` permissions. You can also perform some admin actions programmatically through the Amazon Quick API. For a list of available API operations, see the [Amazon Quick API Reference](#).

Topics

- [Using IAM Identity Center](#)
- [IAM federation](#)
- [Using Active Directory with Amazon Quick Enterprise edition](#)
- [Using multi-factor authentication \(MFA\) with Amazon Quick](#)

Using IAM

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use Amazon Quick resources. IAM is an AWS service that you can use with no additional charge.

Topics

- [Introduction to IAM concepts](#)
- [Using Quick with IAM](#)
- [Passing IAM roles to Quick](#)
- [IAM policy examples for Quick](#)

- [Provisioning users for Amazon Quick](#)
- [Troubleshooting Quick identity and access](#)

Introduction to IAM concepts

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator to more securely control access to AWS resources. Administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use Amazon Quick resources. IAM is an AWS service that you can use with no additional charge.

IAM is used with Amazon Quick in several ways, including the following:

- If your company uses IAM for their identity management, people might have IAM user names and passwords that they use to sign in to Amazon Quick.
- If you want your Amazon Quick users to be automatically created at first sign-in, you can use IAM to create a policy for users who are preauthorized to use Amazon Quick.
- If you want to create specialized access for specific groups of Amazon Quick users or to specific resources, you can use IAM policies to accomplish this.

Topics

- [Audience](#)
- [Authenticating with identities](#)
- [Managing access using policies](#)

Audience

Use the following to help understand the context of the information provided in this section, and how it applies to your role. How you use AWS Identity and Access Management (IAM) differs depending on the work that you do in Amazon Quick.

Service user – In some cases, you might use Amazon Quick as an Author or Reader to interact with data, analyses, and dashboards, spaces, and agents through the Amazon Quick by using the browser interface. In these cases, this section provides only background information for you. You don't directly interact with the IAM service, except if you use IAM to sign into Amazon Quick.

Amazon Quick administrator – If you're in charge of Amazon Quick resources at your company, you probably have full access to Amazon Quick. It's your job to determine which Amazon Quick

features and resources your team members should access. If you have specialized requirements that you can't solve by using the Amazon Quick admin panel, then you can work with your administrator to create permissions policies for your Amazon Quick users. To learn more about IAM, read this page to understand the basic concepts of IAM. To learn more about how your company can use IAM with Amazon Quick, see [Using Amazon Quick with IAM](#).

Administrator – If you're a system administrator, you might want to learn details about how you can write policies to manage access to Amazon Quick. To view examples of Amazon Quick identity-based policies that you can use in IAM, see [IAM identity-based policies for Amazon Quick](#).

Authenticating with identities

Authentication is how you sign in to AWS using your identity credentials. You must be authenticated as the AWS account root user, an IAM user, or by assuming an IAM role.

You can sign in as a federated identity using credentials from an identity source like AWS IAM Identity Center (IAM Identity Center), single sign-on authentication, or Google/Facebook credentials. For more information about signing in, see [How to sign in to your AWS account](#) in the *AWS Sign-In User Guide*.

For programmatic access, AWS provides an SDK and CLI to cryptographically sign requests. For more information, see [AWS Signature Version 4 for API requests](#) in the *IAM User Guide*.

Topics

- [AWS account root user](#)
- [IAM users and groups](#)
- [IAM roles](#)

AWS account root user

When you create an AWS account, you begin with one sign-in identity called the AWS account *root user* that has complete access to all AWS services and resources. We strongly recommend that you don't use the root user for everyday tasks. For tasks that require root user credentials, see [Tasks that require root user credentials](#) in the *IAM User Guide*.

IAM users and groups

An [IAM user](#) is an identity with specific permissions for a single person or application. We recommend using temporary credentials instead of IAM users with long-term credentials. For more

information, see [Require human users to use federation with an identity provider to access AWS using temporary credentials](#) in the *IAM User Guide*.

An [IAM group](#) specifies a collection of IAM users and makes permissions easier to manage for large sets of users. For more information, see [Use cases for IAM users](#) in the *IAM User Guide*.

IAM roles

An [IAM role](#) is an identity with specific permissions that provides temporary credentials. You can assume a role by [switching from a user to an IAM role \(console\)](#) or by calling an AWS CLI or AWS API operation. For more information, see [Methods to assume a role](#) in the *IAM User Guide*.

IAM roles are useful for federated user access, temporary IAM user permissions, cross-account access, cross-service access, and applications running on Amazon EC2. For more information, see [Cross account resource access in IAM](#) in the *IAM User Guide*.

Managing access using policies

You control access in AWS by creating policies and attaching them to AWS identities or resources. A policy defines permissions when associated with an identity or resource. AWS evaluates these policies when a principal makes a request. Most policies are stored in AWS as JSON documents. For more information about JSON policy documents, see [Overview of JSON policies](#) in the *IAM User Guide*.

Using policies, administrators specify who has access to what by defining which **principal** can perform **actions** on what **resources**, and under what **conditions**.

By default, users and roles have no permissions. An IAM administrator creates IAM policies and adds them to roles, which users can then assume. IAM policies define permissions regardless of the method used to perform the operation.

Identity-based policies

Identity-based policies are JSON permissions policy documents that you attach to an identity (user, group, or role). These policies control what actions identities can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see [Define custom IAM permissions with customer managed policies](#) in the *IAM User Guide*.

Identity-based policies can be *inline policies* (embedded directly into a single identity) or *managed policies* (standalone policies attached to multiple identities). To learn how to choose between

managed and inline policies, see [Choose between managed policies and inline policies](#) in the *IAM User Guide*.

Resource-based policies

Resource-based policies are JSON policy documents that you attach to a resource. Examples include *IAM role trust policies* and *Amazon S3 bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. You must [specify a principal](#) in a resource-based policy.

Resource-based policies are inline policies that are located in that service. You can't use AWS managed policies from IAM in a resource-based policy.

Access control lists (ACLs)

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

Amazon S3, AWS WAF, and Amazon VPC are examples of services that support ACLs. To learn more about ACLs, see [Access control list \(ACL\) overview](#) in the *Amazon Simple Storage Service Developer Guide*.

Other policy types

AWS supports additional policy types that can set the maximum permissions granted by more common policy types:

- **Permissions boundaries** – Set the maximum permissions that an identity-based policy can grant to an IAM entity. For more information, see [Permissions boundaries for IAM entities](#) in the *IAM User Guide*.
- **Service control policies (SCPs)** – Specify the maximum permissions for an organization or organizational unit in AWS Organizations. For more information, see [Service control policies](#) in the *AWS Organizations User Guide*.
- **Resource control policies (RCPs)** – Set the maximum available permissions for resources in your accounts. For more information, see [Resource control policies \(RCPs\)](#) in the *AWS Organizations User Guide*.
- **Session policies** – Advanced policies passed as a parameter when creating a temporary session for a role or federated user. For more information, see [Session policies](#) in the *IAM User Guide*.

Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see [Policy evaluation logic](#) in the *IAM User Guide*.

Using Quick with IAM

Applies to: Enterprise Edition and Standard Edition

Intended audience: System administrators

Before you use IAM to manage access to Amazon Quick, you should understand what IAM features are available to use with Amazon Quick. To get a high-level view of how Amazon Quick and other AWS services work with IAM, see [AWS Services That Work with IAM](#) in the *IAM User Guide*.

Topics

- [Amazon Quick Policies \(identity-based\)](#)
- [Amazon Quick policies \(resource-based\)](#)
- [Authorization based on Amazon Quick tags](#)
- [Amazon Quick IAM roles](#)

Amazon Quick Policies (identity-based)

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. Amazon Quick supports specific actions, resources, and condition keys. To learn about all of the elements that you use in a JSON policy, see [IAM JSON Policy Elements Reference](#) in the *IAM User Guide*.

You can use AWS root credentials or IAM user credentials to create an Amazon Quick account. AWS root and administrator credentials already have all of the required permissions for managing Amazon Quick access to AWS resources.

However, we recommend that you protect your root credentials, and instead use IAM user credentials. To do this, you can create a policy and attach it to the IAM user and roles that you plan

to use for Amazon Quick. The policy must include the appropriate statements for the Amazon Quick administrative tasks you need to perform, as described in the following sections.

Important

Be aware of the following when working with Quick and IAM policies:

- Avoid directly modifying a policy that was created by Quick. When you modify it yourself, Quick can't edit it. This inability can cause an issue with the policy. To fix this issue, delete the previously modified policy.
- If you get an error on permissions when you try to create an Amazon Quick account, see [Actions Defined by Amazon Quick](#) in the *IAM User Guide*.
- In some cases, you might have an Amazon Quick account that you can't access even from the root account (for example, if you accidentally deleted its directory service). In this case, you can delete your old Amazon Quick account, then recreate it. For more information, see [Deleting your Amazon Quick subscription and closing the account](#).

Topics

- [Actions](#)
- [Resources](#)
- [Condition keys](#)
- [Examples](#)

Actions

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The Action element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Include actions in a policy to grant permissions to perform the associated operation.

Policy actions in Amazon Quick use the following prefix before the action: `quicksight:`. For example, to grant someone permission to run an Amazon EC2 instance with the Amazon EC2 `RunInstances` API operation, you include the `ec2:RunInstances` action in their policy. Policy

statements must include either an `Action` or `NotAction` element. Amazon Quick defines its own set of actions that describe tasks that you can perform with this service.

To specify multiple actions in a single statement, separate them with commas as follows:

```
"Action": [  
    "quicksight:action1",  
    "quicksight:action2"]
```

You can specify multiple actions using wildcards (*). For example, to specify all actions that begin with the word `Create`, include the following action:

```
"Action": "quicksight:Create*"
```

Amazon Quick provides a number of AWS Identity and Access Management (IAM) actions. All Amazon Quick actions are prefixed with `quicksight:`, such as `quicksight:Subscribe`. For information about using Amazon Quick actions in an IAM policy, see [IAM policy examples for Amazon Quick](#).

To see the most up-to-date list of Amazon Quick actions, see [Actions Defined by Amazon Quick](#) in the *IAM User Guide*.

Resources

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The Resource JSON policy element specifies the object or objects to which the action applies. As a best practice, specify a resource using its [Amazon Resource Name \(ARN\)](#). For actions that don't support resource-level permissions, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*"
```

Following is an example policy. It means that the caller with this policy attached, is able to invoke the `CreateGroupMembership` operation on any group, provided that the user name they are adding to the group is not `user1`.

```
{
```

```
"Effect": "Allow",
"Action": "quicksight:CreateGroupMembership",
"Resource": "arn:aws:quicksight:us-east-1:aws-account-id:group/default/*",
"Condition": {
    "StringNotEquals": {
        "quicksight:UserName": "user1"
    }
}
```

Some Amazon Quick actions, such as those for creating resources, cannot be performed on a specific resource. In those cases, you must use the wildcard (*).

```
"Resource": "*"
```

Some API actions involve multiple resources. To specify multiple resources in a single statement, separate the ARNs with commas.

```
"Resource": [
    "resource1",
    "resource2"
```

To see a list of Amazon Quick resource types and their Amazon Resource Names (ARNs), see [Resources Defined by Amazon Quick](#) in the *IAM User Guide*. To learn with which actions you can specify the ARN of each resource, see [Actions Defined by Amazon Quick](#).

Condition keys

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The **Condition** element specifies when statements execute based on defined criteria. You can create conditional expressions that use [condition operators](#), such as equals or less than, to match the condition in the policy with values in the request. To see all AWS global condition keys, see [AWS global condition context keys](#) in the *IAM User Guide*.

Amazon Quick does not provide any service-specific condition keys, but it does support using some global condition keys. To see all AWS global condition keys, see [AWS Global Condition Context Keys](#) in the *IAM User Guide*.

Examples

To view examples of Amazon Quick identity-based policies, see [Amazon Quick Policies \(identity-based\)](#).

Amazon Quick policies (resource-based)

Amazon Quick doesn't support resource-based policies. However, you can use the Amazon Quick console to configure access to other AWS resources in your AWS account.

Authorization based on Amazon Quick tags

Amazon Quick does not support tagging resources or controlling access based on tags.

Amazon Quick IAM roles

An [IAM role](#) is an entity within your AWS account that has specific permissions. You can use IAM roles to group permissions together to make it easier to manage user's access to Amazon Quick actions.

Amazon Quick doesn't support the following role features:

- Service-linked roles.
- Service roles.
- Temporary credentials (direct use): However, Amazon Quick uses temporary credentials to allow users to assume an IAM role to access embedded dashboards. For more information, see [Embedded analytics for Amazon Quick](#).

For more information on how Amazon Quick uses IAM roles, see [Using Amazon Quick with IAM](#) and [IAM policy examples for Amazon Quick](#).

Passing IAM roles to Quick

Applies to: Enterprise Edition

When your IAM users sign up for Quick, they can choose to use the Amazon Quick-managed role (this is the default role). Or they can pass an existing IAM role to Amazon Quick.

Use the sections below to pass existing IAM roles to Amazon Quick

Topics

- [Prerequisites](#)

- [Attaching additional policies](#)
- [Using existing IAM roles in Quick](#)

Prerequisites

For your users to pass IAM roles to Amazon Quick, your administrator needs to complete the following tasks:

- **Create an IAM role.** For more information about creating IAM roles, see [Creating IAM roles](#) in the *IAM User Guide*.
- **Attach a trust policy to your IAM role that allows Amazon Quick to assume the role.** Use the following example to create a trust policy for the role. The following example trust policy allows the Quick principal to assume the IAM role that it's attached to.

For more information about creating IAM trust policies and attaching them to roles, see [Modifying a Role \(Console\)](#) in the *IAM User Guide*.

```
{
  "Version": "2012-10-17"      ,
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "quicksight.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

- **Assign the following IAM permissions to your administrator (IAM users or roles):**
 - `quicksight:UpdateResourcePermissions` – This grants IAM users who are Amazon Quick administrators the permission to update resource-level permissions in Amazon Quick. For more information about resource types defined by Amazon Quick, see [Actions, resources, and condition keys for Quick](#) in the *IAM User Guide*.
 - `iam:PassRole` – This grants users permission to pass roles to Amazon Quick. For more information, see [Granting a user permissions to pass a role to an AWS service](#) in the *IAM User Guide*.

- `iam:ListRoles` – (Optional) This grants users permission to see a list of existing roles in Amazon Quick. If this permission is not provided, they can use an ARN to use existing IAM roles.

Following is an example IAM permissions policy that allows managing resource-level permissions, listing IAM roles, and passing IAM roles in Quick.

```
{
  "Version": "2012-10-17"
  ,
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "iam:ListRoles",
      "Resource": "arn:aws:iam::account-id:role:*"
    },
    {
      "Effect": "Allow",
      "Action": "iam:PassRole",
      "Resource": "arn:aws:iam::account-id:role/path/role-name",
      "Condition": {
        "StringEquals": {
          "iam:PassedToService": [
            "quicksight.amazonaws.com"
          ]
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": "quicksight:UpdateResourcePermissions",
      "Resource": "*"
    }
  ]
}
```

For more examples of IAM policies that you can use with Amazon Quick, see [IAM policy examples for Amazon Quick](#).

For more information about assigning permissions policies to users or user groups, see [Changing permissions for an IAM user](#) in the *IAM User Guide*.

Attaching additional policies

If you're using another AWS service, such as Amazon Athena or Amazon S3, you can create a permissions policy that grants Amazon Quick permission to perform specific actions. You can then attach the policy to the IAM roles that you later pass to Amazon Quick. The following are examples of how you can set up and attach additional permissions policies to your IAM roles.

For an example managed policy for Amazon Quick in Athena, see [AWSQuicksightAthenaAccess Managed Policy](#) in the *Amazon Athena User Guide*. IAM users can access this role in Amazon Quick using the following ARN: `arn:aws:iam::aws:policy/service-role/AWSQuicksightAthenaAccess`.

The following is an example of a permissions policy for Amazon Quick in Amazon S3. For more information about using IAM with Amazon S3, see [Identity and access management in Amazon S3](#) in the *Amazon S3 User Guide*.

For information on how to create cross-account access from Amazon Quick to an Amazon S3 bucket in another account, see [How do I set up cross-account access from Quick to an Amazon S3 bucket in another account?](#) in the AWS Knowledge Center.

```
{
  "Version": "2012-10-17"
,
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "s3:ListAllMyBuckets",
      "Resource": "arn:aws:s3:::*"
    },
    {
      "Action": [
        "s3:ListBucket"
      ],
      "Effect": "Allow",
      "Resource": [
        "arn:aws:s3:::aws-athena-query-results-us-west-2-123456789"
      ]
    },
    {
      "Action": [
        "s3:GetObject",
        "s3:GetObjectVersion"
      ],
```

```

        "Effect": "Allow",
        "Resource": [
            "arn:aws:s3:::aws-athena-query-results-us-west-2-123456789/*"
        ],
    },
    {
        "Action": [
            "s3:ListBucketMultipartUploads",
            "s3:GetBucketLocation"
        ],
        "Effect": "Allow",
        "Resource": [
            "arn:aws:s3:::aws-athena-query-results-us-west-2-123456789"
        ],
    },
    {
        "Effect": "Allow",
        "Action": [
            "s3:PutObject",
            "s3:AbortMultipartUpload",
            "s3:ListMultipartUploadParts"
        ],
        "Resource": [
            "arn:aws:s3:::aws-athena-query-results-us-west-2-123456789/*"
        ],
    }
]
}

```

Using existing IAM roles in Quick

If you're a Amazon Quick administrator and have permissions to update Amazon Quick resources and pass IAM roles, you can use existing IAM roles in Amazon Quick. To learn more about the prerequisites for passing IAM roles in Amazon Quick, see the [Prerequisites](#) outlined in the previous list.

Use the following procedure to learn how to pass IAM roles in Amazon Quick.

To use an existing IAM role in Amazon Quick

1. In Amazon Quick, choose your account name in the navigation bar at top right and choose **Manage QuickSight**.

2. On the **Manage Amazon Quick** page that opens, choose **Security & Permissions** in the menu at left.
3. In the **Security & Permissions** page that opens, under **Amazon Quick access to AWS services**, choose **Manage**.
4. For **IAM role**, choose **Use an existing role**, and then do one of the following:
 - Choose the role that you want to use from the list.
 - Or, if you don't see a list of existing IAM roles, you can enter the IAM ARN for the role in the following format: `arn:aws:iam::account-id:role/path/role-name`.
5. Choose **Save**.

IAM policy examples for Quick

This section provides examples of IAM policies that you can use with Quick.

IAM identity-based policies for Quick

This section shows examples of identity-based policies to use with Quick.

Topics

- [IAM identity-based policies for Amazon Quick IAM console administration](#)

IAM identity-based policies for Amazon Quick IAM console administration

The following example shows the IAM permissions needed for Amazon Quick IAM console administration actions.

```
{
  "Version": "2012-10-17"
  ,
  "Statement": [
    {
      "Sid": "Statement1",
      "Effect": "Allow",
      "Action": [
        "quicksight:*",
        "iam:ListAttachedRolePolicies",
        "iam:GetPolicy",
        "iam:CreatePolicyVersion",
```

```

        "iam:DeletePolicyVersion",
        "iam:GetPolicyVersion",
        "iam:ListPolicyVersions",
        "iam:DeleteRole",
        "iam:CreateRole",
        "iam:GetRole",
        "iam:ListRoles",
        "iam:CreatePolicy",
        "iam:ListEntitiesForPolicy",
        "iam:listPolicies",
        "s3:ListAllMyBuckets",
        "athena:ListDataCatalogs",
        "athena:GetDataCatalog"
    ],
    "Resource": [
        "*"
    ]
}
]
}

```

IAM identity-based policies for Quick: dashboards

The following example shows an IAM policy that allows dashboard sharing and embedding for specific dashboards.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": "quicksight:RegisterUser",
      "Resource": "*",
      "Effect": "Allow"
    },
    {
      "Action": "quicksight:GetDashboardEmbedUrl",
      "Resource": "arn:aws:quicksight:us-
west-2:111122223333:dashboard/1a1ac2b2-3fc3-4b44-5e5d-c6db6778df89",
      "Effect": "Allow"
    }
  ]
}

```

IAM identity-based policies for Quick: namespaces

The following examples show IAM policies that allow a Amazon Quick administrator to create or delete namespaces.

Creating namespaces

```
{
  "Version": "2012-10-17"      ,
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ds:AuthorizeApplication",
        "ds:UnauthorizeApplication",
        "ds>DeleteDirectory",
        "ds>CreateIdentityPoolDirectory",
        "ds:DescribeDirectories",
        "quicksight:CreateNamespace"
      ],
      "Resource": "*"
    }
  ]
}
```

Deleting namespaces

```
{
  "Version": "2012-10-17"      ,
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ds:UnauthorizeApplication",
        "ds>DeleteDirectory",
        "ds:DescribeDirectories",
        "quicksight>DeleteNamespace"
      ],
      "Resource": "*"
    }
  ]
}
```

IAM identity-based policies for Quick: custom permissions

The following example shows an IAM policy that allows a Amazon Quick administrator or a developer to manage custom permissions.

```
{
  "Version": "2012-10-17"      ,
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "quicksight:*CustomPermissions"
      ],
      "Resource": "*"
    }
  ]
}
```

The following example shows another way to grant the same permissions as shown in the previous example.

```
{
  "Version": "2012-10-17"      ,
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "quicksight:CreateCustomPermissions",
        "quicksight:DescribeCustomPermissions",
        "quicksight:ListCustomPermissions",
        "quicksight:UpdateCustomPermissions",
        "quicksight>DeleteCustomPermissions"
      ],
      "Resource": "*"
    }
  ]
}
```

IAM identity-based policies for Quick: customizing email report templates

The following example shows a policy that allows viewing, updating, and creating email report templates in Amazon Quick, as well as obtaining verification attributes for an Amazon Simple Email Service identity. This policy allows a Amazon Quick administrator to create and update custom email report templates, and to confirm that any custom email address they want to send email reports from is a verified identity in SES.

```
{
  "Version": "2012-10-17"
  ,
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "quicksight:DescribeAccountCustomization",
        "quicksight:CreateAccountCustomization",
        "quicksight:UpdateAccountCustomization",
        "quicksight:DescribeEmailCustomizationTemplate",
        "quicksight:CreateEmailCustomizationTemplate",
        "quicksight:UpdateEmailCustomizationTemplate",
        "ses:GetIdentityVerificationAttributes"
      ],
      "Resource": "*"
    }
  ]
}
```

IAM identity-based policies for Quick: create an Enterprise account with Amazon Quick managed users

The following example shows a policy that allows Amazon Quick admins to create an Enterprise edition Amazon Quick account with Amazon Quick managed users.

```
{
  "Version": "2012-10-17"
  ,
  "Statement": [
    {
      "Sid": "Statement1",
      "Effect": "Allow",
      "Action": [
        "quicksight:*",
        "iam:ListAttachedRolePolicies",

```

```

        "iam:GetPolicy",
        "iam:CreatePolicyVersion",
        "iam:DeletePolicyVersion",
        "iam:GetPolicyVersion",
        "iam:ListPolicyVersions",
        "iam:DeleteRole",
        "iam:CreateRole",
        "iam:GetRole",
        "iam:ListRoles",
        "iam:CreatePolicy",
        "iam:ListEntitiesForPolicy",
        "iam:listPolicies",
        "s3:ListAllMyBuckets",
        "athena:ListDataCatalogs",
        "athena:GetDataCatalog",
        "ds:AuthorizeApplication",
        "ds:UnauthorizeApplication",
        "ds:CheckAlias",
        "ds:CreateAlias",
        "ds:DescribeDirectories",
        "ds:DescribeTrusts",
        "ds:DeleteDirectory",
        "ds:CreateIdentityPoolDirectory"
    ],
    "Resource": [
        "*"
    ]
}
]
}

```

IAM identity-based policies for Quick: creating users

The following example shows a policy that allows creating Amazon Quick users only. For `quicksight:CreateReader`, `quicksight:CreateUser`, and `quicksight:CreateAdmin`, you can limit the permissions to **"Resource":**

"arn:aws:quicksight::<YOUR_AWS_ACCOUNTID>:user/\${aws:user_id}". For all other permissions described in this guide, use **"Resource": "*"**. The resource you specify limits the scope of the permissions to the specified resource.

```

{
    "Version": "2012-10-17"
    ,

```

```

    "Statement": [
      {
        "Action": [
          "quicksight:CreateUser"
        ],
        "Effect": "Allow",
        "Resource": "arn:aws:quicksight::<YOUR_AWS_ACCOUNTID>:user/${aws:userid}"
      }
    ]
  }
}

```

IAM identity-based policies for Quick: creating and managing groups

The following example shows a policy that allows Amazon Quick administrators and developers to create and manage groups.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "quicksight:ListGroup",
        "quicksight:CreateGroup",
        "quicksight:SearchGroups",
        "quicksight:ListGroupMemberships",
        "quicksight:CreateGroupMembership",
        "quicksight>DeleteGroupMembership",
        "quicksight:DescribeGroupMembership",
        "quicksight:ListUsers"
      ],
      "Resource": "*"
    }
  ]
}

```

IAM identity-based policies for Quick: All access for Standard edition

The following example for Amazon Quick Standard edition shows a policy that allows subscribing and creating authors and readers. This example explicitly denies permission to unsubscribe from Amazon Quick.

```

{

```

```

"Version": "2012-10-17"
,
"Statement": [
  {
    "Effect": "Allow",
    "Action": [
      "ds:AuthorizeApplication",
      "ds:UnauthorizeApplication",
      "ds:CheckAlias",
      "ds:CreateAlias",
      "ds:DescribeDirectories",
      "ds:DescribeTrusts",
      "ds>DeleteDirectory",
      "ds>CreateIdentityPoolDirectory",
      "iam:ListAccountAliases",
      "quicksight:CreateUser",
      "quicksight:DescribeAccountSubscription",
      "quicksight:Subscribe"
    ],
    "Resource": "*"
  },
  {
    "Effect": "Deny",
    "Action": [
      "quicksight:Unsubscribe",
      "quicksight>DeleteAccountSubscription"
    ],
    "Resource": "*"
  }
]
}

```

IAM identity-based policies for Quick: All access for Enterprise edition with IAM Identity Center (Pro roles)

The following example for Amazon Quick Enterprise edition shows a policy that allows a Amazon Quick user to subscribe to Amazon Quick, create users, and manage Active Directory in a Amazon Quick account that is integrated with IAM Identity Center.

This policy also allows users to subscribe to Amazon Quick Pro roles that grant access to Amazon Q in Quick Generative BI capabilities. For more information about Pro roles in Amazon Quick, see [Get started with Generative BI](#).

This example explicitly denies permission to unsubscribe from Amazon Quick.

```

{
  "Statement": [
    {
      "Sid": "Statement1",
      "Effect": "Allow",
      "Action": [
        "quicksight:*",
        "iam:ListAttachedRolePolicies",
        "iam:GetPolicy",

IAM identity-based policies for Quick: All access for Enterprise edition with IAM Identity Center

The following example for Amazon Quick Enterprise edition shows a policy that allows subscribing, creating users, and managing Active Directory in a Amazon Quick account that is integrated with IAM Identity Center.

This policy does not grant permissions to create Pro roles in Amazon Quick. To create a policy that grants permission to subscribe to Pro roles in Amazon Quick, see [IAM identity-based policies for Amazon Quick: All access for Enterprise edition with IAM Identity Center \(Pro roles\)](#).

This example explicitly denies permission to unsubscribe from Amazon Quick.

IAM identity-based policies for Quick: using the admin key management console

The following example shows an IAM policy that allows access to the admin key management console.

```
{
  "Version": "2012-10-17"
  ,
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "quicksight:DescribeKeyRegistration",
        "quicksight:UpdateKeyRegistration",
        "quicksight:ListKMSKeysForUser",
        "kms:CreateGrant",
        "kms:ListGrants",
        "kms:ListAliases"
      ],
      "Resource": "*"
    }
  ]
}
```

The "quicksight:ListKMSKeysForUser" and "kms:ListAliases" permissions are required to access customer managed keys from the Amazon Quick console.

"quicksight:ListKMSKeysForUser" and "kms:ListAliases" are not required to use the Amazon Quick key management APIs.

To specify which keys you want a user to be able to access, add the ARNs of the keys that you want the user to access to the UpdateKeyRegistration condition with the quicksight:KmsKeyArns condition key. Users can only access the keys specified in UpdateKeyRegistration. For more information about supported condition keys for Amazon Quick, see [Condition keys for Amazon Quick](#).

The example below grants Describe permissions for all CMKs that are registered to a Amazon Quick account and Update permissions to specific CMKs that are registered to the Amazon Quick account.

```
{
  "Version": "2012-10-17"
  ,
  "Statement": [
```

```

{
  "Effect": "Allow",
  "Action": [
    "quicksight:DescribeKeyRegistration"
  ],
  "Resource": "arn:aws:quicksight:us-west-2:123456789012:*"
},
{
  "Effect": "Allow",
  "Action": [
    "quicksight:UpdateKeyRegistration"
  ],
  "Resource": "arn:aws:quicksight:us-west-2:123456789012:*",
  "Condition": {
    "ForAllValues:StringEquals": {
      "quicksight:KmsKeyArns": [
        "arn:aws:kms:us-west-2:123456789012:key/key-id-of-key1",
        "arn:aws:kms:us-west-2:123456789012:key/key-id-of-key2",
        "..."
      ]
    }
  }
},
{
  "Effect": "Allow",
  "Action": [
    "kms:CreateGrant",
    "kms:ListGrants"
  ],
  "Resource": "arn:aws:kms:us-west-2:123456789012:key/*"
}
]
}

```

AWS resources Quick: scoping policies in Enterprise edition

The following example for Amazon Quick Enterprise edition shows a policy that allows setting default access to AWS resources and scoping policies for permissions to AWS resources.

```

{
  "Version": "2012-10-17"
  ,
  "Statement": [
    {

```

```
        "Action": [
            "quicksight:*IAMPolicyAssignment*",
            "quicksight:AccountConfigurations"
        ],
        "Effect": "Allow",
        "Resource": "*"
    }
}
```

Provisioning users for Amazon Quick

Applies to: Enterprise Edition and Standard Edition

Intended audience: System administrators and Amazon Quick administrators

Self-provisioning an Amazon Quick administrator

Amazon Quick administrators are users who can also manage Amazon Quick features such as account settings and accounts. They can also purchase additional Amazon Quick user subscriptions, purchase [SPICE](#), and cancel the subscription to Amazon Quick for your AWS account.

You can use an AWS user or group policy to give users the ability to add themselves as administrators of Amazon Quick. Users that have been granted this ability can only add themselves as administrators and can't use this policy to add others. Their accounts become active and billable the first time that they open Amazon Quick. To set up self-provisioning, give these users permission to use the `quicksight:CreateAdmin` action.

Alternatively, you can use the following procedure to use the console to set or create the administrator for Amazon Quick.

To make a user the Amazon Quick administrator

1. Create the AWS user:
 - Use IAM to create the user that you want to be the administrator of Amazon Quick. Alternatively, identify an existing user in IAM for the administrator role. You can also put the user inside a new group, for manageability.

- Grant the user (or group) sufficient permissions.
2. Sign in to your AWS Management Console with the target user's credentials.
 3. Go to <http://quicksight.aws.amazon.com/sn/console/get-user-email>, type in the target user's email address, and choose **Continue**.

On success, the target user is now an administrator in Amazon Quick.

Self-provisioning an Amazon Quick author

Amazon Quick authors can create data sources, datasets, analyses, and dashboards. They can share analyses and dashboards with other Amazon Quick users in your Amazon Quick account. However, they don't have access to the **Manage Amazon Quick** menu. They can't change account settings, manage accounts, purchase additional Amazon Quick user subscriptions or [SPICE](#) capacity, or cancel the subscription to Amazon Quick for your AWS account. Author Pro users can additionally create content using natural language, build knowledge bases, configure actions, and access advanced automation capabilities.

You can use an AWS user or group policy to give users the ability to create an Amazon Quick author account for themselves. Their accounts become active and billable the first time they open Amazon Quick. To set up self-provisioning, you need to give them permission to use the `quicksight:CreateUser` action.

Self-provisioning an Amazon Quick read-only user

Amazon Quick read-only users or *readers* can view and manipulate dashboards that are shared with them, but they can't make any changes or save a dashboard for further analysis. Amazon Quick readers can't create data sources, datasets, analyses, or visuals. They can't do any administrative tasks. Choose this role for people who are consumers of the dashboards but don't author their own analysis, for example, executives. Reader Pro users have access to advanced features including AI chat agents, collaborative spaces, flows, and extensions.

If you are using Microsoft Active Directory with Amazon Quick, you can manage read-only permissions by using a group. Otherwise, you can bulk-invite users to use Amazon Quick. You can also use an AWS user or group policy to give people the ability to create an Amazon Quick reader account for themselves.

Reader accounts become active and billable the first time they open Amazon Quick. If you decide to upgrade or downgrade a user, billing for that user is prorated for the month. To set up self-

provisioning, you need to give them permission to use the `quicksight:CreateReader` action. For complete details about when billing begins, proration, and what happens when you remove a user, see [Understanding Amazon Quick user billing](#).

Readers that are used to automatically or programmatically refresh dashboards for near real-time use cases must choose capacity pricing. For readers under user pricing, each reader is limited to manual use by one individual only.

Troubleshooting Quick identity and access

Applies to: Enterprise Edition and Standard Edition

Intended audience: System administrators

Use the following information to help you diagnose and fix common issues that you might encounter when working with Amazon Quick and IAM.

Topics

- [I am not authorized to perform an action in Amazon Quick](#)
- [I am not authorized to perform iam:PassRole](#)
- [I want to allow people outside of my AWS account to access my Amazon Quick resources](#)

I am not authorized to perform an action in Amazon Quick

If the AWS Management Console tells you that you're not authorized to perform an action, then you must contact your administrator for assistance.

The following example error occurs when the `mateojackson` IAM user tries to use the console to view details about a `widget` but does not have `quicksight:GetWidget` permissions.

```
User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform:
quicksight:GetWidget on resource: my-example-widget
```

In this case, Mateo asks his administrator to update his policies to allow him to access the `my-example-widget` resource using the `quicksight:GetWidget` action.

I am not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the `iam:PassRole` action, your policies must be updated to allow you to pass a role to Amazon Quick.

Some AWS services allow you to pass an existing role to that service instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named `marymajor` tries to use the console to perform an action in Amazon Quick. However, the action requires the service to have permissions that are granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform:
iam:PassRole
```

In this case, Mary's policies must be updated to allow her to perform the `iam:PassRole` action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

I want to allow people outside of my AWS account to access my Amazon Quick resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether Amazon Quick supports these features, see [Using Quick with IAM](#).
- To learn how to provide access to your resources across AWS accounts that you own, see [Providing access to an IAM user in another AWS account that you own](#) in the *IAM User Guide*.
- To learn how to provide access to your resources to third-party AWS accounts, see [Providing access to AWS accounts owned by third parties](#) in the *IAM User Guide*.
- To learn how to provide access through identity federation, see [Providing access to externally authenticated users \(identity federation\)](#) in the *IAM User Guide*.
- To learn the difference between using roles and resource-based policies for cross-account access, see [Cross account resource access in IAM](#) in the *IAM User Guide*.

Using IAM Identity Center

Applies to: Enterprise Edition and Standard Edition

Intended audience: System administrators and Amazon Quick administrators

IAM Identity Center helps you securely create or connect your workforce identities and manage their access across AWS accounts and applications.

Before you integrate your Amazon Quick account with IAM Identity Center, set up IAM Identity Center in your AWS account. If you haven't set up IAM Identity Center in your AWS organization, see [Getting started](#) in the *AWS IAM Identity Center User Guide*.

If you want to configure an external identity provider with IAM Identity Center, see [Supported identity providers](#) to view a list of supported identity providers' configuration steps.

Topics

- [Configure your Amazon Quick account with IAM Identity Center](#)

Configure your Amazon Quick account with IAM Identity Center

Applies to: Enterprise Edition

Intended audience: System administrators

IAM Identity Center helps you securely create or configure your existing workforce identities and manage their access across AWS accounts and applications. IAM Identity Center is the recommended approach for workforce authentication and authorization on AWS for organizations of any size and type. To learn more about IAM Identity Center, see [AWS IAM Identity Center](#).

Configure Amazon Quick and IAM Identity Center so that you can sign up for a new Amazon Quick account with an IAM Identity Center configured identity source. With IAM Identity Center, you can configure your external identity provider as an identity source. You can also use IAM Identity Center

as an identity store if you don't want to use a third-party identity provider with Amazon Quick. Identity methods can't be changed after your account is created.

When you integrate your Amazon Quick account with IAM Identity Center, Amazon Quick account administrators can create a new Amazon Quick account that automatically has the identity provider's groups available. This simplifies asset sharing at scale in Amazon Quick.

To learn more how to sign up for an Amazon Quick account with IAM Identity Center, see [Signing up for an Amazon Quick subscription](#).

Set up Amazon Quick with IAM Identity Center multi-Region

You can create an Amazon Quick Enterprise subscription in a supported AWS Region that is configured as an additional Region for your IAM Identity Center instance. When you call `CreateAccountSubscription` against a target Region endpoint, that Region becomes the capacity Region for your Quick default namespace.

This procedure applies only to the IAM Identity Center authentication method. It does not create a second Quick subscription or replicate an existing one. Each AWS account supports one Quick account subscription.

Region concepts

The following Region types are relevant to this procedure:

- **IAM Identity Center primary Region** – The Region where your IAM Identity Center instance was originally created.
- **IAM Identity Center additional Region** – A Region to which your IAM Identity Center instance is replicated and active.
- **Quick capacity Region** – The Region where your Quick default namespace is provisioned. This is determined by the endpoint Region where you call `CreateAccountSubscription`.

Prerequisites

For detailed instructions, see [Multi-Region IAM Identity Center](#) and [Replicate to an additional Region](#) in the *AWS IAM Identity Center User Guide*.

Before you create your Quick subscription in an additional Region, complete the following steps in the order shown:

1. Configure a multi-Region customer managed KMS key for your IAM Identity Center instance in the primary Region.
2. Create a replica of the customer managed KMS key in the target Region.
3. Add the target Region to IAM Identity Center and wait until the Region status is ACTIVE.
4. If your organization uses an external identity provider, add the target Region's Assertion Consumer Service (ACS) URL to your identity provider configuration. For more information, see [Multi-Region workforce access](#) in the *AWS IAM Identity Center User Guide*.
5. Confirm that the target Region is a supported Quick signup Region. For a list of supported Regions, see [Supported AWS Regions for Amazon Quick](#).

To create a subscription in an additional Region

Use the AWS Command Line Interface or an AWS SDK to create an Amazon Quick Enterprise subscription in the target Region.

To create the subscription (AWS CLI)

1. Configure the AWS CLI to use the target Region. The configured Region determines the `CreateAccountSubscription` endpoint.
2. Run the following command. Replace the placeholder values with your own.

```
aws quicksight create-account-subscription \
  --aws-account-id <ACCOUNT_ID> \
  --account-name "<ACCOUNT_NAME>" \
  --notification-email <EMAIL> \
  --edition ENTERPRISE \
  --authentication-method IAM_IDENTITY_CENTER \
  --iam-identity-center-instance-arn <IDC_INSTANCE_ARN> \
  --admin-group "<ADMIN_GROUP_NAME>" \
  --region <TARGET_REGION>
```

The following list describes the required and recommended parameters:

- `--aws-account-id` – Your 12-digit AWS account ID.
- `--account-name` – A name for the Quick account.
- `--notification-email` – The email address for service notifications.
- `--edition ENTERPRISE` – IAM Identity Center authentication requires Enterprise edition.

- `--authentication-method IAM_IDENTITY_CENTER` – Specifies IAM Identity Center as the authentication method.
- `--iam-identity-center-instance-arn` – The ARN of your IAM Identity Center instance.
- `--admin-group` or `--admin-pro-group` – The name of the IAM Identity Center group to assign as Quick administrators.
- `--region` – The target Region for the Quick capacity Region. This must be an active IAM Identity Center additional Region and a supported Quick signup Region.

Verify the subscription

After the command completes, confirm that the subscription exists and is active.

To verify the subscription (AWS CLI)

1. Run the following command to check the account status:

```
aws quicksight describe-account-subscription \  
  --aws-account-id <ACCOUNT_ID> \  
  --region <TARGET_REGION>
```

Confirm that `AccountSubscriptionStatus` is `ACCOUNT_CREATED`.

2. Run the following command to verify the namespace and capacity Region:

```
aws quicksight list-namespaces \  
  --aws-account-id <ACCOUNT_ID> \  
  --region <TARGET_REGION>
```

Confirm that `CreationStatus` is `CREATED` and that `CapacityRegion` matches the target Region.

Considerations

Review the following considerations:

- You must use Amazon Quick Enterprise edition for IAM Identity Center authentication.

- You must specify either `--admin-group` or `--admin-pro-group` when you use IAM Identity Center authentication.
- You must choose a target Region that is both an active IAM Identity Center additional Region and a supported Quick signup Region.
- You can create only one Quick account subscription for each AWS account. If your account already has a subscription, `CreateAccountSubscription` returns a `resource-exists` error.
- You cannot change the authentication method after the Quick account is created.

Considerations

Irreversible actions

The following actions permanently prevent all users from signing in to your Amazon Quick account. You cannot undo these actions.

- Disabling or deleting the Amazon Quick application in the IAM Identity Center console. If you want to delete your Amazon Quick account, see [Closing your Amazon Quick account](#).
- Migrating the Amazon Quick account that contains your IAM Identity Center configuration to an AWS Organization that does not contain the IAM Identity Center instance that your Amazon Quick account is configured to.
- Deleting the IAM Identity Center instance that is configured to your Amazon Quick account.
- Editing IAM Identity Center application attributes, for example the **requires assignment** attribute.

IAM federation

Applies to: Enterprise Edition and Standard Edition

Intended audience: System administrators

⚠ Important

Amazon Quick recommends that you integrate new Amazon Quick subscriptions with IAM Identity Center for identity management. This IAM identity federation user guide is provided as a reference for existing account configurations. For more information on integrating your Amazon Quick account with IAM Identity Center, see [Configure your Amazon Quick account with IAM Identity Center](#).

ℹ Note

IAM identity federation doesn't support syncing identity provider groups with Amazon Quick.

Amazon Quick supports identity federation in both Standard and Enterprise editions. When you use federated users, you can manage users with your enterprise identity provider (IdP) and use AWS Identity and Access Management (IAM) to authenticate users when they sign in to Quick. You can use a third-party identity provider that supports Security Assertion Markup Language 2.0 (SAML 2.0) to provide an onboarding flow for your Amazon Quick users. Such identity providers include Microsoft Active Directory Federation Services, Okta, and Ping One Federation Server. With identity federation, your users get one-click access to their Amazon Quick applications using their existing identity credentials. You also have the security benefit of identity authentication by your identity provider. You can control which users have access to Amazon Quick using your existing identity provider.

Topics

- [Initiating sign-on from the identity provider \(IdP\)](#)
- [Setting up IdP federation using IAM and Amazon Quick](#)
- [Initiating sign-on from Quick](#)
- [Setting up service provider-initiated federation with Quick Enterprise edition](#)
- [Configuring email syncing for federated users in Quick](#)
- [Tutorial: Amazon Quick and IAM identity federation](#)

Initiating sign-on from the identity provider (IdP)

Applies to: Enterprise Edition and Standard Edition

Intended audience: System administrators

Note

IAM identity federation doesn't support syncing identity provider groups with Amazon Quick.

In this scenario, your users initiate the sign-on process from the identity provider's portal. After the users are authenticated, they sign in to Amazon Quick. After Quick checks that they are authorized, your users can access Quick.

Beginning with a user signing into the IdP, authentication flows through these steps:

1. The user browses to `https://applications.example.com` and signs on to the IdP. At this point, the user isn't signed in to the service provider.
2. The federation service and the IdP authenticate the user:
 - a. The federation service requests authentication from the organization's identity store.
 - b. The identity store authenticates the user and returns the authentication response to the federation service.
 - c. When authentication is successful, the federation service posts the SAML assertion to the user's browser.
3. The user opens Amazon Quick:
 - a. The user's browser posts the SAML assertion to the AWS Sign-In SAML endpoint (`https://signin.aws.amazon.com/saml`).
 - b. AWS Sign-In receives the SAML request, processes the request, authenticates the user, and forwards the authentication token to the Amazon Quick service.
4. Amazon Quick accepts the authentication token from AWS and presents Amazon Quick to the user.

From the user's perspective, the process happens transparently. The user starts at your organization's internal portal and lands at an Amazon Quick application portal, without ever having to supply any AWS credentials.

In the following diagram, you can find an authentication flow between Amazon Quick and a third-party identity provider (IdP). In this example, the administrator has set up a sign-in page to access Amazon Quick, called `applications.example.com`. When a user signs in, the sign-in page posts a request to a federation service that complies with SAML 2.0. The end user initiates authentication from the sign-on page of the IdP.

For information from some common providers, see the following third-party documentation:

- CA – [Enabling SAML 2.0 HTTP Post Binding](#)
- Okta – [Planning a SAML deployment](#)
- Ping – [Amazon integrations](#)

Use the following topics to understand using an existing federation with AWS:

- [Identity federation in AWS](#) on the AWS website

- [Providing access to externally authenticated users \(identity federation\)](#) in the *IAM User Guide*
- [Enabling SAML 2.0 federated users to access the AWS Management Console](#) in the *IAM User Guide*

Setting up IdP federation using IAM and Amazon Quick

Applies to: Enterprise Edition and Standard Edition

Intended audience: System administrators

Note

IAM identity federation doesn't support syncing identity provider groups with Amazon Quick.

You can use an AWS Identity and Access Management (IAM) role and a relay state URL to configure an identity provider (IdP) that is compliant with SAML 2.0. The role grants users permissions to access Amazon Quick. The relay state is the portal that the user is forwarded to, after successful authentication by AWS.

Topics

- [Prerequisites](#)
- [Step 1: Create a SAML provider in AWS](#)
- [Step 2: Configure permissions in AWS for your federated users](#)
- [Step 3: Configure the SAML IdP](#)
- [Step 4: Create assertions for the SAML authentication response](#)
- [Step 5: Configure the relay state of your federation](#)

Prerequisites

Before configuring your SAML 2.0 connection, do the following:

- Configure your IdP to establish a trust relationship with AWS:

- Inside your organization's network, configure your identity store, such as Windows Active Directory, to work with a SAML-based IdP. SAML-based IdPs include Active Directory Federation Services, Shibboleth, and so on.
- Using your IdP, generate a metadata document that describes your organization as an identity provider.
- Set up SAML 2.0 authentication, using the same steps as for the AWS Management Console. When this process is complete, you can configure your relay state to match the relay state of Quick. For more information, see [Configure the relay state of your federation](#).
- Create an Amazon Quick account and note the name to use when you configure your IAM policy and IdP. For more information on creating an Amazon Quick account, see [Signing up for an Amazon Quick subscription](#).

After you create the setup to federate to the AWS Management Console as outlined in the tutorial, you can edit the relay state provided in the tutorial. You do so with the relay state of Amazon Quick, described in step 5 following.

For more information, see the following resources:

- [Integrating Third-Party SAML Solution Providers with AWS](#) in the *IAM User Guide*.
- [Troubleshooting SAML 2.0 federation with AWS](#), also in the *IAM User Guide*.
- [Setting up trust between ADFS and AWS and using Active Directory credentials to connect to Amazon Athena with ODBC driver](#) – This walkthrough article is helpful, although you don't need to set up Athena in order to use Amazon Quick.

Step 1: Create a SAML provider in AWS

Your SAML identity provider defines your organization's IdP to AWS. It does so by using the metadata document that you previously generated using your IdP.

To create a SAML provider in AWS

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. Create a new SAML provider, which is an entity in IAM that holds information about your organization's identity provider. For more information, see [Creating SAML Identity Providers](#) in the *IAM User Guide*.

3. As part of this process, upload the metadata document produced by the IdP software in your organization noted in the previous section.

Step 2: Configure permissions in AWS for your federated users

Next, create an IAM role that establishes a trust relationship between IAM and your organization's IdP. This role identifies your IdP as a principal (trusted entity) for the purposes of federation. The role also defines which users authenticated by your organization's IdP are allowed to access Amazon Quick. For more information about creating a role for a SAML IdP, see [Creating a Role for SAML 2.0 Federation](#) in the *IAM User Guide*.

After you have created the role, you can limit the role to have permissions only to Amazon Quick by attaching an inline policy to the role. The following sample policy document provides access to Amazon Quick. This policy allows the user access to Amazon Quick and allows them to create both author accounts and reader accounts.

Note

In the following example, replace `<YOUR_AWS_ACCOUNT_ID>` with your 12-digit AWS account ID (with no hyphens '-').

```
{
  "Statement": [
    {
      "Action": [
        "quicksight:CreateUser"
      ],
      "Effect": "Allow",
      "Resource": [
        "arn:aws:quicksight::<YOUR_AWS_ACCOUNT_ID>:user/${aws:userid}"
      ]
    }
  ],
  "Version": "2012-10-17"
}
```

If you want to provide access to Amazon Quick and also the ability to create Amazon Quick admins, authors (standard users), and readers, you can use the following policy example.

```
{
  "Statement": [
    {
      "Action": [
        "quicksight:CreateAdmin"
      ],
      "Effect": "Allow",
      "Resource": [
        "arn:aws:quicksight::<YOUR_AWS_ACCOUNT_ID>:user/${aws:userid}"
      ]
    }
  ],
  "Version": "2012-10-17"
}
```

You can view account details in the AWS Management Console.

After you have set up SAML and the IAM policy or policies, you don't need to invite users manually. The first time that users open Amazon Quick, they are provisioned automatically, using the highest level permissions in the policy. For example, if they have permissions to both `quicksight:CreateUser` and `quicksight:CreateReader`, they are provisioned as authors. If they also have permissions to `quicksight:CreateAdmin`, they are provisioned as admins. Each permission level includes the ability to create the same level user and below. For example, an author can add other authors or readers.

Users who are invited manually are created in the role assigned by the person who invited them. They don't need to have policies that grant them permissions.

Step 3: Configure the SAML IdP

After you create the IAM role, update your SAML IdP about AWS as a service provider. To do so, install the `saml-metadata.xml` file found at <https://signin.aws.amazon.com/static/saml-metadata.xml>.

To update the IdP metadata, see the instructions provided by your IdP. Some providers give you the option to type the URL, after which the IdP gets and installs the file for you. Others require you to download the file from the URL and then provide it as a local file.

For more information, see your IdP documentation.

Step 4: Create assertions for the SAML authentication response

Next, configure the information that the IdP passes as SAML attributes to AWS as part of the authentication response. For more information, see [Configuring SAML Assertions for the Authentication Response](#) in the *IAM User Guide*.

Step 5: Configure the relay state of your federation

Finally, configure the relay state of your federation to point to the Amazon Quick relay state URL. After successful authentication by AWS, the user is directed to Amazon Quick, defined as the relay state in the SAML authentication response.

The relay state URL for Amazon Quick is as follows.

```
https://quicksight.aws.amazon.com
```

Initiating sign-on from Quick

Applies to: Enterprise Edition

Intended audience: System administrators

Note

IAM identity federation doesn't support syncing identity provider groups with Amazon Quick.

In this scenario, your user initiates the sign-on process from an Amazon Quick application portal without being signed on to the identity provider. In this case, the user has a federated account managed by a third-party IdP. The user might have a user account on Quick. Quick sends an authentication request to the IdP. After the user is authenticated, Quick opens.

Beginning with the user signing into Quick, authentication flows through these steps:

1. The user opens Quick. At this point, the user isn't signed in to the IdP.
2. The user attempts to sign in to Amazon Quick.
3. Amazon Quick redirects the user's input to the federation service and requests authentication.
4. The federation service and the IdP authenticate the user:
 - a. The federation service requests authentication from the organization's identity store.
 - b. The identity store authenticates the user and returns the authentication response to the federation service.
 - c. When authentication is successful, the federation service posts the SAML assertion to the user's browser.
 - d. The user's browser posts the SAML assertion to the AWS Sign-In SAML endpoint (<https://signin.aws.amazon.com/saml>).
 - e. AWS Sign-In receives the SAML request, processes the request, authenticates the user, and forwards the authentication token to the Amazon Quick service.
5. Amazon Quick accepts the authentication token from AWS and presents Amazon Quick to the user.

From the user's perspective, the process happens transparently. The user starts at an Amazon Quick application portal. Amazon Quick negotiates authentication with your organization's federation service and AWS. Amazon Quick opens, without the user needing to supply any additional credentials.

Setting up service provider–initiated federation with Quick Enterprise edition

Applies to: Enterprise Edition

Intended audience: System administrators

Note

IAM identity federation doesn't support syncing identity provider groups with Amazon Quick.

After you have finished configuring your identity provider with AWS Identity and Access Management (IAM), you can set up service provider–initiated sign in through Amazon Quick Enterprise Edition. For Quick-initiated IAM federation to work, you need to authorize Quick to send the authentication request to your IdP. A Quick administrator can configure this by adding the following information provided by the IdP:

- The IdP URL – Quick redirects users to this URL for authentication.
- The relay state parameter – This parameter relays the state that the browser session was in when it was redirected for authentication. The IdP redirects the user back to the original state after authentication. The state is provided as a URL.

The following table shows the standard authentication URL and relay state parameter for redirecting the user to the Quick URL that you provide.

Identity provider	Parameter	Authentication URL
Auth0	RelayState	<code>https://<sub_domain>.auth0.com/samlp/<app_id></code>
Google accounts	RelayState	<code>https://accounts.google.com/o/saml2/initssso?idpid=<idp_id>&spid=<sp_id>&forceauthn=false</code>
Microsoft Azure	RelayState	<code>https://myapps.microsoft.com/signin/<app_name>/<app_id>?tenantId=<tenant_id></code>
Okta	RelayState	<code>https://<sub_domain>.okta.com/app/<app_name>/<app_id>/sso/saml</code>
PingFederate	TargetResource	<code>https://<host>/idp/<idp_id>/startSSO.ping?PartnerSpId=<sp_id></code>
PingOne	TargetResource	<code>https://sso.connect.pingidentity.com/sso/sp/initssso?saasid=<app_id>&idpid=<idp_id></code>

Amazon Quick supports connecting to one IdP per AWS account. The configuration page in Amazon Quick provides you with test URLs based on your entries, so you can test the settings

before you turn on the feature. To make the process even more seamless, Amazon Quick provides a parameter (`enable-sso=0`) to temporarily turn off Amazon Quick initiated IAM federation, in case you need to disable it temporarily.

To set up Amazon Quick as a service provider that can initiate IAM federation for an existing IdP

1. Make sure that you already have IAM federation set up in your IdP, in IAM, and Amazon Quick. To test this setup, check if you can share a dashboard with another person in your company's domain.
2. Open Amazon Quick, and choose **Manage Amazon Quick** from your profile menu at upper right.

To perform this procedure, you need to be a Amazon Quick administrator. If you aren't, you can't see **Manage Amazon Quick** under your profile menu.

3. Choose **Single sign-on (IAM federation)** from the navigation pane.
4. For **Configuration**, **IdP URL**, enter the URL that your IdP provides to authenticate users.
5. For **IdP URL**, enter the parameter that your IdP provides to relay state, for example `RelayState`. The actual name of the parameter is provided by your IdP.
6. Test signing in:
 - To test signing in with your identity provider, use the custom URL provided in **Test starting with your IdP**. You should arrive at the start page for Amazon Quick, for example `https://quicksight.aws.amazon.com/sn/start`.
 - To test signing in with Amazon Quick first, use the custom URL provided in **Test the end-to-end experience**. The `enable-sso` parameter is appended to the URL. If `enable-sso=1`, IAM federation attempts to authenticate.
7. Choose **Save** to keep your settings.

To enable service provider-initiated IAM federation IdP

1. Make sure your IAM federation settings are configured and tested. If you're not sure about the configuration, test the connection by using the URLs from the previous procedure.
2. Open Amazon Quick, and choose **Manage Amazon Quick** from your profile menu.
3. Choose **Single sign-on (IAM federation)** from the navigation pane.

4. For **Status**, choose **ON**.
5. Verify that it's working by disconnecting from your IdP and opening Amazon Quick.

To disable service provider initiated IAM federation

1. Open Amazon Quick, and choose **Manage Amazon Quick** from your profile menu.
2. Choose **Single sign-on (IAM federation)** from the navigation pane.
3. For **Status**, choose **OFF**.

Configuring email syncing for federated users in Quick

Applies to: Enterprise Edition

Intended audience: System administrators and Amazon Quick administrators

Note

IAM identity federation doesn't support syncing identity provider groups with Amazon Quick.

In Amazon Quick Enterprise edition, as an administrator you can restrict new users from using personal email addresses when provisioning through their identity provider (IdP) directly to Quick. Quick then uses the preconfigured email addresses passed through the IdP when provisioning new users to your account. For example, you can make it so that only corporate-assigned email addresses are used when users are provisioned to your Amazon Quick account through your IdP.

Note

Make sure that your users are federating directly to Amazon Quick through their IdP. Federating to the AWS Management Console through their IdP and then clicking into Amazon Quick results in an error and they won't be able to access Amazon Quick.

When you configure email syncing for federated users in Amazon Quick, users who log in to your Amazon Quick account for the first time have preassigned email addresses. These are used to register their accounts. With this approach, users can manually bypass by entering an email address. Also, users can't use an email address that might differ from the email address prescribed by you, the administrator.

Amazon Quick supports provisioning through an IdP that supports SAML or OpenID Connect (OIDC) authentication. To configure email addresses for new users when provisioning through an IdP, you update the trust relationship for the IAM role that they use with `AssumeRoleWithSAML` or `AssumeRoleWithWebIdentity`. Then you add a SAML attribute or OIDC token in their IdP. Last, you turn on email syncing for federated users in Amazon Quick.

The following procedures describe these steps in detail.

Step 1: Update the trust relationship for the IAM role with `AssumeRoleWithSAML` or `AssumeRoleWithWebIdentity`

You can configure email addresses for your users to use when provisioning through your IdP to Amazon Quick. To do this, add the `sts:TagSession` action to the trust relationship for the IAM role that you use with `AssumeRoleWithSAML` or `AssumeRoleWithWebIdentity`. By doing this, you can pass in `principal` tags when users assume the role.

The following example illustrates an updated IAM role where the IdP is Okta. To use this example, update the Federated Amazon Resource Name (ARN) with the ARN for your service provider. You can replace items in red with your AWS and IdP service-specific information.

```
{
  "Version": "2012-10-17"      ,
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Federated": "arn:aws:iam::account-id:saml-provider/Okta"
      },
      "Action": "sts:AssumeRoleWithSAML",
      "Condition": {
        "StringEquals": {
          "SAML:aud": "https://signin.aws.amazon.com/saml"
        }
      }
    }
  ],
}
```

```
{
  "Effect": "Allow",
  "Principal": {
    "Federated": "arn:aws:iam::account-id:saml-provider/Okta"
  },
  "Action": "sts:TagSession",
  "Condition": {
    "StringLike": {
      "aws:RequestTag/Email": "*"
    }
  }
}
```

Step 2: Add a SAML attribute or OIDC token for the IAM principal tag in your IdP

After you update the trust relationship for the IAM role as described in the preceding section, add a SAML attribute or OIDC token for the IAM Principal tag in your IdP.

The following examples illustrate a SAML attribute and an OIDC token. To use these examples, replace the email address with a variable in your IdP that points to a user's email address. You can replace items highlighted in red with your information.

- **SAML attribute:** The following example illustrates a SAML attribute.

```
<Attribute Name="https://aws.amazon.com/SAML/Attributes/PrincipalTag:Email"><AttributeValue>john.doe@example.com</AttributeValue></Attribute>
```

Note

If you're using Okta as your IdP, make sure to turn on a feature flag in your Okta user account to use SAML. For more information, see [Okta and AWS Partner to Simplify Access Via Session Tags](#) on the Okta blog.

- **OIDC token:** The following example illustrates an OIDC token example.

```
"https://aws.amazon.com/tags": {"principal_tags": {"Email": ["john.doe@example.com"]}}
```

Step 3: Turn on email syncing for federated users in Amazon Quick

As described preceding, update the trust relationship for the IAM role and add a SAML attribute or OIDC token for the IAM Principal tag in your IdP. Then turn on email syncing for federated users in Amazon Quick as described in the following procedure.

To turn on email syncing for federated users

1. From any page in Amazon Quick, choose your username at top right, and then choose **Manage Amazon Quick**.
2. Choose **Single sign-on (IAM federation)** in the menu at left.
3. On the **Service Provider Initiated IAM federation** page, for **Email Syncing for Federated Users**, choose **ON**.

When email syncing for federated users is on, Amazon Quick uses the email addresses that you configured in steps 1 and 2 when provisioning new users to your account. Users can't enter their own email addresses.

When email syncing for federated users is off, Amazon Quick asks users to input their email address manually when provisioning new users to your account. They can use any email addresses that they want.

Tutorial: Amazon Quick and IAM identity federation

Applies to: Enterprise Edition and Standard Edition

Intended audience: Amazon Quick Administrators and Amazon Quick developers

Note

IAM identity federation doesn't support syncing identity provider groups with Amazon Quick.

In the following tutorial, you can find a walkthrough for setting up the IdP Okta as a federation service for Amazon Quick. Although this tutorial shows the integration of AWS Identity and Access

Management (IAM) and Okta, you can also replicate this solution using your choice of SAML 2.0 IdPs.

In the following procedure, you create an app in the Okta IdP using their "AWS Account Federation" shortcut. Okta describes this integration app as follows:

"By federating Okta to Amazon Web Services (AWS) Identity and Access Management (IAM) accounts, end users get single sign-on access to all their assigned AWS roles with their Okta credentials. In each AWS account, administrators set up federation and configure AWS roles to trust Okta. When users sign in to AWS, they get Okta single sign-in experience to see their assigned AWS roles. They can then select a desired role, which defined their permissions for the duration of their authenticated session. Customers with large numbers of AWS Accounts, check out the AWS Single Sign-On app as an alternative." (<https://www.okta.com/aws/>)

To create an Okta app using Okta's "AWS Account Federation" application shortcut

1. Sign in to your Okta dashboard. If you don't have one, create a free Okta Developer Edition account by using [this Amazon Quick-branded URL](#). When you have activated your email, sign in to Okta.
2. On the Okta website, choose **<> Developer Console** at upper left, and then choose **Classic UI**.
3. Choose **Add Applications**, and choose **Add app**.
4. Enter **aws** for **Search**, and choose **AWS Account Federation** from the search results.
5. Choose **Add** to create an instance of this application.
6. For **Application label**, enter **AWS Account Federation - Amazon Quick**.
7. Choose **Next**.
8. For **SAML 2.0, Default Relay State**, enter **<https://quicksight.aws.amazon.com>**.
9. Open the context (right-click) menu for **Identity Provider metadata**, and choose to save the file. Name the file `metadata.xml`. You need this file in the next procedure.

The contents of the file look similar to the following.

```
<md:EntityDescriptor xmlns:md="urn:oasis:names:tc:SAML:2.0:metadata"
  entityID="http://www.okta.com/exkffz2hATwiVft645d5">
  <md:IDPSSODescriptor WantAuthnRequestsSigned="false"
    protocolSupportEnumeration="urn:oasis:names:tc:SAML:2.0:protocol">
    <md:KeyDescriptor use="signing">
      <ds:KeyInfo xmlns:ds="http://www.w3.org/2000/09/xmldsig#">
        <ds:X509Data>
```

```

        <ds:X509Certificate>

MIIDpjCCAo6gAwIBAgIGAXVjA82hMA0GCSqGSIb3DQEBCwUAMIGTMQswCQYDVQQGEwJVUzETMBEG
.
.      (certificate content omitted)
.
QE/6cRdPQ6v/eaFpUL6Asd6q3sBeq+giRG4=
        </ds:X509Certificate>
    </ds:X509Data>
    </ds:KeyInfo>
</md:KeyDescriptor>
    <md:NameIDFormat>urn:oasis:names:tc:SAML:1.1:nameid-format:emailAddress</
md:NameIDFormat>
    <md:NameIDFormat>urn:oasis:names:tc:SAML:2.0:nameid-format:unspecified</
md:NameIDFormat>
    <md:SingleSignOnService Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-
POST" Location="https://dev-1054988.okta.com/app/amazon_aws/exkffz2hATwiVft645d5/
sso/saml"/>
    <md:SingleSignOnService Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-
Redirect" Location="https://dev-1054988.okta.com/app/amazon_aws/
exkffz2hATwiVft645d5/sso/saml"/>
    </md:IDPSSODescriptor>
</md:EntityDescriptor>

```

10. After you have the XML file saved, scroll to the bottom of the Okta page, and choose **Done**.
11. Keep this browser window open, if possible. You need it later in the tutorial.

Next, you create an identity provider in your AWS account.

To create a SAML provider in AWS Identity and Access Management (IAM)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Identity providers**, **Create Provider**.
3. Enter the following settings:
 - **Provider Type** – Choose **SAML** from the list.
 - **Provider Name** – Enter **Okta**.
 - **Metadata Document** – Upload the XML file `manifest.xml` from the previous procedure.
4. Choose **Next Step, Create**.

5. Locate the IdP that you created and choose it to view the settings. Note the **Provider ARN**. You need this to finish the tutorial.
6. Verify that the identity provider is created with your settings. In IAM, choose **Identity providers, Okta** (the IdP you added), **Download metadata**. The file should be the one that you recently uploaded.

Next, you create an IAM role to enable the SAML 2.0 federation to act as a trusted entity in your AWS account. For this step, you need to choose how you want to provision users in Amazon Quick. You can do one of the following:

- Grant permission to the IAM role so that first-time visitors become Amazon Quick users automatically.

To create an IAM role for a SAML 2.0 federation as a trusted entity

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Roles, Create Role**.
3. For **Select type of trusted entity**, choose the card labeled **SAML 2.0 federation**.
4. For **SAML provider**, select the IdP that you created in the previous procedure, for example Okta.
5. Enable the option **Allow programmatic and AWS Management Console access**.
6. Choose **Next: Permissions**.
7. Paste the following policy into the editor.

In the policy editor, update the JSON with your provider's Amazon Resource Name (ARN).

```
{
  "Version": "2012-10-17"
,
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "sts:AssumeRoleWithSAML",
      "Resource": "arn:aws:iam::111111111111:saml-provider/Okta",
      "Condition": {
        "StringEquals": {
          "saml:aud": "https://signin.aws.amazon.com/saml"
        }
      }
    }
  ]
}
```

```

    }
  }
}
]
}

```

8. Choose **Review policy**.
9. For **Name**, enter **QuicksightOktaFederatedPolicy**, and then choose **Create policy**.
10. Choose **Create policy, JSON** a second time.
11. Paste the following policy into the editor.

In the policy editor, update the JSON with your AWS account ID. It should be the same account ID that you used in the previous policy in the provider ARN.

```

{
  "Version": "2012-10-17"      ,
  "Statement": [
    {
      "Action": [
        "quicksight:CreateReader"
      ],
      "Effect": "Allow",
      "Resource": [
        "arn:aws:quicksight::111111111111:user/${aws:userid}"
      ]
    }
  ]
}

```

You can omit the AWS Region name in the ARN, as shown following.

```
arn:aws:quicksight::111111111111:user/${aws:userid}
```

12. Choose **Review policy**.
13. For **Name**, enter **QuicksightCreateReader**, and then choose **Create policy**.
14. Refresh the list of policies by choosing the refresh icon at right.
15. For **Search**, enter **QuicksightOktaFederatedPolicy**. Choose the policy to enable it ().

If you don't want to use automatic provisioning, you can skip the following step.

To add a Amazon Quick user, use [register-user](#). To add a Amazon Quick group, use [create-group](#). To add users to the Amazon Quick group, use [create-group-membership](#).

16. (Optional) For **Search**, enter **QuicksightCreateReader**. Choose the policy to enable it ().

Do this step if you want to provision Amazon Quick users automatically, rather than using the Amazon Quick API.

The QuicksightCreateReader policy activates automatic provisioning by allowing use of the quicksight:CreateReader action. Doing this grants dashboard subscriber (reader-level) access to first-time users. A Amazon Quick administrator can later upgrade them from the Amazon Quick profile menu, **Manage Amazon Quick**, **Manage users**.

17. To continue attaching the IAM policy or policies, choose **Next: Tags**.
18. Choose **Next: Review**.
19. For **Role name**, enter **QuicksightOktaFederatedRole**, and choose **Create role**.
20. Verify that you completed this successfully by taking these steps:
 - a. Return to the main page of the IAM console at <https://console.aws.amazon.com/iam/>. You can use your browser's **Back** button.
 - b. Choose **Roles**.
 - c. For **Search**, enter Okta. Choose **QuicksightOktaFederatedRole** from the search results.
 - d. On the **Summary** page for the policy, examine the **Permissions** tab. Verify that the role has the policy or policies that you attached to it. It should have QuicksightOktaFederatedPolicy. If you chose to add the ability to create users, it should also have QuicksightCreateReader.
 - e. Use the  icon to open each policy. Verify that the text matches what is shown in this procedure. Double-check that you added your own AWS account number in place of the example account number 111111111111.
 - f. On the **Trust relationships** tab, verify that the **Trusted entities** field contains the ARN for the identity provider. You can double-check the ARN in the IAM console by opening **Identity providers**, **Okta**.
 - g.

To create an access key for Okta

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. Add a policy that allows Okta to display a list of IAM roles to the user. To do this, choose **Policy, Create policy**.
3. Choose **JSON**, then enter the following policy.

```
{
  "Version": "2012-10-17"      ,
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "iam:ListRoles",
        "iam:ListAccountAliases"
      ],
      "Resource": "*"
    }
  ]
}
```

4. Choose **Review Policy**.
5. For **Name**, enter **OktaListRolesPolicy**. Then choose **Create policy**.
6. Add a user so you can provide Okta with an access key.

In the navigation pane, choose **Users, Add User**.

7. Use the following settings:
 - For **User name**, enter OktaSSOUser.
 - For **Access type**, enable **Programmatic access**.
8. Choose **Next: Permissions**.
9. Choose **Attach existing policies directly**.
10. For **Search**, enter **OktaListRolesPolicy**, and choose **OktaListRolesPolicy** from the search results.
11. Choose **Next: Tags**, and then choose **Next: Review**.
12. Choose **Create user**. Now you can get the access key.

13. Download the key file by choosing **Download .csv**. The file contains the same access key ID and secret access key that displays on this screen. However, because AWS doesn't display this information a second time, make sure to download the file.
14. Verify that you completed this step correctly by doing the following:
 - a. Open the IAM console, and choose **Users**. Search for **OktaSSOUser**, and open it by choosing the username from the search results.
 - b. On the **Permissions** tab, verify that the **OktaListRolesPolicy** is attached.
 - c. Use the  icon to open the policy. Verify that the text matches what is shown in this procedure.
 - d. On the **Security credentials** tab, you can check the access key, although you already downloaded it. You can return to this tab to create an access key when you need a new one.

In the following procedure, you return to Okta to provide the access key. The access key works with your new security settings to allow AWS and the Okta IdP to work together.

To finish configuring the Okta application with AWS settings

1. Return to your Okta dashboard. If requested to do so, sign in. If the developer console is no longer open, choose **Admin** to reopen it.
2. If you have to reopen Okta, you can return to this section by following these steps:
 - a. Sign in to Okta. Choose **Applications**.
 - b. Choose **AWS Account Federation - Amazon Quick**—the application that you created at the beginning of this tutorial.
 - c. Choose the **Sign On** tab, between **General** and **Mobile**.
3. Scroll to **Advanced Sign-On Settings**.
4. For **Identity Provider ARN (Required only for SAML IAM federation)**, enter the provider ARN from the previous procedure, for example:

`arn:aws:iam::111122223333:saml-provider/Okta`
5. Choose **Done** or **Save**. The name of the button varies depending if you are creating or editing the application.

6. Choose the **Provisioning** tab, and at the lower part of the tab, choose **Configure API Integration**.
7. Turn on **Enable API integration** to display the settings.
8. For **Access Key** and **Secret Key**, provide the access key and secret key that you downloaded previously to a file named **OktaSSOUser_credentials.csv**.
9. Choose **Test API Credentials**. Look above the **Enable API integration** setting for a message confirming that **AWS Account Federation was verified successfully**.
10. Choose **Save**.
11. Make sure that **To App** is highlighted at left, and choose **Edit** at right.
12. For **Create Users**, turn on the option **Enable**.
13. Choose **Save**.
14. On the **Assignments** tab, near **Provisioning** and **Import**, choose **Assign**.
15. Do one or more of the following to enable federated access:
 - To work with individual users, choose **Assign to People**.
 - To work with IAM groups, choose **Assign to Groups**. You can choose specific IAM groups or **Everyone (All users in your organization)**.
16. For each IAM user or group, do the following:
 - a. Choose **Assign, Role**.
 - b. Select **QuicksightOktaFederatedRole** from the list of IAM roles.
 - c. For **SAML User Roles**, enable **QuicksightOktaFederatedRole**.
17. Choose **Save and Go Back**, and then choose **Done**.
18. Verify that you completed this step correctly by choosing the **People** or **Groups** filter at left, and checking the users or groups that you entered. If you can't complete this process because the role that you created doesn't appear in the list, return to the previous procedures to verify the settings.

To sign in to Amazon Quick using Okta (IdP to service provider sign-in)

1. If you are using an Okta administrator account, switch to user mode.
2. Sign in to your Okta Applications dashboard with a user that has been granted federated access. You should see a new application with your label, for example **AWS Account Federation - Amazon Quick**.

3. Choose the application icon to launch **AWS Account Federation - Amazon Quick**.

You can now manage identities using Okta and use federated access with Quick.

The following procedure is an optional part of this tutorial. If you follow its steps, you authorize Amazon Quick to forward authorizations requests to the IdP on behalf of your users. Using this method, users can sign in to Amazon Quick with no need to sign in using the IdP page first.

(Optional) To set up Amazon Quick to send authentication requests to Okta

1. Open Amazon Quick, and choose **Manage Amazon Quick** from your profile menu.
2. Choose **Single sign-on (IAM federation)** from the navigation pane.
3. For **Configuration**, **IdP URL**, enter the URL that your IdP provides to authenticate users, for example `https://dev-1-----0.okta.com/home/amazon_aws/0oabababababaGQei5d5/282`. You can find this in your Okta app page, on the **General** tab, in **Embed Link**.
4. For **IdP URL**, enter `RelayState`.
5. Do one of the following:
 - To test signing in with your identity provider first, use the custom URL provided in **Test starting with your IdP**. You should arrive at the start page for Amazon Quick, for example `https://quicksight.aws.amazon.com/sn/start`.
 - To test signing in with Amazon Quick first, use the custom URL provided in **Test the end-to-end experience**. The `enable-sso` parameter is appended to the URL. If `enable-sso=1`, IAM federation attempts to authenticate. If `enable-sso=0`, Amazon Quick doesn't send the authentication request, and you sign in to Amazon Quick as before.
6. For **Status**, choose **ON**.
7. Choose **Save** to keep your settings.

You can create a deep link to a Amazon Quick dashboard to allow users to use IAM federation to connect directly to specific dashboards. To do this, you append the relay state flag and dashboard URL to the Okta single sign-on URL, as described following.

To create a deep link to a Amazon Quick dashboard for single sign-on

1. Locate the Okta application's single sign-on (IAM federation) URL in the `metadata.xml` file that you downloaded beginning of the tutorial. You can find the URL near the bottom of the

file, in the element named `md:SingleSignOnService`. The attribute is named `Location` and the value ends with `/sso/saml`, as shown in the following example.

```
<md:SingleSignOnService Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-Redirect" Location="https://dev-0000001.okta.com/app/amazon_aws/abcdef2hATwiVft645d5/sso/saml"/>
```

2. Take the value of the IAM federation URL and append `?RelayState=` followed by the URL of your Amazon Quick dashboard. The `RelayState` parameter relays the state (the URL) that the user was in when they were redirected to the authentication URL.
3. To the new IAM federation with the relay state added, append the URL of your Amazon Quick dashboard. The resulting URL should resemble the following.

```
https://dev-1-----0.okta.com/app/amazon_aws/abcdef2hATwiVft645d5/sso/saml?RelayState=https://us-west-2.quicksight.aws.amazon.com/sn/analyses/12a12a2a-121a-212a-121a-abcd12abc1ab
```

4. If the link you create doesn't open, check that you are using the most recent IAM federation URL from the `metadata.xml`. Also check that the username you use to sign in isn't assigned in more than one IAM federation Okta app.

Using Active Directory with Amazon Quick Enterprise edition

Applies to: Enterprise Edition

Intended audience: System administrators

Note

IAM identity federation doesn't support syncing identity provider groups with Amazon Quick.

Amazon Quick Enterprise edition supports both [AWS Directory Service for Microsoft Active Directory](#) and [Active Directory Connector](#).

To create a new directory to be your identity manager for Quick, use AWS Directory Service for Microsoft Active Directory, also known as AWS Managed Microsoft AD. This is an Active Directory host in the AWS Cloud that offers most of the same functionality of Active Directory. Currently, you can connect to Active Directory in any AWS Region supported by Amazon Quick, except for Asia Pacific (Singapore). When you create a directory, you use it with a virtual private cloud (VPC). For more information, see [VPC](#).

If you have an existing directory that you want to use for Quick, you can use Active Directory Connector. This service redirects directory requests to your Active Directory—in another AWS Region or on-premises—without caching any information in the cloud.

For a walkthrough about creating and managing a directory with AWS Managed Microsoft AD, see [Use an AWS Managed Microsoft AD with Quick?](#) in the AWS Knowledge Center.

When you use AWS Directory Service to launch a directory, AWS creates an organizational unit (OU) with the same name as your domain. AWS also creates an administrative account with delegated administrative rights for the OU. You can create accounts, groups, and policies within the OU by using Active Directory users and groups. For more information, see [Best Practices for AWS Managed Microsoft AD](#) in the *Directory Service Administration Guide*.

After you establish your directory, you use it with Quick by creating groups for users. Amazon Quick has six specific user roles that can be assigned, including Pro versions that provide access to advanced capabilities:

- **Quick admins** – Admins can change account settings, manage accounts. Admins can also purchase additional Amazon Quick user subscriptions or [SPICE](#) capacity, or cancel the subscription to Amazon Quick for your AWS account. Admin Pro users have additional capabilities including creating content using natural language, building knowledge bases, configuring actions, and accessing advanced automation workflows.
- **Quick authors** – Amazon Quick authors can create data sources, datasets, analyses, and dashboards. They can share analyses and dashboards with other Amazon Quick users. Author Pro users can additionally create content using natural language, build knowledge bases, configure actions, and access advanced automation capabilities.
- **Quick readers** – Readers can view and interact with dashboards that were created by someone else. Reader Pro users have access to advanced features including AI chat agents, collaborative spaces, flows, and extensions.

You can add or refine access by applying IAM policies. For example, you can use IAM policies to allow users to subscribe themselves.

When you subscribe to Amazon Quick Enterprise edition and choose Active Directory as your identity provider, you can associate your AD groups with Amazon Quick. You can also add or change your AD groups later on.

Topics

- [Directory integration with Quick Enterprise edition](#)

Directory integration with Quick Enterprise edition

Applies to: Enterprise Edition

Intended audience: System administrators

Note

IAM identity federation doesn't support syncing identity provider groups with Amazon Quick.

Quick Enterprise supports the following options:

- AWS Directory Service
- AWS Directory Service with AD Connector
- On-premises Active Directory with IAM federation or AD Connector
- IAM federation using AWS IAM Identity Center or another third-party federation service

If you want to use IAM federation with an on-premises Active Directory, you implement AWS Directory Service as a separate Active Directory with a trust relationship to the on-premises Active Directory.

If you want to avoid using a trust relationship, you can deploy a standalone domain for authentication within AWS. Then you can create users and groups in Active Directory. You'd then

map them to users and groups in Quick. In this example, users authenticate using their Active Directory login credentials. To make access to Quick transparent to your users, use IAM federation in this scenario.

Using multi-factor authentication (MFA) with Amazon Quick

Applies to: Enterprise Edition and Standard Edition

Intended audience: System administrators

Important

Amazon Quick recommends that you integrate new Quick subscriptions with IAM Identity Center for identity management. This IAM identity federation user guide is provided as a reference for existing account configurations. For more information on integrating your Quick account with IAM Identity Center, see [Configure your Quick account with IAM Identity Center](#).

Note

IAM identity federation doesn't support syncing identity provider groups with Amazon Quick.

There are several ways that you can use multi-factor authentication (MFA) with Quick. You can use it with AWS Identity and Access Management (IAM). You can use it with AD Connector or your [AWS Directory Service](#) for Microsoft Active Directory, also known as AWS Microsoft Active Directory or AWS Managed Microsoft Active Directory. And if you use an external identity provider (IdP), AWS doesn't need to have any information about MFA because that is part of the authentication handled by the IdP.

For more information, see the following:

- [Using multi-factor authentication \(MFA\) in AWS](#) in the IAM User Guide

- [Enable Multi-Factor Authentication for AWS Managed Microsoft AD](#) in the AWS Directory Service Administration Guide
- [Enable Multi-Factor Authentication for AD Connector](#) in the AWS Directory Service Administration Guide

If you're a developer, see the following:

- [How do I use an MFA token to authenticate access to my AWS resources through the AWS CLI](#) in the [AWS Knowledge Center](#)
- [Configuring MFA-protected API access](#) in the IAM User Guide

Allowlisting Amazon Quick domains

If your end users are signing in to Amazon Quick using AWS root (not recommended), AWS Identity and Access Management (IAM), corporate Active Directory, or native Quick credentials, make sure to allow-list the following domains within your organization's network.

User type	Domain or domains to allow-list
Users who sign in directly through Amazon Quick and Active Directory users	signin.aws and awsapps.com
AWS root user	signin.aws.amazon.com and amazon.com
IAM users	signin.aws.amazon.com

Important

We strongly recommend that you don't use the AWS root user for your everyday tasks, even the administrative ones. Instead, adhere to the best practice of using the root user only to create your first IAM user. Then securely lock away the root user credentials and use them to perform only a few account and service management tasks. For more information, see [AWS account root user](#) in the *IAM User Guide*.

Configuring VPC connections in Amazon Quick Sight

Applies to: Enterprise Edition

Intended audience: System administrators and Amazon Quick administrators

Note

If you're a Amazon Quick system administrator configuring a VPC connection to Amazon Quick Sight, this section is for you. Amazon Quick knowledge bases currently don't support VPC integrations.

Quick Enterprise edition is fully integrated with the Amazon VPC service. A VPC based on this service closely resembles a traditional network that you operate in your own data center. It enables you to secure and isolate traffic between resources. You define and control the network elements to suit your requirements, while still getting the benefit of cloud networking and the scalable infrastructure of AWS.

By creating a VPC connection in Amazon Quick, you're adding elastic network interfaces in your VPC. These network interfaces allow Amazon Quick to exchange network traffic with a network instance within your VPC. You can provide all of the standard security controls for this network traffic, as you do with other traffic in your VPC. Route tables, network access control lists (ACLs), subnets, and security groups settings all apply to network traffic to and from Amazon Quick in the same way that they apply to traffic between other instances in your VPC.

When you register a VPC connection with Amazon Quick, you can securely connect to data that's available only in your VPC, for example:

- Data you can reach by IP address
- Data that isn't available on the public internet
- Private databases
- On-premises data

This works if you set up connectivity between the VPC and your on-premises network. For example, you might set up connectivity with AWS Direct Connect, a virtual private network (VPN), or a proxy.

After you connect to the data, you can use it to create data analyses and publish secure data dashboards.

To further increase security, consider logging data access operations with AWS CloudTrail, as described in [Logging Amazon Quick information with CloudTrail](#). You can even create a dashboard to help you analyze your CloudTrail logs. By combining Amazon Quick logs with logs from your other AWS services, you can get a fuller view of how your data is being used.

You don't need to be a networking expert to connect and use a VPC with Amazon Quick, because Amazon Quick provides a user interface for adding your network information. However, the person who gathers the information that you need for setup should have some understanding of networking concepts and using VPCs. This person also needs read-only access to the services. If network changes are required, we recommend that you don't make changes to your networking configuration without expert assistance.

To use a command line interface to access your VPC, you can use the AWS Command Line Interface (AWS CLI). For more information on using the AWS CLI, see the [AWS CLI User Guide](#).

Topics

- [VPC terminology](#)
- [Supported VPC data sources](#)
- [Setting up a VPC to use with Amazon Quick](#)
- [Finding information to connect to a VPC](#)

VPC terminology

The following terminology can be useful when you work with a VPC and Amazon Quick.

A *VPC* is a virtual private cloud, which works like a private network to isolate the resources within it. The solution described in these topics uses an AWS service called Amazon VPC.

A *route table* contains a set of rules, called *routes*, that are used to determine where network traffic is directed. You can view the route table in the Amazon VPC console at <https://>

console.aws.amazon.com/vpc/. The VPC details display the route table that the VPC is using. You can also see **Route tables** listed in the Amazon VPC console.

A *subnet* is a defined set of network IP addresses that are used to increase the security and efficiency of network communications. You can think of them like postal codes, used for routing packages from one location to another. The **Subnets** list in the Amazon VPC console displays subnet IDs and also their associated VPC IDs, route tables, and network ACLs. You need to provide at least two subnets in different availability zones to create a VPC connection.

A *network interface* represents a virtual network card. The network interface automatically created by Amazon Quick is called a *Amazon Quick network interface*. Each network interface in a VPC connection is configured based on the subnet it's attached to. You can view your Amazon Quick network interfaces in the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>. The network interface displays its network interface ID, subnet ID, VPC ID, security group, and the Availability Zone that it exists in. You can click on the security group name to see its group ID and its inbound and outbound rules. The term *network interface* in the following sections always means elastic network interface.

A *security group* is a set of rules that controls the network access to the resources it is associated with. Access is permitted only to and from the components defined in the security group's inbound and outbound rules. If no rules are defined, the security group prevents all access. You can view security groups from several different consoles, depending on which resource that a particular security group applies to. You can see all the security groups and their settings in one place in the VPC console. For the Amazon Quick VPC connection, create a new security group.

Inbound and outbound rules define the following:

- The type of traffic to allow, for example "**All TCP**" or "**RDS**".
- The protocol to allow (TCP, UDP, or ICMP).
- The traffic source to allow for inbound rules, or the traffic destination to allow for outbound rules. When you work with a VPC and Amazon Quick, you specify the security group ID to use.
- An optional description. We recommend that you add the word **Amazon Quick** to the description for Amazon Quick VPC rules.

An *internet gateway* is a VPC component that allows communication between instances in your VPC and the internet. You don't need an internet gateway to use Amazon Quick VPC connections.

A *VPC endpoint* enables you to privately connect your VPC to supported AWS services without using public IP addresses. You don't need to set up a VPC endpoint to use Amazon Quick VPC connections.

Supported VPC data sources

With a VPC connection, you can connect Amazon Quick to a data source inside your VPC over a private network path. Traffic stays off the public internet. Not every data source can use a VPC connection. VPC connections support the following two categories:

Amazon Quick Sight data sources

Structured data sources, such as databases and data warehouses, that you connect to when you create datasets and analyses. Most of these support VPC connections. For more information about supported Amazon Quick Sight data sources, see [Amazon Quick Sight data sources that support VPC connections](#).

Knowledge base data sources

Data sources that you connect to when you create a knowledge base, including document repositories and content management systems. Amazon Redshift supports VPC connections in this category. For more information about knowledge base data sources, see [Knowledge base data sources that support VPC connections](#).

Both categories share the same configuration requirements. For more information about those requirements, see [Requirements for a VPC data source](#).

Amazon Quick Sight data sources that support VPC connections

The following Amazon Quick Sight data sources support VPC connections. When you create a dataset from one of these sources, you can route the connection through a VPC connection:

- Amazon OpenSearch Service
- Amazon Redshift
- Amazon Relational Database Service
- Amazon Aurora
- Apache Impala
- Databricks

- Exasol
- MariaDB
- Microsoft SQL Server
- MySQL
- Oracle
- PostgreSQL
- Presto
- Snowflake
- Starburst Enterprise
- Teradata
- Trino

Other Amazon Quick Sight data sources can't use a VPC connection. This group includes Amazon Athena, Google BigQuery, Apache Spark, and Amazon Timestream. It also includes the connectors for software as a service (SaaS) applications, such as Salesforce, ServiceNow, Jira, and GitHub. If you attach a VPC connection to a data source that doesn't support one, the request fails with an invalid parameter error.

Knowledge base data sources that support VPC connections

Amazon Redshift supports VPC connections when you use it as a knowledge base data source. When you create a knowledge base from an Amazon Redshift data source, you can choose a VPC connection. Your queries then reach the cluster over a private network path.

The following knowledge base data sources can't use a Quick VPC connection:

- Amazon Bedrock managed knowledge bases
- Amazon Q Business indexes
- Amazon S3
- Box
- Confluence
- Google Drive
- Microsoft OneDrive

- Microsoft SharePoint

If you attach a VPC connection to one of these data sources, the request fails with an invalid parameter error.

 Note

You can still restrict Amazon S3 bucket access to a VPC endpoint. That is a separate mechanism, and you control it through your bucket policy. For more information about restricting Amazon S3 bucket access to a VPC endpoint, see [Configure VPC access for the Amazon S3 connector](#).

Requirements for a VPC data source

Before you can reach a data source in your VPC from Amazon Quick, your configuration must meet the following requirements:

1. The Domain Name System (DNS) name of the VPC data source must resolve from outside your VPC.
2. The connection must return the private IP address of your instance. Databases hosted by Amazon Redshift, Amazon RDS, and Aurora automatically meet this requirement.
3. A clearly defined network path must connect the data source and Amazon Quick.
4. A VPC connection for the VPC must exist in Amazon Quick. You create or select one in the Amazon Quick console.

Setting up a VPC to use with Amazon Quick

Applies to: Enterprise Edition

Intended audience: System administrators

To set up a VPC to use with Amazon Quick Enterprise edition, you need access to Amazon VPC and Amazon EC2. You also need access to each AWS database service that you plan to add to Quick.

You can use the console, or you can use the AWS Command Line Interface (AWS CLI). For more information about the CLI, see the [AWS Command Line Interface User Guide](#). To work with the CLI, go to <https://aws.amazon.com/cli/>.

Before you begin to set up your VPC connection in Amazon Quick, make sure that you understand the components of a VPC deployment. As part of that, familiarize yourself with the VPC's subnets and security groups in relation to the destinations (databases) that you want to reach from Amazon Quick. To set up a successful VPC connection, make sure that the following components work together to allow network traffic to pass between Amazon Quick and your data source:

- The Amazon VPC service
- The subnets that your data source is using
- The Amazon Quick elastic network interfaces and the subnets they use
- The route table
- Inbound and outbound rules for these security groups:
 - Security group for your VPC. We recommend you create a new security group to isolate the rules on the VPC security group from the rules on the Amazon Quick network interface's security group).
 - Security group attached to the Amazon Quick network interface.
 - Security group attached to the database server (for each database server that you want to use).
- (Optional) Amazon Route 53 Resolver inbound endpoints for private DNS resolution.

In the following topics, you can find the network components that are involved. You can also find descriptions of their roles in the network configuration of your VPC and your Amazon Quick VPC connection. The network interface for Amazon Quick that is automatically created during setup is called the *Amazon Quick network interface (QNI)*.

If your VPC is already completely configured, skip to the next section, [Finding information to connect to a VPC](#).

Topics

- [VPC](#)
- [Subnets](#)
- [Security groups: inbound and outbound rules](#)

- [Sample rules](#)
- [Route table](#)
- [Amazon Quick elastic network interface](#)
- [Inbound endpoints for Amazon Route 53 Resolver](#)

VPC

A *virtual private cloud (VPC)* is a virtual network dedicated to your AWS account. The Amazon VPC service that provides it is a networking layer for your AWS resources. Using Amazon VPC, you can define a virtual network in your own logically isolated area within the AWS Cloud. A VPC closely resembles a traditional network that you might operate in your own data center, with the benefits of using the AWS scalable infrastructure. Amazon VPC for Amazon EC2 virtual computing environments, known as *instances*, can be used for a variety of AWS resources.

VPCs offer options that allow for flexibility in a secure environment, for example:

- To configure your VPC, you can set its IP address range, create subnets, configure route tables, network gateways, network interfaces, and security settings.
- To make the AWS Cloud an extension of your data center, you can connect your VPC to your own corporate data center.
- You can connect your instances in the VPC to the internet, or keep your instances isolated on a private network.
- To protect the resources in each subnet, you can use multiple layers of security, including security groups and network access control lists (ACLs).

For more information, see the [Amazon VPC User Guide](#).

If you have a default VPC and don't specify a subnet when you launch an instance, the instance is launched into your default VPC. You can launch instances into your default VPC without needing to know anything about Amazon VPC.

If you don't already have a VPC or want to use a new one, you can create one by following the instructions in [Getting started with Amazon VPC](#) in the *Amazon VPC User Guide*. This section offers guidance on how to set up your VPC. The guidance includes options for public and private subnets and for AWS Site-to-Site VPN access for your corporate network (known as *on-premises access*). You can also use VPC peering or Direct Connect to reach an on-premises database instance.

Using the AWS CLI

You can start to set up a VPC in Amazon EC2 by using the [aws ec2 create-vpc](#) command. To learn more about VPC settings for the AWS CLI, see [Examples for VPC](#) in the *Amazon VPC User Guide*.

Using the Amazon EC2 console

To view your VPC or create a new one in Amazon EC2, sign in to the AWS Management Console and open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>. To create a new VPC, choose **Launch VPC Wizard** and follow the instructions. Note your new VPC ID for future reference. To view VPCs, choose **Your VPCs** on the left side.

Amazon VPC resources in VPC guides and AWS Support articles

For general information, see [Working with VPCs and subnets](#).

For step-by-step instructions for setting up a VPC, see the following topics (choose the ones that relate to your scenario):

- [Create an IPv4 VPC and subnets using the AWS CLI](#)
- [Sharing public subnets and private subnets](#)
- [Working with site-to-site VPN](#)
- [AWS Site-to-Site VPN Network Administrator Guide](#) (choose your network device for specific instructions)
- [Generic Customer Gateway Device Without Border Gateway Protocol](#) (recommended for customer gateways)

If you want to migrate data source instances into the same VPC, see the following AWS Support articles:

- [How do I change the VPC for an Amazon RDS DB instance?](#)
- [How do I move my EC2 instance to another subnet, Availability Zone, or VPC?](#)
- [How do I move my Amazon Redshift cluster from one VPC to another VPC?](#)

For troubleshooting information, see [How do I troubleshoot issues with VPC route tables?](#), an article with video created by AWS Support.

Subnets

A *subnet* is a range of IP addresses in your VPC. You need to provide at least two subnets to create a VPC connection. Each subnet must belong a different availability zone. You can attach AWS resources, such as Amazon EC2 instances and Amazon RDS DB instances, to subnets. You can create subnets to group instances together according to your security and operational needs.

For Amazon Quick to connect to your database, the network needs to route traffic to the data sources that you want to reach from one of the subnets used by the Amazon Quick network interface. Amazon Quick determines which subnet to route traffic through on the backend. If the availability zone that the subnet is attached to experiences an outage, Amazon Quick reroutes the traffic to one of the other subnets that are configured in the VPC connection. If the data sources are on different subnets, make sure that there is a route from the Amazon Quick network interface to your database instance. By default, each subnet in a VPC is associated with one main route table and can reach the other subnets. For more information, see [VPC and Subnets](#) and [Network ACLs](#) in the *Amazon VPC User Guide*.

If you use Amazon RDS, DB instances are associated with a subnet group that you can view either in the Amazon RDS console (<https://console.aws.amazon.com/rds/>) or in the VPC console. For troubleshooting connectivity to Amazon RDS, see the AWS Support article [How can I troubleshoot connectivity to an Amazon RDS instance that uses a public or private subnet of a VPC?](#)

Security groups: inbound and outbound rules

A *security group* acts as a virtual firewall for your instance to control inbound and outbound traffic. For each security group, you add rules that control the inbound traffic to instances, and a separate set of rules that control the outbound traffic.

For your VPC connection, create a new security group with the description QuickSight-VPC. This security group must allow all inbound TCP traffic from the security groups of the data destinations that you want to reach. The following example creates a new security group in the VPC and returns the ID of the new security group.

```
aws ec2 create-security-group \  
--group-name quicksight-vpc \  
--description "QuickSight-VPC" \  
--vpc-id vpc-0daeb67adda59e0cd
```

⚠ Important

Network configuration is sufficiently complex that we strongly recommend that you create a new security group for use with Amazon Quick. It also makes it easier for AWS Support to help you if you need to contact them. Creating a new group isn't absolutely required. However, the following topics are based on the assumption that you follow this recommendation.

To enable Quick to successfully connect to an instance in your VPC, configure your security group rules to allow traffic between the Amazon Quick network interface and the instance that contains your data. To do this, configure the security group attached to your database's instance inbound rules to allow the following traffic:

- From the port that Amazon Quick is connecting to
- From one of the following options:
 - The security group ID that's associated with Amazon Quick network interface (recommended)
 - or
 - The private IP address of the Amazon Quick network interface

For more information, see [Security groups for your VPC](#) and [VPCs and subnets](#) in the *Amazon VPC User Guide*.

Use the topics listed below to learn more about inbound and outbound rules.

Topics

- [Inbound rules](#)
- [Outbound rules](#)

Inbound rules**⚠ Important**

The following section applies to your VPC connection if the connection was created before April 27, 2023.

When you create a security group, it has no inbound rules. No inbound traffic originating from another host to your instance is allowed until you add inbound rules to the security group.

The security group attached to the Amazon Quick network interface behaves differently than most security groups, because it isn't stateful. Other security groups are usually *stateful*. This means that, after they establish an outbound connection to a resource's security group, they automatically allow return traffic. In contrast, the Amazon Quick network interface security group doesn't automatically allow return traffic. Because of this, adding an egress rule to the Amazon Quick network interface security group doesn't work. To make it work for the Amazon Quick network interface security group, make sure to add an inbound rule that explicitly authorizes the return traffic from the database host.

The inbound rule in your security group must allow traffic on all ports. It needs to do this because the destination port number of any inbound return packets is set to a randomly allocated port number.

To restrict Amazon Quick to connect only to certain instances, you can specify the security group ID (recommended) or private IP address of the instances that you want to allow. In either case, your security group inbound rule still needs to allow traffic on all ports (0–65535).

To allow Amazon Quick to connect to any instance in the VPC, you can configure the Amazon Quick network interface security group. In this case, give it an inbound rule to allow traffic on 0.0.0.0/0 on all ports (0–65535). The security group used by the Amazon Quick network interface should be different than the security groups used for your databases. We recommend that you use separate security groups for VPC connection.

Important

If you are using a long-standing Amazon RDS DB instance, check your configuration to see if you're using a DB security group. DB security groups are used with DB instances that are not in a VPC and are on the EC2-Classic platform.

If this is your configuration, and you aren't moving your DB instance into the VPC for use with Amazon Quick, make sure to update your DB security group's inbound rules. Update them to allow inbound traffic from the VPC security group that you're using for Amazon Quick. For more information, see [Controlling Access with Security Groups](#) in the *Amazon RDS User Guide*.

Outbound rules

Important

The following section applies to your VPC connection if the connection was created before April 27, 2023.

By default, a security group includes an outbound rule that allows all outbound traffic. We recommend that you remove this default rule and add outbound rules that allow specific outbound traffic only.

Warning

Do not configure the security group on the Amazon Quick network interface with an outbound rule to allow traffic on all ports. For information on key considerations and recommendations for managing network egress traffic from VPCs, see [Security best practices for your VPC](#) in the *Amazon VPC User Guide*.

The security group attached to Amazon Quick network interface should have outbound rules that allow traffic to each of the database instances in your VPC that you want Amazon Quick to connect to. To restrict Amazon Quick to connect only to certain instances, specify the security group ID (recommended) or the private IP address of the instances to allow. You set this up, along with the appropriate port numbers for your instances (the port that the instances are listening on), in the outbound rule.

The VPC security group must also allow outbound traffic to the security groups of the data destinations, specifically on the port or ports that the database is listening on.

Sample rules

Following, you can find some example configurations of inbound and outbound rules for Amazon RDS and Amazon Redshift.

VPC connection rules: Amazon Quick Sight: Amazon RDS for MySQL

The following tables show rule settings for connecting Amazon Quick Sight to Amazon RDS for MySQL.

Amazon Quick Sight Network interface security group: inbound rule

Type	All TCP
Protocol	TCP
Port Range	0 - 65535
Source	<i>sg-RDS11111111</i>
Description	Amazon Quick Sight - RDS MySQL

Amazon Quick Sight Network interface security group: outbound rule

Type	MYSQL/Aurora
Protocol	TCP
Port Range	3306
Source	sg-RDS11111111
Description	Amazon Quick Sight to RDS MySQL

RDS MySQL: inbound rule

Type	MYSQL/Aurora
Protocol	TCP
Port Range	3306
Source	sg-ENI3333333
Description	Amazon Quick Sight to RDS MySQL

VPC connection rules: Amazon Redshift in Amazon Quick Sight

The following tables show rule settings for connecting Amazon Quick Sight to Amazon Redshift.

Amazon Quick Sight network interface security group: inbound rule

Type	All TCP
Protocol	TCP

Route table

To use VPC peering or Direct Connect to reach an on-premises database instance, update the route table that's associated with the VPC you're using with Amazon Quick. For more information on route tables, see [Route tables](#) in the *Amazon VPC User Guide*.

To learn more about VPC peering and view sample scenarios and configurations, see [What is VPC peering?](#) in the *Amazon VPC Peering Guide*. For an example configuration, see [Example: Services using AWS PrivateLink and VPC peering](#) in the *Amazon VPC User Guide*.

Using the AWS CLI

The following example creates a route table.

```
aws ec2 create-route-table --vpc-id vpc-0daeb67adda59e0cd
```

Then you can use the `create-route` command to create a route. For more information and examples, see [create-route](#) in the *AWS CLI Command Reference*.

For the following examples to work, make sure that you have a subnet in the VPC associated with the route table. The first example describes the route table with the specified VPC ID. The second one describes the route table with the specified route table ID.

```
aws ec2 describe-route-tables \  
--filters "Name=vpc-id,Values=vpc-0daeb67adda59e0cd"  
  
aws ec2 describe-route-tables \  
--route-table-ids rtb-45ac473a
```

The following example describes the specified associations between a specific VPC and your local gateway route tables.

```
aws ec2 describe-local-gateway-route-table-vpc-associations
--filters "Name=vpc-id,Values=vpc-0daeb67adda59e0cd"
```

Amazon Quick elastic network interface

The *Amazon Quick elastic network interface* is a logical networking component in a VPC that represents a virtual network card. Quick creates at least two of these network interfaces to use with a VPC connection based off of the subnets that are attached to it. Then you add the VPC connection to each Amazon Quick Sight data source you create. The Quick network interface alone doesn't give Quick direct access to your databases. The VPC connection works only for the Amazon Quick Sight data sources that are configured to use it.

When you use the Amazon Quick Sight data source to query a database or other instance within your VPC, all the network traffic from Amazon Quick originates from this Amazon Quick network interface. Because the Amazon Quick network interface exists inside your VPC, traffic originating from it can reach destinations within your VPC by using their private IP addresses. Each Amazon Quick network interface gets its own private IP address that comes from the subnet you configure. The private IP address is unique for each AWS account, unlike the public IP range.

Inbound endpoints for Amazon Route 53 Resolver

Amazon Route 53 Resolver provides DNS query capabilities to your VPC. Route 53 Resolver resolves all local DNS queries and recursively looks up any DNS queries that aren't local on public DNS servers.

Amazon Quick can't directly use Route 53 Resolver to query private DNS servers. However, you can set up Route 53 Resolver inbound endpoints to make these queries indirectly. For more information about inbound endpoints, see [Forwarding inbound DNS queries to your VPCs](#) in the *Route 53 Resolver Developer Guide*. To use inbound endpoints in Amazon Quick, provide the IP addresses of the endpoints for **DNS resolver endpoints** when you create a VPC connection.

Finding information to connect to a VPC

Applies to: Enterprise Edition

Intended audience: System administrators

To gather the information to have ready when you create a VPC connection in Amazon Quick Enterprise edition, take the steps listed following.

Steps

- [Identify the data sources to use](#)
- [Identify the AWS Region to use](#)
- [Identify the VPC ID to use](#)
- [Identify the subnet IDs to use](#)
- [Identify the security group to use](#)

Identify the data sources to use

Start by identifying all the data sources that you want to connect to using Quick. For each of these, note the database's private IP, security group, and subnets. Amazon Quick connects to your data using the private IP. However, you don't need to enter this or the security group or subnet information for the VPC connection. This information helps you identify the other components you need for the Amazon Quick VPC connection.

Note

For the connection to your data source to work, make sure that there's a traceable route from your data source to the VPC ID. For more details, see [Identify the data sources to use](#).

Identify the AWS Region to use

For the connection to work, the data, the subnets, and the security group must be in the same VPC. Make sure also that you use Quick in the same AWS Region with the VPC.

You can't use Amazon Quick in one AWS Region and expect to connect to a VPC in a different AWS Region.

If your team is already using Amazon Quick, you can see your current AWS Region displayed at the upper right of the Amazon Quick home screen. You can change the AWS Region you're using in Amazon Quick by changing the Region at the upper right of the Amazon Quick home screen. All the people who plan to use the data in the VPC must be using the same AWS Region in Amazon Quick.

Note

The AWS Region that displays in the Amazon Quick console doesn't have to match your AWS CLI configuration. Take care not to mistake your current Amazon Quick console settings with the settings that apply in any AWS CLI commands that you run or the settings in other consoles. Changing the current AWS Region in any console doesn't change the Region anywhere except for that page.

For example, let's say you have three tabs open in one browser window. You can have the Amazon Quick console open in one AWS Region, the Amazon VPC console open in a second Region, the Amazon RDS console open in a third Region, and the AWS CLI running in a fourth Region.

Identify the VPC ID to use

The VPC ID is assigned when the VPC is created.

Using the AWS CLI

The following `describe-vpcs` example retrieves details for all of your VPCs.

```
aws ec2 describe-vpcs
```

The following `describe-vpcs` example retrieves details for the specified VPC.

```
aws ec2 describe-vpcs \  
--vpc-ids vpc-06e4ab6c6cEXAMPLE
```

Using the Amazon VPC console

In the VPC console (<https://console.aws.amazon.com/vpc/>), choose **Your VPCs** at left. Choose the VPC-ID that you want to use. The correct one has Availability Zones in your AWS Region and also meets the requirements described in [Finding information to connect to a VPC](#). Also note the ID of **Main Route Table**, because you need this to identify related subnets.

Tip

In the Amazon VPC console, you can filter by VPC. This option is located at the top left of the console. If you filter by your VPC ID, all the other menus display only the network elements that are in your selected VPC.

Identify the subnet IDs to use

To locate the subnet IDs for the subnets used by the VPC, open the VPC console. Locate the VPC you are using, and at least two subnets in different availability zones. Amazon Quick creates its Amazon Quick elastic network interface (Amazon Quick network interface) for the subnets that you choose. The Amazon Quick network interfaces get created after you save your VPC connection settings, described in the following section.

Your database instances can reside in different subnets. However, make sure you can trace the route from this subnet to any data destinations that you want to reach.

Using the AWS CLI

The following example describes all existing subnets.

```
aws ec2 describe-subnets
```

The following `describe-subnets` example uses a filter to retrieve details for the subnets of the specified VPC.

```
aws ec2 describe-subnets \
--filters "Name=vpc-id,Values=vpc-06e4ab6c6cEXAMPLE"
```

Using the Amazon VPC console

In the VPC console (<https://console.aws.amazon.com/vpc/>), choose **Subnets** at left, and find the correct **Subnet ID**. Any subnet is correct if your database subnet has a route to the subnet that you choose at this point. In most cases, if you haven't configured the VPC network yourself, all subnets are connected.

Identify the security group to use

The security group contains rules that control the inbound and outbound network traffic on your data source instances. The security group you are using should have the description "QuickSight-VPC" to make it easier to identify.

When you locate the correct security group, copy its **Group ID** value.

Using the AWS CLI

The following example displays the security groups in a specific AWS Region. It displays only the group ID, name, and description. It filters the result to display only groups for a specific VPC ID that also have a description of "QuickSight-VPC".

```
aws ec2 describe-security-groups \
--region us-west-2 \
--query 'SecurityGroups[*].[GroupId, GroupName, Description]' \
--filters "Name=vpc-id,Values=vpc-06e4ab6c6cEXAMPLE"
"Name=description,Values=QuickSight-VPC"
```

The following example displays information about the security group with the ID sg-903004f8. Note that you can't reference a security group for EC2-VPC by name.

```
aws ec2 describe-security-groups
--group-ids sg-903004f8
--region us-west-2
```

The following example queries the results to describe VPC the inbound and outbound rules of a security group with a specific ID (sg-903004f8), in a specific AWS Region (us-west-2).

```
aws ec2 describe-security-groups \
--region us-west-2 \
--group-ids sg-903004f8 \
--query 'SecurityGroups[*].[GroupId, GroupName, Description,
IpPermissions,IpPermissionsEgress]'
```

The following example uses filters to describe VPC security groups that have a specific rule that allows SQL Server traffic (port 1433). The example also has a rule that allows traffic from all addresses (0.0.0.0/0). The output is filtered to display only the group IDs, names, and descriptions of the security groups. Security groups must match all filters to be returned in the results. However, a single rule doesn't have to match all filters. (EC2-VPC only)

```
aws ec2 describe-security-groups \
--filters Name=ip-permission.from-port,Values=1433 \
Name=ip-permission.to-port,Values=1433 \
Name=ip-permission.cidr,Values='0.0.0.0/0' \
--query 'SecurityGroups[*].[GroupId, GroupName, Description]'
```

Using the Amazon VPC console

In the VPC console (<https://console.aws.amazon.com/vpc/>), choose **Security groups** at left, and find the correct group ID. The correct one has your VPC ID on it. It should also have a tag or description that includes the word "QuickSight".

Configuring Amazon Quick Sight access to AWS data sources

Use this section to help you configure access to resources in other AWS services.

We recommend that you use SSL to secure Amazon Quick Sight connections to your data sources. To use SSL, you must have a certificate signed by a recognized certificate authority (CA). Amazon Quick doesn't accept certificates that are self-signed or issued from a nonpublic CA. For more information, see [Amazon Quick SSL and CA certificates](#).

Topics

- [Required permissions](#)
- [Network and database configuration requirements](#)
- [Allowing autodiscovery of AWS resources](#)
- [Authorizing connections from Amazon Quick Sight to AWS data stores](#)
- [Exploring your AWS data in Amazon Quick](#)
- [AWS service connectors](#)

Required permissions

When you connect to a Amazon Quick Sight data source that requires a user name, the user name must have SELECT permissions on some system tables. These permissions allow Amazon Quick Sight to do things such as discover table schemas and estimate table size.

The following table identifies the tables that the account must have SELECT permissions for, depending on the type of database you are connecting to. These requirements apply for all

database instances you connect to, regardless of their environment. In other words, they apply whether your database instances are on-premises, in Amazon RDS, in Amazon EC2, or elsewhere.

Instance type	Tables
Amazon Aurora	INFORMATION_SCHEMA.STATISTICS INFORMATION_SCHEMA.TABLES
Amazon Redshift	pg_stats pg_class pg_namespace
MariaDB	INFORMATION_SCHEMA.STATISTICS INFORMATION_SCHEMA.TABLES
Microsoft SQL Server	DBCC SHOW_STATISTICS sp_statistics
MySQL	INFORMATION_SCHEMA.STATISTICS INFORMATION_SCHEMA.TABLES
Oracle	DBA_TAB_COLS ALL_TABLES dba_segments all_segments user_segments
PostgreSQL	pg_stats pg_class pg_namespace

Instance type	Tables
ServiceNow	<code>sys_dictionary</code> (column metadata) <code>sys_db_object</code> (table metadata) <code>sys_glide_object</code> (field type metadata)

Note

If you are using MySQL or PostgreSQL, verify that you are connecting from an allowed host or IP address. For more detail, see [Database configuration requirements for self-administered instances](#).

Network and database configuration requirements

To serve as data sources, databases need to be configured so that Amazon Quick can access them. Use the following sections to make sure that your database is configured appropriately.

Important

Because a database instance on Amazon EC2 is administered by you rather than AWS, it must meet both the [Network configuration requirements](#) as well as the [Database configuration requirements for self-administered instances](#).

Topics

- [Network configuration requirements](#)
- [Database configuration requirements for self-administered instances](#)

Network configuration requirements

Intended audience: System administrators

For you to use your database server from Amazon Quick, your server must be accessible from the internet. It must also allow inbound traffic from Amazon Quick servers.

If the database is on AWS and in the same AWS Region as your Amazon Quick account, you can auto-discover the instance to make connecting to it easier. To do this, you must grant Amazon Quick permissions to access it. For more information, see [Accessing data sources](#).

Topics

- [Network configuration for an AWS instance in a default VPC](#)
- [Network configuration for an AWS instance in a nondefault VPC](#)
- [Network configuration for an AWS instance in a private VPC](#)
- [Network configuration for an AWS instance that is not in a VPC](#)
- [Network configuration for a database instance other than AWS](#)

Network configuration for an AWS instance in a default VPC

In some cases, your database might be on an AWS cluster or instance that you created in a default VPC. Thus, it's publicly accessible (that is, you didn't choose to make it private). In such cases, your database is already appropriately configured to be accessible from the internet. However, you still need to enable access from Amazon Quick servers to your AWS cluster or instance. For further details on how to do this, choose the appropriate topic following:

- [Authorizing connections from Amazon Quick to Amazon RDS database instances](#)
- [Authorizing connections from Amazon Quick to Amazon Redshift clusters](#)
- [Authorizing connections from Amazon Quick to Amazon EC2 instances](#)

Network configuration for an AWS instance in a nondefault VPC

If you are configuring an AWS instance in a nondefault VPC, make sure that the instance is publicly accessible and that the VPC has the following:

- An internet gateway.
- A public subnet.
- A route in the route table between the internet gateway and the AWS instance.
- Network access control lists (ACLs) in your VPC that allow traffic between the cluster or instance and Amazon Quick servers. These ACLs must do the following:

- Allow inbound traffic from the appropriate Amazon Quick IP address range and all ports to the IP address and port that the database is listening on.
- Allow outbound traffic from the database's IP address and port to the appropriate Amazon Quick IP address range and all ports.

For more information about Amazon Quick IP address ranges, see [IP address ranges for Amazon Quick](#) following.

For more information about configuring VPC ACLs, see [Network ACLs](#).

- Security group rules that allow traffic between the cluster or instance and Amazon Quick servers. For further details on how to create appropriate security group rules, see [Authorizing connections to AWS data sources](#).

For more information about configuring a VPC in the Amazon VPC service, see [Networking in Your VPC](#).

Network configuration for an AWS instance in a private VPC

If your database is on an AWS cluster or instance that you created in a private VPC, you can use it with Amazon Quick. For more information, see [Connecting to a Amazon VPC with Amazon Quick](#).

For more information on Amazon VPC, see [Amazon VPC](#) and [Amazon VPC Documentation](#).

Network configuration for an AWS instance that is not in a VPC

If you are configuring an AWS instance that is not in a VPC, make sure that the instance is publicly accessible. Also, make sure that there is a security group rule that allows traffic between the cluster or instance and Amazon Quick servers. For further details on how to do this, choose the appropriate topic following:

- [Authorizing connections from Amazon Quick to Amazon RDS database instances](#)
- [Authorizing connections from Amazon Quick to Amazon Redshift clusters](#)
- [Authorizing connections from Amazon Quick to Amazon EC2 instances](#)

Network configuration for a database instance other than AWS

To use SSL to secure your connections to your database (*recommended*), make sure that you have a certificate signed by a recognized certificate authority (CA). Amazon Quick doesn't accept

certificates that are self-signed or issued from a nonpublic CA. For more information, see [Amazon Quick SSL and CA certificates](#).

If your database is on a server other than AWS, you must change that server's firewall configuration to accept traffic from the appropriate Amazon Quick IP address range. For more information about Amazon Quick IP address ranges, see [IP address ranges for Amazon Quick](#). For any other steps that you need to take to enable internet connectivity, see your operating system documentation.

Amazon Quick SSL and CA certificates

We recommend that you use a public certificate issued by [AWS Certificate Manager \(ACM\)](#). Amazon Quick supports the same certificate authorities (CAs) as Mozilla, so if you don't use ACM, use a certificate issued by a CA on the [Mozilla Included CA Certificate List](#).

IP address ranges for Amazon Quick

For more information on the IP address ranges for Amazon Quick in supported Regions, see [AWS Regions, websites, IP address ranges, and endpoints](#).

Database configuration requirements for self-administered instances

Intended audience: System administrators and Amazon Quick administrators

For a database to be accessible to Amazon Quick, it must meet the following criteria:

- It must be accessible from the internet. To enable internet connectivity, see your database management system documentation.
- It must be configured to accept connections and authenticate access using the user credentials that you provide as part of creating the data set.
- If you are connecting to MySQL or PostgreSQL, the database engine must be accessible from your host or IP range. This optional security limitation is specified in MySQL or PostgreSQL connection settings. If this limitation is in place, any attempt to connect from a nonspecified host or IP address is rejected, even if you have the correct username and password.
- In MySQL, the server accepts the connection only if the user and host are verified in the user table. For more information, see [Access Control, Stage 1: Connection Verification](#) in the MySQL documentation.

- In PostgreSQL, you control client authentication by using the `pg_hba.conf` file in the database cluster's data directory. However, this file might be named and located differently on your system. For more information, see [Client Authentication](#) in the PostgreSQL documentation.

Allowing autodiscovery of AWS resources

Applies to: Enterprise Edition and Standard Edition

Intended audience: System administrators

Each AWS service that you access from Amazon Quick needs to allow traffic from Quick. Instead of opening each service console separately to add permissions, a Quick administrator can do this in the administration screen. Before you begin, make sure that you have addressed the following prerequisites.

If you choose to enable autodiscovery of AWS resources for your Quick account, Quick creates an AWS Identity and Access Management (IAM) role in your AWS account. This IAM role grants your account permission to identify and retrieve data from your AWS data sources.

Because AWS limits the number of IAM roles that you can create, make sure that you have at least one free role. You need this role for Amazon Quick to use if you want Amazon Quick to autodiscover your AWS resources.

You can have Amazon Quick autodiscover Amazon RDS DB instances or Amazon Redshift clusters that are associated with your AWS account. These resources must be located in the same AWS Region as your Amazon Quick account.

If you choose to enable autodiscovery, choose one of the following options to make the AWS resource accessible:

- For Amazon RDS DB instances that you created in a default VPC and didn't make private, or that aren't in a VPC (EC2-Classic instances), see [Authorizing connections from Amazon Quick to Amazon RDS instances](#). In this topic, you can find information on creating a security group to allow connections from Amazon Quick servers.
- For Amazon Redshift clusters that you created in a default VPC and didn't choose to make private, or that aren't in a VPC (that is, EC2-Classic instances), see [Authorizing connections from](#)

[Amazon Quick to Amazon Redshift clusters](#). In this topic, you can find information on creating a security group to allow connections from Amazon Quick servers.

- For an Amazon RDS DB instance or Amazon Redshift cluster that is in a nondefault VPC, see [Authorizing connections from Amazon Quick to Amazon RDS instances](#) or [Authorizing connections from Amazon Quick to Amazon Redshift clusters](#). In these topics, you can find information on first creating a security group to allow connections from Amazon Quick servers. In addition, you can find information on then verifying that the VPC meets the requirements described in [Network configuration for an AWS instance in a nondefault VPC](#).
- If you don't use a private VPC, set up the Amazon RDS instance to allow connections from the Amazon Quick Region's public IP address.

Enabling autodiscovery is the easiest way to make this data available in Amazon Quick. You can still manually create data connections whether or not you enable autodiscovery.

Authorizing connections from Amazon Quick Sight to AWS data stores

Applies to: Enterprise Edition and Standard Edition

Intended audience: System administrators

For Amazon Quick Sight to access your AWS resources, you must create security groups for them that authorize connections from the IP address ranges used by Amazon Quick Sight servers. You must have AWS credentials that permit you to access these AWS resources to modify their security groups.

Use the procedures in the following sections to enable Amazon Quick Sight connections.

Topics

- [Authorizing connections from Amazon Quick Sight to Amazon RDS DB instances](#)
- [Authorizing connections from Amazon Quick Sight to Amazon Redshift clusters](#)
- [Authorizing connections from Amazon Quick to Amazon EC2 instances](#)
- [Authorizing connections through AWS Lake Formation](#)
- [Authorizing connections to Amazon OpenSearch Service](#)
- [Authorizing connections to Amazon Athena](#)

- [Data access integrations](#)

Authorizing connections from Amazon Quick Sight to Amazon RDS DB instances

Applies to: Enterprise Edition and Standard Edition

Intended audience: System administrators

For Amazon Quick Sight to connect to an Amazon RDS DB instance, you must create a new security group for that DB instance. This security group contains an inbound rule authorizing access from the appropriate IP address range for the Quick servers in that AWS Region. To learn more about authorizing Quick connections, see [Manually enabling access to an Amazon RDS instance in a VPC](#) or [Manually enabling access to an Amazon RDS instance that is not in a VPC](#).

To learn more about authorizing Amazon Quick Sight connections manually, see [Manually enabling access to an Amazon RDS instance in a VPC](#) or [Manually enabling access to an Amazon RDS instance that is not in a Amazon VPC](#).

To create and assign a security group for an Amazon RDS DB instance, you must have AWS credentials that permit access to that DB instance.

Enabling connection from Amazon Quick servers to your instance is just one of several prerequisites for creating a data set based on an AWS database data source. For more information about what is required, see [Creating a dataset from a database](#).

Topics

- [Manually enabling Amazon Quick Sight access to an Amazon RDS instance in a VPC](#)
- [Manually enabling access from Amazon Quick Sight to an Amazon RDS instance that is not in a VPC](#)

Manually enabling Amazon Quick Sight access to an Amazon RDS instance in a VPC

Use the following procedure to enable Amazon Quick Sight access to an Amazon RDS DB instance in a VPC. If your Amazon RDS DB instance is in subnet that is private (in relation to Amazon Quick) or that has Internet Gateways attached, see [Connecting to a VPC with Amazon Quick](#).

To enable Amazon Quick Sight access to an Amazon RDS DB instance in a VPC

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose **Databases**, locate the DB instance, and view its details. To do this, you click directly on its name (a hyperlink in the **DB identifier** column).
3. Locate **Port** and note the **Port** value. This can be a number or a range.
4. Locate **VPC** and note the **VPC** value.
5. Choose the **VPC** value to open the VPC console. In the Amazon VPC Management Console, choose **Security Groups** in the navigation pane.
6. Choose **Create Security Group**.
7. On the **Create Security Group** page, enter the security group information as follows:
 - For **Name tag** and **Group name**, enter **Amazon-QuickSight-access**.
 - For **Description**, enter **Amazon-QuickSight-access**.
 - For **VPC**, choose the VPC for your instance. This VPC is the one with the **VPC ID** that you noted previously.
8. Choose **Create**. On the confirmation page, note the **Security Group ID**. Choose **Close** to exit this screen.
9. Choose your new security group from the list, and then choose **Inbound Rules** from the tab list below.
10. Choose **Edit rules** to create a new rule.
11. On the **Edit inbound rules** page, choose **Add rule** to create a new rule.

Use the following values:

- For **Type**, choose **Custom TCP Rule**.
- For **Protocol**, choose **TCP**.
- For **Port Range**, enter the port number or range of the Amazon RDS cluster. This port number (or range) is the one that you noted previously.
- For **Source**, choose **Custom** from the list. Next to the word "Custom", enter the CIDR address block for the AWS Region where you plan to use Amazon Quick.

For example, for Europe (Ireland) you would enter Europe (Ireland)'s CIDR address block: 52.210.255.224/27. For more information on the IP address ranges for Amazon Quick in supported AWS Regions, see [AWS Regions, websites, IP address ranges, and endpoints](#).

 Note

If you have activated Amazon Quick in multiple AWS Regions, you can create inbound rules for each Amazon Quick endpoint CIDR. Doing this allows Amazon Quick to have access to the Amazon RDS DB instance from any AWS Region defined in the inbound rules.

Anyone who uses Amazon Quick in multiple AWS Regions is treated as a single user. In other words, even if you are using Amazon Quick in every AWS Region, both your Amazon Quick subscription (sometimes called an 'account') and your users are global.

12. For **Description**, enter a useful description, for example "*Europe (Ireland) QuickSight*".
13. Choose **Save rules** to save your new inbound rule. Then choose **Close**.
14. Go back to the detailed view of the DB instance. Return the Amazon RDS console (<https://console.aws.amazon.com/rds/>) and choose **Databases**.
15. Choose the DB identifier for the relevant RDS instance. Choose **Modify**. The same screen displays whether you choose Modify from the databases screen or the DB instance screen: **Modify DB Instance**.
16. Locate the **Network & Security** section (the third section from the top).

The currently assigned security group or groups are already chosen for **Security Group**. Don't remove any of the existing ones unless you are sure.

Instead, choose your new security group to add it to the other groups that are selected. If you followed the name suggested previously, this group might be named something similar to **Amazon-QuickSight-access**.

17. Scroll to the bottom of the screen. Choose **Continue**. and then choose **Modify DB Instance**.
18. Choose **Apply during the next scheduled maintenance** (the screen indicates when this will occur).

Don't choose **Apply immediately**. Doing this also applies any additional changes that are in the pending modifications queue. Some of these changes might require downtime. If you bring

the server down outside the maintenance window, this can cause a problem for users of this DB instance. Consult your system administrators before applying immediate changes.

19. Choose **Modify DB Instance** to confirm your changes. Then, wait for the next maintenance window to pass.

Manually enabling access from Amazon Quick Sight to an Amazon RDS instance that is not in a VPC

Use the following procedure to access an Amazon RDS DB instance that is not in a VPC. You can associate a security group with a DB instance by using **Modify** on the RDS console, the `ModifyDBInstance` Amazon RDS API, or the `modify-db-instance` AWS CLI command.

Note

This section included for backwards compatibility purposes.

To use the console to access an Amazon RDS DB instance that is not in a VPC

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose **Databases**, select the DB instance, and choose **Modify**.
3. Choose **Security Groups** in the navigation pane.
4. Choose **Create DB Security Group**.
5. Enter **Amazon-QuickSight-access** for the **Name** and **Description** values, and then choose **Create**.
6. The new security group is selected by default.

Select the details icon next to the security group, as shown following.

7. For **Connection Type**, choose **CIDR/IP**.
8. For **CIDR/IP to Authorize**, enter the appropriate CIDR address block. For more information on the IP address ranges for Amazon Quick in supported AWS Regions, see [AWS Regions, websites, IP address ranges, and endpoints](#).
9. Choose **Authorize**.
10. Return to the **Instances** page of the Amazon RDS Management Console, choose the instance that you want to enable access to, choose **Instance Actions**, and then choose **Modify**.

11. In the **Network & Security** section, the currently assigned security group or groups already is chosen for **Security Group**. Press CTRL and choose **Amazon-QuickSight-access** in addition to the other selected groups.
12. Choose **Continue**, and then choose **Modify DB Instance**.

Authorizing connections from Amazon Quick Sight to Amazon Redshift clusters

Applies to: Enterprise Edition and Standard Edition

Intended audience: System administrators

You can provide access to Amazon Redshift data using three authentication methods: trusted identity propagation, run-as IAM role, or Amazon Redshift database credentials.

With trusted identity propagation, a user's identity is passed to Amazon Redshift with single sign-on that is managed by IAM Identity Center. A user that accesses a dashboard in Amazon Quick Sight has their identity propagated to Amazon Redshift. In Amazon Redshift, fine grained data permissions are applied on the data before the data is presented in a Amazon Quick asset to the user. Amazon Quick authors can also connect to Amazon Redshift data sources without a password input or IAM role. If Amazon Redshift Spectrum is used, all permission management is centralized in Amazon Redshift. Trusted identity propagation is supported when Amazon Quick and Amazon Redshift use the same organization instance of IAM Identity Center. Trusted identity propagation is not currently supported for the following features.

- SPICE datasets
- Custom SQL on data sources
- Alerts
- Email reports
- Amazon Quick Q
- CSV, Excel, and PDF exports
- Anomaly detection

For Amazon Quick to connect to an Amazon Redshift instance, you must create a new security group for that instance. This security group contains an inbound rule that authorizes access from the appropriate IP address range for the Amazon Quick servers in that AWS Region. To learn more about authorizing Amazon Quick connections, see [Manually enabling access to an Amazon Redshift cluster in a VPC](#).

Enabling connection from Amazon Quick servers to your cluster is just one of several prerequisites for creating a data set based on an AWS database data source. For more information about what is required, see [Creating a dataset from a database](#).

Topics

- [Enabling trusted identity propagation with Amazon Redshift](#)
- [Manually enabling access to an Amazon Redshift cluster in a VPC](#)
- [Enabling access to Amazon Redshift Spectrum](#)

Enabling trusted identity propagation with Amazon Redshift

Trusted identity propagation authenticates the end user in Amazon Redshift when they access Amazon Quick assets that leverage a trusted identity propagation enabled data source. When an author creates a data source with trusted identity propagation, the identity of the data source consumers in Amazon Quick Sight is propagated and logged in CloudTrail. This allows database administrators to centrally manage data security in Amazon Redshift and automatically apply all data security rules to data consumers in Amazon Quick. With other authentication methods, the data permissions of the author who created the data source are applied to all data source consumers. The data source author can choose to apply additional row and column level security to the data sources that they create in Amazon Quick Sight.

Trusted identity propagation data sources are supported only in Direct Query datasets. SPICE datasets do not currently support trusted identity propagation.

Topics

- [Prerequisites](#)
- [Enabling trusted identity propagation in Amazon Quick Sight](#)
- [Connecting to Amazon Redshift with trusted identity propagation](#)

Prerequisites

Before you get started, make sure that you have all of the required prerequisites ready.

- Trusted identity propagation is only supported for Amazon Quick accounts that are integrated with IAM Identity Center. For more information, see [Configure your Amazon Quick account with IAM Identity Center](#).
- An Amazon Redshift application that is integrated with IAM Identity Center. The Amazon Redshift cluster that you use must be in the same organization in AWS Organizations as the Amazon Quick account that you want to use. The cluster must also be configured with the same organization instance in IAM Identity Center that your Amazon Quick account is configured to. For more information about configuring a Amazon Redshift cluster, see [Integrating IAM Identity Center](#).

Enabling trusted identity propagation in Amazon Quick Sight

To configure Amazon Quick Sight to connect to Amazon Redshift data sources with trusted identity propagation, configure Amazon Redshift OAuth scopes to your Amazon Quick account.

To add a scope that allows Amazon Quick to authorize identity propagation to Amazon Redshift, specify the AWS account ID of the Amazon Quick account and the service that you want to authorize identity propagation with, in this case 'REDSHIFT'.

Specify the IAM Identity Center application ARN of the Amazon Redshift cluster that you are authorizing Amazon Quick to propagate user identities to. This information can be found in the Amazon Redshift console. If you don't specify authorized targets for the Amazon Redshift scope, Amazon Quick authorizes users from any Amazon Redshift cluster that share the same IAM Identity Center instance. The example below configures Amazon Quick to connect to Amazon Redshift data sources with trusted identity propagation.

```
aws quicksight update-identity-propagation-config --aws-account-id "AWSACCOUNTID"  
--service "REDSHIFT" --authorized-targets "arn:aws:sso::XXXXXXXXXXXX:application/  
ssoins-XXXXXXXXXXXX/ap1-XXXXXXXXXXXX" "arn:aws:sso::XXXXXXXXXXXX:application/  
ssoins-XXXXXXXXXXXX/ap1-XXXXXXXXXXXX"
```

The following example deletes OAuth scopes from a Amazon Quick account.

```
aws quicksight delete-identity-propagation-config --aws-account-id "AWSACCOUNTID"  
--service "REDSHIFT" --authorized-targets "arn:aws:sso::XXXXXXXXXXXX:application/
```

```
ssoins-XXXXXXXXXXXXap1-XXXXXXXXXXXX "arn:aws:sso::XXXXXXXXXXXX:application/  
ssoins-XXXXXXXXXXXX/ap1-XXXXXXXXXXXX"
```

The following example lists all OAuth scopes that are currently on a Amazon Quick account.

```
aws quicksight list-identity-propagation-configs --aws-account-id "AWSACCOUNTID"
```

Connecting to Amazon Redshift with trusted identity propagation

Use the procedure below to connect to Amazon Redshift trusted identity propagation.

To connect to Amazon Redshift with trusted identity propagation

1. Create a new dataset in Amazon Quick. For more information about creating a dataset, see [Creating datasets](#).
2. Choose Amazon Redshift as the data source for the new dataset.

Note

The authentication type of an existing data source can't be changed to trusted identity propagation

3. Choose IAM Identity Center as the identity option for the data source, and then choose **Create data source**.

Manually enabling access to an Amazon Redshift cluster in a VPC

Applies to: Enterprise Edition

Use the following procedure to enable Amazon Quick Sight access to an Amazon Redshift cluster in a VPC.

To enable Amazon Quick Sight access to an Amazon Redshift cluster in a VPC

1. Sign in to the AWS Management Console and open the Amazon Redshift console at <https://console.aws.amazon.com/redshiftv2/>.
2. Navigate to the cluster that you want to make available in Amazon Quick.
3. In the **Cluster Properties** section, find **Port**. Note the **Port** value.

4. In the **Cluster Properties** section, find **VPC ID** and note the **VPC ID** value. Choose **VPC ID** to open the Amazon VPC console.
5. On the Amazon VPC console, choose **Security Groups** in the navigation pane.
6. Choose **Create Security Group**.
7. On the **Create Security Group** page, enter the security group information as follows:
 - For **Security group name**, enter **redshift-security-group**.
 - For **Description**, enter **redshift-security-group**.
 - For **VPC**, choose the VPC for your Amazon Redshift cluster. This is the VPC with the VPC ID that you noted.
8. Choose **Create security group**.

Your new security group should appear on the screen.

9. Create a second security group with the following properties.
 - For **Security group name**, enter **quicksight-security-group**.
 - For **Description**, enter **quicksight-security-group**.
 - For **VPC**, choose the VPC for your Amazon Redshift cluster. This is the VPC with the VPC ID that you noted.
10. Choose **Create security group**.
11. After you create the new security groups, create inbound rules for the new groups.

Choose the new **redshift-security-group** security group, and input the following values.

- For **Type**, choose **Amazon Redshift**.
 - For **Protocol**, choose **TCP**.
 - For **Port Range**, enter the port number of the Amazon Redshift cluster to which you are providing access. This is the port number that you noted in an earlier step.
 - For **Source**, enter the security group ID of **quicksight-security-group**.
12. Choose **Save rules** to save your new inbound rule.
 13. Repeat the previous step for **quicksight-security-group** and enter the following values.
 - For **Type**, choose **All traffic**.
 - For **Protocol**, choose **All**.
 - For **Port Range**, choose **All**.

- For **Source**, enter the security group ID of `redshift-security-group`.
14. Choose **Save rules** to save your new inbound rule.
 15. In Amazon Quick, navigate to the **Manage Amazon Quick** menu.
 16. Choose **Manage VPC connections**, and then choose **Add VPC connection**.
 17. Configure the new VPC connection with the following values.
 - For **VPC connection name**, choose a meaningful name for the VPC connection.
 - For **VPC ID**, choose the VPC in which the Amazon Redshift cluster exists.
 - For **Subnet ID**, choose the subnet for the Availability Zone (AZ) that is used for Amazon Redshift.
 - For **Security group id**, copy and paste the security group ID for `quicksight-security-group`.
 18. Choose **Create**. It might take several minutes for the new VPC to generate.
 19. In the Amazon Redshift console, navigate to the Amazon Redshift cluster that `redshift-security-group` is configured to. Choose **Properties**. under **Network and security settings**, enter the name of the security group.
 20. In Amazon Quick, choose **Datasets**, and then choose **New dataset**. Create a new dataset with the following values.
 - For **Data source**, choose **Amazon Redshift Auto-discovered**.
 - Give the data source a meaningful name.
 - The instance ID should auto populate with the VPC connection that you created in Amazon Quick. If the instance ID doesn't auto populate, choose the VPC that you created from the dropdown list.
 - Enter the database credentials. If your Amazon Quick account uses trusted identity propagation, choose **Single sign-on**.
 21. Validate the connection, and then choose **Create data source**.

If you want to restrict the default outbound rules further, update the outbound rule of `quicksight-security-group` to allow only Amazon Redshift traffic to `redshift-security-group`. You can also delete the outbound rule that's located in the `redshift-security-group`.

Enabling access to Amazon Redshift Spectrum

Using Amazon Redshift Spectrum, you can connect Amazon Quick to an external catalog with Amazon Redshift. For example, you can access the Amazon Athena catalog . You can then query unstructured data on your Amazon S3 data lake using an Amazon Redshift cluster instead of the Athena query engine.

You can also combine data sets that include data stored in Amazon Redshift and in S3. Then you can access them using the SQL syntax in Amazon Redshift.

After you've registered your data catalog (for Athena) or external schema (for a [Hive metastore](#)), you can use Amazon Quick to choose the external schema and Amazon Redshift Spectrum tables. This process works just as for any other Amazon Redshift tables in your cluster. You don't need to load or transform your data.

For more information on using Amazon Redshift Spectrum, see [Using Amazon Redshift Spectrum to query external data](#) in the *Amazon Redshift Database Developer Guide*.

To connect using Redshift Spectrum, do the following:

- Create or identify an IAM role associated with the Amazon Redshift cluster.
- Add the IAM policies `AmazonS3ReadOnlyAccess` and `AmazonAthenaFullAccess` to the IAM role.
- Register an external schema or data catalog for the tables that you plan to use.

Redshift Spectrum lets you separate storage from compute, so you can scale them separately. You only pay for the queries that you run.

To connect to Redshift Spectrum tables, you don't need to grant Amazon Quick access to Amazon S3 or Athena. Amazon Quick needs access only to the Amazon Redshift cluster. For full details on configuring Redshift Spectrum, see [Getting started with Amazon Redshift Spectrum](#) in the *Amazon Redshift Database Developer Guide*.

Authorizing connections from Amazon Quick to Amazon EC2 instances

Applies to: Enterprise Edition and Standard Edition

Intended audience: System administrators

For Amazon Quick Sight to connect to an Amazon EC2 instance, you must create a new security group for that instance. This security group contains an inbound rule authorizing access from the appropriate IP address range for the Quick servers in that AWS Region.

To modify the security groups for these Amazon EC2 instances, you must have AWS credentials that permit you to access to the instances.

Enabling connection from Quick servers to your instance is just one of several prerequisites for creating a data set based on an AWS database data source. For more information about what is required, see [Creating a dataset from a database](#).

To enable Amazon Quick access to an Amazon EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. If your EC2 instance is in a VPC, choose the instance to view the instance details pane. Find its VPC ID and note that ID for later use.
3. Choose **Security Groups** in the **NETWORK & SECURITY** section of the navigation pane. Then choose **Create Security Group**, as shown following.
4. Enter the security group information as follows:
 - For **Security group name**, enter **Amazon-QuickSight-access**.
 - For **Description**, enter **Amazon-QuickSight-access**.
 - For **VPC**, choose the VPC ID that you noted in step 2 if your Amazon EC2 instance is in a VPC. Otherwise, choose **No VPC**.
5. Choose **Add Rule** on the **Inbound** tab.
6. Create a new rule with the following values:
 - For **Type**, choose **Custom TCP Rule**.
 - For **Protocol**, choose **TCP**.
 - (Optional) For **Port Range**, enter the port number used by the instance on this Amazon EC2 instance to which you are providing access.
 - For **Source**, enter the CIDR address block for the AWS Region where you plan to use Amazon Quick. For example, here is the CIDR address block for Europe (Ireland): 52.210.255.224/27. For more information on the IP address ranges for Amazon Quick in supported AWS Regions, see [AWS Regions, websites, IP address ranges, and endpoints](#).

Note

If you have activated Amazon Quick in multiple AWS Regions, you can create inbound rules for each Amazon Quick endpoint CIDR. Doing this allows Amazon Quick to have access to the Amazon RDS DB instance from any AWS Region defined in the inbound rules.

An Amazon Quick user or administrator who uses Amazon Quick in multiple AWS Regions is treated as a single user. In other words, even if you are using Amazon Quick in every AWS Region, both your Amazon Quick account and your users are global.

7. Choose **Create**.
8. Choose **Instances** in the **INSTANCES** section of the navigation pane, and then choose the instance that you want to enable access to.
9. Choose **Actions**, then **Networking**, and then **Change Security Groups**.
10. In **Change Security Groups**, choose the **Amazon-QuickSight-access** security group.

Then choose **Assign Security Groups**, as shown following.

Authorizing connections through AWS Lake Formation

Applies to: Enterprise Edition

Intended audience: System administrators

If you are querying data with Amazon Athena, you can use AWS Lake Formation to simplify how you secure and connect to your data from Amazon Quick Sight. Lake Formation adds to the AWS Identity and Access Management (IAM) permissions model by providing its own permissions model that is applied to AWS analytics and machine learning services. This centrally defined permissions model controls data access at a granular level through a simple grant and revoke mechanism. You can use Lake Formation instead of, or in addition to, using scoped-down policies with IAM.

When you set up Lake Formation, you register your data sources to allow it to move the data into a new data lake in Amazon S3. Lake Formation and Athena both work seamlessly with AWS Glue

Data Catalog, making it easy to use them together. Athena databases and tables are metadata containers. These containers describe the underlying schema of the data, the data definition language (DDL) statements, and the location of the data in Amazon S3.

The following diagram shows the relationships of the AWS services involved.

After Lake Formation is configured, you can use Amazon Quick to access databases and tables by name or through SQL queries. Amazon Quick provides a full-featured editor where you can write SQL queries. Or you can use the Athena console, the AWS CLI, or your favorite query editor. For more information, see [Accessing Athena](#) in the *Amazon Athena User Guide*.

Use the topics below to configure a Lake Formation connection through Lake Formation or through Amazon Quick.

Topics

- [Enabling connection from Lake Formation](#)
- [Enabling connection from Amazon Quick](#)

Enabling connection from Lake Formation

Before you begin using this solution with Quick, make sure that you can access your data using Athena with Lake Formation. After you verify that the connection is working through Athena, you need to verify only that Amazon Quick can connect to Athena. Doing this means you don't have to troubleshoot connections through all three products at once. One easy way to test the connection is to use the [Athena query console](#) to run a simple SQL command, for example `SELECT 1 FROM table`.

To set up Lake Formation, the person or team who works on it needs access to create a new IAM role and to Lake Formation. They also need the information shown in the following list. For more information, see [Setting up lake formation](#) in the *AWS Lake Formation Developer Guide*.

- Collect the Amazon Resource Names (ARNs) of the Quick users and groups that need to access the data in Lake Formation. These users should be Amazon Quick authors or administrators.

To find Amazon Quick user and group ARNs

1. Use the AWS CLI to find user ARNs for Amazon Quick authors and admins. To do this, run the following `list-users` command in your terminal (Linux or Mac) or at your command prompt (Windows).

```
aws quicksight list-users --aws-account-id 111122223333 --namespace default --  
region us-east-1
```

The response returns information for each user. We show the Amazon Resource Name (ARN) in bold in the following example.

```
RequestId: a27a4cef-4716-48c8-8d34-7d3196e76468  
Status: 200  
UserList:  
- Active: true
```

```

Arn: arn:aws:quicksight:us-east-1:111122223333:user/default/SaanviSarkar
Email: SaanviSarkar@example.com
PrincipalId: federated/iam/AIDAJVCZ0VSR3DESMJ7TA
Role: ADMIN
UserName: SaanviSarkar

```

To avoid using the AWS CLI, you can construct the ARNs for each user manually.

2. (Optional) Use the AWS CLI to find ARNs for Amazon Quick groups by running the following `list-group` command in your terminal (Linux or Mac) or at your command prompt (Windows).

```
aws quicksight list-groups --aws-account-id 111122223333 --namespace default --region us-east-1
```

The response returns information for each group. The ARN appears in bold in the following example.

```

GroupList:
- Arn: arn:aws:quicksight:us-east-1:111122223333:group/default/DataLake-Scorecard
  Description: Data Lake for CX0 Balanced Scorecard
  GroupName: DataLake-Scorecard
  PrincipalId: group/d-90671c9c12/6f9083c2-8400-4389-8477-97ef05e3f7db
  RequestId: c1000198-18fa-4277-a1e2-02163288caf6
  Status: 200

```

If you don't have any Amazon Quick groups, add a group by using the AWS CLI to run the `create-group` command. There currently isn't an option to do this from the Amazon Quick console. For more information, see [Creating and managing groups in Amazon Quick](#).

To avoid using the AWS CLI, you can construct the ARNs for each group manually.

Enabling connection from Amazon Quick

To work with Lake Formation and Athena, make sure that you have AWS resource permissions configured in Amazon Quick:

- Enable access to Amazon Athena.

- Enable access to the correct buckets in Amazon S3. Usually S3 access is enabled when you enable Athena. However, because you can change S3 permissions outside of that process, it's a good idea to verify them separately.

For information about how to verify or change AWS resource permissions in Quick, see [Allowing autodiscovery of AWS resources](#) and [Accessing data sources](#).

Authorizing connections to Amazon OpenSearch Service

Applies to: Enterprise Edition

Intended audience: System administrators

Before you can use OpenSearch in a Amazon Quick Sight dataset, there are a few tasks for the Quick administrator to complete with the cooperation of a person who has access to the OpenSearch console.

To get started, identify each OpenSearch domain that you want to connect to. Then gather the following information for each domain:

- The name of the OpenSearch domain.
- The OpenSearch version used by this domain.
- The Amazon Resource Name (ARN) of the OpenSearch domain.
- The HTTPS endpoint.
- The OpenSearch Dashboards URL, if you use Dashboards. You can extrapolate the Dashboards URL by appending `"/dashboards/"` to an endpoint.
- If the domain has a VPC endpoint, gather all the related information on the VPC tab of the OpenSearch Service console:
 - The VPC ID
 - The VPC security groups
 - The associated IAM role or roles
 - The associated Availability Zones
 - The associated subnets

- If the domain has a regular endpoint (not a VPC endpoint), note that it uses the public network.
- The start hour for the daily automated snapshot (if your users want to know).

Before you proceed, the Amazon Quick administrator enables authorized connections from Amazon Quick to OpenSearch Service. This process is required for every AWS service that you connect to from Amazon Quick. You need to do this only once per AWS account for each AWS service that you use as a data source.

For OpenSearch Service, the authorization process adds the AWS managed policy `AWSQuickSightOpenSearchPolicy` to your AWS account.

Important

Make sure that the IAM policy for your OpenSearch domain doesn't conflict with the permissions in `AWSQuickSightOpenSearchPolicy`. You can find the domain access policy in the OpenSearch Service console. For more information, see [Configuring access policies](#) in the *Amazon OpenSearch Service Developer Guide*.

To turn on or turn off connections from Amazon Quick to OpenSearch Service

1. Within Amazon Quick, choose **Administrator** and **Manage Amazon Quick**.
2. Choose **Security & permissions, Add or remove**.
3. To enable connections, select the **Amazon OpenSearch Service** check box.

To disable connections, clear the **Amazon OpenSearch Service** check box.

4. Choose **Update** to confirm your choices.

If needed, use the topics below to configure a OpenSearch VPC connection and permissions for Amazon Quick to access OpenSearch.

Topics

- [Using a VPC connection](#)
- [Using OpenSearch permissions](#)

Using a VPC connection

In some cases, your OpenSearch domain is in a virtual private cloud (VPC) based on the Amazon VPC service. If so, make sure to determine if Amazon Quick is already connected to the VPC ID that the OpenSearch domain uses. You can reuse an existing VPC connection. If you're not sure if it's working, you can test it. For more information, see [Testing the connection to your Amazon VPC data source](#).

If a connection isn't already defined in Amazon Quick for the VPC that you want to use, you can create one. This task is a multistep process that you need to complete before you proceed. To learn how to add Amazon Quick to a VPC and add a connection from Amazon Quick to the VPC, see [Connecting to a Amazon VPC with Amazon Quick](#).

Using OpenSearch permissions

After you configure Amazon Quick to connect to OpenSearch Service, you might need to enable permissions in OpenSearch. For this part of the setup process, you can use the OpenSearch Dashboards link for each OpenSearch domain. Use the following list to help determine what permissions you need:

1. For domains that use fine-grained access control, configure permissions in the form of a role. This process is similar to using scoped-down policies in Amazon Quick.
2. For each domain that you create a role for, add a role mapping.

For more information, see following.

If your OpenSearch domain has [fine-grained access control](#) enabled, there are some permissions to configure so the domain is accessible from Amazon Quick. Perform these steps for each domain that you want to use.

The following procedure uses OpenSearch Dashboards, which is an open-source tool that works with OpenSearch. You can find the link to Dashboards on the domain dashboard on the OpenSearch Service console.

To add permissions to a domain to allow access from Amazon Quick

1. Open OpenSearch Dashboards for the OpenSearch domain that you want to work with. The URL is `opensearch-domain-endpoint/dashboards/`.
2. Choose **Security** from the navigation pane.

If you don't see the navigation pane, open it by using the menu icon at upper left. To keep the menu open, choose **Dock navigation** at lower left.

3. Choose **Roles, Create role**.
4. Name the role **quicksight_role**.

You can choose a different name, but we recommend this one because we use it in our documentation and it's thus easier to support.

5. Under **Cluster permissions**, add the following permissions:

- `cluster:monitor/main`
- `cluster:monitor/health`
- `cluster:monitor/state`
- `indices:data/read/scroll`
- `indices:data/read/scroll/clear,`

6. Under **Index permissions** specify `*` as the index pattern.

7. For **Index permissions**, add the following permissions:

- `indices:admin/get`
- `indices:admin/mappings/get`
- `indices:admin/mappings/fields/get*`
- `indices:data/read/search*`
- `indices:monitor/settings/get`

8. Choose **Create**.
9. Repeat this procedure for each OpenSearch domain that you're planning to use.

Use the following procedure to add a role mapping for the permissions that you added in the previous procedure. You might find it more efficient to add the permissions and the role mapping as part of a single process. These instructions are separate for clarity.

To create a role mapping for the IAM role you added

1. Open OpenSearch Dashboards for the OpenSearch domain that you want to work with. The URL is *opensearch-domain-endpoint*/dashboards/.
2. Choose **Security** from the navigation pane.

3. Search for and open **quicksight_role** from the list.
4. On the **Mapped users** tab, choose **Manage mapping**.
5. In the **Backend roles** section, enter the ARN of the AWS-managed IAM role for Amazon Quick. Following is an example.

```
arn:aws:iam::AWS-ACCOUNT-ID:role/service-role/aws-quicksight-service-role-v0
```

6. Choose **Map**.
7. Repeat this procedure for each OpenSearch domain that you want to use.

Authorizing connections to Amazon Athena

If you need use Amazon Quick Sight with Amazon Athena or Amazon Athena Federated Query, you first need to authorize connections to Athena and the associated buckets in Amazon Simple Storage Service (Amazon S3). Amazon Athena is an interactive query service that makes it easy to analyze data directly in Amazon S3 using standard SQL. Athena Federated Query provides access to more types of data by using AWS Lambda. Using a connection from Quick to Athena, you can write SQL queries to interrogate data that's stored in relational, non-relational, object, and custom data sources. For more information, see [Using Athena federated query](#) in the Amazon Athena User Guide.

Review the following considerations when setting up access to Athena from Quick:

- Athena stores query results from Amazon Quick Sight in a bucket. By default, this bucket has a name similar to `aws-athena-query-results-AWSREGION-AWSACCOUNTID`, for example `aws-athena-query-results-us-east-2-111111111111`. Therefore, it's important to make sure Amazon Quick Sight has permissions to access the bucket Athena is currently using.
- If your data file is encrypted with an AWS KMS key, grant permissions to the Amazon Quick Sight IAM role to decrypt the key. The easiest way to do this is to use the AWS CLI.

You can run the KMS [create-grant](#) API operation in AWS CLI to do this.

```
aws kms create-grant --key-id <KMS_KEY_ARN> /  
--grantee-principal <QS_ROLE_ARN> --operations Decrypt
```

The Amazon Resource Name (ARN) for the Amazon Quick role has the format
`arn:aws:iam::<account id>:role/service-role/aws-quicksight-s3-consumers-`

role-v<version number> and can be accessed from the IAM console. To find your KMS key ARN, use the S3 console. Go to the bucket that contains your data file and choose the **Overview** tab. The key is located near **KMS key ID**.

- For Amazon Athena, Amazon S3, and Athena Query Federation connections, Amazon Quick uses the following IAM role by default:

```
arn:aws:iam::AWS-ACCOUNT-ID:role/service-role/aws-quicksight-s3-consumers-role-v0
```

If the aws-quicksight-s3-consumers-role-v0 is not present, then Amazon Quick uses:

```
arn:aws:iam::AWS-ACCOUNT-ID:role/service-role/aws-quicksight-service-role-v0
```

- If you assigned scope-down policies to your users, verify that the policies contain the `lambda:InvokeFunction` permission. Without this permission, your users can't access Athena Federated Queries. For more information about assigning IAM policies to your users in Amazon Quick, see [Setting granular access to AWS services through IAM](#). For more information about the `lambda:InvokeFunction` permission, see [Actions, resources, and condition keys for AWS Lambda](#) in the *IAM User Guide*.

To authorize Amazon Quick to connect to Athena or Athena federated data sources

1. (Optional) If you are using AWS Lake Formation with Athena, you also need to enable Lake Formation. For more information, see [Authorizing connections through AWS Lake Formation](#).
2. Open your profile menu at top right and choose **Manage QuickSight**. You must be a Amazon Quick administrator to do this. If you don't see **Manage QuickSight** on the profile menu, you don't have sufficient permissions.
3. Choose **Security & permissions, Add or remove**.
4. Choose the box near Amazon Athena, **Next**.

If it was already enabled, you might have to double-click it. Do this even if Amazon Athena is already enabled, so you can view the settings. No changes are saved until you choose **Update** at the end of this procedure.

5. Enable the S3 buckets you want to access.
6. (Optional) To enable Athena federated queries, select the Lambda functions you want to use.

Note

You can only see Lambda functions for the Athena catalogs in the same region of Amazon Quick.

7. To confirm your changes, choose **Finish**.

To cancel, choose **Cancel**.

8. To save changes to security and permissions, choose **Update**.

To test the connection authorization settings

1. From the Amazon Quick start page, choose **Datasets, New dataset**.
2. Choose the Athena card.
3. Follow the screen prompts to create a new Athena data source using the resources you need to connect to. Choose **Validate connection** to test the connection.
4. If the connection validates, you have successfully configured an Athena or Athena Federated Query connection.

If you don't have sufficient permissions to connect to an Athena dataset or run an Athena query, an error displays directing you to contact a Amazon Quick administrator. This error means need to recheck your connection authorization settings to find the discrepancy.

5. After you can connect successfully, you or your Amazon Quick authors can create data sources connections and share them with other Amazon Quick authors. The authors can then create multiple datasets from the connections, to use in Amazon Quick dashboards.

For troubleshooting information on Athena, see [Connectivity issues when using Athena with Amazon Quick](#).

Using trusted identity propagation with Athena

Trusted identity propagation gives AWS services access to AWS resources based on the user's identity context and securely shares this user's identity with other AWS services. These capabilities enable user access to be more easily defined, granted, and logged.

When administrators configure Quick, Athena, Amazon S3 Access Grants, and AWS Lake Formation with IAM Identity Center, they can now enable trusted identity propagation across these services

and allow the user's identity to be propagated across services. When data is accessed from Quick by an IAM Identity Center user, Athena or Lake Formation can make authorization decisions using the permissions defined for their user or group membership from the organization's identity provider.

Trusted identity propagation with Athena only works when permissions are managed through Lake Formation. User permissions to data reside in Lake Formation.

Prerequisites

Before you get started, make sure that you have the following required prerequisites completed.

Important

As you complete the following prerequisites, note that your IAM Identity Center instance, Athena workgroup, Lake Formation and Amazon S3 Access Grants must all be deployed in the same AWS Region.

- Configure your Quick account with IAM Identity Center. Trusted identity propagation is only supported for Quick accounts that are integrated with IAM Identity Center. For more information, see [Configure your Amazon Quick account with IAM Identity Center](#).

Note

To create Athena data sources, you must be an IAM Identity Center user (author) in a Quick account that uses IAM Identity Center.

- An Athena workgroup that is enabled with IAM Identity Center. The Athena workgroup that you use must be using the same IAM Identity Center instance as the Quick account. For more information about configuring an Athena workgroup, see [Creating an IAM Identity Center enabled Athena workgroup](#) in the *Amazon Athena User Guide*.
- Access to Athena query results bucket is managed with Amazon S3 Access Grants. For more details, see [Managing access with Amazon S3 Access Grants](#) in the *Amazon S3 User Guide*. If your query results are encrypted with an AWS KMS key, the Amazon S3 Access Grant IAM role and the Athena workgroup role both need permissions to AWS KMS.
- For more information, see [Amazon S3 Access Grants and corporate directory identities](#) in the *Amazon S3 User Guide*.

- The Amazon S3 Access Grant role should have the STS: SetContext action in its trust policy for identity propagation. To see an example, see [Register a location](#) in the Amazon S3 User Guide.
- Permissions to data must be managed with Lake Formation and Lake Formation must be configured with the same IAM Identity Center instance as Quick and the Athena workgroup. For configuration information, see [Integrating IAM Identity Center](#) in the *AWS Lake Formation Developer Guide*.
- The data lake administrator needs to grant permissions to IAM Identity Center users and groups in Lake Formation. For more details, [Granting permissions to users and groups](#) in the *AWS Lake Formation Developer Guide*.
- The Quick administrator needs to authorize connections to Athena. For details, see [Authorizing connections to Amazon Athena](#). Note, with trusted identity propagation, you do not need to give the Quick role Amazon S3 bucket permissions or AWS KMS permissions. You need to keep your users and groups that have permissions to the workgroup in Athena in sync with the Amazon S3 bucket that stores query results with Amazon S3 Access Grants permissions so that users can successfully run queries and retrieve query results in the Amazon S3 bucket using trusted identity propagation.

Configure IAM role with required permissions

To use trusted identity propagation with Athena, your Quick account must have the required permissions to access your resources. To provide those permissions, you must configure your Quick account to use an IAM role with the permissions.

If your Quick account is already using a custom IAM role, you can modify that one. If you do not have an existing IAM role, create one by following the instructions in [Create a role for an IAM user](#) in the *IAM User Guide*.

The IAM role you create or modify must contain the following trust policy and permissions.

Required trust policy

For information about updating the trust policy of an IAM role, see [Update a role trust policy](#).

Required Athena permissions

For information about updating the trust policy of an IAM role, see [Update permissions for a role](#).

Note

The Resource uses the * wildcard. We recommend that you update it to include only the Athena resources you want to use with Quick.

      "Action": [
        "athena:BatchGetQueryExecution",
        "athena:CancelQueryExecution",
        "athena:GetCatalogs",
        "athena:GetExecutionEngine",
        "athena:GetExecutionEngines",
        "athena:GetNamespace",
        "athena:GetNamespaces",
        "athena:GetQueryExecution",
        "athena:GetQueryExecutions",
        "athena:GetQueryResults",
        "athena:GetQueryResultsStream",
        "athena:GetTable",
        "athena:GetTables",
        "athena:ListQueryExecutions",
        "athena:RunQuery",
        "athena:StartQueryExecution",
        "athena:StopQueryExecution",
        "athena:ListWorkGroups",
        "athena:ListEngineVersions",
        "athena:GetWorkGroup",
        "athena:GetDataCatalog",
        "athena:GetDatabase",
        "athena:GetTableMetadata",
        "athena:ListDataCatalogs",
        "athena:ListDatabases",
        "athena:ListTableMetadata"
      ],
      "Resource": "*"
    }
  ]
}
```

```
}  
]  
}
```

Configure your Quick account to use the IAM role

After configuring the IAM role in the previous step, you must configure your Quick account to use it. For information about how to do that, see [Using existing IAM roles in Quick](#).

Update the identity propagation config with the AWS CLI

To authorize Quick to propagate end user identities to Athena workgroups, run the following `update-identity-propagation-config` API from the AWS CLI, replacing the following values:

- Replace `us-west-2` with the AWS Region that your IAM Identity Center instance is in.
- Replace `111122223333` with your AWS account ID.

```
aws quicksight update-identity-propagation-config \  
--service ATHENA \  
--region us-west-2 \  
--aws-account-id 111122223333
```

Create an Athena dataset in Quick

Now, create an Athena dataset in Quick configured with the IAM Identity Center enabled Athena workgroup you want to connect to. For information about how to create an Athena dataset, see [Creating a dataset using Amazon Athena data](#).

Key callouts, considerations, and limits

The following list contains some important considerations when using trusted identity propagation with Quick and Athena.

- Quick Athena data sources that use trusted identity propagation have Lake Formation permissions evaluated against the IAM Identity Center end user and the IAM Identity Center groups that the user might belong to.
- When using Athena data sources that use trusted identity propagation, we recommend any fine tuned access control is done in Lake Formation. However, If you elect to use Quick's scope down policy feature, scope down policies will be evaluated against the end user.

- The following features are disabled for data sources and data sets that use trusted identity propagation: SPICE datasets, Custom SQL on data sources, threshold alerts, email reports, Q Topics, stories, scenarios, CSV, Excel, and PDF exports, anomaly detection.
- If you experience high latency or timeouts, it may be because of a combination of high number of IAM Identity Center groups, Athena databases, tables, and Lake Formation rules. We recommend trying to use only the necessary number of those resources.

Data access integrations

Data access integrations in Amazon Quick establish secure connections to external data sources. They serve as the foundation for creating knowledge bases. Unlike connectors that perform actions, data access integrations focus on accessing and indexing content from third-party applications and services.

Data access integrations only configure authentication and point to the project or organization of the service. They cannot be used directly for analysis or by AI agents. You must create a connected knowledge base to make the data accessible.

How data access integrations work

Data access integrations configure authentication and establish connections to third-party service organizations or projects. You cannot use these integrations directly for analysis. You must create knowledge bases connected to the data access integration to make the data accessible for AI agents, chat interfaces, and spaces.

The relationship between data access integrations and knowledge bases is one-to-many:

- One data access integration can support multiple knowledge bases.
- Each knowledge base selects specific content from the connected data source.
- Knowledge bases inherit authentication and access permissions from their parent data access integration.

Create a data access integration

Use the following procedure to create a data access integration that establishes authentication and connection details for knowledge base creation. The following example demonstrates the process for setting up a Microsoft OneDrive data access integration, but the general steps are applicable to other data access integrations.

To create a data access integration

1. Scroll to the Set up a new integration area of the page. Find the application that you want to create an integration and knowledge base. Select "OneDrive".

Note

The Integration page defaults Knowledge bases tab and there may be existing knowledge bases that have been set up by others and shared. If you have previously set up an integration, check the data tab and use the action menu to create a knowledge base from there.

2. Select the plus (+) icon button on the application to create a new integration and knowledge base.
3. Select Bring data from Microsoft OneDrive option and click Next button.

Note

Some application integrations support data ingestion and read/write actions. The set up varies for each one. To set up actions, you'll need more information from your admin.

4. Complete the authentication process:
 - a. A Microsoft OneDrive sign in popup will appear automatically. If it doesn't, click Sign in to Microsoft OneDrive button.
 - b. Sign in using your Amazon credentials.
 - c. Wait until a success banner appears.
 - d. Click the "Next" button.
5. Select the data that should be ingested into the knowledge base using the file picker for OneDrive and click Add button.
6. Type in a knowledge base a Name and Description (optional), then click Create.
7. There will be a success toast notification and the data ingestion and sync will begin.
8. The data can take several minutes to sync, depending on the number files that are being ingested. The Status column will stay in the Syncing status until it is ready changing to Available.

9. When the knowledge base is ready, use the chat to ask questions and interact with it.

 Note

By default, the chat uses 'all data and apps' that you have access to and that are set up on your behalf. If you want to chat with a single knowledge base, select the knowledge base in the chat data picker.

 Note

You can also attach a knowledge base to a Space by navigating to the Space and adding it.

After successful creation, your data access integration appears in the integrations list. You can now create knowledge bases that use this integration to access and index content from the connected data source.

 Note

For detailed configuration steps specific to each data source, see [the section called "Supported integrations"](#).

Supported data sources

Amazon Quick supports data access integrations with the following applications and services. These integrations allow you to create knowledge bases from external data sources:

- **Amazon S3** - Access documents and files stored in S3 buckets using AWS credentials.
- **Atlassian Confluence** - Index pages, spaces, and attachments using user authentication or service authentication.
- **Google Drive** - Connect to personal and shared drives using OAuth 2.0 authentication.
- **Microsoft OneDrive** - Access OneDrive for Business content using user authentication or service authentication.

- **Microsoft SharePoint** - Index SharePoint Online and Server content using OAuth 2.0 authentication.
- **Web Crawler** - Index content from internal and external websites using basic authentication or form/SAML authentication.

Each data source supports different authentication methods and content access capabilities. The relationship between data access integrations and knowledge bases is one-to-many - one integration can support multiple knowledge bases, each selecting specific content from the connected data source.

Data source categories

Data access integrations are organized into the following categories based on the type of content and access patterns:

Cloud storage and file systems

- AWS S3 - Access documents and files stored in S3 buckets.
- Google Drive - Index content from personal and shared drives.
- Microsoft OneDrive - Connect to OneDrive for Business content.

Content management systems

- Atlassian Confluence - Access pages, spaces, and attachments.
- Microsoft SharePoint - Index SharePoint Online and Server content.

Web content

- Web Crawler - Index content from internal and external websites.

Authentication and security

Data access integrations use secure authentication methods to protect your data and maintain access controls. The authentication method depends on the specific data source and your organization's security requirements.

OAuth authentication

Most cloud-based integrations (Google Drive, OneDrive, Confluence Cloud) use OAuth 2.0 for secure, token-based authentication. This method allows Amazon Quick to access your data without storing your credentials.

Service account authentication

Enterprise integrations may use service accounts for programmatic access. This method is common for AWS S3 and other infrastructure-based data sources.

No authentication

Some integrations, such as web crawlers accessing public websites, may not require authentication. However, access controls are still enforced based on your Amazon Quick permissions.

Note

Authentication requirements and available methods vary by user tier. Readers may have limited authentication options compared to Authors.

Access control and permissions

Data access integrations maintain security by enforcing access controls at multiple levels. When users query content through knowledge bases, Amazon Quick ensures they can only access content they have permission to view.

- **Source-level permissions** - Users must have appropriate permissions in the source system (Google Drive, SharePoint, etc.).
- **Integration-level permissions** - Access to the integration itself is controlled by Amazon Quick permissions.
- **Knowledge base permissions** - Individual knowledge bases can have their own access controls.
- **Entity-level access controls** - When users query content, Amazon Quick verifies permissions for each document or item.

Key features and capabilities

Data access integrations provide several features to enhance your data integration experience:

- **Real-time synchronization** - Content is automatically updated when changes occur in the source system.

- **Selective indexing** - Choose specific folders, sites, or content types to include in your knowledge bases.
- **Content type support** - Index various file formats including documents, spreadsheets, presentations, and web pages.
- **Metadata preservation** - Maintain important metadata such as creation dates, authors, and tags.
- **Natural language querying** - Enable AI-powered search and question-answering across your indexed content.

Before you begin

Before creating data access integrations, ensure you have the following requirements in place:

- **Amazon Quick permissions** - Author or Admin role to create and manage integrations.
- **Source system access** - Appropriate permissions in the target system (administrative access may be required for some integrations).
- **Authentication credentials** - Valid credentials or service accounts for the target system.
- **Network connectivity** - Ensure Amazon Quick can access your data sources. Network requirements differ by integration type:
 - **Knowledge bases** - Do not support VPC connectivity. Data sources must be accessible over the public internet.
 - **Connectors** - Support VPC connectivity for resource servers within your VPC. However, authentication servers must remain publicly accessible.

Exploring your AWS data in Amazon Quick

Applies to: Enterprise Edition and Standard Edition

Intended audience: System administrators

Use this section to learn how to explore AWS data in Amazon Quick using the AWS Management Console. Using the **Explore in Amazon Quick Sight** shortcut, you can access a customizable dashboard template showing your data. Just as with any Amazon Quick Sight dashboard, this

dashboard can be refreshed on a schedule, published, and shared with other users in your organization.

To use this feature, you must first enable Amazon S3 analytics storage class analysis for your Amazon S3 buckets. For more on enabling storage class analysis in Amazon S3, see [Amazon S3 analytics – Storage class analysis](#) in the *Amazon Amazon S3 Developer Guide*.

After you have enabled storage class analysis, you can use Amazon Quick to explore your Amazon S3 analytics data.

To explore Amazon S3 analytics data in Amazon Quick

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. Choose a bucket to explore. The bucket must have storage class analysis enabled, with at least one filter.
3. Choose the **Management** tab.
4. Then choose **Analytics**.
5. Choose **Explore in QuickSight**.

Note

If you don't have an Amazon Quick account, you're prompted to create one before you can use the dashboard.

When you choose the option to explore in Amazon Quick, your Amazon S3 analytics data is automatically loaded into the dashboard template. The dashboard contains multiple visualizations to help you to understand the storage access pattern of your bucket.

Use the template as is, or customize it to suit your needs. For example, one visual on the default template helps you identify infrequently accessed data. It compares the amount of data retrieved to the amount of storage consumed, for objects of different ages.

You can also add your own visualizations to the dashboard. For example, you can break down the data access patterns, using filters for storage class analysis that you already have defined in Amazon S3 analytics.

To learn more about using S3 analytics and storage class analysis, see [Amazon S3 analytics – Storage class analysis](#) in the *Amazon Amazon S3 Developer Guide*.

AWS service connectors

With AWS service connectors in Amazon Quick, you can create connectors that interact directly with AWS services like Amazon Bedrock, Amazon Textract, and Amazon Comprehend. These connectors enable automated workflows that leverage AWS AI and machine learning capabilities.

What you can do

AWS service connectors enable you to integrate powerful AWS capabilities into your automated workflows. For example, you can use Amazon Bedrock to generate content with foundation models, Amazon Textract to extract text and data from documents, or Amazon Comprehend to analyze sentiment and extract insights from text. These connectors allow you to build sophisticated automation workflows that combine multiple AWS services for document processing, content generation, and data analysis—all while maintaining security through IAM role-based authentication.

Note

AWS services connectors can only be used with Amazon Quick Automate because they require an IAM identity for authentication. These connectors are created through the admin console and provide direct access to AWS service APIs.

Supported AWS services

Amazon Quick supports the following AWS services for connectors:

- **Amazon Bedrock Agent** - Invoke Bedrock agents for complex AI workflows.
- **Amazon Bedrock Runtime** - Access foundation models for text generation and conversation.
- **Amazon Bedrock Data Automation** - Automate data processing workflows with AI.
- **Amazon Comprehend** - Analyze text for sentiment, entities, and key phrases.
- **Amazon Comprehend Medical** - Extract medical information from healthcare text.
- **Amazon Textract** - Extract text and data from documents and images.
- **Amazon S3** - Manage objects and buckets in S3.

Before you begin

Before you set up an AWS service connectors, make sure you have the following:

- AWS account with access to the desired AWS services.
- IAM role with appropriate permissions for the AWS services you want to use.
- Amazon Quick Admin access to create connectors.
- Amazon Quick Automate access to use the connectors in workflows.

Prepare IAM role and permissions

Before setting up the connectors in Amazon Quick, prepare your IAM role with the necessary permissions for the AWS services you want to use.

Required IAM permissions

Configure your IAM role with the appropriate permissions based on the AWS services you plan to use. Make sure your IAM role includes a trust policy that allows Amazon Quick to assume the role for executing actions.

IAM Role for Resource Access

First, you will need to create an IAM role that will be used by Amazon Quick to call the AWS service needed in your Amazon Quick Automate workflow.

1. Log in to the AWS Console of the AWS account where the Amazon Quick subscription resides.
2. Open IAM and create a new IAM role.
3. Give it all the permissions for the AWS service you want to invoke via connectors. For example, you can assign a managed policy like `AmazonS3FullAccess` if you need to invoke Amazon S3.
4. In the trust relationship, give the assume role permission to `quicksight.amazonaws.com`. This allows Amazon Quick to assume this role and call AWS services on your behalf.
5. Once the Customer Role is created, take a note of the IAM role ARN.

Example trust policy:

```
{
  "Version": "2012-10-17"
  ,
  "Statement": [
    {
```

```
        "Sid": "Statement1",
        "Effect": "Allow",
        "Principal": {
            "Service": [
                "quicksight.amazonaws.com"
            ]
        },
        "Action": "sts:AssumeRole"
    }
}
```

Create AWS services connector

After preparing your IAM role and permissions, follow these steps to set up AWS Actions in Quick Suite.

Note

You need administrative access to Amazon Quick Suite to perform the following steps. See documentation on [Configure Amazon Quick subscriptions](#) to learn more.

Steps to create a new AWS integration

1. Choose the **profile icon**, then select **Manage Quick Suite**.
2. Select **AWS actions** under the **Permissions** section.
3. Choose **New Action** to create a new AWS integration.
4. Choose one of the **supported AWS services**.
5. Select **Next** to review available actions for this service.
6. Select **Next** to configure the connection details:
 - **Name** – Enter a descriptive name for your integration.
 - **Description** – Optionally, add notes about how this integration will be used.
 - **Role ARN** – Enter the ARN of the IAM role to be used for this AWS service.
7. Select **Next** to share the integration with users and/or user groups.
 - Provide **Owner access** for any users who need to edit, share, and delete the integration.

Note

Owner access is required to add integrations to Automation Groups in order to give access within Quick Automate.

- Provide **User access** for any users who need to invoke actions across Quick Suite.

For a list of integrations supported in various Quick Suite capabilities, see [Connector compatibility matrix](#).

8. Select **Add** to finish creating the integration.

See [Integration workflows](#) to learn more.

Next steps

After creating your action integration, you can:

- Share the integration with additional users or groups as needed.
- Add the integration to an **Automation Group** in order to use it in Quick Automate. See [Setup tasks](#) for more details.
- Monitor the integration's usage and performance through the admin console.
- Update the integration's configuration or permissions as requirements change.

Amazon Quick account management

If you are an Amazon Quick administrator, the account you use to sign in to Quick is in the ADMIN Quick group. There are also some permissions granted through IAM, which you might have already, or you can talk to your AWS account administrators to learn more.

Use the following topics to manage Quick.

Topics

- [Account details in Amazon Quick](#)
- [Amazon Quick asset management](#)
- [Manage Amazon Q permissions](#)

Account details in Amazon Quick

Use this section to change the account-wide settings in Amazon Quick. To open your account settings, choose the profile icon, and then select **Manage Quick**. Then, click on **Account settings**.

Deleting your Amazon Quick subscription and closing your account

Warning

Deleting your Amazon Quick subscription permanently destroys all organizational data across all AWS regions and cannot be reversed.

This action will immediately and permanently delete:

- Every dashboard, analysis, and dataset across your entire organization in all regions
- All user accounts and their associated work
- Custom data sources and connections
- All sharing permissions and folder structures
- Historical usage data and audit logs
- All customizations, themes, and organizational settings

Account deletion from any region affects your entire global Quick deployment. Even if you have Quick resources in multiple AWS regions, this single action deletes everything worldwide.

There is no recovery option. Once deleted, this data cannot be restored by AWS or recovered through any means.

Before proceeding: Export critical dashboards, back up datasets, and ensure all stakeholders are informed of this permanent action.

The act of deleting your Amazon Quick subscription is immediate and final. Deletion removes every Amazon Quick asset on the AWS account you are using. It doesn't delete namespaces that you added. (The **Default** namespace is deleted automatically.) You can locate and delete namespaces by using the API operations [ListNamespaces](#) and [DeleteNamespace](#).

You can terminate your Amazon Quick account from the **Manage Quick** menu or by using the API. To prevent someone from deleting a Amazon Quick user account accidentally or maliciously,

Amazon Quick uses permissions, a switch for the **Account termination protection** setting, and a required confirmation word.

After your account is deleted, you can create a new Amazon Quick account. The process doesn't take more than 15 minutes. The settings for edition and user authorization method on the new account can be the same or different.

Before you can delete your Amazon Quick account, make sure of the following:

- You're signed in using an IAM user or role with administrator permissions in Amazon Quick. We strongly recommend using an IAM identity instead of the AWS root account. For more information about root user security best practices, see [AWS account root user](#) in the *IAM User Guide*.
- You understand that your AWS account is not deleted when you terminate your Amazon Quick account. To instead close your AWS account, see [Closing an AWS account](#).
- Terminating your account deletes all users, all uploaded data, and assets (for example, datasets, data sources, queries, dashboards, analyses, settings, and so on).

Topics

- [Permissions and access to account termination](#)
- [Deleting your account](#)

Permissions and access to account termination

You need the following special permissions to terminate a Amazon Quick account. Without these permissions, you won't be able to terminate a Amazon Quick user account. Contact your account administrator for help.

- You're a Amazon Quick administrator and have an Admin role in Amazon Quick.
- You need permissions to run the following (except if you're the root admin user (IAM) who added Amazon Quick)
 - `quicksight:Unsubscribe`
 - `quicksight>DeleteAccountSubscription`
 - `ds:UnauthorizeApplication`
 - `ds>DeleteDirectory`

- `ds:DescribeDirectories`
- `quicksight:UpdateAccountSettings`

 Note

The `DeleteAccountSubscription` Amazon Quick API requires both `quicksight:Unsubscribe` and `quicksight>DeleteAccountSubscription` IAM permissions. An explicit deny on either permission results in an `AccessDeniedException`.

- To remove custom namespaces, you need permission to run the following API operations:
 - `quicksight:ListNamespaces`
 - `quicksight>DeleteNamespace`

You don't need extra permissions to delete the default namespace.

 Warning

Terminating your account is an instant action that cannot be undone by you or by AWS.

Deleting your account

The following sections outlines the different ways you can terminate your Amazon Quick instance.

To terminate your Amazon Quick account without the Amazon Quick UI

- Sign in to AWS where you want to remove Amazon Quick.

To terminate your account by using the Amazon Quick UI

1. Choose your profile on the application bar, and then choose **Manage Quick**.
2. Use one of the following methods to open the **Account termination** screen.
 - Use this [direct link](#) to the screen.
 - Choose **Account settings, Manage**.

3. On the **Account termination** page, confirm that you are viewing the correct Amazon Quick account by checking the name listed for account name.
4. Toggle off **Account termination protection is on**. Doing this enables the **Delete account** section.
5. For **Type "confirm" to delete this account**, enter the word confirmation word shown on your screen.

Amazon Quick asset management

Use this section to manage all of the assets in your Amazon Quick account in one unified view. You can manage the following Quick assets: Analyses, Dashboards, Datasets, Data sources, Shared folders, and Agents.

For the full model of how user removal affects a user's assets and data, see [User lifecycle and data handling in Amazon Quick](#).

Here are some common reasons to use the asset manager:

- **Transfer assets** – Quickly transfer assets from one user or group to another, for example when the original owner is no longer present.
- **Onboard new employees** – Speed up onboarding of new employees by giving them access to the same assets that their teammates using.
- **Support authors** – Better support authors in tenancies by giving support engineers temporary access to the author's dashboard.
- **Revoke access** – Quickly audit and revoke permissions, for example after implementations, customer support, or unexpected events.

To manage Amazon Quick assets

1. Choose the profile icon, then **Manage Quick**.
2. Open the asset manager by clicking on **Manage assets**.
3. You can search for assets by name, or browse for them in a list. Choose one of the following methods:

To search by name, select the appropriate search bar, using the name as your guide. Enter your search term and press **ENTER**. Find assets a user or group has access to by using the **Search by User or Group name** bar. Find other assets by using the **Search by asset name** bar.

To browse for assets by type, select a button by its name to view a type of asset, for example: browse analyses by selecting the **Analyses** button, browse for Data sources by selecting the **Data sources** button, and so on.

4. When you are viewing a list of your search results, you can interact with the assets listed. Here are a few examples:
 - Select an asset by toggling the box at the beginning of each row. Or, select everything by clicking the box at the top left of the list.
 - Change the type you are browsing for by selecting a different asset type from the **Asset type** list.
 - Use the vertical dot menu at right to perform an action on the asset in that row.
 - Use the **Share** button to share all of the selected assets. A popup window displays sharing options to apply to the users or groups you specify.
 - Select one or more assets, then choose the **Transfer** button to transfer the selected assets from one user or group to another. The **Transfer** button only appears after you select at least one asset. A popup window displays transferring options to apply to the users or groups you specify.

When you need to share a Amazon Quick asset with 100 or more users, consider using Amazon Quick groups. For more information on Amazon Quick groups, see [Creating and managing groups in Amazon Quick](#).

Manage Amazon Q permissions

Amazon Q is an AI-powered capability in Amazon Quick that enhances your data analysis experience. Quick admins can manage Amazon Q permissions in the Quick administration console. These permissions control how Amazon Q interacts with your data and users.

Topics

- [Manage personalization permissions](#)
- [Manage dashboard and visual indexing for search](#)
- [Manage Dashboard Q&A](#)

Manage personalization permissions

Amazon Q can use user metadata to provide more context-aware responses. This feature allows for a more personalized experience when interacting with Amazon Q.

To manage personalization permissions:

1. Open the [Quick console](#).
2. Choose the user icon at the top right, and then choose **Manage Quick**.
3. Under the **Account** section, choose **Amazon Q**.
4. Locate the **Manage personalization permissions** section.
5. Use the toggle switch next to **Personalized responses** to enable or disable this feature.

When enabled, Amazon Q can read user metadata to tailor its responses to individual users. This may include considering the user's role, location, or prior documents when providing information or suggestions.

Manage dashboard and visual indexing for search

Amazon Q can index information from dashboards to make them easily searchable across applications. This feature enhances the discoverability of your dashboards and their contents.

To manage dashboard and visual indexing:

1. Open the [Quick console](#).
2. Choose the user icon at the top right, and then choose **Manage Amazon Quick**.
3. Under the **Account** section, choose **Amazon Q**.
4. Locate the **Manage dashboard and visual indexing for search** section.
5. Use the toggle switch next to **Dashboard & visual indexing** to enable or disable this feature.

When enabled, Amazon Q can read dashboard metadata and visual information such as keywords, data fields, and refresh times to quickly respond to queries.

Manage Dashboard Q&A

The Dashboard Q&A feature allows Amazon Q to answer questions about your data without requiring the use of Quick Topics. This provides a more flexible and intuitive way for users to interact with their dashboards.

To manage Dashboard Q&A:

1. Open the [Quick console](#).
2. Choose the user icon at the top right, and then choose **Manage Amazon Quick**.
3. Under the **Account** section, choose **Amazon Q**.
4. Locate the **Manage Dashboard Q&A** section.
5. Use the toggle switch next to **Dashboard Q&A** to enable or disable this feature.

When enabled, Amazon Q can read dashboard metadata and visual information such as keywords, data fields, and refresh times to quickly respond to queries. This will eliminate the need for predefined Quick Topics.

Managing Quick subscriptions

Subscription management in Amazon Quick involves configuring and optimizing your service usage to meet your organization's needs while controlling costs. This section covers essential subscription-related tasks including upgrading or downgrading user subscriptions between Quick Professional and Enterprise, managing SPICE memory capacity to ensure optimal performance for your in-memory datasets, and configuring data capacity limits for unstructured data storage. Proper subscription management helps you balance performance, functionality, and cost while ensuring your users have the resources they need to create and share insights effectively.

Topics

- [Configure Amazon Quick subscriptions](#)
- [Configure SPICE memory capacity](#)
- [Index capacity](#)

Configure Amazon Quick subscriptions

You can purchase user subscriptions to get discounted pricing on Amazon Quick. When you invite additional users to Quick, you're charged for those accounts on a month-by-month basis.

To understand how Amazon Quick subscription names on the pricing page map to user roles in the admin console, see [Understanding Amazon Quick subscriptions and roles](#).

When you purchase an annual subscription, you pay for a Quick user account on an annual rather than monthly basis. With an annual subscription, you receive a discounted price in return for the

extended time commitment. You don't need to purchase an annual subscription to create or add users.

When you purchase a set of standard user subscriptions, you choose the number of accounts you want to cover. You also choose when to start the subscriptions (any time from the month following the current month, to one year in the future) and whether to autorenew them. All subscriptions that you purchase together must use the same values for these settings.

You can edit an existing set of user subscriptions to change whether it autorenews. If the set is not yet active, you can also change the number of subscriptions it covers, or delete it entirely.

Topics

- [Viewing current subscriptions](#)
- [Purchase subscriptions](#)
- [Editing a subscription](#)
- [Delete a subscription](#)
- [Upgrading or downgrading user subscriptions](#)
- [Understanding Amazon Quick user billing](#)

Viewing current subscriptions

Use the following procedure to view your current user subscriptions.

To view your current user subscriptions

1. Choose your user name on the application bar and then choose **Manage Quick**.
2. Choose **Manage pricing**.
3. Use the subscription meter to see how many accounts you have and how they are billed. In the following example, the account has 21 users total:
 - Seven users with annual subscriptions. Only currently active subscriptions are shown here.
 - 13 month-to-month users.

Pause over any section of the meter bar to display details about that user segment.

4. Use the information in the subscriptions table to see what current and future subscriptions you have.

Purchase subscriptions

Use the following procedure to purchase subscriptions.

To purchase subscriptions

1. Choose your user name on the application bar and then choose **Manage Quick**.
2. Choose **Manage pricing**.
3. Navigate to the **Authors and Admins** section, and then choose **Purchase plan**.
4. Choose or enter the number of subscriptions you want.
5. Choose the month and year when the subscriptions will start.
6. Choose whether the subscriptions autorenew.
7. Choose **Purchase**.

Editing a subscription

Use the following procedure to edit subscriptions.

To edit subscriptions

1. Choose your user name on the application bar and then choose **Manage Quick**.
2. Choose **Manage pricing**.
3. Next to the set of subscriptions you want to change, choose **Manage**.
4. (Optional) If the subscriptions haven't started yet, change the number of subscriptions.
5. Choose whether the subscriptions autorenew.
6. Choose **Save changes**.

Delete a subscription

Warning

Deleting Amazon Quick subscriptions affects user access. When you delete subscriptions:

- Users covered by deleted subscriptions may lose access to Quick features and content
- Subscription changes affect your entire organization's access to Quick capabilities

- Deleted subscriptions cannot be recovered - you must purchase new subscriptions to restore access

Before proceeding: Verify that affected users have alternative access methods and understand the implications of subscription changes.

Use the following procedure to delete subscriptions. You can only delete subscriptions that haven't started yet.

To delete subscriptions

1. Choose your user name on the application bar and then choose **Manage Quick**.
2. Choose **Manage pricing**.
3. Next to the set of subscriptions that you want to delete, choose **Edit**.
4. Choose **Delete Subscription**.

Note

If you use AWS Key Management Service or AWS Secrets Manager with Amazon Quick, you are billed for access and maintenance as described in the pricing pages for each AWS product. For more information on how these products are billed, see the following:

- [AWS Key Management Service Pricing page](#)
- [AWS Secrets Manager Pricing page](#)

In your billing statement, the costs are itemized under the appropriate product and not under Amazon Quick.

Upgrading or downgrading user subscriptions

Amazon Quick Professional and Amazon Quick Enterprise are per-user subscriptions that you assign through group membership. To change a user's subscription, you move them between the groups that are mapped to Quick roles. The Reader Pro role corresponds to the Amazon Quick Professional subscription, and the Author Pro role corresponds to the Amazon Quick Enterprise

subscription. For more information about how subscriptions map to roles, see [Understanding Amazon Quick subscriptions and roles](#).

For a full comparison of the capabilities included with each subscription and current per-user pricing, see [Amazon Quick pricing](#).

Upgrading from Professional to Enterprise

To upgrade a user from the Amazon Quick Professional subscription to the Amazon Quick Enterprise subscription, move the user to a group that is mapped to the Author Pro role. If you use IAM Identity Center or Active Directory, you make this change by updating the user's group membership in your identity provider. For the procedure, see [Changing a user's role](#).

Users can also request an upgrade themselves when they encounter a feature or usage limit that requires the Enterprise subscription. Depending on your organization's settings, these requests can process automatically or require administrator approval. For more information, see [User-driven license upgrades](#).

After the change takes effect, the user has immediate access to Enterprise capabilities. Changes to users or groups can take up to five minutes to propagate.

Downgrading from Enterprise to Professional

To downgrade a user from the Amazon Quick Enterprise subscription to the Amazon Quick Professional subscription, move the user out of the group that is mapped to the Author Pro role and into a group that is mapped to the Reader Pro role. As with an upgrade, you make this change through your identity provider when you use IAM Identity Center or Active Directory. For the procedure, see [Changing a user's role](#).

Important

If a user belongs to multiple groups that are mapped to different roles, they keep the subscription that grants the broadest level of access. To complete a downgrade, remove the user from every group that is mapped to the Author Pro role.

After you downgrade a user, they lose access to the capabilities included only with the Amazon Quick Enterprise subscription. Before you downgrade, make sure any assets the user owns that you want to keep are transferred to another user. Changes to users or groups can take up to five minutes to propagate.

Note

For questions about billing adjustments or refunds related to a subscription change, contact [AWS Support](#).

Understanding Amazon Quick user billing

Your charges for a Quick user follow the user's lifecycle in your account, from the moment you provision the user through the period after you remove the user. The following sections explain when billing begins, how your first billing period is prorated, how ongoing monthly charges apply, and how removing a user affects your charges.

Topics

- [When billing begins](#)
- [Your first billing period](#)
- [Ongoing monthly billing](#)
- [Billing when you remove a user](#)
- [Billing examples](#)

When billing begins

Billing for a Quick user begins when you provision the user in your account, not when the user first signs in. This is independent of user activity. If you provision a user who never signs in during a billing period, you are still billed for that user for that period.

The exact moment billing begins depends on how you provision the user:

- For users you provision through the API, such as by registering a user or creating an account subscription, billing begins when the API call creates the user, whether or not the user has signed in.
- For users who self-provision, billing begins the first time the user opens Amazon Quick.
- For users you map from a group in IAM Identity Center or Active Directory, billing begins when Amazon Quick detects the user through group synchronization.

Your first billing period

When you provision a user partway through a billing period, your charge for that first period is prorated. The proration is based on the portion of the period that remains after the provisioning date. In the next full billing period, you pay the standard rate for the user's role.

Ongoing monthly billing

For each billing period a user remains in your account, you pay the monthly rate for that user's role. These subscription charges are separate from usage-based charges such as SPICE capacity or reader session usage. For a full comparison of the capabilities included with each subscription and current per-user pricing, see [Amazon Quick pricing](#).

Billing when you remove a user

When you remove a user partway through a billing period, you still pay for the full billing period in which the removal occurs. You are not charged for the user in any later billing period. This differs from provisioning. Your first billing period is prorated, but your final billing period is not.

To avoid charges for a user you no longer need, remove the user before the next billing period begins.

Billing examples

The following examples show how your charges apply across a user's lifecycle:

- For a user you provision partway through a billing period, your charge for that period covers the provisioning date through the end of the period, and the full rate applies in the next period.
- For a user you remove partway through a billing period, you pay for the full period, and no charge applies in the following period.
- For a user you provision and remove within the same billing period, you pay for that full period, and no charge applies afterward.
- For a user who never signs in, you pay each billing period the user remains in your account, the same as an active user, until you remove the user.

This billing behavior applies to all Amazon Quick user roles across editions and in all AWS Regions where Amazon Quick is available.

Configure SPICE memory capacity

SPICE (Super-fast, Parallel, In-memory Calculation Engine) is the robust in-memory engine that Amazon Quick uses. It's engineered to rapidly perform advanced calculations and serve data. In Enterprise edition, data stored in SPICE is encrypted at rest. For more information, see [Data encryption in Quick](#).

SPICE capacity is allocated separately per AWS Region. For each AWS account, SPICE capacity is shared by all the people using Quick in a single AWS Region. The other AWS Regions have no SPICE capacity unless you choose to purchase some.

Quick administrators can view how much [SPICE](#) capacity you have in each AWS Region and how much of it is currently in use. Administrators can also purchase additional SPICE capacity or release unused SPICE capacity. You can only release SPICE capacity that isn't currently used by a dataset. Datasets in SPICE stay there until someone remove them from SPICE. To change that, you can either delete the datasets or change them so they aren't stored in SPICE.

Purchasing or releasing SPICE capacity only affects the capacity for the currently selected AWS Region. Each AWS account can have a separate Amazon Quick subscription and can be used in multiple AWS Regions.

Before you make any changes to SPICE capacity, make sure that you're using the correct AWS account and AWS Region. It's possible to be using different AWS accounts or AWS Regions at the same time in different contexts, as follows:

- If you open Amazon Quick using the `http://quicksight.aws.amazon.com` URL, Amazon Quick automatically selects your account and AWS Region. You can't view your AWS account from Amazon Quick. We recommend using a different method to open Amazon Quick when you want to work with SPICE capacity.
- If you open Amazon Quick from the AWS Management Console, Amazon Quick opens in the account that you used to sign in to that console. However, it opens in the last AWS Region that you selected in Amazon Quick. The AWS Management Console and the Amazon Quick console each have an AWS Region selector that works independently from the other. Changing the selected AWS Region in the AWS console doesn't change the AWS Region in Amazon Quick.
- If you use the AWS Command Line Interface (AWS CLI) to run Amazon Quick commands, make sure to provide the relevant AWS account for each Amazon Quick API operation you use. The AWS Region isn't always required, and if you don't provide it, the AWS CLI uses your default AWS Region from your AWS configuration. We recommend that you always explicitly provide the AWS Region, to make sure you apply the command to the correct AWS Region.

You must be signed in as a Amazon Quick administrator to view or manage SPICE capacity.

Topics

- [Finding your current AWS account and AWS Region](#)
- [Viewing SPICE capacity and usage in an AWS Region](#)
- [Hiding SPICE capacity labels](#)
- [Purchasing SPICE capacity in an AWS Region](#)
- [Turning on SPICE auto capacity purchasing](#)
- [Releasing SPICE capacity in an AWS Region](#)

Finding your current AWS account and AWS Region

To select the correct AWS account and AWS Region (console)

1. Open the AWS console, using the AWS account that you want to view SPICE information for. If you have only one AWS account, you can skip this step.

You can verify the account number by following these steps:

- a. On the navigation bar at the top of the page, choose the account name or number at right. If a number displays, this might be your AWS account ID.
- b. Choose **My Security Credentials** to display your credential-related information and options. Your AWS account ID displays near the top of the page.

To return to the original page, choose the AWS logo at upper left.

2. Open Amazon Quick by first entering "**quicksight**" into the **Find Services** search box. When the word Amazon Quick appears following the search box, choose it from the list.
3. In Amazon Quick, open the profile menu by choosing your profile icon at top right. The AWS name of the AWS Region that Amazon Quick is using displays in the menu.

The same AWS Region also displays in the URL, for example: `https://us-east-1.quicksight.aws.amazon.com/sn/admin`. If this is your URL, the profile menu displays the name N. Virginia.

To switch AWS Regions, display the list of supported Regions by choosing the Region name from the profile menu. Then choose the Region that you want to use. Switching to a different

AWS Region changes the SPICE usage information that you can view. It also changes the Amazon Quick assets that you can use, for example data sources and dashboards.

Viewing SPICE capacity and usage in an AWS Region

To view current SPICE capacity and usage (console)

1. Open Amazon Quick. Make sure that you're using the correct AWS account and AWS Region as described previously in [Finding your current AWS account and AWS Region](#).
2. Open the administration page by choosing **Manage Quick** from your profile menu.
3. Choose **SPICE capacity** from the left navigation pane . The following information displays:
 - The **Total SPICE capacity** section displays the total amount of used and unused SPICE capacity. A bar graph shows how much of this storage space is in each of the following categories for this AWS account in the AWS Region that's currently selected in Amazon Quick:
 - Purchased SPICE capacity – This is the additional SPICE capacity.
 - SPICE capacity bundled with Amazon Quick – This is the total default capacity associated with your paid users.

Hover over any section of the meter to see details on that capacity type.

- The **SPICE usage** section displays the total amount of the used and unused SPICE capacity. A bar graph shows how much of this storage space is in each of the following categories for this AWS account in the AWS Region that's currently selected in Amazon Quick:
 - Used SPICE capacity – This is the used portion of the default SPICE capacity that you get for each user.
 - Unused SPICE capacity – This is the unused portion of the default SPICE capacity that you get for each user.
 - Releasable unused capacity – This is the purchased capacity that isn't in use, and so can be released to reduce costs.

Hiding SPICE capacity labels

Amazon Quick account admins can choose to hide the account-wide SPICE capacity usage and remaining size labels from Amazon Quick authors. This feature is available to all enterprise

accounts that use custom permissions. For more information about custom permissions in Amazon Quick, see [Customizing access to Amazon Quick capabilities](#)

Use the following procedure to hide SPICE capacity usage from the Amazon Quick console.

1. Open the [Quick console](#).
2. From any page in the Amazon Quick console, choose your profile name, and then choose **Manage Quick**.

The **Manage Quick** menu is only available to Amazon Quick admins. If you are unable to access this menu, contact your Amazon Quick account admin for assistance.

3. Choose **Manage users**, and then choose **Manage permissions**.
4. Edit or create a new custom permission. For **Restrict access to**, under **Datasets**, select **Viewing account SPICE capacity**.
5. When you are finished creating or changing the custom permission, choose **Create** or **Update**.

After you create or update a custom permission to hide SPICE capacity usage, assign the new permission to users with the `UpdateUser` API.

Purchasing SPICE capacity in an AWS Region

To purchase more SPICE capacity (console)

1. Open Amazon Quick. Make sure that you're using the correct AWS account and AWS Region as described previously in [Finding your current AWS account and AWS Region](#).
2. Open the administration page by choosing **Manage Quick** from your profile menu.
3. Choose **SPICE capacity** from the left navigation pane .
4. Choose the **Purchase more capacity** button.
5. Enter a number of gigabytes of SPICE capacity to purchase for the AWS Region that is currently selected in Amazon Quick.
6. To confirm your choice, choose **Purchase SPICE capacity**. To exit without making any changes, choose **Cancel**.

Turning on SPICE auto capacity purchasing

Turn on SPICE auto capacity purchasing to allow Amazon Quick to automatically manage your Amazon Quick account's SPICE capacity. When you turn auto capacity purchasing on, Amazon

Quick evaluates how much capacity is needed based on your account's usage. As your account uses more SPICE storage, Amazon Quick automatically purchases SPICE capacity as needed on your behalf. This allows users to ingest data as needed without the need to estimate usage or manually purchase SPICE data. Auto capacity purchasing makes it easier for new customers, ISVs, and larger companies to directly access SPICE without needing to understand, track, or manually purchase their account's SPICE capacity. Amazon Quick admins can still purchase and release SPICE capacity manually.

Auto capacity purchasing doesn't support auto-decrement. If users want to reduce their SPICE usage, capacity release must be done manually.

By default, all new Amazon Quick accounts that are created in the Amazon Quick console have auto capacity purchasing turned on in the region that their capacity is located. To turn on auto capacity purchasing for other regions, Amazon Quick account admins can manually turn on auto capacity from the **SPICE capacity** management page.

By default, all new Amazon Quick accounts that were created with the Amazon Quick API and all existing Amazon Quick accounts have auto capacity purchasing turned off. To turn on auto capacity purchasing, Amazon Quick account admins can manually turn on auto capacity from the **SPICE capacity** management page.

To turn SPICE capacity purchasing on or off

1. Open the [Quick console](#).
2. From any page in the Amazon Quick console, choose your profile name, and then choose **Manage Quick**.

The **Manage Quick** menu is only available to Amazon Quick admins. If you are unable to access this menu, contact your Amazon Quick account admin for assistance.

3. Choose **SPICE capacity**.
4. On the **SPICE Capacity** page that opens, toggle the **Auto-purchase capacity** on.

To turn auto capacity purchasing off, follow the procedure above and toggle **Auto-purchase capacity** off. When auto purchase capacity is turned off, ingestions or refreshes that exceed the account's SPICE capacity automatically fail.

Amazon Quick admins can turn auto capacity pricing on or off at any time. If you turn auto capacity purchasing off after it's been in use, your account's current capacity becomes your account's

purchased capacity. If your account has no remaining capacity when you turn auto purchase off, the next ingestion or refresh will fail.

If your account already exceeds its SPICE capacity when you turn auto capacity purchasing on, Amazon Quick automatically matches your account's capacity to your current usage. After Amazon Quick matches your account's capacity, the auto-purchase logic starts.

Releasing SPICE capacity in an AWS Region

To release unused SPICE capacity (console)

1. Open Amazon Quick. Make sure that you're using the correct AWS account and AWS Region as described previously in [Finding your current AWS account and AWS Region](#).
2. Open the administration page by choosing **Manage Quick** from your profile menu.
3. Choose **SPICE capacity** from the left navigation pane .
4. Choose **Release unused purchased capacity**.
5. Do one of the following:
 - To release all SPICE capacity from the AWS Region that is currently selected in Amazon Quick, choose **Release all**.
 - To release some of gigabytes of SPICE capacity from the AWS Region that is currently selected in Amazon Quick, enter the number of gigabytes to release.
6. To confirm your choice, choose **Release SPICE capacity**. To exit without making any changes, choose **Cancel**.

Index capacity

An index is a structured corpus of documents that allows for efficient searching, sorting, and data access. Amazon Quick uses an index to store, prepare, sync any files you upload to your Quick spaces. It then uses this indexed data to generate agent-driven responses during chat conversations.

Topics

- [Storage allocation](#)
- [Regional allocation](#)
- [Manual scaling & autoscaling](#)

- [Total index capacity](#)
- [To view index capacity usage](#)
- [Release unused index capacity](#)
- [Switch between capacity modes](#)

Storage allocation

You get index capacity measured as the original file size of documents at their source location (such as SharePoint, S3, Confluence) before any processing by Quick. Quick automatically creates an index when you sign up in your home region with auto-scaling enabled (a mechanism where your index capacity is adjusted automatically based on usage). Your Quick Index storage allocation is based on your user count and subscription tier. **Professional users** get 25 GB of storage per user and **Enterprise users** get 50 GB per user. Overages are billed at \$5 per GB per month. Allocated storage and overages are pooled on a payer account level. This replaces the previously auto-provisioned 50 MB (extracted text) default index capability.

Regional allocation

Your Quick Index storage allocation is billed as a discount to your home region, the region you selected during your Quick subscription setup. If you provision Quick Index capacity in additional regions beyond your home region, that storage counts as overage and is billed at \$5 per GB per month.

Manual scaling & autoscaling

You can purchase additional capacity via the Quick console in two ways. First, auto-purchase is enabled by default for all accounts. When your usage approaches your organizational allocation, the system automatically purchases additional capacity in 0.25 GB increments up to a maximum of 2 TB. Second, you can manually purchase capacity from 0.25 GB, up to 2 TB in 0.25 GB increments. The pre-populated auto-purchase limit is set to 2 TB, which you can adjust in the console. The default manual purchase amount is set to 0.25 GB. For manual purchase mode, you will be billed based on the storage capacity you have purchased, while in auto scale mode you will be billed based on 0.25 GB increment bundles, depending on how much you have consumed.

Quick Index has an auto-scaling limit currently set at 2 TB of storage per account, replacing the previous limit of 60 GB of extracted text. If you need to index more than 2 TB, please open a ticket with AWS support to extend this limit.

Total index capacity

You must purchase data storage capacity for your Amazon Quick index to ingest data from knowledge bases and upload files to spaces. In the index capacity page, the first horizontal bar shows your total index capacity. This is the current capacity available in your index to support file uploads and knowledge bases. You can switch between manual and auto-scaled index capacity modes as per your needs. When auto-scaling mode is **ON**, this capacity automatically adjusts to reflect the latest available capacity based on your ingestion needs. When manual mode is **ON**, this total capacity represents the actual capacity you have purchased for your account based on your estimate of the ingestion needs.

If you previously purchased Index capacity measured in extracted MBs of storage, your existing purchased capacity will be converted to the new Raw Storage dimension automatically. When buying capacity manually, you can also release unused capacity. If you want to release all provisioned index capacity, you can do so after deleting corresponding data—like file uploads in spaces and knowledge bases—in your Amazon Quick instance.

Note

With auto-scaling enabled, Amazon Quick may temporarily provision capacity above your maximum purchase limit during periods of high concurrent usage to maintain performance. However, you are only charged for capacity up to your configured maximum purchase limit, not for any temporary over-provisioning that occurs.

To manage purchase options

1. Log in to the Amazon Quick console.
2. Select **Manage Quick**.
3. From the admin console left navigation menu, select **Subscriptions**, and then select **Index capacity**.
4. In **Index capacity**, from **Total index capacity** select **Manage capacity**, and do the following:
 - a. In **Manage purchase options**, do one of the following:
 - i. To automatically scale index capacity as per usage, select **Auto-scale (Recommended)**. This automatically adjusts index capacity in 0.25 GB increments based on your usage, purchasing or releasing as needed. Then, in **Maximum purchase**

limit set the limit at which auto-purchase stops. The value of the maximum purchase limit must be 2 TB. Maximum purchase limit cannot be lower than current used capacity.

- ii. To manually purchase capacity, select **Manual**. Then, in **Index capacity**, set the total capacity you want your index to hold. The capacity must be between 0.25 GB-2 TB and you can increase it in 0.25 GB increments. When you want to lower the current capacity held by the index, it can't be lowered below the used capacity. Since capacity is managed in 0.25 GB increments, you can only decrease to the next 0.25 GB unit above your current usage. For example, if your index has 2 GB capacity with 1.1 GB consumed, you can reduce capacity to 1.25 GB but not to 1 GB since part of the 1-1.25 GB unit is already in use.
- b. Select **Confirm**.

To view index capacity usage

The Amazon Quick admin console displays both your purchased index capacity and your index capacity usage. The following procedure shows you how to view them.

To view index data capacity usage

1. Log in to the Amazon Quick console.
2. Select **Manage Quick**.
3. From the left navigation menu, select **Subscriptions**, and then select **Index capacity**.
4. In **Index capacity**, you'll find your capacity usage under **Index capacity usage**. First bar shows you total purchased capacity and second bar shows you index capacity usage.

Release unused index capacity

The Amazon Quick admin console displays both your purchased index capacity and your index capacity usage. If you've manually provisioned capacity, you can choose to release unused index capacity. If you've enabled auto-scaling for your index, you don't need to release index capacity as Amazon Quick automatically scales index capacity to your usage. The following procedure shows you how to release unused index capacity.

 Note

To release any provisioned index capacity, you must delete all datasets and files uploaded to spaces. Then, follow the steps to release unused index capacity.

To release index data capacity

1. Log in to the Amazon Quick console.
2. Select **Manage Quick**.
3. From the left navigation menu, select **Subscriptions**, and then select **Index capacity**.
4. In **Index capacity**, select **Manage capacity**.
5. In **Manage index capacity**, reduce the **Index capacity** to your desired value.

Switch between capacity modes

You can switch between manual and auto-scale index capacity modes at any time. When switching from auto-scale to manual, your current capacity becomes your fixed manual capacity. When switching from manual to auto-scale, you set a maximum purchase limit and Amazon Quick automatically adjusts capacity based on usage.

To switch from auto-scale to manual capacity

1. Log in to the Amazon Quick console.
2. Select **Manage Quick**.
3. From the admin console left navigation menu, select **Subscriptions**, and then select **Index capacity**.
4. In **Index capacity**, from **Total index capacity** select **Manage capacity**.
5. In **Manage index capacity**, select **Manual**.
6. In **Index capacity**, set your desired manual capacity. The value must be between 0.25 GB-2 TB in 0.25 GB increments and can't be less than current usage.
7. Select **Confirm**.

To switch from manual to auto-scale capacity

1. Log in to the Amazon Quick console.

2. Select **Manage Quick**.
3. From the admin console left navigation menu, select **Subscriptions**, and then select **Index capacity**.
4. In **Index capacity**, from **Total index capacity** select **Manage capacity**.
5. In **Manage index capacity**, select **Auto-scale (Recommended)**.
6. In **Maximum purchase limit**, set your maximum purchase limit. The value must be between 0.25 GB-2 TB in 0.25 GB increments and can't be less than current usage.
7. Select **Confirm**.

Managing identities

Identity management in Amazon Quick involves controlling who can access your Quick resources and what actions they can perform. This section covers the essential tasks for managing user identities, including adding and removing users, organizing them into groups for easier permission management, and transitioning between different identity management systems. Whether you're using IAM Identity Center, federated identity providers, or other authentication methods, these topics will help you establish proper access controls and maintain security for your Quick environment.

Before managing user access, it's important to understand how Amazon Quick subscription names map to user roles. For information about subscription types and their capabilities, see [Understanding Amazon Quick subscriptions and roles](#).

Topics

- [Managing user access inside Amazon Quick](#)
- [User-driven license upgrades](#)
- [Creating and managing groups in Amazon Quick](#)

Managing user access inside Amazon Quick

Intended audience: System administrators and Amazon Quick administrators

Amazon Quick administrators manage user access in Quick. User access management in Quick is determined by your Quick account identity configuration. For accounts that use IAM Identity Center

or Active Directory, groups are assigned to Quick roles. Groups can be assigned the Admin, Author, Reader, Admin Pro, Author Pro, or Reader Pro roles. For more information about Pro roles in Quick see [Get started with Generative BI](#). Note that Reader Pro maps to Amazon Quick Professional subscription and Author Pro maps to Amazon Quick Enterprise subscription. For more information about integrating your Amazon Quick account with IAM Identity Center, see [Managing access for IAM Identity Center users](#).

To understand how subscription names relate to user roles and their capabilities, see [Understanding Amazon Quick subscriptions and roles](#).

Amazon Quick accounts that use Quick and IAM users create users directly in Quick. These users and their roles are managed at the user level. For more details, see [Managing access for Quick and IAM users](#).

Topics

- [Managing access for IAM Identity Center users](#)
- [Managing access for Amazon Quick and IAM users](#)

Managing access for IAM Identity Center users

Applies to: Enterprise Edition

Intended audience: System administrators and Amazon Quick administrators

AWS administrators can use this topic to learn more about managing accounts that are integrated with IAM Identity Center. The information in this section also applies to Quick accounts that use Active Directory.

To manage Quick users, you must have administrative privileges in Quick and also the appropriate AWS permissions. For more information about the necessary AWS permissions, see [IAM policy examples for Quick](#). If you are using directory groups, you need to be a network administrator.

Each Quick Enterprise edition account can have an unlimited number of users. User names that contain a semicolon (;) aren't supported.

Use the following topics to add, view, and deactivate Quick users.

Important

You can't remap Amazon Quick users or groups from one identity store to another. For example, if you are migrating from an on-premises Active Directory to Directory Service, or the other way around, you unsubscribe and resubscribe to Amazon Quick. You do this because even if the user's aliases remain the same, the underlying identity data changes. To make the transition easier, request in advance that your users document all their Amazon Quick assets and settings before the migration.

Topics

- [Adding users](#)
- [Managing user access](#)
- [Deactivating user accounts](#)
- [Changing a user's role](#)
- [Deleting Enterprise accounts](#)

Adding users

With IAM Identity Center, add users to Amazon Quick by associating their IAM Identity Center group to an Admin, Admin Pro, Author, Author Pro, Reader, or Reader Pro role in Quick. All users in the selected groups are authorized to sign in to Quick.

For more information about Pro roles in Quick see [Get started with Generative BI](#).

To see which groups are integrated with your Quick account, follow the procedure in [Managing user access](#).

Managing user access

Use the following procedure to view groups that are assigned to a role that grants access to Quick.

1. Open the [Quick console](#).
2. Choose your user name on the application bar and then choose **Manage Account**.
3. Choose **Manage Users**.
4. Choose **Manage role groups**.

5. In the **Manage role groups** page, use the tables to add or remove groups in IAM Identity Center or Active Directory from the Admin, User, or Reader roles in Quick.

Deactivating user accounts

Deactivating a Amazon Quick group or user account removes that group or user's access to Quick resources, like analyses or data sets. IAM Identity Center or Active Directory users that are removed from a group that grants them access to Quick lose access to Quick. These users appear in the **Inactive users** list in Quick and remain there until an administrator removes them. Before you deactivate a user, you can reassign their resources to another user with the asset management console.

If you later need to reactivate a Quick user's account, put the user into a group with access to Quick. Doing this restores their access to Quick and to any existing resources that are still associated with that user.

Note

With IAM Identity Center integrated into your Amazon Quick account or Active Directory users, you can change a user's role type by moving them to a group that is associated with a different Amazon Quick role. If a user is in multiple groups that are mapped to different Amazon Quick role types, the user is able to access Amazon Quick with the role that offers the broadest level of access. Accounts that use other identity types can't upgrade or downgrade a user by transferring them between groups. For more information, see [Changing a user's role](#).

You can activate or deactivate multiple users at once by adding or removing one or more IAM Identity Center or Active Directory groups that are associated with a role in Amazon Quick.

Changing a user's role

If you're using IAM Identity Center or Active Directory, you can change a user's role by adding or removing them from a group that's mapped to the role that you want to assign them in Quick. You can also perform this task by adding a new group to a role in Quick. To do this, you need both administrative privileges in Quick and also appropriate AWS permissions.

With IAM Identity Center integrated users, you can change role types for a user by moving them to a group that is associated with a different Quick role. If a user belongs to multiple groups that

are mapped to different role types, the user is able to access Quick with the role that offers the broadest level of access.

When you make changes to users or groups in Quick, it can take up to five minutes for the change to take effect. Examples of such changes are the following:

- Deleting a user
- Changing a user from an admin to an author
- Adding or removing group members

The five-minute time period allows changes to propagate throughout the system.

Deleting Enterprise accounts

If a user is deleted from IAM Identity Center or Active Directory or is removed from a group that's associated with a role in Quick, the user no longer exists in Quick. You do not need to delete the user in the Quick application. The deleted user will appear in the **Inactive users** list in Quick until the first day of the following month. After that date passes, the user is automatically removed from the list.

When a user is removed from your identity provider, the user's assets are not transferred or deleted automatically. Administrators can review deleted users and transfer their assets to another user. To transfer assets that no longer have an owner, see [Amazon Quick asset management](#). For the full model of how user removal affects assets and data, see [User lifecycle and data handling in Amazon Quick](#).

Removing a user affects billing for the current billing period. For how billing works when you remove a user, see [Understanding Amazon Quick user billing](#).

Managing access for Amazon Quick and IAM users

Amazon Quick account administrators can use this topic to learn more about managing accounts that use IAM or Quick for identity federation.

To manage Quick users, you must have administrative privileges in Quick and also the appropriate AWS permissions. For more information about the necessary AWS permissions, see [IAM policy examples for Quick](#).

Each Quick Enterprise edition account can have an unlimited number of users. User names that contain a semicolon (;) aren't supported.

Use the topics below to learn more about managing access for Quick and IAM users.

Topics

- [Inviting users to access Amazon Quick](#)
- [Viewing Amazon Quick account details](#)
- [Deleting a Amazon Quick user account](#)

Inviting users to access Amazon Quick

Applies to: Enterprise Edition and Standard Edition

Intended audience: Amazon Quick administrators

Use the following procedure to invite a user to access Quick.

1. Choose your user name on the application bar and then choose **Manage Quick**.
2. Choose **Manage Users**. On this screen, you can manage users who already exist in your account.
3. Choose **Invite users**.
4. In the **Invite users to this account** table, enter a new user name for a person to whom you want to grant access to Quick. If the user is an IAM user, enter their IAM username. Then press **+**. A user's IAM username can be the same as their email address.

Repeat this step until you have entered everyone who you want to invite. Then go to the next step to enter details.

5. For **Email**, enter an email address for the account.

Note

Currently, email addresses are case-sensitive. Email distribution lists are not supported for inviting users. Instead, send individual invitations to each user. To share assets like dashboards, datasets, and agents with multiple users, create user groups in Quick.

6. For **Role**, choose the role to assign to each person you're inviting. A *role* determines the permission level to grant to that account.

- **ADMIN roles:**

- **ADMIN** – The user is able to both use Amazon Quick for authoring and for performing administrative tasks like managing users or purchasing [SPICE](#) capacity.
- **ADMIN PRO** – The user is able to perform all actions of a Amazon Quick Admin and utilize applicable Amazon Quick Generative BI capabilities. For more information about Pro roles in Amazon Quick, see [Get started with Generative BI](#).

There are some differences in the administrative tasks that IAM users and Amazon Quick administrators can perform. These differences occur because some administrative tasks require permissions in AWS, which Amazon Quick-only users lack. The differences are these:

- Amazon Quick administrators can manage users, SPICE capacity, and subscriptions.
- IAM users with administrative permissions can also manage users, SPICE capacity, and subscriptions. In addition, they can manage Amazon Quick permissions to AWS resources, upgrade to Enterprise edition, and unsubscribe from Amazon Quick.

If you want to create a user with administrator permissions with IAM access, check with your AWS administrator. Make sure that the IAM user has the all necessary statements in their IAM permissions policy to work with Amazon Quick resources. For more information about what statements are required, see [IAM policy examples for Amazon Quick](#).

- **AUTHOR roles:**

- **AUTHOR**– The user is able to author analyses and dashboards in Amazon Quick but not perform any administrative tasks in Amazon Quick.
- **AUTHOR PRO**– The user is able to perform all actions of a Amazon Quick Author and utilize applicable Amazon Quick Generative BI capabilities. For more information about Pro roles in Amazon Quick, see [Get started with Generative BI](#).

- **READER roles (Enterprise only):**

- **READER**– Users are able to interact with shared dashboards, but not author analyses or dashboards or perform any administrative tasks.
- **READER PRO**– The user is able to perform all actions of a Amazon Quick Reader and utilize applicable Amazon Quick Generative BI capabilities. For more information about Pro roles in Amazon Quick, see [Get started with Generative BI](#).

7. For **IAM User**, verify that it says **Yes** for accounts that are associated with IAM users, and **No** for those that are Amazon Quick-only.
8. (Optional) To delete a user, choose the delete icon at the end of the relevant row.
9. Choose **Invite**.

Viewing Amazon Quick account details

Intended audience: Amazon Quick administrators

You can view Amazon Quick accounts on the **Manage Users** page. To view a Amazon Quick user account, use the following procedure.

1. Choose your user name on the application bar and then choose **Manage Quick**.
2. Choose **Manage Users** to view details about people who are Amazon Quick users. The information that displays includes:
 - Username – The person's user name.
 - Email – The email associated with this user name.
 - Role – The security cohort that the person's user name belongs to: **ADMIN**, **ADMIN PRO**, **AUTHOR**, **AUTHOR PRO**, **READER**, or **READER PRO**.
 - Last active – The last date and time that this person accessed the Amazon Quick console. Anyone who isn't an active user has a **Last active** status of User has no activity.

You can also see deleted or inactive users in this screen.

3. To find a user name, enter a part or all of a user's name or email the search box. Search is case-insensitive and wildcards aren't supported. To clear the search results and view all user names, delete your search entry.

Deleting a Amazon Quick user account

Intended audience: Amazon Quick administrators

⚠ Warning

Deleting user accounts has permanent, organization-wide consequences. When you delete a user account:

- Assets owned solely by the user are permanently removed unless you transfer them to another user before deletion.
- Assets that have other owners remain available to those owners; the deleted user is removed from their permissions.
- **This action cannot be undone – deleted resources cannot be recovered.**

Always transfer critical resources to another user before deleting an account. Review all user-owned assets using the asset management console before proceeding with any account deletion.

For the full model of how user removal affects assets and data, see [User lifecycle and data handling in Amazon Quick](#).

Accounts can be deleted by either an AWS administrator or an Amazon Quick administrator. Deleting a Amazon Quick user account works the same in both the Standard and Enterprise editions of Amazon Quick.

Deleting a Amazon Quick user account removes or transfers their resources. In Enterprise edition, the network administrator can temporarily deactivate a Amazon Quick user account by removing it from the network group that has access to Amazon Quick. If a user is deleted, but not deactivated, that user can still access Amazon Quick as a new user. For more information about deactivating an Enterprise account, see [Deactivating user accounts](#).

Use the following procedure to delete a Amazon Quick user account.

1. Choose your user name on the application bar and then choose **Manage Quick**.
2. Choose **Manage Users**.
3. Locate the account you want to delete and then choose the delete icon at the end of that row.
4. Choose to either delete or transfer any resources owned by the user and then choose **OK**.
5. Do one of the following:

- If you chose to transfer user resources, enter the user name of the account to transfer them to and then choose **Delete and transfer resources**.
- If you chose to delete user resources, choose **Delete**. You can't undo this action.

User-driven license upgrades

Applies to: Enterprise Edition

Intended audience: System administrators and Amazon Quick administrators

User-driven license upgrades allow users to seamlessly transition between license tiers as their needs grow. When users encounter a feature that requires a higher tier or reach their usage limits, Amazon Quick provides contextual upgrade prompts to help them continue their work without interruption.

Note

Depending on your organization's settings, upgrades may process automatically or require administrator approval.

Overview

User-driven license upgrades enable Amazon Quick users to request higher-tier licenses when they encounter features or reach usage limits that require additional capabilities. This self-service approach reduces friction in the user experience while maintaining administrative control over licensing decisions.

The upgrade process is designed to be contextual and non-disruptive. Users see upgrade prompts at the moment they need additional capabilities, allowing them to continue their work seamlessly after approval.

Available upgrade paths

Users can request upgrades along the following paths:

- **BI Reader to Professional:** Enables advanced analytics, custom visualizations, and enhanced sharing capabilities.
- **Professional to Enterprise:** Unlocks enterprise features including advanced security, governance, and administrative controls.

Each upgrade path provides immediate access to new features upon approval, with billing changes taking effect according to your organization's billing cycle.

Feature-based upgrades

When users attempt to access features not available in their current tier, Amazon Quick presents contextual upgrade prompts. These prompts explain the benefits of the higher tier and guide users through the upgrade request process.

Common scenarios that trigger feature-based upgrade prompts include:

- Accessing advanced visualization types
- Attempting to use AI-powered features
- Trying to create or modify certain dashboard elements
- Accessing enterprise security or governance features

Threshold-based upgrades

Users receive upgrade prompts when they approach or exceed usage limits for their current license tier. These prompts appear in context, allowing users to upgrade and continue their work without interruption.

Threshold-based upgrades are triggered by:

- Reaching data source connection limits
- Exceeding dashboard or analysis creation limits
- Approaching user or sharing limits
- Hitting storage or compute usage thresholds

The system provides clear information about current usage, limits, and the benefits of upgrading to the next tier.

Topics

- [How users upgrade their license](#)
- [Administrator configuration](#)
- [Managing upgrade requests](#)
- [Monitoring upgrades](#)
- [User-driven license upgrades FAQ](#)

How users upgrade their license

Applies to: Enterprise Edition

To upgrade from the Home Page

1. Navigate to the Amazon Quick Home Page
2. Locate the "Explore the powerful new features of Amazon Quick" section at the top of the page
3. If needed, choose **Show More** to view all available feature cards
4. Select a feature card that interests you (such as AI features or Automation)
5. Review the feature description and benefits in the modal that appears
6. Choose **Request an upgrade to Professional** or **Request an upgrade to Enterprise**
7. Choose **Confirm Upgrade**

What happens next:

- **Auto-approval enabled:** Users see a message: "Your access is being upgraded. Check back in 10 min to continue." The upgrade processes automatically within approximately 10 minutes.
- **Admin approval required:** Users see a message: "Your request has been sent. An email will be sent when approved." The administrator will review and process the request.

To upgrade when reaching usage limits

- When users reach their usage threshold, a notification appears in their current workflow
- Users review their current usage and the limits of the next tier

- Choose **Upgrade Now** to continue work
- Review the pricing and features included in the new tier
- Choose **Confirm Upgrade**

To view and compare license tiers

- From any upgrade prompt, choose **View License Tiers**
- Review the features and pricing for each tier
- Compare current tier with available upgrade options
- Select the tier that best meets needs
- Choose **Upgrade** to proceed

Viewing current license

To check current license tier and usage:

1. Choose the profile icon in the top-right corner
2. The current license tier is displayed directly in the profile dropdown

Administrator configuration

Applies to: Enterprise Edition

Intended audience: System administrators and Amazon Quick administrators

As a Amazon Quick administrator, you can configure various settings for user-driven license upgrades, including enabling the feature, setting approval policies, and configuring custom permissions profiles.

Enabling user-driven upgrades

Before users can request license upgrades, you must enable the user-driven upgrade feature in your Amazon Quick account settings.

Access Administrator Settings

- Log in to your Amazon Quick administrator account
- Navigate to the 'Manage Account' section of the console
- Check for User upgrades Section
- Use the toggle button to Enable/Disable - Automatically approve upgrades

Configuring approval settings

Administrators can configure three types of upgrade governance:

- **Turned off altogether** — Users cannot request upgrades
- **Admin Approval** (default for IAM Identity Center and AD) — Users can request upgrades that require administrator approval
- **User Driven Upgrades** (default for IdP) — Users can upgrade automatically without approval

Creating a custom permissions profile for Amazon Quick account that is integrated with IAM Identity Center or Active Directory

Amazon Quick account administrators can use the following procedure to create a custom permissions profile for an Amazon Quick account that is integrated with IAM Identity Center or Active Directory.

To create a custom permissions profile for an Amazon Quick account that is integrated with IAM Identity Center or Active Directory

1. Sign in to the [AWS Management Console](#).
2. Open Amazon Quick.
3. The Amazon Quick Admin console opens. Choose **Custom Permissions**.
4. The **Manage custom permissions** page opens. Choose one of the following options.
5. To create a new custom permissions profile, choose **Create**.
6. To edit or view an existing custom permissions profile, choose the ellipses (three dots) next to the profile that you want, and then choose **Edit**.
7. If you want to create or update a custom permissions profile, make selections for the following items.
8. For **Name**, enter a name for the custom permissions profile.

9. For **Restrictions**, choose "Allow users to upgrade or request upgrades" under "User Upgrades". Choose any other options that you want to deny. Any option that you don't choose is allowed.
10. Choose **Create** or **Update** to confirm your choices. To go back without making any changes, choose **Back**.
11. Once you are done making changes, record the name of the custom permissions profile. Provide the name of the custom permissions profile to API users so that they can apply the custom permissions profile to roles or users.

Creating a custom permissions profile for an Amazon Quick account that uses Amazon Quick managed users

Amazon Quick account administrators can use the following procedure to create a custom permissions profile for an Amazon Quick account that uses Amazon Quick managed users.

To create a custom permissions profile for Amazon Quick managed users

1. Open the [Amazon Quick console](#).
2. From any page in the Amazon Quick console, choose **Manage Amazon Quick** at the top right corner.
3. Only Amazon Quick administrators have access to the **Manage Amazon Quick** menu option. If you don't have access to the **Manage Amazon Quick** menu, contact your Amazon Quick administrator for assistance.
4. Choose **Custom permissions**. You can also choose the **Manage users** section and then choose **Manage custom permissions**.
5. The **Manage custom permissions** page opens. Choose one of the following options.
6. To create a new custom permissions profile, choose **Create**.
7. To edit or view an existing custom permissions profile, choose the ellipses (three dots) next to the profile that you want, and then choose **Edit**.
8. If you want to create or update a custom permissions profile, make selections for the following items.
9. For **Name**, enter a name for the custom permissions profile.
10. For **Restrictions**, choose "Allow users to upgrade or request upgrades" under "User Upgrades". Choose any other options that you want to deny. Any option that you don't choose is allowed.
11. Choose **Create** or **Update** to confirm your choices. To go back without making any changes, choose **Back**.

12. Once you are done making changes, record the name of the custom permissions profile.
Provide the name of the custom permissions profile to API users so that they can apply the custom permissions profile to roles or users.

Applying custom permissions profiles

Apply a custom permissions profile to an Amazon Quick role with the Amazon Quick API

For more information, see [Apply custom permissions profile to role](#).

Apply a custom permissions profile to a user with the Amazon Quick API

For more information, see [Apply custom permissions profile to user](#).

Apply a custom permissions profile to an account

For more information, see [Apply custom permissions profile to account](#).

Apply a custom permissions profile to an account using the Amazon Quick APIs

For more information, see [Apply custom permissions profile using APIs](#).

Managing upgrade requests

Applies to: Enterprise Edition

Intended audience: System administrators and Amazon Quick administrators

As an administrator, you can view and manage user license upgrade requests through the Amazon Quick admin console. This section describes how to approve, deny, or verify upgrade requests based on your organization's identity management setup.

Viewing upgrade requests

To view pending upgrade requests, navigate to the User upgrades section in the admin console. The requests table displays the username, current role, requested role, request date, and available actions for each pending request.

To view upgrade requests

1. Sign in to the Amazon Quick console as an administrator.
2. Choose **Manage Amazon Quick** from the top right corner.
3. Navigate to the **User upgrades** section.
4. Review the pending requests in the table.

Processing upgrade requests

The process for handling upgrade requests varies depending on your organization's identity management setup.

Processing requests for IdP identity type

For organizations using Identity Provider (IdP) authentication, administrators can directly approve or deny requests.

To process IdP upgrade requests

1. In the upgrade requests table, choose **View details** for the request you want to process.
2. Review the request details in the modal that opens.
3. Choose one of the following options:
 - **Approve** — Grants the requested license upgrade immediately
 - **Deny** — Rejects the upgrade request
4. Confirm your selection. The system displays a success message and removes the processed request from the pending list.

Processing requests for IAM Identity Center and Active Directory identity types

For organizations using IAM Identity Center or Active Directory, administrators must add users to the appropriate groups before verifying the upgrade.

To process IAM Identity Center and Active Directory upgrade requests

1. In the upgrade requests table, choose **View details** for the request you want to process.
2. Note the required group name(s) displayed in the modal.
3. Navigate to your IAM Identity Center or Active Directory management console.

4. Add the user to the required group for the requested license tier.
5. Return to the Amazon Quick admin console and choose **Verify**.
6. The system checks the user's group membership and completes the upgrade if verification succeeds.

Alternatively, you can choose **Deny** to reject the upgrade request without making any group changes.

Understanding upgrade request statuses

Upgrade requests can have the following statuses:

- **Pending** — Request is awaiting administrator action
- **Approved** — Request has been approved and the user's license has been upgraded
- **Denied** — Request has been rejected by an administrator
- **Verified** — For IAM Identity Center/AD setups, the user has been added to the required group and the upgrade is complete

Monitoring upgrades

Applies to: Enterprise Edition

Intended audience: System administrators and Amazon Quick administrators

Administrators can monitor user upgrades through:

- **CloudTrail logs** — Provides audit trails of all upgrade requests and approvals.

Billing considerations for administrators

- Users are billed for their highest license tier within each billing period.
- **Prorated Billing:** When you upgrade a user subscription in Amazon QuickSuite, billing is prorated for the month of the upgrade. This means:

If you upgrade from BI Reader (\$3/month) to Professional (\$20/month), you're billed at the \$20/month rate from the time of upgrade until the end of that billing month.

If you then upgrade again from Professional (\$20/month) to Enterprise (\$40/month) within the same month, you're billed at the \$40/month rate from that second upgrade time until the end of the month.

User-driven license upgrades FAQ

Applies to: Enterprise Edition

What are user-driven license upgrades?

User-driven license upgrades allow Amazon Quick users to request license upgrades directly from the console, such as upgrading from Reader to Author or from Standard to Pro subscriptions. All requests require administrator approval.

Who can request license upgrades?

Any user with an active Amazon Quick account can request upgrades, provided the feature is enabled by their administrator and they meet the eligibility criteria for the requested upgrade type.

Can users downgrade their license tier?

License downgrades are not supported.

What happens to usage limits when upgrading?

Usage limits increase immediately to match the new tier. However, current usage does not reset—it carries over to the new tier.

How long does the approval process take?

- **Auto-approval:** Approximately 10 minutes
- **Admin approval:** Typically 1-2 business days, depending on administrator response time

Creating and managing groups in Amazon Quick

Intended audience: System administrators

Applies to: Enterprise Edition

Note

If your Amazon Quick account is integrated with IAM Identity Center (recommended), groups are not managed in the Quick application. Instead, groups are managed in IAM Identity Center or in the third-party identity provider that you configured in IAM Identity Center. Groups are synced automatically between Quick and IAM Identity Center.

Admins with IAM credentials who have access to the Quick console can organize sets of users into groups that make it easier to manage access and security. For example, you can create a group of users that you can share Amazon Quick assets with all at once. You can create and manage groups using the Amazon Quick console or the AWS Command Line Interface (AWS CLI). You can create up to 10,000 groups in a namespace. If you want to create more than 10,000 groups in a namespace, contact [AWS Support](#).

Use the topics below to create, and modify groups with in the Amazon Quick console or with the Amazon Quick APIs.

Topics

- [Create a group with the Amazon Quick console](#)
- [Change a group description with the Amazon Quick console](#)
- [Manage group membership in the Amazon Quick console](#)
- [Create and manage groups with the AWS CLI](#)

Create a group with the Amazon Quick console

Use the following procedure to create a group in the Quick console.

To create a user group in the Amazon Quick console:

1. On the Amazon Quick start page, choose **Manage Quick**, and then choose **Manage groups**.
2. Choose **NEW GROUP**.
3. On the **Create new group** page, enter the name and description of the new group in the corresponding boxes.
4. When you're finished, choose **Create** to create the new group.

Note

You can't delete a group from the Amazon Quick console, but you can delete a group with the AWS CLI. For more information on deleting a Amazon Quick group with the AWS CLI, see [Create and manage groups with the AWS CLI](#).

Change a group description with the Amazon Quick console

After you have created a new group, you can't change the group's title but you can change the group's description.

To change the description of a group:

1. On the Amazon Quick start page, choose **Manage Quick**, and then choose **Manage groups**.
2. Choose the group that you want to change, and then choose the **Edit** link next to the group description.
3. In the **Edit description** box that appears, enter the new description and choose **Save**.

Manage group membership in the Amazon Quick console

After you create a group, you can add and remove users from the **Manage groups** page. You can't add a user to a group if you haven't added the user to your account. For more information on adding users to your Amazon Quick account, see [Managing user access inside Amazon Quick](#).

To add a user to a group

1. On the Amazon Quick start page, choose **Manage Quick**, and then choose **Manage groups**.
2. Choose the group that you want to add a user to, and choose **ADD USER** at the page's upper right.
3. Enter the user name or email of the user that you want to add, and choose the correct user for **Search users**.

To remove a user from a group:

1. On the Amazon Quick start page, choose **Manage Quick**, and then choose **Manage groups**.
2. Choose the group that you want to remove a user from.
3. Find the user that you want to remove and choose **Remove**.

Choosing **remove** automatically removes the selected user from the group.

You can also search for a group member by entering the user's full user name into the search bar on the right-hand side of the group's page.

Create and manage groups with the AWS CLI

Before you begin, make sure that you have the AWS CLI installed. For more information, see [Installing the AWS CLI](#) in the *AWS CLI User Guide*.

Use the following procedure to create an Quick user group.

1. Open a terminal window. If you are using Microsoft Windows, open a command prompt.
2. Enter the following command at the prompt to create a group. Substitute the correct values for your parameters.

```
aws quicksight create-group --aws-account-id=111122223333 --namespace=default --  
group-name="Sales-Management" --description="Sales Management - Forecasting"
```

You might find it easier to create the command in a text editor before entering it at the prompt. For more information on `create-group` and other available commands, see the [Amazon Quick API reference](#).

3. Verify that the group exists by using a command similar to one of the following. The following command lists all groups.

```
aws quicksight list-groups --aws-account-id 111122223333 --namespace default
```

The following command describes a specific group.

```
aws quicksight describe-group --aws-account-id 111122223333 --namespace default --group-name Sales
```

The following command searches for groups in a specified Amazon Quick namespace.

```
aws quicksight search-groups --region us-west-2 --aws-account-id 111122223333 --namespace default --filters "[{\"Operator\": \"StartsWith\", \"Name\": \"GROUP_NAME\", \"Value\": \"Mar\"}]"
```

4. Add a member to the new group by using a command similar to the following.

```
aws quicksight create-group-membership --aws-account-id 111122223333 --namespace default --group-name Sales --member-name Pat
```

The following command determines if a user is a member of a specified group.

```
aws quicksight describe-group-membership --region us-west-2 --aws-account-id 111122223333 --namespace default --group-name Marketing-East --member-name user
```

Enter the following command at the prompt to delete a group. Substitute the correct values for your parameters.

```
aws quicksight delete-group --aws-account-id 111122223333 --namespace default --group-name Marketing-East
```

You might find it easier to create the command in a text editor before entering it at the prompt. For more information on `delete-group` and other available commands, see the [Amazon Quick API reference](#).

Managing security

Security management in Amazon Quick encompasses multiple layers of protection to ensure your data and resources remain secure. This section covers key security features including domain

management for controlling access to specific organizational domains, namespace configuration for multi-tenant environments, mobile device security settings, IP address and VPC restrictions, VPC connection management, and customer-managed encryption keys. These security controls help you implement defense-in-depth strategies and meet your organization's compliance requirements while maintaining the flexibility to share insights securely across your organization.

Topics

- [Managing domains](#)
- [Supporting multitenancy with isolated namespaces](#)
- [Managing mobile settings](#)
- [Managing IP/VPC restrictions](#)
- [Managing VPC connection in Amazon Quick](#)
- [AI guardrails in Amazon Quick](#)
- [Encrypting your Amazon Quick data with AWS Key Management Service customer managed keys](#)

Managing domains

Applies to: Enterprise Edition

Intended audience: Amazon Quick administrators

In Amazon Quick Enterprise edition, you can embed Amazon Quick Sight dashboards, visuals, consoles, and Q search bars in an app or web page. Domains that are going to host these embedded assets must be on an *allow list*, the list of approved domains for your Quick subscription. This requirement protects your data by preventing unapproved domains from hosting embedded dashboards. To embed a Amazon Quick Sight dashboard, visual, console, or Q search bar to a web page or app, add approved domains to a static allow list in the Quick console. Alternatively, add them at runtime with the Quick API.

Use the following sections to learn more about adding domains for embedded analytics.

Topics

- [Allow listing static domains](#)

- [Allow listing domains at runtime with the Amazon Quick API](#)

Allow listing static domains

You can add static domains to your allow list through the Amazon Quick console. All domains on your allow list (such as development, staging, and production) must be explicitly allowed, and they must use HTTPS. You can add up to 100 domains to the allow list.

To embed a dashboard to a static domain:

- Approve the hosting domains and subdomains for embedding.
- Publish the dashboard.
- Share the dashboard with users or groups so they can see the embedded version of it.

Use the following procedure to view or edit the list of approved domains.

To view or edit the list of approved domains

1. Choose the profile icon at top right.
2. Choose **Manage Amazon Quick**. You must be an Amazon Quick admin to access this screen.
3. Choose **Domains and Embedding** on the left. The domains that you can embed a dashboard in are listed at the bottom of the page.
4. (Optional) Add a new domain here by entering it in the **Domain** box. You can also choose **Include subdomains** to allow embedded dashboards on all subdomains. Choose **Add** to add the domain.

You can edit or delete existing domain by choosing the icons next to each domain in the list at the bottom of the page.

Make sure that you use a valid HTTPS URL. The following list shows examples of URLs that are valid for embedded dashboards that use a static domain:

- https://example-1.com
- https://www.アマゾンドメイン.jp
- https://www.亚马逊域名.cn:1234
- https://111.222.33.44:1234

- `https://111.222.33.44`
- `http://localhost`

The following list shows examples of URLs that are *not* valid for embedded dashboards:

- `http://example`
- `https://example.com.*.example-1.co.uk`
- `https://co.uk`
- `https://111.222.33.44.55:1234`
- `https://111.222.33.44.55`

Allow listing domains at runtime with the Amazon Quick API

You can add a domain at runtime to an allow list with the `AllowedDomains` parameter of a `GenerateEmbedUrlForAnonymousUser` or a `GenerateEmbedUrlForRegisteredUser` API call. The `AllowedDomains` parameter is an optional parameter. It grants you the option as a developer to override the static domains that are configured in the **Manage Amazon Quick** menu.

You can list up to three domains or subdomains. Adding domains to the allow list at runtime also adds HTTP support for the domain `localhost`. The generated URL is then embedded in a developer's website. Only the domains that are listed in the parameter can access the embedded dashboard.

Security best practice for IAM condition operators

Improperly configured IAM condition operators can allow unauthorized access to your embedded Quick resources through URL variations. When using the `quicksight:AllowedEmbeddingDomains` condition key in your IAM policies, use condition operators that either allow specific domains or deny all domains that are not specifically allowed. For more information about IAM condition operators, see [IAM JSON policy elements: Condition operators](#) in the IAM User Guide.

Many different URL variations can point to the same resource. For example, the following URLs all resolve to the same content:

- `https://example.com`
- `https://example.com/`

- `https://Example.com`

If your policy uses operators that do not account for these URL variations, an attacker can bypass your restrictions by providing equivalent URL variations.

You must validate that your IAM policy uses appropriate condition operators to prevent bypass vulnerabilities and ensure that only your intended domains can access your embedded resources.

To embed a dashboard to a domain at runtime, see [Embedding with the Amazon Quick APIs](#).

Make sure that you use a valid URL. The following list shows examples of URLs that are valid for embedded dashboards that use a runtime domain:

- `https://example-1.com`
- `http://localhost`
- `https://www.アマゾンドメイン.jp`
- `https://*.sapp.amazon.com`

The following list shows examples of URLs that are *not* valid for embedded dashboards:

- `https://example.com.*.example-1.co.uk`
- `https://co.uk`
- `https://111.222.33.44.55:1234`
- `https://111.222.33.44.55`

For more information about embedded dashboards, see [Embedding with the Amazon Quick APIs](#).

Supporting multitenancy with isolated namespaces

Amazon Quick Enterprise edition supports multitenancy through namespaces. An Amazon Quick *namespace* is a logical container that you can use to organize clients, subsidiaries, teams, and so on. Namespaces can help you achieve the following goals:

- Your Amazon Quick subscription allows users to discover shared content and share with other users. At the same time, in the Amazon Quick end-user console experience, users in

one namespace can't see or interact with users in another namespace. The Amazon Quick administrative console uses a different permission model. For more information, see the following important note.

- You can securely isolate data and also support diverse workloads without adding additional AWS accounts. Access to data is still strictly controlled by AWS security features. Users can see assets (like data and dashboards) only if they have the correct resource permissions. Also, users who have permissions can't inadvertently expose content to people who outside of their namespace. For more information, see [Supporting multitenancy with isolated namespaces](#).
- You can monitor data flows and usage reports, neatly partitioned by namespace. Categorizing data and reports by namespace can help simplify cost and security analysis.
- After you've registered users into your namespace, there's no additional administrative complexity or overhead.
- Namespaces are designed to span AWS Regions, so the use containment doesn't change even if a person signs in to a different AWS Region.

Namespace isolation and the administrative console

Amazon Quick uses two different permission models depending on the console experience. In the Amazon Quick end-user console, namespace-level isolation is enforced. Each user's Amazon Quick role determines the actions that they can perform, and their namespace determines which users and groups they can interact with.

In the Amazon Quick administrative console, only AWS Identity and Access Management (IAM) permissions are enforced. Users operate outside of the namespace context, and the user's IAM policies determine access, not their namespace membership.

Users can operate under both permission models. When they use the end-user console, their Amazon Quick role and namespace determine their access. When they use the administrative console, their IAM permissions determine their access. For example, an IAM administrator with the appropriate permissions can view and manage users and groups across namespaces from the administrative console.

Namespaces currently have the following limitations:

- Custom namespaces—those that are not the default namespace—are only accessible to IAM Federated Single-Sign On users.
- Use default namespaces instead of custom namespaces if you need to support the following:

- Integrating your Amazon Quick account with IAM Identity Center. For more information on integrating your Amazon Quick account with IAM Identity Center, see [AWS security in Amazon Quick](#).
- Password-based logins.
- Credential-based Active Directory logins.
- You can't transfer users directly from one namespace to another. You can choose to do some or all of this work programmatically. For more information, see the [Quick API reference](#). At the bottom of the page of each API operation, there's a list of links to the same operation in the SDKs for other languages. To see what SDKs are available, see [SDKs and toolkits](#) in the [AWS getting started resource center](#).
- Namespaces are useful for isolating users and permissions, but not for sharing assets. Dashboards, datasets, and analyses can be shared with users in different namespaces. By default, users can't access items that exist in the same namespace by default, but gain access to specific assets when the asset is shared with them.

If you don't have an existing AWS account or you need to sign up for Amazon Quick, read the following guidelines, then follow the applicable instructions in [Signing up for an Amazon Quick subscription](#):

- Sign up for Enterprise edition.
- When asked which method you want to connect with, choose **Role Based Federation (IAM)**. Currently, namespaces support only customers who use an AWS Identity and Access Management (IAM) role with a web identity federation. For more information, see [Creating a role for a third-party Identity Provider \(federation\)](#)
- Complete the process of signing up.
- Use the Amazon Quick [CreateNamespace](#) API operation to create one or more namespaces.
- To start adding users, first follow the instructions in [Setting up IdP federation using IAM and Amazon Quick](#). Then use the [RegisterUser](#) API operation to add users to the appropriate namespace.

If you already signed up for Standard edition, you can easily upgrade your subscription to Enterprise edition. The person performing the upgrade must be a Amazon Quick user with administrator privileges. For more information, see [Upgrading your Amazon Quick subscription](#).

If you have an Enterprise edition subscription that you've been using for some time, it's also possible to migrate your users into namespaces. When you sign up for Amazon Quick and add users, all of them reside in the default namespace. All of the users can interact directly with each other and share data and dashboards with each other. To isolate your users from each other, you can create one or more additional namespaces.

 Important

Amazon Quick assets and resources, including datasets, data sources, dashboards, analyses, and so on, exist outside of any namespace. They're visible only to users who have resource permissions granted to them.

To implement namespaces, you use the following Amazon Quick API operations:

- [CreateNamespace](#)
- [DescribeNamespace](#)
- [ListNamespaces](#)
- [DeleteNamespace](#)

Namespaces are not supported in the Regions listed below:

- af-south-1 Africa (Cape Town)
- ap-southeast-3 Asia Pacific (Jakarta)
- ap-southeast-5 Asia Pacific (Malaysia)
- eu-south-1 Europe (Milan)
- eu-central-2 Europe (Zurich)

 Note

If you need to install the AWS CLI, see [Installing the AWS CLI version 2](#) in the *AWS Command Line Interface User Guide*.

To add users to a namespace, you use the [RegisterUser](#) API operation. Each namespace has a completely independent set of users. The user ARNs include the namespace qualifier to distinguish them, as shown in the following examples:

- Amazon Quick considers these two entities to be different persons:
 - `arn:aws:quicksight:us-east-1:111122223333:user/namespace-123/username123`
 - `arn:aws:quicksight:us-east-1:111122223333:user/namespace-456/username123`
- Amazon Quick considers these two entities to be the same person:
 - `arn:aws:quicksight:us-east-1:111122223333:user/namespace-123/username123`
 - `arn:aws:quicksight:us-west-2:111122223333:user/namespace-123/username123`

When you use [RegisterUser](#), you select an access level for each user. After a person's user name is assigned to one of the security cohorts, their access to the console and API is restricted. People using Amazon Quick can have a single access level, as follows:

- Reader access, for read-only subscribers of a dashboard
- Author access, for analysts and dashboard designers
- Admin access, for Amazon Quick administrators

To migrate existing users in one namespace to a different namespace

Follow the procedure below to migrate existing users from one namespace to a different namespace.

1. Identify the users that you want to transfer to a different namespace by using the Amazon Quick user and group API operations. For more information, see [API operations for controlling access](#) in the [Quick API reference](#).
2. Create users in the new namespace by using the [RegisterUser](#) API operation. Within a namespace, user names are unique.

If a namespace user starts using the Amazon Quick console or API in a new AWS Region, that user is still constrained to the namespace that you added them to. Each namespace represents

a user directory of an identity provider. As such, it originates in the primary AWS Region where Amazon Quick is set up. However, because the user directory is propagated globally in your AWS account, the namespace is accessible from any AWS Region where your users are using Amazon Quick.

3. To identify the asset and resource permissions that the new namespace users need, use the Amazon Quick API operations associated with each type of asset (dashboards, datasets, and so on). For more information, see [QuickSight API operations to control assets](#) in the [Quick API reference](#).

For example, let's say you are focusing on dashboards. You can use `ListDashboards` to list all the dashboard IDs in your AWS account. Then, to determine which users or groups can access these dashboards, you can use `DescribeDashboardPermissions` on the result set generated by `ListDashboards`. If you need to identify specific versions of a dashboard, you can `ListDashboardVersions` for that. You can also collect information about the location of the data that's used in the dashboard with the data source and dataset API operations. For more information, see [QuickSight API operations to control data resources](#) in the [Quick API reference](#).

For more information about filtering API response output, see the SDK documentation for the language you're using. For information relating to the AWS Command Line Interface (AWS CLI), see [Controlling command output from the AWS CLI](#) in the [AWS Command Line Interface User Guide](#).

4. For Amazon Quick assets and resources, copy the permissions that the source namespace user has for each asset. Then use, for example, `UpdateDashboardPermissions` to apply the same permissions to the target namespace user. Each asset type has its own separate set of API operations for controlling the permissions that users have to use it. For more information, see [QuickSight API operations for asset and resource permissions](#) in the [Quick API reference](#).
5. When you are finished adding users and permissions, it's a good practice to allow some time for user acceptance testing. Doing this ensures that everyone is successfully using the new namespace. It also ensures that all assets and resources are accessible in the new namespace.

After you're certain that you no longer need the original user names, you can begin to deprecate their permissions in the original namespace. Finally, when the users are ready, you can remove the unused group and user names in the source namespace. Do this in each AWS Region where your users were previously active.

Managing mobile settings

Mobile settings allow Amazon Quick admins to enhance data security and maintain compliance standards for users accessing Quick through mobile devices. These settings apply to all users accessing Quick through the mobile application.

To access mobile settings:

1. Open the [Quick console](#).
2. Choose the user icon at the top right, and then choose **Manage Amazon Quick**.
3. Under the **Security** section, choose **Mobile settings**.
4. Choose settings to enhance your data security on mobile devices:
 - **Require use of biometrics or PIN to unlock device** - Check the box to enable this security requirement. When enabled, users must use fingerprint recognition, Face ID, device PINs, or other biometric authentication methods supported by their device to access Amazon Quick.
 - **Require devices to use the latest version of the mobile operating system** - Check the box to enable this security requirement. When enabled, users must keep their mobile devices' operating systems up to date to access Amazon Quick.
5. To manage how long users can remain logged in on mobile devices:
 - a. Locate the **Current session lifetime for all devices** setting.
 - b. Select the desired duration from the dropdown menu. The maximum session lifetime depends on your identity provider:
 - **IAM Identity Center**: Maximum session lifetime is 7 days.
 - **All other identity providers**: Maximum session lifetime is 30 days (default).

The minimum session lifetime for all identity providers is 12 hours.

- c. Choose **Update** to apply your changes.

Best practices

- Regularly review and update mobile security settings to align with your organization's security policies
- Set an appropriate session lifetime that balances security with user convenience

- Enable biometric/PIN requirements for additional security, especially when dealing with sensitive data
- Keep operating system requirements enabled to ensure devices have the latest security updates
- Communicate changes in mobile settings to your users before implementation

Managing IP/VPC restrictions

Turning on Internet Protocol (IP) and VPC endpoint restrictions in Amazon Quick

Applies to: Enterprise Edition

You can limit access to your organization's Amazon Quick account to a predefined list of IP ranges, VPC IDs, and VPC endpoint IDs. For example, you can create an IP rule that allows users to access your Quick account only from IP addresses associated with your company's office or remote virtual private network (VPN). You can also create a VPC endpoint rule that allows users access to your Quick account only from the VPC that is used for Direct Connect.

For more information about setting up VPC endpoints in Quick, see [Quick Interface VPC endpoints \(AWS PrivateLink\)](#) for more information about how to setup VPC endpoints.

Note

For Quick accounts integrated with IAM Identity Center, browser-based authentication requires access to the public AWS sign-in and IAM Identity Center endpoints. VPC endpoints do not provide this browser sign-in path. You don't need public IP addresses. Outbound internet connectivity, such as a network address translation (NAT) gateway or proxy, can provide access to these endpoints. For more information, see [Enable access to the IAM Identity Center access portal](#) and [Considerations for private access](#) in the *IAM Identity Center User Guide*.

Only admins with AWS Identity and Access Management (IAM) credentials who have access to the Quick console pages can access the IP and VPC endpoint restrictions table.

Topics

- [Adding an IP or VPC endpoint rule](#)

- [Update an existing rule](#)
- [Delete a rule](#)
- [Turning on your IP and VPC endpoint rules](#)

Adding an IP or VPC endpoint rule

An *IP rule* is created when you add a CIDR address with a public IP version 4 address to the restrictions table. A *VPC endpoint rule* is created when you add either a VPC ID or a VPC endpoint ID to the restrictions table. You can add up to 100 IP and VPC endpoint rules combined to the restrictions table. To request a higher limit, contact AWS Support. You can only add rules from the AWS Region where your account is. All traffic that is not allowed by either the IP rule or the VPC endpoint rule is blocked when the restriction is turned on.

A *CIDR address* is composed of two parts: the prefix and the suffix. The prefix is the CIDR's network address and is written like a normal IP address. The suffix shows how many bits are in the address. An example of a complete CIDR address is `10.24.34.0/23`.

IP and VPC endpoint rules apply only to Quick web, embedded, and mobile access and don't restrict access to the public API. Your users can still call all API operations from restricted IP ranges. For information on restricting calls to the public API from specific IP addresses, see [AWS: Denies access to AWS based on the source IP](#) in the *IAM User Guide*.

Before you save any rule changes or turn on other rules, make sure that you have a rule that includes your IP address or VPC endpoint ID. If there isn't a rule that allows your traffic, you can't save your changes.

To add an IP or VPC endpoint rule

1. On the Quick start page, choose **Manage QuickSight**, and then choose **Security and Permissions**.
2. Choose **IP and VPC endpoint restrictions**.
3. Perform one of the following actions.
 - a. For **IP restriction**, enter the CIDR address that defines the IP range that you want to create a rule for.
 - b. For **VPC endpoint restriction**, enter either the VPC ID or the VPC endpoint ID of the endpoint that you want to create a rule for.

4. (Optional) For **Description**, enter a description for the rule. Doing this can help you differentiate your rules.
5. Choose **Add**.
6. Choose **Save changes** in the box that appears to apply the rule.

It can take up to 10 minutes for a rule to be fully implemented.

Update an existing rule

After you create an IP or VPC endpoint rule, use the IP and VPC restrictions table to make changes to the rule. Use the following procedure to update an existing IP or VPC endpoint rule in the IP and VPC restrictions table.

To update an existing IP or VPC endpoint rule

1. On the Quick start page, choose **Manage QuickSight**, and then choose **Security and Permissions**.
2. Choose **IP and VPC endpoint restrictions**.
3. Choose the edit icon to the right of the rule that you want to change.
4. Make your changes and choose **Update**.
5. Choose **Save changes** in the box that appears to update the rule.

It can take up to 10 minutes for an updated rule to be fully implemented.

Delete a rule

Use the following procedure to delete an IP or VPC endpoint rule from the IP and VPC endpoint restrictions table.

To delete an IP or VPC endpoint rule

1. On the Quick start page, choose **Manage QuickSight**, and then choose **Security and Permissions**.
2. Choose **IP and VPC endpoint restrictions**.
3. Locate the rule that you want to delete, and then choose the delete icon next to it. The rule appears with a strikethrough to show that it is marked for deletion.
4. Choose **Save changes** in the box that appears to delete the rule.

It can take up to 10 minutes for an updated rule to be deleted.

Turning on your IP and VPC endpoint rules

You can turn on or turn off your account's IP and VPC endpoint restrictions by using the **Rules** option at the top of the IP and VPC restrictions page. When rules are turned on, users from sources that are not on the restrictions table can't access Quick mobile, embedded, and website pages. IP and VPC endpoint rules are global and apply to all AWS Regions.

If a user is accessing the Quick account from a source that is not on the rule list when you turn on restrictions, they lose access to the account.

Account holders can audit users who make changes to the IP and VPC endpoint restrictions table by using AWS CloudTrail. For more information, see the [AWS CloudTrail User Guide](#).

Managing VPC connection in Amazon Quick

Applies to: Enterprise Edition

Intended audience: System administrators and Amazon Quick administrators

With Amazon Quick Enterprise Edition, account admins can configure a secure, private VPC connection to a Amazon Quick account from the Amazon Quick console or from the Amazon Quick CLI. Read the following walkthroughs on how to create, edit, and delete a VPC connection from a Amazon Quick account.

Topics

- [Configuring the VPC connection in the Amazon Quick console](#)
- [Configuring the VPC connection with the Amazon Quick CLI](#)
- [Testing the connection to your VPC data source](#)

Configuring the VPC connection in the Amazon Quick console

To create a secure private connection to the Amazon VPC service from the Amazon Quick console, use the following procedure.

Prerequisites

- Sign in to Amazon Quick as a Amazon Quick admin to set up a VPC connection in Amazon Quick. To verify that you're a Amazon Quick administrator, choose your profile icon in the upper-right. If your profile menu contains the option **Manage Amazon Quick**, then you're a Amazon Quick administrator. Make sure your admin role in IAM includes the following permissions. The "iam:PassRole" permission needs to be applied only to the execution role that is created in the procedures below.
 - "quicksight:ListVPCConnections"
 - "quicksight:CreateVPCConnection"
 - "quicksight:DescribeVPCConnection"
 - "quicksight>DeleteVPCConnection"
 - "quicksight:UpdateVPCConnection"
 - "ec2:describeSubnets"
 - "ec2:describeVpcs"
 - "ec2:describeSecurityGroups"
 - "iam:ListRoles"
 - "iam:PassRole"

The following example shows an IAM policy that applies "iam:PassRole" only to the execution role.

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "iam:PassRole"
      ],
      "Resource": "arn:aws:iam::111122223333:role/vpc-role-for-qs"
    }
  ]
}
```

- Before you begin, make sure that you have the following information available to copy and paste into the **VPC Connection** screen. For more information, see [Finding information to connect to a VPC](#).
 - AWS Region – The AWS Region where you plan to create a connection to your data source.
 - VPC ID – The ID of the VPC that contains the data, the subnets, and the security groups that you plan to use.
 - Execution role– An IAM role that contains a trust policy that allows Amazon Quick to create, update, and delete network infrastructure in your account. This policy is required for all VPC connections. At minimum, the IAM policy needs the following Amazon EC2 permissions:
 - DescribeSecurityGroups
 - DescribeSubnets
 - CreateNetworkInterface
 - DeleteNetworkInterface
 - ModifyNetworkInterfaceAttribute

The following example shows an IAM policy that you can add to an existing IAM role to create, delete, or modify a VPC connection:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:CreateNetworkInterface",
        "ec2:ModifyNetworkInterfaceAttribute",
        "ec2>DeleteNetworkInterface",
        "ec2:DescribeSubnets",
        "ec2:DescribeSecurityGroups"
      ],
      "Resource": "*"
    }
  ]
}
```

After you add the necessary permissions to an IAM role, attach a trust policy to allow Amazon Quick to configure the VPC connection to your account. The following example shows a trust policy that you can add to an existing IAM role to allow Amazon Quick access to the role:

JSON

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "quicksight.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

- Subnet IDs – The IDs of the subnets that the Amazon Quick network interface is using. Each VPC connection needs at least two subnets.
- Security group IDs – The IDs of the security groups. Each VPC connection needs at least one security group.

To create a secure private connection to the Amazon VPC service from Quick Enterprise edition

1. In Amazon Quick, choose your profile icon in the upper-right, then choose **Manage Amazon Quick**.

Only Amazon Quick administrators can view the **Manage Amazon Quick** option. If you don't see this option on your profile menu, you're not an administrator. In this case, contact your Amazon Quick account administrators for assistance.

2. In the left navigation pane, choose **Manage VPC connections**.
3. On the **Manage VPC connections** page that opens, choose **Add VPC connection**.
4. For **VPC connection name**, enter a unique descriptive name of your choice. This name doesn't need to be an actual VPC ID or name.
5. In the **VPC ID** dropdown menu, choose the ID of the VPC in Amazon EC2 that you want to connect to your Amazon Quick account. This field can't be changed later.

6. In the **Execution role** dropdown menu, choose the appropriate IAM role to use for the VPC connection. The **Execution role** dropdown only shows IAM policies that contain a trust policy that allows Amazon Quick to configure the VPC connection to your account.
7. In the **Subnets** table, choose a subnet ID from the **Subnet ID** dropdown menu of at least two of the listed **Availability zones**. The Availability Zones listed in the **Subnets** table are determined based on how you configured the VPC connection in the Amazon EC2 console.
8. (Optional) If you aren't using DNS resolver endpoints, skip to the next step.

If your database host IP address must be resolved through private DNS servers in your AWS account, enter IP addresses for Route 53 Resolver inbound endpoints (one per line).

Make sure that you are entering an endpoint, rather than a database address like the one you plan to use in Amazon Quick. Most databases that are hosted by AWS don't need to resolve DNS queries between VPCs and a customer's network. For more information, see [Resolving DNS queries between VPCs and your network](#) in the *Amazon Route 53 Developer Guide*. You only need this endpoint if you can't resolve the IP address that connects to your database by using the public DNS server system.

9. Review your choices, then choose **ADD**.

When you finish creating a VPC connection, the new connection appears in the **Manage VPC connections** table. In some cases, the status of the new VPC might be **UNAVAILABLE** until the connection is configured on the backend. After Amazon Quick is finished configuring the new connection, the status of the connection switches to **AVAILABLE**, which indicates that the connection has been established. The following table describes the different **Status** values for a VPC connection.

Status	Description
AVAILABLE	The VPC connection is established and can be used.
PARTIALLY AVAILABLE	One of the network interfaces that is configured to the VPC connection is unavailable. The VPC connection can still be used.
UNAVAILABLE	The VPC connection is not established and can't be used.

To see a summary of a VPC connection, choose a VPC connection from the **VPC connection name** row of the **Manage VPC connections** table. The pop-up box that appears shows information about the network interfaces associated with the VPC connection.

The following table describes the different **Status** values for a network interface.

Status	Description
CREATING	The network interface creation is in progress.
AVAILABLE	The network interface is available for use.
CREATION_FAILURE	The network interface couldn't be created.
UPDATING	The security group associated with the network interface is updating.
UPDATE_FAILED	The security group associated with the network interface did not update successfully.
DELETING	The network interface is in the process of being deleted.
DELETED	The network interface is deleted and can no longer be used.
DELETION_FAILED	The network interface deletion failed and can still be used.
DELETION_SCHEDULED	This network interface is scheduled for deletion.
ATTACHMENT_FAILED_ROLLBACK_FAILED	The elastic interface failed to attach and Amazon Quick was unable to delete the elastic network interface that was created within your account.

When you delete a network interface from a VPC connection, the status of the connection changes to **PARTIALLY AVAILABLE** to indicate the loss of a network interface.

To make changes to an existing VPC connection, choose the more actions (three-dots) button to the right of the connection that you want to modify, and choose **Edit**. In the **Edit VPC connection** window that appears, make your changes, and then choose **SAVE**.

To delete a VPC connection, choose the more actions (three-dots) button to the right of the connection that you want to delete and choose **Delete**. In the **Delete Amazon Quick VPC Connection** pop-up that appears, confirm that you want to delete the connection, and then choose **Delete**.

Configuring the VPC connection with the Amazon Quick CLI

To create a secure private connection to the Amazon VPC service from Quick with the Amazon Quick CLI, use the following procedure:

Prerequisites

- Before you begin, make sure that you have the following information available to copy and paste into the **VPC Connection** page. For more information, see [Finding information to connect to a VPC](#).
 - AWS Region – The AWS Region where you plan to create a connection to your data source.
 - VPC ID – The ID of the VPC that contains the data, the subnets, and the security groups that you plan to use.
 - Execution role– An IAM role that contains a trust policy that allows Amazon Quick to create, update, and delete network infrastructure in your account. This policy is required for all VPC connections. At minimum, the IAM policy needs the following Amazon EC2 permissions:
 - DescribeSecurityGroups
 - DescribeSubnets
 - CreateNetworkInterface
 - DeleteNetworkInterface
 - ModifyNetworkInterfaceAttribute

The following example shows an IAM policy that you can add to an existing IAM role to create, delete, or modify a VPC connection:

JSON

```
{  
  "Version": "2012-10-17",
```

```

    "Statement": [
      {
        "Effect": "Allow",
        "Action": [
          "ec2:CreateNetworkInterface",
          "ec2:ModifyNetworkInterfaceAttribute",
          "ec2>DeleteNetworkInterface",
          "ec2:DescribeSubnets",
          "ec2:DescribeSecurityGroups"
        ],
        "Resource": "*"
      }
    ]
  }
}

```

After you add the necessary permissions to an IAM role, attach a trust policy to allow Amazon Quick to configure the VPC connection to your account. The following shows an example trust policy that you can add to an existing IAM role to allow Amazon Quick access to the role:

JSON

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "quicksight.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}

```

- Subnet IDs – The IDs of the subnets that the Amazon Quick network interface is using. Each VPC connection needs at least two subnets.
- Security group IDs – The IDs of the security groups. Each VPC connection needs at least one security group.

Using the AWS CLI

The following example creates a VPC connection.

```
aws quicksight create-vpc-connection \  
--aws-account-id 123456789012\  
--vpc-connection-id test \  
--name test \  
--subnet-ids ['subnet-12345678', 'subnet-12345678'] \  
--security-group-ids ['sg-12345678'] \  
--role-arn arn:aws:iam::123456789012:role/test-role \  
--region us-west-2
```

After you create a VPC connection, you can update, delete, or request a summary of the VPC connection.

The following example updates a VPC connection.

```
aws quicksight update-vpc-connection \  
--aws-account-id 123456789012 \  
--vpc-connection-id test \  
--name test \  
--subnet-ids ['subnet-12345678', 'subnet-12345678'] \  
--security-group-ids ['sg-12345678'] \  
--role-arn arn:aws:iam::123456789012:role/test-role \  
--region us-west-2
```

The following example deletes a VPC connection.

```
aws quicksight delete-vpc-connection \  
--aws-account-id 123456789012 \  
--vpc-connection-id test \  
--region us-west-2
```

The following example describes a VPC connection.

```
aws quicksight describe-vpc-connection \  
--aws-account-id 123456789012 \  
--vpc-connection-id test \  
--region us-west-2
```

The following table describes the different **Status** values for a network interface that `describe-vpc-connection` returns.

Status	Description
CREATING	The network interface creation is in progress.
AVAILABLE	The network interface is available for use.
CREATION_FAILURE	The network interface couldn't be created.
UPDATING	The security group associated with the network interface is updating.
UPDATE_FAILED	The security group associated with the network interface did not update successfully.
DELETING	The network interface is in the process of being deleted.
DELETED	The network interface is deleted and can no longer be used.
DELETION_FAILED	The network interface deletion failed and can still be used.
DELETION_SCHEDULED	This network interface is scheduled for deletion.
ATTACHMENT_FAILED_ROLLBACK_FAILED	The elastic interface failed to attach and Amazon Quick was unable to delete the elastic network interface that was created within your account.

You can also use the AWS CLI to generate a list of all VPC connections in your Amazon Quick account.

```
aws quicksight list-vpc-connections \
--aws-account-id 123456789012 \
```

```
--region us-west-2
```

Testing the connection to your VPC data source

Applies to: Enterprise Edition

Intended audience: Amazon Quick administrators and authors

To test whether you can connect to your data source through an existing Quick VPC connection, use the following procedure.

Before you begin, collect the information you need to connect. If you plan to copy and paste settings from a file, make sure that it doesn't contain any of the following: formatting (list bullets or numbers), blank space (spaces, tabs), or invisible "gremlin" (non-ASCII, null (ASCII 0), or control) characters.

1. On the Amazon Quick start page, choose **Manage data**.
2. On the **Datasets** page, choose **New data set**.
3. In the **FROM NEW DATA SOURCES** section of the **Create a data set** page, choose a supported data source that you want to connect to. For a list of data sources that support VPC, see [Identify the data sources to use](#).

Your data source instance must use the same VPC that you used to create the VPC connection. Also, the associated security group must be properly configured. For more information, see [Setting up a VPC to use with Amazon Quick](#).

4. Enter the connection information for the data source. The fields for the data source are sometimes displayed in different order depending on which data source you choose. For more information, see [Creating a data source](#).
 - For **Data source name**, enter a descriptive name for the new data source. This name appears beside the data source logo on a tile on the **Create a data set** page. For testing purposes, name it "**VPC test -**" followed by the database name or location, whichever is unique.
 - For **Connection Type**, choose the name of the VPC connection that has a route to your data source. If the correct VPC is missing from the list, ask a Amazon Quick administrator to

verify that the VPC connection is correct in Amazon Quick. If it looks correct, ask a system administrator to verify that the data source and VPC are set up for this purpose.

- The name or other identifier for the server or instance to connect to. The descriptors vary depending on which one you're connecting to, but it's usually one or more of the following: hostname, IP address, cluster ID, instance ID, connector, or site based URL.
- **Database name** shows the default database for the **Instance ID** cluster or instance. If you want to use a different database on that cluster or instance, enter its name.
- The name of the collection of data that you want to use.

The descriptor varies depending on the provider, but it's usually one of the following: database, warehouse, or catalog. In this topic, we use the word "database" as a generic term.

- For **Credentials**, enter a username and password to use for everyone who connects from Amazon Quick using this data source. The username must have permissions to do the following:
 - Access the target database.
 - Read (perform a SELECT statement on) all of the tables that you want to use in that database.
5. Choose **Validate connection** to verify your connection information is correct. If your connection doesn't validate, correct the connection information and try again. If the information looks correct but doesn't validate, do one or all of the following:
- Contact your data source administrator to verify your connection settings.
 - Contact your Amazon Quick administrator to verify the settings in the Amazon Quick VPC connection.
 - Contact your AWS administrator to verify that the VPC is correctly configured for use with Amazon Quick.
6. After the connection validates, choose **Create data source** to save the connection profile. Or, choose **Cancel** if you don't need to save it (recommended) after testing is complete.

AI guardrails in Amazon Quick

Amazon Quick takes a defense-in-depth approach to help keep chat interactions safe and responsible in the Amazon Quick web experience. Multiple safety layers work together, each addressing different risks at different points in an interaction. No single layer is designed to catch every risk on its own.

Usage of Amazon Quick AI features is subject to the [AWS Responsible AI Policy](#) on the AWS website.

The following topics describe how these controls work and how to configure them.

Topics

- [How AI safety controls work together](#)
- [Blocked words and phrases](#)

How AI safety controls work together

Amazon Quick uses the following controls together:

- **Built-in safety screening** – Amazon Bedrock Guardrails and Quick safeguards screen user requests for harmful content. This includes hate speech, insults, sexual content, violence, and misconduct. These checks also assess user requests for prompt attacks.
- **Prompt-level safety instructions** – Quick instructs the model to promote responsible behavior, resist attempts to override safety settings, and avoid exposing internal system information.
- **Access and permission controls** – Identity, data-access, and action-permission controls limit what data and operations are available during an interaction. These limits match the signed-in person's permissions. For more information about identity and permissions, see [Identity and access management in Quick](#) and [Custom permissions](#).
- **Administrator-configured controls** – You can set up blocked words and phrases for chat interactions in the Amazon Quick web experience.

These controls help reduce risk. However, they do not replace your responsibility to configure access, permissions, agents, flows, and data sources for your use case.

Blocked words and phrases

You can block up to 50 words or phrases in chat interactions in the Amazon Quick web experience. This applies to chat agents and flows. Each entry can contain up to 36 characters. Quick checks both user requests and generated responses for these phrases. Quick doesn't block any words or phrases by default.

Add blocked words and phrases

Use the following procedure to add blocked words and phrases for chat agents and flows in the Amazon Quick web experience.

To add blocked words and phrases

1. Sign in to Quick and choose **Manage Quick**.
2. From the navigation pane, choose **Customization**, and then choose **Chat agent customization**.
3. In **Chat agent customization**, under **Guardrails and safety controls**, choose **Add** to add blocked words and phrases. You can add up to 50 words and phrases. Each entry can contain up to 36 characters.

Edit blocked words and phrases

Use the following procedure to add or remove blocked words and phrases for chat agents and flows in the Amazon Quick web experience.

To edit blocked words and phrases

1. Sign in to Quick and choose **Manage Quick**.
2. From the navigation pane, choose **Customization**, and then choose **Chat agent customization**.
3. In **Chat agent customization**, under **Guardrails and safety controls**, choose **Remove** to remove existing entries, or choose **Add** to add entries. You can add up to 50 words and phrases. Each entry can contain up to 36 characters.

Encrypting your Amazon Quick data with AWS Key Management Service customer managed keys

Amazon Quick enables you to encrypt your Amazon Quick data with the keys you have stored in AWS Key Management Service. This provides you with the tools to audit access to data and satisfy regulatory security requirements. If you need to do so, you have the option to immediately lock down access to your data by revoking access to AWS KMS keys. The use of your AWS KMS keys by Amazon Quick is logged in AWS CloudTrail. You can use these events to verify which key protects a resource. These events record AWS KMS key use. Administrators and auditors can use these events to trace when and where your AWS KMS keys were used. For application-level activity in Amazon Quick, see [Incident response, logging, and monitoring in Amazon Quick](#).

To create customer managed KMS keys, you use AWS Key Management Service (AWS KMS) in the same AWS account and AWS Region as the Amazon Quick resource. An Amazon Quick administrator can then use a customer managed KMS key to encrypt your Amazon Quick data and control access.

You can create and manage customer managed KMS keys in the Amazon Quick console or with the Amazon Quick APIs. For more information about creating and managing customer managed KMS keys with the Amazon Quick APIs, see [Key management operations](#).

The following rules apply to using customer managed KMS keys with Amazon Quick resources:

- Amazon Quick doesn't support asymmetric AWS KMS keys.
- You can have multiple customer managed KMS keys and one default customer managed KMS key per AWS account per AWS Region.
- By default, Amazon Quick resources are encrypted with Amazon Quick–native encryption strategies.
- Data currently encrypted by a customer managed KMS key will stay encrypted by the key.
- Accounts configured with a customer managed KMS key do not support chat memory. For more information, see [Memory and response personalization](#).

 Note

If you use AWS Key Management Service with Amazon Quick, you are billed for access and maintenance as described in the [AWS Key Management Service Pricing page](#). In your billing statement, the costs are itemized under AWS KMS and not under Amazon Quick.

Where a customer managed KMS key does not apply, Amazon Quick protects data with AWS owned or service-managed keys.

Database server certificates that are not managed by AWS are the responsibility of the customer and should be signed by a trusted CA. For more information, see [Network and database configuration requirements](#).

Use the following topics to learn more about using customer managed KMS keys with Amazon Quick. To learn more about data encryption in Amazon Quick, see [Data protection in Amazon Quick](#).

Topics

- [Customer managed KMS key scope](#)
- [Amazon Q data key](#)
- [Add a customer managed KMS key to your account](#)
- [Verify the key used by Amazon Quick](#)
- [Changing the default customer managed KMS key](#)
- [Removing the default customer managed KMS key](#)
- [Auditing customer managed KMS key usage in CloudTrail](#)
- [Revoking access to a customer managed KMS key](#)
- [Recovering encrypted Amazon Quick data](#)

Customer managed KMS key scope

Amazon Quick uses resource-specific encryption at rest. Support for a customer managed KMS key, and the way that key is applied, differs by resource type. If a resource type is not listed in the following table, do not assume that a customer managed KMS key applies to it.

Amazon Quick applies customer managed KMS keys in two ways:

- **Account default key.** Participating resource types select the account default key when data is written or when a resource-level key association is created. Changing the default affects future writes or resources that resolve it, but does not automatically re-encrypt existing content. The exact lifecycle is resource-specific.
- **Amazon Q data key.** Amazon Q data uses a single account-level key that is set the first time Amazon Q data is created in your account and **cannot be changed afterward**. To use a customer managed KMS key for Amazon Q data, register it as your account default key *before* you create any Amazon Q data.

Customer managed KMS key support requires an Amazon Quick Enterprise subscription.

A customer managed KMS key must be a symmetric AWS KMS key in the same AWS account and AWS Region as the Amazon Quick resource. You can configure one default customer managed KMS key for each Amazon Quick account and Region.

Your key policy must allow the Amazon Quick service principals that use the key. Your key policy must permit both `quicksight.amazonaws.com` and `qbusiness.amazonaws.com`. This applies

when the same key serves as both your default customer managed KMS key and the Amazon Q data key. Omitting `qbusiness.amazonaws.com` can cause knowledge base sync operations to fail.

Amazon Quick uses AWS KMS grants to encrypt and decrypt your data with a customer managed KMS key, and creates these grants on your behalf. If a key policy or service control policy restricts `kms:CreateGrant` for the Amazon Quick service principals, encryption operations can fail. Retiring a grant removes Amazon Quick access to the key for that resource.

Enabling automatic key rotation in AWS KMS rotates the key material without changing the key ARN, so it does not change how Amazon Quick uses the key and requires no action in Amazon Quick. Rotating to a *different* AWS KMS key is a default-key change; see the following scope table for how each resource type behaves. The Amazon Q data key cannot be moved to a different key.

To see both values for your account, call `DescribeKeyRegistration`. The response returns your registered keys in `KeyRegistration` and your Amazon Q data key in `QDataKey`. The `QDataKey` value is read-only.

Key registration support follows Amazon Quick Region availability. Individual Amazon Quick features and their customer managed KMS key integrations might have narrower Region or account availability; see the documentation for that feature and use `DescribeKeyRegistration` to inspect your account.

For more information about supported AWS Regions, see [AWS Regions, websites, IP address ranges, and endpoints](#).

Amazon Quick resource type	Key used	When it applies	Existing-resource behavior
SPICE dataset	Account default key	A new dataset uses the default key at creation.	To move an existing dataset to a new default key, perform a full refresh.
Report artifact from a dashboard snapshot, scheduled report, export, or dashboard	Account default key	A newly generated artifact uses the current default key.	Existing artifacts remain encrypted with their existing key and are not re-encrypted.

Amazon Quick resource type	Key used	When it applies	Existing-resource behavior
Data-source credentials, OAuth tokens, and OAuth client applications	Account default key	Encrypted at creation with the current default key.	Re-encrypted with the current default key whenever the credential is updated or an OAuth token is refreshed. If no default key is registered, Amazon Quick uses a service-managed key.
Flows – definitions, publication data, run/session state, history, and uploaded-file names	Account default key	Participating Flow content uses the current default key when written.	Existing encrypted content remains tied to the key recorded when it was written; changing the default does not automatically re-encrypt it.
Automate – participating group and trigger content; validated inbound-email content, attachments, and email sender, subject, and attachment-name audit fields	Account default key	Applies only to these participating Automate stores where the integration is available.	Existing records retain the key used for encryption. Other Automate-owned persistence, including workflow/deployment/run data, execution artifacts, and credentials, uses service-controlled keys rather than the account default key.

Amazon Quick resource type	Key used	When it applies	Existing-resource behavior
Research – artifacts , documents, reports/exports, and encrypted record fields	Account default key associated at Research creation	A new Research resource associates the current default key when available ; otherwise Amazon Quick uses service encryption. To use a customer managed KMS key for a Research resource, register it as your default key before creating the resource – a Research resource created without a key association cannot be moved to one later.	Existing Research resources remain associated with their creation-time key when the account default changes. All content in the resource, including new writes, continues to use the creation-time key.
Amazon Q data – knowledge bases, spaces and space uploads, conversations, agents, actions, extensions (including extension access configuration), topics, and Quick Index	Amazon Q data key	Set the first time Amazon Q data is created in the account, from the default key registered at that moment.	Cannot be changed. Not affected when you change or remove the default key.

Amazon Q data key

Amazon Quick protects Amazon Q data with a single account-level key called the Amazon Q data key. Amazon Quick sets this key the first time Amazon Q data is created in your account:

- If a default customer managed KMS key is registered at that moment, the Amazon Q data key is set to that key and `QDataKey.QDataKeyType` is CMK.

- If no default key is registered, Amazon Quick uses an AWS owned key and `QDataKey.QDataKeyType` is `AWS_OWNED`.

The Amazon Q data key cannot be changed after it is set. Changing or removing your default customer managed KMS key does not change it, and does not return an account to an AWS owned key. To use a customer managed KMS key for Amazon Q data, register that key as your account default key before you create any Amazon Q data.

To check the current value, call `DescribeKeyRegistration` and read the `QDataKey` field.

Important

If the key referenced by your Amazon Q data key becomes unavailable, Amazon Q data becomes inaccessible and creating new Amazon Q resources fails. A key can become unavailable if it is disabled, if access is denied, or if it is scheduled for deletion. Because the Amazon Q data key cannot be changed, removing the key registration does not resolve this. Registering a different customer managed KMS key also does not resolve this. The only way to restore Amazon Q functionality is to restore the original key: re-enable it, restore access to it, or cancel its pending deletion. If the key has been permanently deleted, Amazon Q data encrypted with it cannot be recovered. To restore Amazon Q functionality, you must unsubscribe from Amazon Quick and subscribe again. This permanently deletes all of your Amazon Quick data. Before you disable, deny access to, or schedule deletion of any AWS KMS key, call `DescribeKeyRegistration` and confirm the key is not your Amazon Q data key.

Add a customer managed KMS key to your account

Before you begin, make sure that you have an IAM role that grants the admin user access to the Amazon Quick admin key management console. For more information on the required permissions, see [IAM identity-based policies for Amazon Quick: using the admin key management console](#).

You can add keys that already exist in AWS KMS to your Amazon Quick account, so that you can encrypt your Amazon Quick data.

To learn more about how you can create a key to use in Amazon Quick, see the [AWS Key Management Service Developer Guide](#).

To add a new customer managed KMS key to your Amazon Quick account.

1. On the Amazon Quick start page, choose **Manage Amazon Quick**, and then choose **KMS keys**.
2. On the **KMS keys** page, choose **Manage**. The **KMS keys** dashboard opens.
3. On the **KMS Keys** dashboard, choose **Select key**.
4. On the **Select key** pop-up box, choose **Key** to open the list. Then, select the key that you want to add.

If your key isn't in the list, you can manually enter the key's ARN.

5. (Optional) Select the **Use as default encryption key for all new data in the current region of this Amazon Quick account** to set the selected key as your default key. A badge appears next to the default key to indicate its status.

When you choose a default key, new data for participating resource types is encrypted with that key. Support and lifecycle differ by resource type; see [Customer managed KMS key scope](#).

6. (Optional) Add more keys by repeating the previous steps in this procedure. While you can add as many keys as you want, you can only have one default key at one time.

Verify the key used by Amazon Quick

When a key is used, an audit log is created in AWS CloudTrail. You can use the log to track the key's usage. If you need to know which key the Amazon Quick data is encrypted by, you can find this information in CloudTrail.

To learn more about which data can be managed with the key, see [Encrypting your Amazon Quick data with AWS Key Management Service customer managed keys](#).

Verify the customer managed KMS key that's currently used by a SPICE dataset

1. Navigate to your CloudTrail log. For more information, see [Logging Amazon Quick operations with AWS CloudTrail](#).
2. Locate the most recent grant events for the SPICE dataset, using the following search arguments:
 - The event name (eventName) contains Grant.
 - The request parameters requestParameters contain the Amazon Quick ARN for the dataset.

```
{
  "eventVersion": "1.08",
  "userIdentity": {
    "type": "AWSService",
    "invokedBy": "quicksight.amazonaws.com"
  },
  "eventTime": "2022-10-26T00:11:08Z",
  "eventSource": "kms.amazonaws.com",
  "eventName": "CreateGrant",
  "awsRegion": "us-west-2",
  "sourceIPAddress": "quicksight.amazonaws.com",
  "userAgent": "quicksight.amazonaws.com",
  "requestParameters": {
    "constraints": {
      "encryptionContextSubset": {
        "aws:quicksight:arn": "arn:aws:quicksight:us-
west-2:111122223333:dataset/12345678-1234-1234-1234-123456789012"
      }
    },
    "retiringPrincipal": "quicksight.amazonaws.com",
    "keyId": "arn:aws:kms:us-
west-2:111122223333:key/87654321-4321-4321-4321-210987654321",
    "granteePrincipal": "quicksight.amazonaws.com",
    "operations": [
      "Encrypt",
      "Decrypt",
      "DescribeKey",
      "GenerateDataKey"
    ]
  },
  ....
}
```

3. Depending on the event type, one of the following applies:

CreateGrant – You can find the most recently used customer managed KMS key in the key ID (keyID) for the last CreateGrant event for the SPICE dataset.

RetireGrant – If latest CloudTrail event of the SPICE datasets is RetireGrant, there is no key ID and the resource is no longer customer managed KMS key encrypted.

Verify the customer managed KMS key that's currently used when generating report artifacts

1. Navigate to your CloudTrail log. For more information, see [Logging Amazon Quick operations with AWS CloudTrail](#).
2. Locate the most recent GenerateDataKey events for the report execution, using the following search arguments:
 - The event name (eventName) contains GenerateDataKey or Decrypt.
 - The request parameters (requestParameters) contain the Amazon Quick ARN for the analysis or dashboard the report was generated for.

```
{
  "eventVersion": "1.11",
  "userIdentity": {
    "type": "AWSService",
    "invokedBy": "quicksight.amazonaws.com"
  },
  "eventTime": "2025-07-23T23:33:46Z",
  "eventSource": "kms.amazonaws.com",
  "eventName": "GenerateDataKey",
  "awsRegion": "us-west-2",
  "sourceIPAddress": "quicksight.amazonaws.com",
  "userAgent": "quicksight.amazonaws.com",
  "requestParameters": {
    "keyId": "arn:aws:kms:us-west-2:111122223333:key/87654321-4321-4321-4321-210987654321",
    "keySpec": "AES_256",
    "encryptionContext": {
      "aws:quicksight:arn": "arn:aws:quicksight:us-west-2:111122223333:dashboard/1ca456fe-eb34-4250-805c-b1b9350bd164",
      "aws:s3:arn": "arn:aws:s3:::amazon-quick-owned-bucket"
    }
  },
  ...
}
```

3. `aws:s3:arn` is the Amazon Quick owned S3 bucket where your report artifacts are stored.
4. If you no longer see GenerateDataKey, then new report executions are no longer customer managed KMS key encrypted. Existing report artifacts will remain encrypted.

Verify the customer managed KMS key that's currently used for data-source credentials

1. Navigate to your CloudTrail log. For more information, see [Logging Amazon Quick operations with AWS CloudTrail](#).
2. Locate the most recent Encrypt events for the data source, using the following search arguments:
 - The event name (eventName) is Encrypt.
 - The request parameters (requestParameters) contain the encryption context aws:quicksight:arn with the Amazon Quick ARN for the data source.

```
{
  "eventVersion": "1.11",
  "userIdentity": {
    "type": "AWSService",
    "invokedBy": "quicksight.amazonaws.com"
  },
  "eventTime": "2025-07-23T23:33:46Z",
  "eventSource": "kms.amazonaws.com",
  "eventName": "Encrypt",
  "awsRegion": "us-west-2",
  "sourceIPAddress": "quicksight.amazonaws.com",
  "userAgent": "quicksight.amazonaws.com",
  "requestParameters": {
    "keyId": "arn:aws:kms:us-west-2:111122223333:key/87654321-4321-4321-4321-210987654321",
    "encryptionContext": {
      "aws:quicksight:arn": "arn:aws:quicksight:us-west-2:111122223333:datasource/example-data-source-id"
    }
  },
  ...
}
```

3. The keyId on the most recent Encrypt event is the key currently protecting the credential. Credentials are re-encrypted with the current default key whenever the credential is updated or an OAuth token is refreshed, so the most recent event reflects the key in use.

Changing the default customer managed KMS key

You can change the default key to another key that already exists in the **KMS keys** dashboard. When you change the default key, new writes and new resources for participating resource types use the new key. Existing content remains encrypted with the key that was in effect when it was written; how and whether it moves to the new key differs by resource type – for example, a SPICE dataset moves on its next full refresh, data-source credentials move on their next update or token refresh, and report artifacts are never re-encrypted. The Amazon Q data key is not affected. For more information, see [Customer managed KMS key scope](#).

To learn more about which data can be managed with the key, see [Encrypting your Amazon Quick data with AWS Key Management Service customer managed keys](#).

To change the default key to an existing key

1. On the Amazon Quick start page, choose **Manage Amazon Quick**, and then choose **KMS keys**.
2. Choose **MANAGE** to open the **KMS keys** dashboard.
3. Navigate to the key that you want to set as your new default. Choose **Actions** (three dots) on the row of the key that you want to open the key's menu.
4. Choose **Set as default**, and then choose **Set**.

The selected key is now your default key.

Removing the default customer managed KMS key

Removing your default customer managed KMS key ends the use of that key for **new resources or writes that resolve the account default key**. Removing the key does not delete the AWS KMS key, change the key that protects existing resources, change your Amazon Q data key, or remove encryption at rest.

Where no customer managed KMS key applies, Amazon Quick continues to protect data with its own encryption. Existing resources remain encrypted with the key they were created with.

Important

Before you remove your default customer managed KMS key, call `DescribeKeyRegistration` and confirm that the key is not your Amazon Q data key. If the key is your Amazon Q data key, removing it from the default registration does not

change the Amazon Q data key, but future Amazon Q resource behavior depends on continued access to that key. For more information, see [Amazon Q data key](#).

To remove the default customer managed KMS key

1. On the Amazon Quick start page, choose **Manage Amazon Quick**, and then choose **KMS keys**.
2. On the **KMS keys** page, choose **Manage** to open the **KMS keys** dashboard.
3. Choose **Actions** (three dots) on the row of the default key, and then choose **Delete**.
4. In the pop-up box that appears, choose **Remove**.

Auditing customer managed KMS key usage in CloudTrail

You can audit your account's customer managed KMS key usage in AWS CloudTrail. To audit your key usage, log in to your AWS account, open CloudTrail, and choose **Event history**.

Note

Amazon Q data key use appears in CloudTrail as a single account-level key rather than as per-resource grants. `DescribeKeyRegistration` is the authoritative source for the current Amazon Q data key value.

Revoking access to a customer managed KMS key

You can revoke access to your customer managed KMS keys. When you revoke access to a key that is used to encrypt your Amazon Quick data, access to it is denied, and operations that depend on the key can fail until you undo the revoke. The following methods are examples of how you can revoke access:

- Turn off the key in AWS KMS.
- Add a Deny policy to your Amazon Quick AWS KMS policy in IAM.

Important

Before you revoke access to a AWS KMS key, call `DescribeKeyRegistration` and confirm the key is not your Amazon Q data key. If you revoke access to your Amazon Q

data key, Amazon Q data becomes inaccessible and creating new Amazon Q resources fails. This is not reversible by registering a different customer managed KMS key. For more information, see [Amazon Q data key](#).

To learn more about which data can be managed with the key, see [Encrypting your Amazon Quick data with AWS Key Management Service customer managed keys](#).

Use the following procedure to revoke access to your customer managed KMS keys in AWS KMS.

To turn off a customer managed KMS key in AWS Key Management Service

1. Log in to your AWS account, open AWS KMS, and choose **Customer managed keys**.
2. Select the key that you want to turn off.
3. Open the **Key actions** menu and choose **Disable**.

The following is a revocation example that uses a Deny policy in AWS Identity and Access Management (IAM) to prevent further use of the customer managed KMS key. Use "Service": "quicksight.amazonaws.com" as the principal and the ARN of the key as the resource. Deny the following actions: "kms:Encrypt", "kms:Decrypt", "kms:ReEncrypt*", "kms:GenerateDataKey*", "kms:DescribeKey".

Important

After you revoke access by using any method, it can take up to 15 minutes for the data to become inaccessible.

Recovering encrypted Amazon Quick data

The following procedure applies when access to a AWS KMS key has been revoked (for example, by disabling the key or adding a Deny policy), but the key itself still exists in AWS KMS.

Important

If the AWS KMS key has been permanently deleted, data encrypted with it cannot be recovered. AWS KMS enforces a waiting period before key deletion; if the key is still pending deletion, you can cancel the scheduled deletion to restore it. If the permanently

deleted key is your Amazon Q data key, Amazon Q functionality can only be restored by unsubscribing from Amazon Quick and subscribing again, which permanently deletes all of your Amazon Quick data.

To recover Amazon Quick data while its access is revoked

1. Restore access to the customer managed KMS key. Usually, this is enough to recover the Amazon Quick data.
2. Test the Amazon Quick data to check if you can see it.
3. (Optional) If a SPICE dataset is not fully recovered even after you restore access to the customer managed KMS key, perform a full refresh on the dataset. Full refresh applies only to SPICE datasets; it is not applicable to other resource types such as conversations, spaces, agents, or actions.

To learn more about which data can be managed with the key, see [Encrypting your Amazon Quick data with AWS Key Management Service customer managed keys](#).

Permissions

Permission management in Quick controls what actions users can perform and which resources they can access within your Amazon Quick environment. This section covers essential permission-related tasks including configuring access to AWS data sources, setting default access levels for new users, managing IAM policy assignments, creating custom permission profiles tailored to your organization's needs, configuring connectors for third-party integrations, managing extension application access, and integrating with SageMaker AI for machine learning capabilities. Proper permission management ensures users have appropriate access to perform their roles while maintaining security and compliance requirements.

Topics

- [Accessing AWS resources](#)
- [Default access policy](#)
- [IAM policy assignments](#)
- [Extension access](#)
- [Custom permissions](#)

- [Limit profiles](#)

Accessing AWS resources

Applies to: Enterprise Edition and Standard Edition

Intended audience: System administrators and Amazon Quick administrators

You can control the AWS resources that Amazon Quick can access and scope down access to these resources at a more granular level. In Enterprise edition, you can also set up general access defaults for everyone in your account, and you can set up specific access for individual users and groups.

These access configurations are essential for Amazon Quick Sight data source connectivity, enabling secure connections to AWS services like Amazon S3, Amazon RDS, Amazon Redshift, and Athena for data analysis and visualization. Proper resource access setup ensures that Amazon Quick Sight can retrieve and process data from your AWS data sources while maintaining appropriate security boundaries.

Use the following sections to help you configure your AWS resources to work with Quick.

Before you begin, make sure that you have the correct permissions; your system administrator can give you these. To do so, your system administrator creates a policy that enables you to use certain IAM actions. Your system administrator then associates that policy with your user or group in IAM. The required actions are the following:

- **quicksight:AccountConfigurations** – To enable setting default access to AWS resources
- **quicksight:ScopeDownPolicy** – Scoping policies for permissions to AWS resources
- You can also bring your own IAM roles into Amazon Quick. For more information, see [Passing IAM roles to Amazon Quick](#).

To enable or disable the AWS services that Amazon Quick can access

1. Sign in to Amazon Quick at <https://quicksight.aws.amazon.com/>.
2. At the upper right, choose your user name, and then choose **Manage Quick**.
3. Choose **Security & permissions**.

4. Under **QuickSight access to AWS services**, choose **Add or remove**.

A screen appears where you can enable all available AWS services.

 Note

If you see a permissions error, and you're an authorized Amazon Quick administrator, contact your system administrator for assistance.

5. Select the check boxes for the services that you want to allow. Clear check boxes for services that you don't want to allow.

If you have already enabled an AWS service, the check box for that service is already selected. If Amazon Quick can't access a particular AWS service, its check box is not selected.

In some cases, you might see a message like the following.

This policy used by Amazon Quick for AWS resource access was modified outside of Amazon Quick, so you can no longer edit this policy to provide AWS resource permission to Amazon Quick. To edit this policy permissions, go to the IAM console and delete this policy permission with policy arn - `arn:aws:iam::111122223333:policy/service-role/AWSQuickSightS3Policy`.

This type of message means that one of the IAM policies that Amazon Quick uses was manually altered. To fix this, the system administrator needs to delete the IAM policy listed in the error message and reload the **Security & permissions** screen before you try again.

6. Choose **Update** to confirm, or **Cancel** to return to the previous screen.

Setting granular access to AWS services through IAM

Applies to: Enterprise Edition

Intended audience: System administrators and Amazon Quick administrators

In Enterprise edition, Amazon Quick provides a way for you to set up detailed access to resources in AWS services. Like every other AWS service, Quick uses IAM policies to control access for users and groups.

Before you begin, ask an administrator to set up the necessary IAM policies ahead of time. If these are set up, you can select them as part of the procedure in this section. For information about creating IAM policies to use with Quick, see [Identity and access management in Quick](#).

To assign an IAM policy to a user or group

1. Sign in to Quick at <https://quicksight.aws.amazon.com/>.
2. At upper left, choose your user name, and then choose **Manage QuickSight**.
3. Choose **Security & permissions**.
4. Under **Resource access for individual users and groups**, choose **IAM policy assignments**.

The remaining steps at this point involve choosing an IAM policy to assign to the user or group. You can assign multiple IAM policies to one Amazon Quick user or group. To determine permissions, Amazon Quick performs a union and an intersection with the AWS account-level policies.

If you already have active IAM policy assignments, they are listed on this page. You can search for existing assignments by using the search box. If you have drafts that aren't active yet, they are listed under **Assignment drafts**.

5. Choose one of the following:
 - To create an IAM policy assignment, choose **Add new assignment**.
 - To edit an existing assignment, choose the **Edit assignment** icon for that assignment.
 - To enable or disable a policy, select the check box for that policy, and then choose **Enable** or **Disable**. You can select multiple policy assignments at a time.
 - To delete an existing assignment, choose the **Remove assignment** icon near the name of the assignment. To confirm your choice, choose **Delete** on the confirmation screen. Or choose **Back** to cancel deletion.

If you are creating or editing an assignment, continue to the next step. Otherwise, skip to the end of this procedure.

6. On the next screen, you perform the policy assignment process, which is divided into steps. As you work through the steps, you can go forward or backward to make changes. When you exit the screen, your changes from all of the steps are saved.
 - a. **Step 1: Name assignment** – If this is a new assignment, enter a name for the assignment, and then choose **Next** to continue. If you want to change the name, choose **Step 1** at left.
 - b. **Step 2: Select an IAM policy** – Choose an IAM policy that you want to use. From this screen, you can interact with the policies as follows:
 - Choose a policy that you want to use.
 - Search for a policy name.
 - Filter the list to see all IAM policies, AWS-managed policies, or customer-managed policies.
 - View a policy, by choosing **View policy**.

To choose a policy, choose the button beside it, and then choose **Next** to continue.

- c. **Step 3: Assign users and groups** – Choose specific users or groups. Or choose to use the selected IAM policy for all users and groups.

Choose one of the following.

- For **Assign to all users and groups**, select the check box to assign the IAM policy to all Amazon Quick users and groups. Choosing this option assigns the policy to all current and future users and groups.
- Choose the users and groups you want to assign to this IAM policy. You can search for them by name, email address, or group name.

When you are finished selecting users and groups, choose **Next** to continue.

- d. **Step 4: Review and enable changes** – Save your changes.

Choose one of the following.

- To edit any of your choices, choose that step to edit it.

- To save this policy assignment as a draft, choose **Save as draft**. You can enable the draft later.
- To immediately enable this policy, choose **Save and enable**. This option overwrites any existing policy assignment with the same name.

Using AWS Secrets Manager secrets instead of database credentials in Quick

Intended audience: Amazon Quick Administrators and Amazon Quick developers

AWS Secrets Manager is a secret storage service that you can use to protect database credentials, API keys, and other secret information. Using a key helps you ensure that the secret can't be compromised by someone examining your code, because the secret isn't stored in the code. For an overview, see the [AWS Secrets Manager User Guide](#).

Quick administrators can grant Amazon Quick read-only access to secrets they create in Secrets Manager. These secrets can be used in place of database credentials when creating and editing data sources using the Quick API.

Quick supports using secrets with data source types that support credential pair authentication. Jira and ServiceNow are not currently supported.

Note

If you use AWS Secrets Manager with Quick, you are billed for access and maintenance as described in the [AWS Secrets Manager Pricing page](#). In your billing statement, the costs are itemized under Secrets Manager and not under Amazon Quick.

Use the procedures described in the following sections to integrate Secrets Manager with Amazon Quick.

Topics

- [Granting Amazon Quick access to Secrets Manager and selected secrets](#)
- [Creating or updating a data source with secret credentials using the Amazon Quick API](#)
- [What's in the secret](#)

- [Modify a secret](#)

Granting Amazon Quick access to Secrets Manager and selected secrets

If you're an administrator and you have secrets in Secrets Manager, you can grant Amazon Quick read-only access to selected secrets.

To grant Amazon Quick access to Secrets Manager and selected secrets

1. In Amazon Quick, choose your user icon on the upper right, and then choose **Manage Quick**.
2. Choose **Security & permissions** on the left.
3. Choose **Manage** in **Amazon Quick access to AWS resources**.
4. In **Allow access and autodiscovery for these resources**, choose **AWS Secrets Manager, Select secrets**.

The **AWS Secrets Manager secrets** page opens.

5. Select the secrets that you want to grant Amazon Quick read-only access to.

Secrets in your Amazon Quick sign-up Region are shown automatically. To select secrets outside your home Region, choose **Secrets in Other AWS Regions**, and then enter the Amazon Resource Names (ARNs) for those secrets.

6. When you're done, choose **Finish**.

Amazon Quick creates an IAM role called `aws-quicksight-secretsmanager-role-v0` in your account. It grants users in the account read-only access to the specified secrets and looks similar to the following:

When Amazon Quick users create analyses from or view dashboards that use a data source with secrets, Amazon Quick assumes this Secrets Manager IAM role. For more information about secret permissions policies, see [Authentication and access control for AWS Secrets Manager](#) in the *AWS Secrets Manager User Guide*.

The specified secret in the Amazon Quick IAM role may have an additional resource policy that denies access. For more information, see [Attach a permissions policy to a secret](#) in the *AWS Secrets Manager User Guide*.

If you're using an AWS managed AWS KMS key to encrypt your secret, Amazon Quick doesn't require any additional permissions setup in Secrets Manager.

If you're using a customer managed key to encrypt your secret, ensure that the Amazon Quick IAM role, `aws-quicksight-secretsmanager-role-v0` has `kms:Decrypt` permissions. For more information, see [Permissions for the KMS key](#) in the *AWS Secrets Manager User Guide*.

For more information about the types of keys used in AWS Key Management Service, see [Customer keys and AWS keys](#) in the *AWS Key Management Service guide*.

Creating or updating a data source with secret credentials using the Amazon Quick API

After the Amazon Quick administrator has granted Amazon Quick read-only access to Secrets Manager, you can create and update data sources in the API using a secret the administrator selected as credentials.

Following is an example API call to create a data source in Amazon Quick. This example uses the `create-data-source` API operation. You can also use the `update-data-source` operation. For more information, see [CreateDataSource](#) and [UpdateDataSource](#) in the *Amazon Quick API Reference*.

The user specified in the permissions in the following API call example can delete, view, and edit data sources for the specified MySQL data source in Amazon Quick. They can also view and update the data source permissions. Instead of a Amazon Quick username and password, a secret ARN is used as credentials for the data source.

```
aws quicksight create-data-source
  --aws-account-id AWSACCOUNTID \
  --data-source-id DATASOURCEID \
  --name NAME \
  --type MYSQL \
  --permissions '[{"Principal": "arn:aws:quicksight:region:accountID:user/namespace/username", "Actions": ["quicksight:DeleteDataSource",
    "quicksight:DescribeDataSource", "quicksight:DescribeDataSourcePermissions",
    "quicksight:PassDataSource", "quicksight:UpdateDataSource",
    "quicksight:UpdateDataSourcePermissions"]}]' \
  --data-source-parameters='{"MySQLParameters":{"Database": "database",
    "Host": "hostURL", "Port": "port"}}' \
  --
credentials='{"SecretArn": "arn:aws:secretsmanager:region:accountID:secret:secretname"}' \
  --region us-west-2
```

In this call, Amazon Quick authorizes `secretsmanager:GetSecretValue` access to the secret based on the API caller's IAM policy, not the IAM service role's policy. The IAM service role acts on the account level and is used when an analysis or dashboard is viewed by a user. It cannot be used to authorize secret access when a user creates or updates the data source.

When they edit a data source in the Amazon Quick UI, users can view the secret ARN for data sources that use AWS Secrets Manager as the credential type. However, they can't edit the secret, or select a different secret. If they need to make changes, for example to the database server or port, users first need to choose **Credential pair** and enter their Amazon Quick account username and password.

Secrets are automatically removed from a data source when the data source is altered in the UI. To restore the secret to the data source, use the `update-data-source` API operation.

What's in the secret

Amazon Quick requires the following JSON format to access your secret:

```
{
  "username": "username",
  "password": "password"
}
```

The `username` and `password` fields are required for Amazon Quick to access secrets. All other fields are optional and are ignored by Amazon Quick.

The JSON format may vary depending on the type of database. For more information, see [JSON structure of AWS Secrets Manager database credential secrets](#) in the *AWS Secrets Manager User Guide*.

Modify a secret

To modify a secret, you use Secrets Manager. After you make changes to a secret, the updates become available the next time Amazon Quick requests access to the secret.

Default access policy

Applies to: Enterprise Edition

Intended audience: System administrators and Amazon Quick administrators

In the Enterprise edition, you can configure specific permissions for the AWS services that an Amazon Quick user can access. If no such configuration occurs, Quick uses a default set of permissions based on the user's settings. The current behavior is displayed in a blue information box.

To change the default resource access for all users (to use when no other permissions are configured)

1. Sign in to Amazon Quick.
2. At upper right, choose the profile icon, and then choose **Manage Quick**.
3. Under **Permissions**, choose **Default access policy**.
4. Choose one of the following:
 - Allow access to all AWS data and resources to all users and groups.
 - Deny access to all AWS data and resources to all users and groups.
5. Choose **Update**.

IAM policy assignments

IAM policy assignments allow you to control access to AWS resources for users and groups within Amazon Quick. By assigning IAM policies, you can define and manage permissions for various AWS services and resources that Quick may need to access. Assignments can be enabled, disabled, or deleted at any time.

To add a new IAM policy assignment:

1. Open the [Quick console](#).
2. Choose the user icon at the top right, and then choose **Manage Quick**.
3. Under the **Permissions** section, choose **IAM policy assignments**.
4. Choose **Add new assignment**.
5. Enter a name for this assignment and choose **Next**.
6. Select an IAM policy by either searching for it directly or scrolling through the displayed list, and then choose **Next**.

7. Assign users or groups to the IAM policy by either searching by name, email address, or group name, or scrolling through the displayed list and selecting the appropriate users or groups. You can also choose to assign the policy to all users and groups by selecting the checkbox; this will apply the policy to all current and future users and groups.
8. Choose **Next**.
9. Review your selections and choose **Save and enable**.
10. You can enable or disable the assignment at any time by selecting the checkbox next to the assignment name and choosing **Enable** or **Disable**. You can view the status of the policy assignment under the **Status** column.

To edit an IAM policy assignment:

1. Open the [Quick console](#).
2. Choose the user icon at the top right, and then choose **Manage Quick**.
3. Under the **Permissions** section, choose **IAM policy assignments**.
4. Choose the edit (pencil) icon.
5. Review the sections and choose **Edit** to make any changes.
6. Choose **Save and enable** to apply your updates.

To delete an IAM policy assignment:

1. Open the [Quick console](#).
2. Choose the user icon at the top right, and then choose **Manage Quick**.
3. Under the **Permissions** section, choose **IAM policy assignments**.
4. Choose the delete (trash) icon.
5. A confirmation modal will appear to ensure you want to proceed with the deletion. Choose **Delete** to delete the IAM policy assignment.

Extension access

Extension access connects your Amazon Quick account to third party applications like Microsoft Teams, Microsoft Outlook, Microsoft Word, Microsoft Excel, Microsoft PowerPoint, and Slack. Think of it as giving permission for Amazon Quick to work inside the apps your team already uses, helping them accomplish their work, assisted by generative AI, and without context switching.

As an admin, you configure extension access. Then, either an admin or an author must install the extension in the Amazon Quick console to make the extension available to end users. This default extension is available for use to all users on eligible subscriptions after setup. Installed extensions are available under **Connections > Extensions** in the Amazon Quick menu for further configuration and management.

If you're an admin user of Amazon Quick, you configure Amazon Quick access to extensions, and can also deploy extensions for end user use. As an admin, you can also allow authors to edit and deploy extensions after you configure access.

User roles and extension permissions work as follows:

- **IAM Administrators:** Can enable/remove extension access, create extensions, assign owners, and control extension availability for the organization.
- **Authors:** Can create and install extensions using administrator-enabled access, and edit/delete extensions they own.
- **Readers (Reader Pro only):** Can use all enabled extensions but cannot create or modify them.

Here's what you need to know about extension access:

- **What it is:** A secure connection between your Amazon Quick instance and your organization's account in third-party apps (like your Microsoft 365 or Slack workspace).
- **Why it matters:** It gives your Amazon Quick instance permission to work within your organization's specific tenant or workspace in these apps.
- **Who sets it up:** Only administrators with IAM credentials can configure extension access and deploy extensions (or give authors permission to edit and deploy extensions) - it's a privileged operation that must be done before your team can start using extensions. Note that IAM admin users can access the **Extension access** pages from the **Manage Quick** menu, but to configure a extension they may need to re-log in to the system and select **Connections > Extensions** from the Amazon Quick menu.

Topics

- [Browser extension](#)
- [Amazon Quick Microsoft Outlook extension](#)
- [Amazon Quick Microsoft Excel extension](#)
- [Amazon Quick Microsoft Word extension](#)

- [Amazon Quick Microsoft PowerPoint extension](#)
- [Amazon Quick Slack extension](#)
- [Amazon Quick Microsoft Teams extension](#)

Browser extension

The Amazon Quick browser extension is available within Amazon Quick to all eligible users by default and requires no administrative setup for user access. Users can find the browser extension installation link under **Connections > Extensions**. The following procedures are for IT administrators who want to automatically deploy or disable the Amazon Quick browser extension across all browsers in their organization using managed device policies.

Topics

- [Deploy the browser extension](#)
- [Disable the browser extension](#)

Deploy the browser extension

Note

The following deployment guide applies only when you have a managed device fleet with managed browsers.

To deploy the browser extension to all users in your organization, you can define an **ExtensionSettings** policy and distribute this policy to your managed devices.

Topics

- [Install using ExtensionSettings policy](#)
- [Distribute ExtensionSettings policy](#)

Install using ExtensionSettings policy

The **ExtensionSettings** policy is an administrative setting for Chrome, Edge, and Firefox that allows you to manage the installation, permissions, and runtime behavior of specific extensions on managed devices. This policy provides granular control by letting administrators specify custom

configurations, such as setting installation modes like force install and restricting or allowing specific site access and permissions for individual extensions or all extensions.

The format of the **ExtensionSettings** policy depends on the operating system where you want to distribute this policy. Windows, Mac, and Linux are supported.

To set the install mode in the **ExtensionSettings** policy, you need the extension identifier and the store URL:

- **Chrome/Edge**

- ID: innkphffipcmiflfibbeghfnkifiokgo
- URL: <https://clients2.google.com/service/update2/crx>

- **Firefox**

- ID: quick-browser-extension@amazon.com
- URL: <https://addons.mozilla.org/firefox/downloads/latest/amazon-quick/latest.xpi>

Distribute ExtensionSettings policy

Distributing the **ExtensionSettings** policy depends on the device and browser management solution used by your organization. You can use managed solutions like **Chrome Enterprise Core** or **Microsoft Edge** management service, or distribute the **ExtensionSettings** policy using **Group Policy**, which differs per operating system.

Disable the browser extension

Note

The following deployment guide applies only when you have a managed device fleet with managed browsers.

To disable the browser extension for all users in your organization, you can define an **ExtensionSettings** policy and distribute this policy to your managed devices.

Topics

- [Disable using ExtensionSettings policy](#)

- [Distribute ExtensionSettings policy](#)

Disable using ExtensionSettings policy

The **ExtensionSettings** policy is an administrative setting for Chrome, Edge, and Firefox that allows you to manage the installation, permissions, and runtime behavior of specific extensions on managed devices. This policy provides granular control by letting administrators specify custom configurations, such as disabling individual extensions.

The format of the **ExtensionSettings** policy depends on the operating system where you want to distribute this policy. See the documentation for the **ExtensionSettings** policy to determine the format. Windows, Mac, and Linux are supported.

To block the use of the extension in the **ExtensionSettings** policy, you need the extension identifier:

- **Chrome/Edge**

ID: innkphffipcmiflfibbeghfnkifiokgo

- **Firefox**

ID: quick-browser-extension@amazon.com

Distribute ExtensionSettings policy

Distributing the **ExtensionSettings** policy depends on the device and browser management solution used by your organization. You can use managed solutions like **Chrome Enterprise Core** or **Microsoft Edge** management service, or distribute the **ExtensionSettings** policy using **Group Policy**, which differs per operating system.

Amazon Quick Microsoft Outlook extension

The Quick extension for Microsoft Outlook integrates AI-powered assistance directly into your email workflows. Users can leverage Quick within Outlook to streamline their inbox and calendar management, draft contextual emails using their Quick data, and perform external actions without switching applications.

The Outlook extension enables users to:

- Prioritize and organize their inbox.

- Search for relevant email content for a topic using natural language.
- Schedule meetings and manage their calendars.
- Summarize emails and draft contextual responses using Quick data.
- Access their enterprise data and perform actions in external applications.

The Amazon Quick Outlook extension is available within Amazon Quick to all eligible users by default and requires no administrative setup for user access if users can access the Microsoft Outlook app store. Users can search for Amazon Quick in the Microsoft Outlook app store or visit the [Quick for Outlook Microsoft store page](#) to add the extension.

Important

- The Amazon Quick Outlook extension uses generative AI to create and execute code within your Outlook application sandbox to help you perform your Outlook tasks. AI can make mistakes and perform inaccurate actions within your Outlook mailbox.
- Amazon Quick does not use your user data for service improvement or for training its underlying large language models (LLMs).

The following procedures are for IT administrators who want to automatically deploy the Amazon Quick Outlook extension across their organization on behalf of their users.

Topics

- [Prerequisites for deploying the Microsoft Outlook extension to your organization](#)
- [Microsoft Outlook extension permissions](#)
- [Deploying the Microsoft Outlook extension to your organization](#)

Prerequisites for deploying the Microsoft Outlook extension to your organization

Before configuring access to the Amazon Quick extension to Microsoft Outlook, administrators must complete the following steps:

1. Have a Microsoft 365 Business subscription and be a Global Admin or have administrative permissions (specifically `AppCatalog.ReadWrite.All`).
2. Have an Amazon Quick instance.

3. Grant tenant-wide admin consent for Microsoft Graph permissions. This allows the extension to access inbox, calendar, and contact data for all users in your organization. Without these permissions, the extension can only respond to questions about the currently open email thread. For instructions, see [the section called "Grant tenant-wide admin consent"](#).

Microsoft Outlook extension permissions

The Amazon Quick Outlook extension uses the ReadWriteMailbox Office JavaScript API permission level. This is an Office add-in manifest permission, not a Microsoft Graph API scope.

The default app capabilities for the Outlook add-in are:

- Can read and make changes to your document
- Access your profile information such as your name, email address, company name, and preferred language
- Can send data over the Internet

Graph API delegated permissions

The Outlook extension uses Microsoft Graph integration, which requires additional delegated permissions.

Important

These permissions are required for the Amazon Quick Outlook extension to provide its full range of capabilities. Without these permissions granted, the extension can only answer questions about the currently open email thread and draft a reply. It cannot summarize your inbox, manage your calendar, or perform inbox-wide operations such as searching, organizing, or triaging emails.

Note

The Amazon Quick Outlook extension does not send emails or create calendar appointments automatically. It uses Human-in-the-Loop (HITL) confirmation before any sending action, so users always review and approve outgoing messages and calendar changes.

Users are prompted to sign in the first time they interact with the extension. Administrators can pre-approve these permissions by granting tenant-wide admin consent (see [the section called "Grant tenant-wide admin consent"](#)).

The following table lists the delegated Graph API permissions used by the Outlook extension.

Permission	Purpose
<code>Calendars.Read.Shared</code>	Read events in user's and shared/delegate calendars for availability checks
<code>Calendars.ReadWrite</code>	Create, update, and delete calendar events; accept/decline invites; check free/busy times
<code>Contacts.ReadWrite</code>	Resolve recipients by name, look up contact details, and save new contacts
<code>Files.Read</code>	Read user's OneDrive/SharePoint files to summarize or reference attachments
<code>Mail.Read</code>	Read full email content, attachments, and threads for summarization and action items
<code>Mail.ReadBasic</code>	Read email metadata (subject, sender, date) for efficient mailbox listing and search
<code>Mail.ReadWrite</code>	Organize mail: move, delete, mark read/unread, create drafts, and manage attachments
<code>MailboxSettings.ReadWrite</code>	Read and update timezone, working hours, out-of-office, inbox rules, and categories
<code>offline_access</code>	Obtain refresh token for persistent sessions without repeated re-authentication
<code>People.Read</code>	Suggest recipients and resolve names using collaboration and org signals
<code>Tasks.ReadWrite</code>	Create, update, complete, and delete tasks and task lists across To Do/Planner

Permission	Purpose
User.Read	Identify the signed-in user's profile, email, job title, and timezone
User.ReadBasic.All	Read basic profile info (name, email, photo) of other users in the org

Grant tenant-wide admin consent

To enable the full capabilities of the Amazon Quick Outlook extension for all users in your organization, grant tenant-wide admin consent for the Microsoft Graph permissions listed above. This pre-approves the permissions so that individual users are not prompted to approve them when they first use the extension.

You can complete this process using either Microsoft Graph PowerShell or Microsoft Graph Explorer.

Prerequisites

Before granting admin consent, ensure you have a role that includes the following permissions:

- Application.ReadWrite.All
- DelegatedPermissionGrant.ReadWrite.All

Grant admin consent using PowerShell

Follow these steps to grant admin consent using Microsoft Graph PowerShell:

1. Connect to Microsoft Graph with the required permissions:

```
Connect-MgGraph -Scopes  
"Application.ReadWrite.All","DelegatedPermissionGrant.ReadWrite.All"
```

2. Look up the Microsoft Graph service principal ID for your tenant and save the ID:

```
Get-MgServicePrincipal -Filter "displayName eq 'Microsoft Graph'"
```

3. Create a service principal for the Amazon Quick Outlook extension in your tenant and save the returned ID:

```
New-MgServicePrincipal -AppId "a5342f89-ebb1-4b1d-966c-34e8df972aaf"
```

- Grant admin consent for all delegated permissions on behalf of all users in your tenant. Replace *ServicePrincipalId* with the ID from step 3 and *GraphServicePrincipalId* with the ID from step 2:

```
$params = @{
    "ClientId"      = "ServicePrincipalId"
    "ConsentType"   = "AllPrincipals"
    "ResourceId"    = "GraphServicePrincipalId"
    "Scope"         = "Calendars.Read.Shared Calendars.ReadWrite Contacts.ReadWrite
Files.Read Mail.Read Mail.ReadBasic Mail.ReadWrite MailboxSettings.ReadWrite
offline_access People.Read Tasks.ReadWrite User.Read User.ReadBasic.All"
}
New-MgOauth2PermissionGrant -BodyParameter $params
```

Grant admin consent using Graph Explorer

Follow these steps to grant admin consent using Microsoft Graph Explorer:

- Sign in to Microsoft Graph Explorer with a role that has the `Application.ReadWrite.All` and `DelegatedPermissionGrant.ReadWrite.All` permissions.
- Look up the Microsoft Graph service principal ID for your tenant and save the ID from the response:

```
GET https://graph.microsoft.com/v1.0/servicePrincipals?$filter=displayName eq
'Microsoft Graph'&$select=id,displayName
```

- Create a service principal for the Amazon Quick Outlook extension in your tenant and save the returned ID:

```
POST https://graph.microsoft.com/v1.0/servicePrincipals
```

Request body:

```
{
    "appId": "a5342f89-ebb1-4b1d-966c-34e8df972aaf"
```

```
}
```

4. Grant admin consent for all delegated permissions on behalf of all users in your tenant. Replace *ServicePrincipalId* with the ID from step 3 and *GraphServicePrincipalId* with the ID from step 2:

```
POST https://graph.microsoft.com/v1.0/oauth2PermissionGrants
```

Request body:

```
{
  "clientId": "ServicePrincipalId",
  "consentType": "AllPrincipals",
  "resourceId": "GraphServicePrincipalId",
  "scope": "Calendars.Read.Shared Calendars.ReadWrite Contacts.ReadWrite
Files.Read Mail.Read Mail.ReadBasic Mail.ReadWrite MailboxSettings.ReadWrite
offline_access People.Read Tasks.ReadWrite User.Read User.ReadBasic.All"
}
```

After granting admin consent, users in your organization will not be prompted to approve permissions individually when they first use the Amazon Quick Outlook extension. The extension will have immediate access to its full capabilities.

Where to review permissions

To review permissions for the Outlook extension, go to Microsoft Entra > **Enterprise Applications** > find the app called "Amazon Quick Outlook Agent" > **Permissions**.

Deploying the Microsoft Outlook extension to your organization

After completing the prerequisites and granting admin consent for Microsoft Graph permissions, follow these steps to deploy the extension to your users:

1. Sign in to the M365 admin center.
2. Select **Settings** > **Integrated apps** in the left navigation menu.
3. Choose **Get apps**.
4. Search for "Amazon Quick".
5. Locate the tile for Amazon Quick in Outlook and choose **Get it now**.

6. Confirm that you want to add the app.
7. Under **Assign users**, choose **Entire organization** or **Specific users/groups** depending on your needs.
8. After selecting the users, review the app's requested permissions and capabilities and choose **Next**.
9. Choose **Finish Deployment**.

Amazon Quick Microsoft Excel extension

The Quick extension for Microsoft Excel integrates AI-powered assistance directly into your spreadsheet workflows. Users can leverage Quick within Excel to perform analysis, import data and build workbooks, and streamline spreadsheet operations like creation of tables, charts, and formatting.

The Excel extension enables users to:

- Perform in-depth analysis of their workbooks and generate insights.
- Import, clean up, and format data from Quick's enterprise knowledge and apps.
- Generate tables and charts.
- Automate spreadsheet operations such as formatting and applying filters and transformations.
- Apply Excel functions and build and decode complex workbooks.

The Quick Excel extension is available within Amazon Quick to all eligible users by default and requires no administrative setup for user access if users can access the Microsoft Excel app store. Users can search for Amazon Quick in the Microsoft Excel app store or visit the [Quick for Excel Microsoft store page](#) to add the extension.

Important

- The Amazon Quick Excel extension uses generative AI to create and execute code within your Excel application sandbox to help you perform tasks within Excel. AI can make mistakes and perform inaccurate actions within your Excel workbook.
- Amazon Quick does not use your user data for service improvement or for training its underlying large language models (LLMs).

The following procedures are for IT administrators who want to automatically deploy the Amazon Quick Excel extension across their organization on behalf of their users.

Topics

- [Prerequisites for deploying the Microsoft Excel extension to your organization](#)
- [Deploying the Microsoft Excel extension to your organization](#)
- [Microsoft Excel extension permissions](#)

Prerequisites for deploying the Microsoft Excel extension to your organization

Before configuring access to the Amazon Quick extension to Microsoft Excel, administrators must complete the following steps:

1. Have a Microsoft 365 Business subscription and be a Global Admin or have administrative permissions (specifically `AppCatalog.ReadWrite.All`).
2. Have an Amazon Quick instance.

Deploying the Microsoft Excel extension to your organization

Follow these steps to deploy the extension to your users:

1. Login to M365 admin center.
2. Select **Settings** > **Integrated apps** in the left navigation menu.
3. Click on **Get apps**.
4. Search for "Amazon Quick".
5. Locate the tile for the Amazon Quick in Excel and click on **Get it now**.
6. Confirm that you want to add the app.
7. Under **Assign users** you can choose **Entire organization** or **Specific users/groups** depending on your needs.
8. After selecting the users, review the app's requested permissions and capabilities and click **Next**.
9. Click **Finish Deployment**.

Microsoft Excel extension permissions

The Amazon Quick Excel extension uses the ReadWriteDocument Office JavaScript API permission level. This is an Office add-in manifest permission, not a Microsoft Graph API scope. No Graph API permissions are needed during deployment.

The default app capabilities for the Excel add-in are:

- Can read and make changes to your document
- Access your profile information such as your name, email address, company name, and preferred language
- Can send data over the Internet

Administrators should review the permissions listed during the consent step of deployment through the M365 admin center integrated apps portal.

Amazon Quick Microsoft Word extension

The Quick extension for Microsoft Word integrates AI-powered assistance directly in your Word document. Users can leverage Quick within Word to draft content, make formatted edits, and perform reviews with track changes and comments enabled.

The Word extension enables users to:

- Generate formatted documents using style guides and templates and Quick's enterprise data and apps.
- Make small- or large-scale edits to your document while maintaining its writing style and structure.
- Format or restructure your documents.
- Redline your documents with track changes and/or comments enabled.

The Quick Word extension is available within Amazon Quick to all eligible users by default and requires no administrative setup for user access if users can access the Microsoft Word app store. Users can search for Amazon Quick in the Microsoft Word app store or visit the [Quick for Word Microsoft store page](#) to add the extension.

Important

- The Amazon Quick Word extension uses generative AI to create and execute code within your Word application sandbox to help you perform tasks within Word. AI can make mistakes and perform inaccurate actions within your Word document.
- Amazon Quick does not use your user data for service improvement or for training its underlying large language models (LLMs).

The following procedures are for IT administrators who want to automatically deploy the Amazon Quick Word extension across their organization on behalf of their users.

3. Click on **Get apps**.
4. Search for "Amazon Quick".
5. Locate the tile for the Amazon Quick in Word and click on **Get it now**.

6. Confirm that you want to add the app.
7. Under **Assign users**, you can choose **Entire organization** or **Specific users/groups** depending on your needs.
8. After selecting the users, review the app's requested permissions and capabilities and click **Next**.
9. Click **Finish Deployment**.

Microsoft Word extension permissions

The Amazon Quick Word extension uses the ReadWriteDocument Office JavaScript API permission level. This is an Office add-in manifest permission, not a Microsoft Graph API scope. No Graph API permissions are needed during deployment.

The default app capabilities for the Word add-in are:

- Can read and make changes to your document
- Access your profile information such as your name, email address, company name, and preferred language
- Can send data over the Internet

Administrators should review the permissions listed during the consent step of deployment through the M365 admin center integrated apps portal.

Amazon Quick Microsoft PowerPoint extension

The Amazon Quick extension for PowerPoint integrates AI-powered assistance directly in your slide deck. Users can leverage Quick within PowerPoint to create presentations, add new slides, and make formatted edits to slides using their Quick enterprise data and apps.

The PowerPoint extension enables users to:

- Create visually appealing and formatted templates using their own templates and brand guidelines.
- Create and edit slides and visuals within PowerPoint using natural language and their Quick enterprise data and apps.
- Make decks presentation ready by streamlining operations such as restructuring presentations, applying transitions, and more.

The Quick PowerPoint extension is available within Amazon Quick to all eligible users by default and requires no administrative setup for user access if users can access the Microsoft PowerPoint app store. Users can search for Amazon Quick in the Microsoft PowerPoint app store or visit the [Quick for PowerPoint Microsoft store page](#) to add the extension.

Important

- The Amazon Quick PowerPoint extension uses generative AI to create and execute code within your PowerPoint application sandbox to help you perform tasks within PowerPoint. AI can make mistakes and perform inaccurate actions within your PowerPoint slide deck.
- Amazon Quick does not use your user data for service improvement or for training its underlying large language models (LLMs).

The following procedures are for IT administrators who want to automatically deploy the Amazon Quick PowerPoint extension across their organization on behalf of their users.

Topics

- [Prerequisites for deploying the Microsoft PowerPoint extension to your organization](#)
- [Deploying the Microsoft PowerPoint extension to your organization](#)
- [Microsoft PowerPoint extension permissions](#)

Prerequisites for deploying the Microsoft PowerPoint extension to your organization

Before configuring access to the Amazon Quick extension to Microsoft PowerPoint, administrators must complete the following steps:

1. Have a Microsoft 365 Business subscription and be a Global Admin or have administrative permissions (specifically `AppCatalog.ReadWrite.All`).
2. Have an Amazon Quick instance.

Deploying the Microsoft PowerPoint extension to your organization

Follow these steps to deploy the extension to your users:

1. Login to M365 admin center.

2. Select **Settings** > **Integrated apps** in the left navigation menu.
3. Click on **Get apps**.
4. Search for "Amazon Quick".
5. Locate the tile for the Amazon Quick in PowerPoint and click on **Get it now**.
6. Confirm that you want to add the app.
7. Under **Assign users**, you can choose **Entire organization** or **Specific users/groups** depending on your needs.
8. After selecting the users, review the app's requested permissions and capabilities and click **Next**.
9. Click **Finish Deployment**.

Microsoft PowerPoint extension permissions

The Amazon Quick PowerPoint extension uses the ReadWriteDocument Office JavaScript API permission level. This is an Office add-in manifest permission, not a Microsoft Graph API scope. No Graph API permissions are needed during deployment.

The default app capabilities for the PowerPoint add-in are:

- Can read and make changes to your document
- Access your profile information such as your name, email address, company name, and preferred language
- Can send data over the Internet

Administrators should review the permissions listed during the consent step of deployment through the M365 admin center integrated apps portal.

Amazon Quick Slack extension

The Quick extension for Slack integrates AI-powered assistance directly into your team communication workflows. Users can access Quick knowledge and capabilities within Slack channels and direct messages without switching between applications.

The Slack extension enables users to:

- Add Amazon Quick as a collaborator using **@Amazon Quick** mentions.
- Get conversation summaries and insights.

- Access organizational knowledge bases and documents directly from Slack channels.
- Generate notes and action items from discussions in Slack threads.
- Get help with data analysis and report generation using uploaded files.

Important

- When Amazon Quick is used in public Slack channels, responses are based on the invoking user's permissions. This may include content that other channel members aren't authorized to access. Carefully evaluate using Amazon Quick in public channels to prevent unintended exposure of sensitive information.
- Amazon Quick does not use your user data for service improvement or for training its underlying large language models (LLMs).

Topics

- [Prerequisites for Slack extension](#)
- [Configure Slack extension access](#)

Prerequisites for Slack extension

Before adding the Amazon Quick Slack Extension, administrators must complete the following requirements:

- Have a paid Slack workspace.
- Have admin access to your Slack workspace.
- Get started with Amazon Quick.
- Your Slack workspace ID (must start with 'T' and be alphanumeric). One way to find your Slack workspace ID is by navigating to your Slack workspace and starting a chat with the Slack Developer Tools app running the `/sdt whoami` command. For more information, see [Locate your Slack URL or ID](#) in the Slack help center.

If you configured the authentication to connect to Amazon Quick with IAM Identity Center, complete the following additional steps:

1. Ensure you have an IAM Identity Center instance enabled on your AWS account.

2. If you are connecting an external IAM provider to IAM Identity Center, ensure that every user under your IAM provider configuration has an email associated with them.
3. If you are using Entra ID, set up SCIM identity propagation between the Microsoft Entra ID instance and IAM Identity Center. For detailed steps, see [Configure SAML and SCIM with Microsoft Entra ID and IAM Identity Center](#).

Configure Slack extension access

As an administrator, you must allow your Amazon Quick Slack extension to connect to your Amazon Quick application environment. You can use the Amazon Quick console to manage extension access configurations.

User attribute mapping

When you configure a Slack extension, user identity is mapped by default using the following attributes:

- **Amazon Quick user attribute** - Email address is used to map Amazon Quick users to their corresponding Slack accounts. The system uses the email address to establish the connection between user identities.
- **Slack user attribute** - User Profile Email is used to match against Slack user accounts. This maps to the email address associated with the user's Slack profile.

These default mappings ensure secure and accurate user identification across both platforms without requiring additional configuration.

Topics

- [Add Slack extension access for accounts using IAM Identity Center](#)
- [Add Slack extension access for accounts using other authentication methods](#)
- [Edit Slack extension access](#)
- [Delete Slack extension access](#)

Add Slack extension access for accounts using IAM Identity Center

Configuring extension access with IAM Identity Center requires completing steps specific to your identity provider (Entra ID or Okta) followed by common setup steps in AWS.

Configure IAM Identity Center with Entra ID

Follow these steps only if you are using IAM Identity Center with Entra ID to set up and configure an Azure tenant on your Microsoft Azure portal:

To set up an Azure tenant

1. In the Azure account, create a new app registration.
 - a. Go to **App registrations**.
 - b. In the **App registrations** screen, choose **New registration**. Under the **Supported account types** option, choose **Accounts in this organizational directory only (Personal use only - Single tenant)**. Once finished, choose **Register**.
 - c. Note the client ID. You will need this later.
 - d. Create a client secret for the app registration and keep note of it. You will need this later.
2. Add callback URLs for each Region in which your Slack extension will be installed.
 - a. Navigate to the app registration's **Authentication** tab.
 - b. Choose **Platform Configurations, Add a platform**.
 - c. Choose **Web**.
 - d. Compose a callback URL using the following format, replacing *your-region* with your Amazon Quick instance Region. The Slack extension supports the following Regions: ap-southeast-2, eu-west-1, us-west-2, and us-east-1.

```
qbs-cell1001.dp.appintegrations.your-region.prod.plato.ai.aws.dev/auth/idc-tti/callback
```
 - e. Insert the callback URL as the redirect URI and choose **Configure** when done.

Follow these steps to configure a Trusted Token Issuer on your IAM Identity Center instance in your AWS Console:

To configure a Trusted Token Issuer

1. Go to your AWS account and navigate to your IAM Identity Center instance.
2. Navigate to **Settings, Authentication**.
3. Choose **Create trusted token issuer**.

4. Add the issuer URL, which should follow this template, where *Tenant ID* refers to your Entra tenant ID:

```
login.microsoftonline.com/Tenant ID/v2.0
```

 Note

The issuer URL should be the OIDC discovery endpoint of your identity without the well-known document URI path. If you include the well-known document URI path, this will not work. See Trusted token issuer configuration settings.

5. Choose **Email** as the Identity Provider attribute and IAM Identity Center attribute.
6. Note the trusted token issuer ARN. You will need this in a later step.

After completing these Entra ID-specific steps, proceed to the [Complete AWS Configuration \(all providers\)](#) section below.

Configure IAM Identity Center with Okta

Follow these steps only if you are using IAM Identity Center with Okta to set up and configure your App Integration in the Okta Admin console:

To set up an Okta Application

1. In your Okta account, create a new Okta App Integration.
 - a. In your Okta Admin console, navigate to **Applications > Applications**.
 - b. Click on **Create App Integration**.
 - c. For the Sign-in method, select **OIDC - OpenID Connect**.
 - d. For the Application type, select **Web Application**.
 - e. Click on **Next**.
 - f. Provide an App integration name.
 - g. Under **Grant type > Core grants**, ensure **Authorization Code** and **Refresh Token** are selected.
 - h. Under **Grant type > Advanced > Other grants**, ensure **Implicit (hybrid)** is selected.
2. Add callback URIs for each Region in which your Slack extension will be installed

- a. Compose a callback URI using the following format, replacing *your-region* with your Amazon Quick instance Region for each region where you wish to configure the extension. The Slack extension supports the following Regions: ap-southeast-2, eu-west-1, us-west-2, and us-east-1.

`qbs-cell001.dp.appintegrations.your-region.prod.plato.ai.aws.dev/auth/idc-tti/callback`
 - b. Under **Sign-in redirect URIs**, click on **Add URI** and paste each of the URIs you generated from the previous step.
3. Provide your organization access to the app:
 - a. Under **Assignments** > **Controlled access**, select the groups in your organization that need to have access.
 - b. Under **Assignments** > **Enable immediate access**, select **Enable immediate access with Federation Broker Mode**.
 - c. Click on **Save**.
 4. Note down the **Client ID** and **Client Secret** for the app integration you just created. You will need this in the next steps.

To configure a Trusted Token Issuer

1. Go to your AWS account and navigate to your IAM Identity Center instance.
2. Navigate to **Settings** > **Authentication**.
3. Choose **Create trusted token issuer**.
4. Add the issuer URL, which should follow this template, where *yourOktaDomain* refers to the okta URL for your organization, which may look like `your-organization.okta.com`:

`https://{yourOktaDomain}/oauth2/default`

Note

The issuer URL should be the OIDC discovery endpoint of your identity without the well-known document URI path. If you include the well-known document URI path, this will not work. See Trusted token issuer configuration settings.

5. Choose **Email** as the Identity Provider attribute and IAM Identity Center attribute.
6. Note the trusted token issuer ARN. You will need this in a later step.

After completing these Okta-specific steps, proceed to the [Complete AWS Configuration \(all providers\)](#) section below.

Complete AWS Configuration (all providers)

Follow these steps to set up permissions on AWS Console:

To set up permissions

1. Navigate to Secrets Manager on AWS console.
2. Choose **Store a new secret**.
3. Choose **Other type of secret** and choose the **Plaintext** tab.
4. Your secret should be in the following format and use the app registration client ID and app registration client secret that you saved from the earlier steps:

```
{
  "client_id": "Your app registration client ID",
  "client_secret": "Your app registration client secret"
}
```

5. Navigate to the secret you just created and save the ARN for later.
6. Now navigate to IAM on AWS console.
7. Choose **Access Management, Roles** in the left navigation bar.
8. Choose **Create role**.
9. Choose **Custom trust policy**.
10. Configure the role to trust our service principal for the relevant Region that you selected when configuring your identity provider app integration by adding the following statement replacing *your-region* with the Region you chose when creating your identity provider app integration:

```
{
  "Version": "2012-10-17",
  "Statement": [
```

```
{
  "Effect": "Allow",
  "Principal": {
    "Service": "your-region.prod.appintegrations.plato.aws.internal"
  },
  "Action": "sts:AssumeRole",
  "Condition": {}
}
```

11. Choose **Next**.
12. Provide a name and description and choose **Create role**.
13. Navigate to the role you just created and choose it.
14. Choose **Add Permissions, Create inline policy**.
15. Choose **JSON**.
16. Configure the role with permissions to read secrets from Secrets Manager and permissions to invoke `sso:DescribeTrustedTokenIssuer` by adding the following statement:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "BasePermissions",
      "Effect": "Allow",
      "Action": [
        "secretsmanager:GetSecretValue",
        "sso:DescribeTrustedTokenIssuer"
      ],
      "Resource": "*"
    }
  ]
}
```

17. Provide a policy name and choose **Create policy**.
18. Copy and save the ARN of the IAM role you created for later. You will need it in the next steps.

Now you can follow these steps to create a new extension access configuration that will allow Amazon Quick to integrate with your Slack environment:

To create an extension access configuration

1. Sign in to the Amazon Quick console.
2. Choose the profile picture icon.
3. From the drop-down menu, choose **Manage account**.
4. Under **Permissions**, choose **Extension access**.
5. Choose **New extension access**.
6. If this is your first time setting up extension access, you are prompted to complete the **Trusted Token Issuer Setup**. Configure the following fields and then choose **Next**:
 - **Trusted Token Issuer ARN** – Enter the trusted token issuer ARN that you noted from the earlier steps.
 - **Aud claim** – Enter the client ID from your app registration (Entra ID) or app integration (Okta) that you saved from the earlier steps.

Note

This is a one-time setup that establishes a trusted identity source for all extensions. Once completed, you won't need to do this again for other extension accesses.

7. Select **Slack**. Then, choose **Next**.
8. Configure the following fields:
 - **Name** - A name for your extension is pre-filled for you. You can edit this and enter a descriptive name for the Slack extension (maximum 512 alphanumeric characters, hyphens allowed but no spaces).
 - **Description (optional)** - A description for your extension is pre-filled for you. You can edit this and enter a new description to provide additional context about this extension configuration (maximum 1000 characters).
 - **Slack Workspace ID** - Enter your Slack workspace identifier. Workspace IDs must start with 'T' and be between 1 and 256 alphanumeric characters.
 - **Secrets Role ARN** - Paste the ARN of the IAM role you created from the previous steps.
 - **Secrets ARN** - Paste the ARN of the Secrets Manager secret you created from the previous steps.
9. Choose **Add** to save the new access configuration.

A success message will open up on the top right of your screen.

10. From the success message, choose **View extensions** to finish installing your extension.

 Note

You can also navigate to the installation screen from **Connections > Extensions** in the Amazon Quick menu.

Once created, this extension access configuration enables authors and other admin in your organization to create and deploy Amazon Quick extensions within your Slack environment.

 Note

For your end users to begin using your Slack extension, an admin or author must finish deploying a extension after you configure extension access. Notify your authors that they can view, edit, and complete installation of this extension under **Extensions** in the left navigation once it has been shared. To learn how to do this see Installing your Slack extension in the Slack extension author guide.

Add Slack extension access for accounts using other authentication methods

Follow these steps to create a new extension access configuration that will allow Amazon Quick to integrate with your Slack environment.

1. Sign in to the Amazon Quick console.
2. Choose the profile picture icon.
3. From the drop-down menu, select **Manage account**.
4. Under **Permissions**, select **Extension access**.
5. Choose **New extension access**.
6. Select Slack, then, **Next**.
7. Configure the following fields:

- **Name** - A name for your extension is pre-filled for you. You can edit this and enter a descriptive name for the Slack extension (maximum 512 alphanumeric characters, hyphens allowed but no spaces).
 - **Description** (optional) - A description for your extension is pre-filled for you. You can edit this and enter a new description to provide additional context about this extension configuration (maximum 1000 characters).
 - **Slack Workspace ID** - Enter your Slack workspace identifier. Workspace ID must start with T and be between 1 and 256 alphanumeric characters long.
8. Select **Add** to save the new access configuration.

A success message will open up on the top right of your screen.

9. From the success message, select **View extensions** to finish installing your extension.

 Note

You can also navigate to the installation screen from **Connections > Extensions** in the Amazon Quick menu.

Once created, this extension access configuration enables authors and other admins in your organization to deploy Amazon Quick Slack extensions in their workspace.

 Note

For your end users to begin using your Slack extension, an admin or author must finish deploying a extension after you configure extension access. Notify your authors that they can view, edit, and complete installation of this extension under **Extensions** in the left navigation once it has been shared. To learn how to do this see [Installing your Slack extension in the Slack extension author guide](#).

Edit Slack extension access

Use these steps to modify the configuration settings of an existing Slack extension access.

1. Sign in to the Amazon Quick console.
2. Choose the profile picture icon.

3. From the drop-down menu, select **Manage account**.
4. Under **Permissions**, select **Extension access**.
5. Select the three dot menu icon for the Slack Extension you need to edit.
6. Select **Edit**.
7. Edit the configuration as required and select **Save** to confirm the changes.

Your changes to the Slack extension access configuration are saved and will take effect immediately.

Delete Slack extension access

Follow these steps to permanently remove a Slack extension access configuration. This action cannot be undone.

1. Sign in to the Amazon Quick console.
2. Choose the profile picture icon.
3. From the drop-down menu, select **Manage account**.
4. Under **Permissions**, select **Extension access**.
5. Select the three dot menu icon for the Slack Extension you need to delete.
6. Select **Delete**.
7. Enter the word, "confirm", and select **DELETE**.

Note

Deleting a extension access removes access for all users in your Slack workspace and deletes all extensions created for Slack. If delete extension access fails, the admin must switch to the author view and delete the Slack extensions that are using the configured extension access before returning to delete the extension access.

With Slack extension access configured, your team can now use **@Amazon Quick** mentions in channels and direct messages to access AI assistance and organizational knowledge directly within their Slack workspace.

Amazon Quick Microsoft Teams extension

The Quick extension for Microsoft Teams integrates AI-powered assistance directly into your team communication workflows. Users can mention @Amazon Quick in conversations to access company knowledge, use configured action connectors, and get contextual assistance without leaving their Teams environment.

The Teams extension enables users to:

- Mention **@Amazon Quick** in conversations in Teams channels to add it as a collaborator.
- Use actions from connectors configured in Amazon Quick.
- Access any company knowledge sources added to your Amazon Quick instance from within Microsoft Teams.

Important

- The Amazon Quick customer integrating Microsoft Teams must have a paid Microsoft Teams organization with an *M365 subscription for their organization*.
- Amazon Quick does not use your user data for service improvement or for training its underlying large language models (LLMs).

Topics

- [Prerequisites for Microsoft Teams extension](#)
- [Microsoft Teams extension permissions](#)
- [Configure Microsoft Teams extension access](#)

Prerequisites for Microsoft Teams extension

Before configuring access for the Amazon Quick extension to Microsoft Teams, administrators must complete the following steps:

1. Have a Microsoft 365 Business subscription and be a Global Admin or have administrative permissions (specifically `AppCatalog.ReadWrite.All`).
2. Have a Amazon Quick instance.

3. Your Microsoft 365 tenant ID. You can find this by going to the Azure portal > **Azure Active Directory** > **Properties**, or by using PowerShell. For detailed steps, see [How to find your tenant ID - Microsoft Entra](#) in the Microsoft Learn portal.

If you configured the authentication to connect to Amazon Quick with IAM Identity Center, complete the following additional steps:

1. Ensure you have an IAM Identity Center instance enabled on your AWS account.
2. If you are connecting an external IAM provider to IAM Identity Center, ensure that every user under your IAM provider configuration has an email associated with them.
3. If you are using Entra ID, set up SCIM identity propagation between the Microsoft Entra ID instance and IAM Identity Center. For detailed steps, see [Configure SAML and SCIM with Microsoft Entra ID and IAM Identity Center](#).

Microsoft Teams extension permissions

The Amazon Quick Microsoft Teams extension uses Microsoft's Resource-Specific Consent (RSC) framework. The bot only gets access to the specific meetings and chats where it is installed — not tenant-wide access to all Teams data. These permissions are granted automatically when the app is added to a meeting or chat; no additional admin action is needed.

The following table lists the RSC permissions used by the Teams extension.

Permission	Purpose	Feature
ChatMessage.Read.Chat	Read chat messages for AI assistant context	General chat assistant
ChatMember.Read.Chat	Resolve attendee emails and identify the meeting organizer for summary delivery	Meeting Summary
OnlineMeeting.ReadBasic.Chat	Read meeting name, schedule, and organizer info	Meeting Summary
OnlineMeetingTranscript.Read.Chat	Retrieve transcripts after a meeting ends	Meeting Summary

Permission	Purpose	Feature
OnlineMeetingParticipant.Read.Chat	Read participant join/leave times and roles	Meeting Summary
ChannelMessage.Read.Group	Read thread context when the bot is @mentioned in a channel	General chat assistant
ChannelMeeting.ReadBasic.Group	Read basic properties of channel meetings	Meeting Summary
ChannelMeetingTranscript.Read.Group	Retrieve transcripts of channel meetings	Meeting Summary
ChannelMeetingParticipant.Read.Group	Read participant info for channel meetings	Meeting Summary

Installation permission (revoke after install)

The following permission is automatically granted during app installation and must be revoked afterward. It is not required for ongoing operation.

Permission	Purpose	Required admin action
AppCatalog.ReadWrite.All	Read and write to all app catalogs (used during installation only)	Revoke after installation via Microsoft Entra > Enterprise Applications > Permissions

Important

After installation, go to Microsoft Entra > **Enterprise Applications**, find the app starting with "qbs" and ending with "teams", navigate to **Permissions**, and revoke AppCatalog.ReadWrite.All.

Where to review permissions

Use the following locations to review permissions for the Microsoft Teams extension:

- **RSC Permissions:** Teams Admin Center > **Teams apps** > **Manage apps** > **Amazon Quick** > **Permissions**
- **Application Permissions:** Microsoft Entra > **Enterprise Applications** > find the app starting with "qbs" and ending with "teams" > **Permissions**

Configure Microsoft Teams extension access

As an administrator, you must allow the Amazon Quick Microsoft Teams to connect to your Amazon Quick application environment. You can use the Amazon Quick console to manage extension access configurations.

User attribute mapping

When you configure a Microsoft Teams extension, user identity is mapped by default using the following attributes:

- **Amazon Quick user attribute** - Email address is used to map Amazon Quick users to their corresponding Microsoft 365 accounts. The system uses the email address to establish the connection between user identities.
- **M365 Office add-in user attribute** - User Principal Name (UPN) is used to match against Microsoft 365 user accounts. Users need to use the User Principal Name (UPN) to sign in to Microsoft 365. Email address that works on both cloud and on-premise systems.

These default mappings ensure secure and accurate user identification across both platforms without requiring additional configuration.

Topics

- [Add Microsoft Teams extension access for accounts using IAM Identity Center](#)
- [Add Microsoft Teams extension access for accounts using other authentication methods](#)

- [Delete Microsoft Teams extension access](#)

Add Microsoft Teams extension access for accounts using IAM Identity Center

Configuring extension access with IAM Identity Center requires completing steps specific to your identity provider (for example, Entra ID or Okta) followed by common setup steps in AWS.

Configure IAM Identity Center with Entra ID

Follow these steps only if you are using IAM Identity Center with Entra ID to set up and configure an Azure tenant on your Microsoft Azure portal:

To set up an Azure tenant

1. In the Azure account, create a new app registration.
 - a. Go to **App registrations**.
 - b. In the **App registrations** screen, choose **New registration**. Under the **Supported account types** option, choose **Accounts in this organizational directory only (Personal use only - Single tenant)**. Once finished, choose **Register**.
 - c. Note the client ID. You will need this later.
 - d. Create a client secret for the app registration. Copy and save the secret's **Value** attribute. You need it later. This value is only shown once and cannot be retrieved after you leave the page.
2. Add callback URLs for each Region in which your Teams extension will be installed.
 - a. Navigate to the app registration's **Authentication** tab.
 - b. Choose **Platform Configurations, Add a platform**.
 - c. Choose **Web**.
 - d. Compose a callback URL using the following format, replacing *your-region* with your Amazon Quick instance Region. The Teams extension supports the following Regions: ap-southeast-2, eu-west-1, us-west-2, and us-east-1.

`qbs-cell001.dp.appintegrations.your-region.prod.plato.ai.aws.dev/auth/idc-tti/callback`
 - e. Insert the callback URL as the redirect URI and choose **Configure** when done.

Follow these steps to configure a Trusted Token Issuer on your IAM Identity Center instance in your AWS Console:

To configure a Trusted Token Issuer

1. Go to your AWS account and navigate to your IAM Identity Center instance.
2. Navigate to **Settings, Authentication**.
3. Choose **Create trusted token issuer**.
4. Add the issuer URL, which should follow this template, where *Tenant ID* refers to your Entra tenant ID:

```
login.microsoftonline.com/Tenant ID/v2.0
```

Note

The issuer URL should be the OIDC discovery endpoint of your identity without the well-known document URI path. If you include the well-known document URI path, this will not work. See Trusted token issuer configuration settings.

5. Choose **Email** as the Identity Provider attribute and IAM Identity Center attribute.
6. Note the trusted token issuer ARN. You will need this in a later step.

After completing these Entra ID-specific steps, proceed to the [Complete AWS Configuration \(all providers\)](#) section below.

Configure IAM Identity Center with Okta

Follow these steps only if you are using IAM Identity Center with Okta to set up and configure your App Integration in the Okta Admin console:

To set up an Okta Application

1. In your Okta account, create a new Okta App Integration.
 - a. In your Okta Admin console, navigate to **Applications > Applications**.
 - b. Click on **Create App Integration**.
 - c. For the Sign-in method, select **OIDC - OpenID Connect**.
 - d. For the Application type, select **Web Application**.
 - e. Click on **Next**.
 - f. Provide an App integration name.

- g. Under **Grant type** > **Core grants**, ensure **Authorization Code** and **Refresh Token** are selected.
 - h. Under **Grant type** > **Advanced** > **Other grants**, ensure **Implicit (hybrid)** is selected.
 2. Add callback URIs for each Region in which your Teams extension will be installed
 - a. Compose a callback URI using the following format, replacing *your-region* with your Amazon Quick instance Region for each region where you wish to configure the extension. The Teams extension supports the following Regions: ap-southeast-2, eu-west-1, us-west-2, and us-east-1.

```
qbs-cell001.dp.appintegrations.your-region.prod.plato.ai.aws.dev/auth/idc-tti/callback
```
 - b. Under **Sign-in redirect URIs**, click on **Add URI** and paste each of the URIs you generated from the previous step.
3. Provide your organization access to the app:
 - a. Under **Assignments** > **Controlled access**, select the groups in your organization that need to have access.
 - b. Under **Assignments** > **Enable immediate access**, select **Enable immediate access with Federation Broker Mode**.
 - c. Click on **Save**.
4. Note down the **Client ID** and **Client Secret** for the app integration you just created. You will need this in the next steps.

To configure a Trusted Token Issuer

1. Go to your AWS account and navigate to your IAM Identity Center instance.
2. Navigate to **Settings** > **Authentication**.
3. Choose **Create trusted token issuer**.
4. Add the issuer URL, which should follow this template, where *yourOktaDomain* refers to the okta URL for your organization, which may look like `your-organization.okta.com`:

```
https://{yourOktaDomain}/oauth2/default
```

Note

The issuer URL should be the OIDC discovery endpoint of your identity without the well-known document URI path. If you include the well-known document URI path, this will not work. See Trusted token issuer configuration settings.

5. Choose **Email** as the Identity Provider attribute and IAM Identity Center attribute.
6. Note the trusted token issuer ARN. You will need this in a later step.

After completing these Okta-specific steps, proceed to the [Complete AWS Configuration \(all providers\)](#) section below.

Complete AWS Configuration (all providers)

Follow these steps to set up permissions on AWS Console:

To set up permissions

1. Navigate to Secrets Manager on AWS console.
2. Choose **Store a new secret**.
3. Choose **Other type of secret** and choose the **Plaintext** tab.
4. Your secret should be in the following format and use the app registration client ID and app registration client secret that you saved from the earlier steps:

```
{
  "client_id": "Your app registration client ID",
  "client_secret": "Your app registration client secret value"
}
```

5. Navigate to the secret you just created and save the ARN for later.
6. Now navigate to IAM on AWS console.
7. Choose **Access Management, Roles** in the left navigation bar.
8. Choose **Create role**.
9. Choose **Custom trust policy**.
10. Configure the role to trust our service principal for the relevant Region that you selected when configuring your identity provider app integration by adding the following statement

replacing *your-region* with the Region you chose when creating your identity provider app integration:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "your-region.prod.appintegrations.plato.aws.internal"
      },
      "Action": "sts:AssumeRole",
      "Condition": {}
    }
  ]
}
```

11. Choose **Next**.
12. Provide a name and description and choose **Create role**.
13. Navigate to the role you just created and choose it.
14. Choose **Add Permissions, Create inline policy**.
15. Choose **JSON**.
16. Configure the role with permissions to read secrets from Secrets Manager and permissions to invoke `sso:DescribeTrustedTokenIssuer` by adding the following statement:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "BasePermissions",
      "Effect": "Allow",
      "Action": [
        "secretsmanager:GetSecretValue",
        "sso:DescribeTrustedTokenIssuer"
      ],
      "Resource": "*"
    }
  ]
}
```

```
}
```

17. Provide a policy name and choose **Create policy**.
18. Copy and save the ARN of the IAM role you created for later. You will need it in the next steps.

Now you can follow these steps to create a new extension access configuration that will allow Amazon Quick to integrate with your Microsoft Teams environment:

To create an extension access configuration

1. Sign in to the Amazon Quick console.
2. Choose the profile picture icon.
3. From the drop-down menu, choose **Manage account**.
4. Under **Permissions**, choose **Extension access**.
5. Choose **New extension access**.
6. If this is your first time setting up extension access, you are prompted to complete the **Trusted Token Issuer Setup**. Configure the following fields and then choose **Next**:
 - **Trusted Token Issuer ARN** – Enter the trusted token issuer ARN that you noted from the earlier steps.
 - **Aud claim** – Enter the client ID from your app registration (Entra ID) or app integration (Okta) that you saved from the earlier steps.

Note

This is a one-time setup that establishes a trusted identity source for all extensions. Once completed, you won't need to do this again for other extension accesses.

7. Select **Microsoft Teams**. Then, choose **Next**.
8. Configure the following fields:
 - **Name** - A name for your extension is pre-filled for you. You can edit this and enter a descriptive name for the Teams extension (maximum 512 alphanumeric characters, hyphens allowed but no spaces).

- **Description (optional)** - A description for your extension is pre-filled for you. You can edit this and enter a new description to provide additional context about this extension configuration (maximum 1000 characters).
 - **M365 tenant ID** - Enter your Microsoft 365 tenant identifier (must be 36 characters).
 - **Secrets Role ARN** - Paste the ARN of the IAM role you created from the previous steps.
 - **Secrets ARN** - Paste the ARN of the Secrets Manager secret you created from the previous steps.
9. Choose **Add** to save the new access configuration.

A success message will open up on the top right of your screen.

10. From the success message, choose **View extensions** to finish installing your extension.

 Note

You can also navigate to the installation screen from **Connections > Extensions** in the Amazon Quick menu.

Once created, this extension access configuration enables authors and other admin in your organization to create and deploy Amazon Quick extensions within your Microsoft Teams environment.

 Note

For your end users to begin using your Microsoft Teams extension, an admin or author must finish deploying a extension after you configure extension access. Notify your authors that they can view, edit, and complete installation of this extension under **Extensions** in the left navigation once it has been shared. To learn how to do this see Installing your Microsoft Teams extension in the Microsoft Teams extension author guide.

Add Microsoft Teams extension access for accounts using other authentication methods

Follow these steps to create a new extension access configuration that will allow Amazon Quick to integrate with your Microsoft Teams environment.

1. Sign in to the Amazon Quick console.

2. Choose the profile picture icon.
3. From the drop-down menu, select **Manage account**.
4. Under **Permissions**, select **Extension access**.
5. Choose **New extension access**.
6. Select **Microsoft Teams**, then, **Next**.
7. Configure the following fields:
 - **Name** - A name for your extension is pre-filled for you. You can edit this and enter a descriptive name for the Teams extension (maximum 512 alphanumeric characters, hyphens allowed but no spaces).
 - **Description** (optional) - A description for your extension is pre-filled for you. You can edit this and enter a new description to provide additional context about this extension configuration (maximum 1000 characters).
 - **M365 tenant ID** - Enter your Microsoft 365 tenant identifier (must be 36 characters).
8. Select **Add** to save the new access configuration.

A success message will open up on the top right of your screen.

9. From the success message, select **View extensions** to finish installing your extension.

 Note

You can also navigate to the installation screen from **Connections > Extensions** in the Amazon Quick menu.

Once created, this extension access configuration enables authors and other admins in your organization to deploy your Microsoft Teams Amazon Quick extension within your Microsoft Teams environment.

 Note

For your end users to begin using your Microsoft Teams extension, an admin or author must finish deploying a extension after you configure extension access. Notify your authors that they can view, edit, and complete installation of this extension under **Extensions** in the left

navigation once it has been shared. To learn how to do this see [Installing your Microsoft Teams extension in the Microsoft Teams extension author guide](#).

Edit Microsoft Teams extension access

Use these steps to modify the configuration settings of an existing Microsoft Teams extension access.

1. Sign in to the Amazon Quick console.
2. Choose the profile picture icon.
3. From the drop-down menu, select **Manage account**.
4. Under **Permissions**, select **Extension access**.
5. Select the three dot menu icon for the Microsoft Teams extension you need to edit.
6. Select **Edit**.
7. Edit the configuration as required and select **Save** to confirm the changes.

Your changes to the Microsoft Teams extension access configuration are saved and will take effect immediately.

Delete Microsoft Teams extension access

Follow these steps to permanently remove a Microsoft Teams extension access configuration. This action cannot be undone.

1. Sign in to the Amazon Quick console.
2. Choose the profile picture icon.
3. From the drop-down menu, select **Manage account**.
4. Under **Permissions**, select **Extension access**.
5. Select the three dot menu icon for the Microsoft Teams Extension you need to delete.
6. Select **Delete**.
7. Enter the word, "confirm", and select **DELETE**.

Note

Deleting a extension access removes access for all users in your M365 tenant and deletes all extensions created for Teams. If delete extension access fails, the admin must switch to the author view and delete the Teams extensions that are using the configured extension access before returning to delete the extension access.

With Microsoft Teams extension access configured, your team can now use **@Quick** mentions in conversations to access AI assistance, company knowledge, and connectors directly within their Teams environment.

Custom permissions

Applies to

Applies to: Enterprise Edition

Intended audience: Administrators and Amazon Quick developers

In Enterprise edition, you can use custom permissions profiles to restrict the capabilities and features that people can access in Amazon Quick. Custom permissions is a scope-down policy. It can only restrict what a user has access to based on the default set of capabilities available to their role. It cannot be used to grant capabilities that a user does not already have.

You can configure custom permissions at the account, role (admin, author, reader), and user levels for all identity types in Quick. You can assign custom permissions profiles to users and roles directly in the Amazon Quick admin console, or by using the Amazon Quick API and AWS Command Line Interface. The admin console also provides a Check permissions feature that lets you verify which profile is active for any user and at which level (user, role, or account) it applies.

Permissions precedence

If a user has custom permissions assigned at multiple levels, Quick evaluates them in the following order of precedence. The most specific level wins.

1. **User-level** – Custom permissions assigned directly to a user take highest priority.
2. **Role-level** – Custom permissions assigned to a role (Admin, Author, Reader) apply to all users in that role unless overridden by a user-level assignment.

3. **Account-level** – Custom permissions assigned at the account level apply to all users unless overridden by a role-level or user-level assignment.

The first match wins. A user with a user-level allow-by-default profile is not subject to an account-level Deny by Default profile. Assign Deny by Default profiles at the appropriate level for your requirements.

 Tip

For an in-depth explanation of using custom permissions to establish enterprise controls in Quick, see [Establishing enterprise governance in Amazon Quick using custom permissions](#) on the AWS Business Intelligence Blog.

The following limitations apply to custom permissions.

- You can't grant permissions that are above a user's default role. For example, if a user has reader access, you can't grant permissions for that user to edit dashboards.
- To customize user or role permissions, you need to be a Quick administrator with the following IAM permissions:
 - `quicksight:CreateCustomPermissions`
 - `quicksight>DeleteCustomPermissions`
 - `quicksight:DescribeCustomPermissions`
 - `quicksight:ListCustomPermissions`
 - `quicksight:UpdateCustomPermissions`
 - `quicksight>DeleteAccountCustomPermission`
 - `quicksight>DeleteRoleCustomPermission`
 - `quicksight>DeleteUserCustomPermission`
 - `quicksight:DescribeAccountCustomPermission`
 - `quicksight:DescribeRoleCustomPermission`
 - `quicksight:ListCustomPermissionAssignments`
 - `quicksight:UpdateAccountCustomPermission`
 - `quicksight:UpdateRoleCustomPermission`
 - `quicksight:UpdateUserCustomPermission`

You can create custom permission profiles to restrict access to any combination of the following features. Parent capabilities let you restrict an entire asset's feature set. When you deny a parent capability, all of its child features are also denied. The reverse isn't true: denying every child feature doesn't deny the parent capability. This is because a parent can control functionality that isn't exposed as a separate child feature. To restrict a capability completely, deny the parent.

 **Parent capability overrides child features**

You can't allow an individual child feature while its parent capability is denied. If you set a parent capability to DENY and one of its child features to ALLOW, the child feature remains restricted. Quick accepts this combination without an error, so verify the result in the console after you apply it. To allow specific child features, leave the parent capability allowed and deny only the child features you want to restrict.

Features that show **Not applicable** in the **Parent capability** column have no parent capability. Restrict them individually, or restrict their whole category. For more information, see [the section called “Deny by Default”](#).

Quick capabilities and features

The following tables list the capabilities and features that you can restrict with custom permissions profiles. Capabilities are organized into four groups that match the console layout.

The **Badge** column indicates the governance category for each capability. **AI** means the capability belongs to the AI governance category, which is the category that you can restrict wholesale with Deny by Default. **Contains AI** means the parent capability is not itself in the AI category but has children that are.

AI capabilities

Use this group to control access to AI-powered features such as natural language Q&A, executive summaries, anomaly detection, and AI-generated insights.

Feature	Amazon Quick behavior	Badge	Parent capability
Apps	Restricts all app capabilities, including creating, updating, sharing, and using apps.	AI	Not applicable

Feature	Amazon Quick behavior	Badge	Parent capability
Access apps native data store when using existing apps	Restricts apps from accessing their native data store when users run existing apps.	AI	Apps
Create and update apps	Users can't create or update apps.	AI	Apps
Invoke AI inference when using existing apps	Restricts apps from invoking AI inference when users run existing apps.	AI	Apps
Share apps	Users can't share apps with other users. Apps that were previously shared remain accessible to those users.	AI	Apps
Automate	Restricts access to Automate. Users can't create, update, or run automations.	AI	Not applicable
Chat agents	Users can't view or access any chat agents. The agent library and navigation are hidden.	AI	Not applicable
Create chat agents	Users can't create new chat agents.	AI	Chat agents
Share chat agents	Users can't share chat agents with other users. Chat agents that were previously shared remain accessible to those users.	AI	Chat agents
Extensions	Restricts access to Quick through all browser and Microsoft Office extensions.	AI	Not applicable

Feature	Amazon Quick behavior	Badge	Parent capability
Browser extension	Prevents access to Quick through the browser extension for Chrome, Firefox, and Edge.	AI	Extensions
Excel extension	Prevents access to Quick through the Microsoft Excel add-in.	AI	Extensions
Outlook extension	Prevents access to Quick through the Microsoft Outlook add-in.	AI	Extensions
PowerPoint extension	Prevents access to Quick through the Microsoft PowerPoint add-in.	AI	Extensions
Word extension	Prevents access to Quick through the Microsoft Word add-in.	AI	Extensions
Flows	Restricts all Flows capabilities, including creating, sharing, and running flows.	AI	Not applicable
(Preview) Enable UI agent to perform browser tasks	Restricts the Flows UI agent from performing browser tasks.	AI	Flows
All eligible users can review and approve flow sharing requests	Restricts which users can review and approve flow sharing requests.	AI	Flows
Allow creators to share without approval	Creators can't share flows without approval.	AI	Flows
Enable Bedrock model usage in General knowledge step for output refinement	Restricts usage of Bedrock models.	AI	Flows

Feature	Amazon Quick behavior	Badge	Parent capability
Quick desktop	Restricts all Quick desktop capabilities.	AI	Not applicable
Automate browser actions	Restricts Quick desktop from automating browser actions.	AI	Quick desktop
Build and manage engrams	Users can't build or manage engrams in Quick desktop.	AI	Quick desktop
Create and access knowledge memory	Users can't create or access knowledge memory in Quick desktop.	AI	Quick desktop
Execute code locally	Restricts Quick desktop from running code locally.	AI	Quick desktop
Generate images with AI	Users can't generate images with AI in Quick desktop.	AI	Quick desktop
Manage agents	Users can't manage agents in Quick desktop.	AI	Quick desktop
Manage tasks	Users can't manage tasks in Quick desktop.	AI	Quick desktop
Receive chat notifications	Restricts chat notifications in Quick desktop.	AI	Quick desktop
Use coding agents (ACP)	Users can't use coding agents (ACP) in Quick desktop.	AI	Quick desktop
Research	Restricts access to Research.	AI	Not applicable
Skills	Restricts access to skills, including sharing skills.	AI	Not applicable
Share skills with individuals	Users can't share skills with individuals.	AI	Skills

Feature	Amazon Quick behavior	Badge	Parent capability
Spaces	Restricts all Spaces capabilities, including creating and sharing spaces.	AI	Not applicable
Create spaces	Users can't create new spaces. Existing spaces remain accessible and unchanged.	AI	Spaces
Share spaces	Users can't share spaces with other users. Spaces that were previously shared remain accessible to those users.	AI	Spaces
Triggers	Restricts all trigger capabilities.	AI	Not applicable
Inbound email triggers	Users can't create or use inbound email triggers.	AI	Triggers
Quick event triggers	Users can't create or use Quick event triggers.	AI	Triggers
Schedule triggers	Users can't create or use schedule triggers.	AI	Triggers
Use internet to enhance results	Restricts usage of web-based search in Chat agents and Research.	AI	Not applicable

BI capabilities

Use this group to control creation and management of core business intelligence assets: dashboards, analyses, datasets, SPICE capacity, and scheduled reports.

Feature	Amazon Quick behavior	Badge	Parent capability
Analyses	Restricts all analysis capabilities.	Contains AI	Not applicable
Build calculation with AI	Users can't build calculated fields with AI.	AI	Analyses
Edit visual with AI	Users can't edit visuals with AI.	AI	Analyses
Generate analyses	Users can't generate analyses with AI.	AI	Analyses
Sharing analyses	Access to the Share option on the File menu is disabled for analyses.	Not applicable	Analyses
Adding or running anomaly detection	Access to the Add anomaly to sheet option on the Insights menu is disabled for analyses. Users can't add anomaly detection to sheets.	AI	Not applicable
Content within scheduled email reports	Restricts including content within scheduled email reports.	Not applicable	Not applicable
Creating or updating scheduled email reports	Restricts creating or updating scheduled email reports.	Not applicable	Not applicable
Creating or updating themes	Users can't create new custom themes or edit existing themes. Users can still view or apply existing themes.	Not applicable	Not applicable
CSV attachments in scheduled email reports	Restricts including CSV attachments in scheduled email reports.	Not applicable	Not applicable

Feature	Amazon Quick behavior	Badge	Parent capability
Dashboards	Restricts all dashboard capabilities.	Contains AI	Not applicable
Create executive summary	Users can't create executive summaries with AI for dashboards.	AI	Dashboards
Sharing dashboards	Access to the share icon on the navigation menu is disabled for dashboards.	Not applicable	Dashboards
Subscribing to scheduled email reports	Users can't subscribe to scheduled email reports.	Not applicable	Dashboards
Creating or updating all datasets	Access to creating or updating all datasets is disabled.	Not applicable	Not applicable
Creating or updating only SPICE datasets	Access to creating or updating SPICE datasets is disabled.	Not applicable	Creating or updating all datasets
Sharing datasets	Access to sharing datasets is disabled.	Not applicable	Not applicable
Excel attachments in scheduled email reports	Restricts including Excel attachments in scheduled email reports.	Not applicable	Not applicable
Export sheet to PDF	Access to the Export to PDF option on the File menu is disabled for analyses. Access to the Generate PDF option on the Export menu is disabled for dashboards.	Not applicable	Not applicable

Feature	Amazon Quick behavior	Badge	Parent capability
Export visual to CSV	Access to the Export to CSV option on the actions menu for each visual is disabled for both analyses and dashboards.	Not applicable	Not applicable
Export visual to Excel	Access to the Export to Excel option on the actions menu for each table is disabled for both analyses and dashboards.	Not applicable	Not applicable
PDF attachments in scheduled email reports	Restricts including PDF attachments in scheduled email reports.	Not applicable	Not applicable
Print sheet	Access to the Print option on the File menu is disabled for analyses. Access to the Print option on the Export menu is disabled for dashboards.	Not applicable	Not applicable
Scenarios	Restricts access to scenarios.	AI	Not applicable
Managing shared folders	Restricts creating, updating, deleting, and viewing shared folders, adding assets to shared folders, and sharing folders. Doesn't prevent inheriting access to assets shared through folder membership.	Not applicable	Not applicable
Creating shared folders	Restricts creating shared folders.	Not applicable	Managing shared folders

Feature	Amazon Quick behavior	Badge	Parent capability
Renaming shared folders	Restricts renaming shared folders.	Not applicable	Managing shared folders
Stories	Restricts access to stories.	AI	Not applicable
Creating or updating threshold alerts	Users can't create or update threshold alerts.	Not applicable	Not applicable
Topics	Restricts access to topics.	AI	Not applicable
Viewing account SPICE capacity	Restricts retrieving the account's SPICE capacity.	Not applicable	Not applicable

Connectors

Use this group to control data source connections, including adding, editing, and removing third-party integrations such as Salesforce, Google Sheets, and databases.

Feature	Amazon Quick behavior	Badge	Parent capability
Actions	Restricts all connector capabilities.	AI	Not applicable
Creating or updating all data sources	Access to creating or updating all data sources is disabled.	Not applicable	Not applicable
Sharing data sources	Access to sharing data sources is disabled.	Not applicable	Not applicable
Knowledge base	Restricts all knowledge base capabilities.	AI	Not applicable

Feature	Amazon Quick behavior	Badge	Parent capability
Creating or updating all knowledge bases	Users can't create or update knowledge bases.	AI	Knowledge base
Share all knowledge bases	Users can't share knowledge bases with other users.	AI	Knowledge base

Connector features

In addition to the features listed in the preceding sections, you can restrict access to individual connectors. Each connector supports the following permissions:

- **Create and Update action** – Restricts the ability to create or update actions for the connector.
- **Share action** – Restricts the ability to share actions for the connector.
- **Use action** – Restricts the ability to use actions for the connector.

These permissions are available under **Actions**, in the **Connectors** group of the **Capabilities & features** section. For a list of available connectors, see [Connectors](#).

Knowledge base connectors

You can restrict access to individual knowledge base connectors. Each knowledge base connector supports the following permissions:

- **Create and Update** – Restricts the ability to create or update knowledge bases for the connector.
- **Share** – Restricts the ability to share knowledge bases for the connector.
- **Use** – Restricts the ability to use knowledge bases for the connector.

These permissions are available under **Knowledge base**, in the **Connectors** group of the **Capabilities & features** section. For a list of available knowledge base connectors, see [Knowledge bases](#).

Administration

Use this group to control account-level settings, including user management, permission sets, billing, audit logs, and governance policies.

Feature	Amazon Quick behavior	Badge	Parent capability
Allow users to upgrade or request upgrades	Users can't upgrade their own role or request a role upgrade.	Not applicable	Not applicable

Creating custom permissions profiles

Custom permissions profiles can be created for Amazon Quick accounts that are integrated with IAM Identity Center, Active Directory, or for Quick accounts that have Quick managed users. The identity type that an Quick account uses determines the way an Quick admin configures a custom permissions profile.

Creating or editing a custom permissions profile (Quick console)

To create a custom permissions profile

1. Open the [Quick console](#).
2. Choose **Manage Quick**.
3. In the left navigation, choose **Permissions**, and then choose **Custom permissions**.
4. On the **Custom permissions** page, choose **Create profile**.
5. For **Profile name**, enter a descriptive name for the profile.
6. (Optional) For **Description**, enter a description.
7. (Optional) To restrict a whole capability category, turn on the corresponding toggle in the **Restrict capabilities** section – for example, **Restrict AI capabilities**. Quick restricts all capabilities in that category for users assigned to this profile, including capabilities that it launches later. Allow any capabilities in the category that your users need in the **Capabilities & features** section. For more information, see [the section called “Deny by Default”](#).
8. In the **Capabilities & features** section, choose which capabilities to restrict. Capabilities are organized into four groups: **AI capabilities**, **BI capabilities**, **Connectors**, and **Administration**. Expand a capability to view and configure its individual features. Review the preview panel on the right to see the effect of your selections.
 - To restrict an entire group of features, select the parent capability.
 - To restrict specific features, expand the parent capability and select only the features you want to restrict.

9. Choose **Create**.

Important

Test custom permissions configurations in a development or staging account before applying them to production users to verify the behavior matches your expectations.

After you create the profile, Quick takes you to the assignment page where you can assign it to users, roles, or the account. For more information, see [the section called “Assign profiles”](#).

To edit an existing custom permissions profile

1. On the **Custom permissions** page, locate the profile you want to edit.
2. Choose the actions menu next to the profile, and then choose **Edit**.
3. Make your changes to the profile configuration, including the profile name, Deny by Default settings, and capability restrictions.
4. Choose **Update** to save your changes.

Creating a custom permissions profile (AWS CLI)

Before you begin, you need to set up and configure the AWS CLI. For more information about installing the AWS CLI, see [Install or update the latest version of the AWS CLI](#) and [Configure the AWS CLI](#) in the AWS Command Line Interface User guide.

Use the latest CLI version

Use the latest version of the AWS Command Line Interface. Quick adds capability identifiers to the AWS Command Line Interface as it releases new capabilities. If you receive Unknown parameter in Capabilities for a capability that appears in the console, update the AWS Command Line Interface and try again.

The following example creates a custom permissions profile with ExportToCsv and ExportToPdf denied.

```
aws quicksight create-custom-permissions \
```

```
--aws-account-id AWSACCOUNTID \  
--custom-permissions-name PERMISSIONNAME \  
--capabilities '{"ExportToCsv": "DENY", "ExportToPdf": "DENY"}'
```

Assigning custom permissions profiles

After you create a custom permissions profile, you can assign it to users, roles, or accounts.

Users with sufficient permissions can also use the [AWS::QuickSight::CustomPermissions](#) CloudFormation resource to manage Amazon Quick custom permissions profiles.

Assigning a custom permissions profile (Quick console)

You can assign a custom permissions profile to specific users, roles, or to the entire account.

Assigning a profile replaces any existing assignment at that level. A user, role, or account can only have one active custom permissions profile at a time.

Note

If a user or role already has a custom permissions profile assigned, the new assignment replaces the previous one. The original profile is no longer active for that user or role. Similarly, if an account-level profile is already active, Quick displays a warning before you replace it.

To assign a custom permissions profile

1. Open the [Quick console](#).
2. Choose **Manage Quick**.
3. In the left navigation, choose **Permissions**, and then choose **Custom permissions**.
4. On the **Custom permissions** page, locate the profile you want to assign. Choose the actions menu next to the profile, and then choose **Assign**.

Tip

You can also assign a profile immediately after creating one. After you choose **Create** on the profile creation page, Quick takes you directly to the assignment page.

5. On the assignment page, configure who receives this profile:

- **Users** – Enter the usernames of the users you want to assign this profile to. You can add multiple users.
 - **Roles** – Select the Quick roles (Admin, Author, Reader) that you want to assign this profile to.
 - **Set as account default** – Select this option to apply the profile as the account-level default. If an account-level profile is already active, Quick displays a warning indicating that the existing assignment will be replaced.
6. When you are ready, choose **Assign**. You are returned to the custom permissions list page.

Assigning custom permissions profiles (AWS CLI)

Before you begin, you need to set up and configure the AWS CLI. For more information about installing the AWS CLI, see [Install or update the latest version of the AWS CLI](#) and [Configure the AWS CLI](#) in the AWS Command Line Interface User guide. You also need permissions to use the Quick API.

Updating custom permissions assignments

The following example updates the custom permissions that are assigned to a role.

```
aws quicksight update-role-custom-permission \  
--role ROLE \  
--aws-account-id AWSACCOUNTID \  
--namespace default \  
--custom-permissions-name PERMISSIONNAME
```

The following example applies a custom permissions profile to a user.

```
aws quicksight update-user-custom-permission \  
--aws-account-id AWSACCOUNTID \  
--namespace default \  
--user-name USER_NAME \  
--custom-permissions-name PERMISSIONNAME
```

The following example updates the custom permissions that are assigned to an account.

```
aws quicksight update-account-custom-permission \  
--aws-account-id AWSACCOUNTID \  
--custom-permissions-name PERMISSIONNAME
```

Removing custom permissions assignments

The following example deletes a custom permissions profile from a role.

```
aws quicksight delete-role-custom-permission \  
--role ROLE \  
--aws-account-id AWSACCOUNTID \  
--namespace default
```

The following example deletes a custom permissions profile from a user.

```
aws quicksight delete-user-custom-permission \  
--user-name USER_NAME \  
--aws-account-id AWSACCOUNTID \  
--namespace default
```

The following example removes a custom permissions profile from an account.

```
aws quicksight delete-account-custom-permission \  
--aws-account-id AWSACCOUNTID
```

Describing custom permissions assignments

The following example returns the custom permissions profile that is assigned to a role.

```
aws quicksight describe-role-custom-permission \  
--role ROLE \  
--aws-account-id AWSACCOUNTID \  
--namespace default
```

The following example returns the custom permissions profile that is assigned to an account.

```
aws quicksight describe-account-custom-permission \  
--aws-account-id AWSACCOUNTID
```

To test the custom permissions that are applied to a role or user, log in to the user's account. When a user logs into Quick, they are granted the highest privilege role that they have access to. The highest privileged role a user can be granted is Admin. The lowest privileged role that a user can be granted is Reader. For more information about roles in Quick, see [Managing user access inside Quick](#).

Verifying permissions for a user

After you assign a custom permissions profile, you can verify which profile is active for any user and at which level it applies.

To verify a user's active permissions profile

1. Open the [Quick console](#).
2. Choose **Manage Quick**.
3. In the left navigation, choose **Permissions**, and then choose **Custom permissions**.
4. Choose **Check permissions**.
5. Enter the username of the user you want to verify.
6. Quick displays the active profile name and the level at which it applies (user, role, or account).

Use this feature to confirm that Deny by Default profiles are correctly applied and that precedence is working as expected.

Deny by Default

Important

Test Deny by Default configurations in a development or staging account before applying them to production users. Verify that the behavior matches your expectations before broad deployment.

Overview

What is Deny by Default?

Without Deny by Default, any new capability that Amazon Quick ships is automatically available to all users upon release. Administrators must manually restrict each new capability after every release. This reactive approach can expose regulated environments to unapproved capabilities before administrators have time to evaluate them.

With Deny by Default enabled, new capabilities in a restricted category are automatically denied on launch day without administrator action. Administrators can then evaluate each new capability and explicitly allow it when ready. Restricting a category also restricts the capabilities that already exist in it, so you allow the ones your users need.

How category restriction works

When you restrict a capability category in a custom permissions profile, Quick restricts every capability in that category for assigned users. This includes capabilities that Quick launches in the future. To keep specific capabilities available, allow them explicitly in the profile.

Existing profiles are not changed

Restricting a category affects only the profile you configure it in. Existing custom permissions profiles do not inherit the restriction. To use it, either create a new profile with the category restricted, or edit an existing profile. If you enable it on an existing profile, all capabilities in that category become restricted – including capabilities the profile previously allowed. Allow the ones your users need.

When to use this feature

Deny by Default is designed for organizations that require explicit approval before new capabilities reach users. Common use cases include:

- Financial services organizations with model risk management (MRM) policies that require review of AI capabilities before adoption
- Healthcare organizations that must evaluate capabilities for compliance before making them available to users
- Enterprises running controlled rollouts where new features are introduced incrementally
- Organizations with regulatory or compliance requirements that mandate review before capability adoption

Key concepts

The following table describes the key terms and concepts for Deny by Default.

Term	Definition
Custom permissions profile	A named configuration object that defines which Amazon Quick capabilities are restricted for a set of users or roles. You can assign profiles at the user, role, or account level.

Term	Definition
Capability category	A named grouping of Amazon Quick capabilities used as the unit of control for Deny by Default. At launch, the supported category is AI (all AI and LLM-powered capabilities).
Deny by Default	A setting you can enable within a custom permissions profile to restrict all capabilities in a designated category. Capabilities that Quick launches in that category later are also restricted automatically, without requiring administrator action at launch time.
Category restriction	Restricting a capability category denies every capability in that category for users assigned to the profile, current and future, except capabilities explicitly allowed in the profile.
Profile scope	Restricting a category affects only the profile it is configured in. Existing custom permissions profiles do not inherit the restriction.
Precedence hierarchy	Evaluation order when a user has permissions at multiple levels: User overrides Role, which overrides Account. The most specific level takes precedence.
DefaultCategoryEffects	The API field that specifies Deny by Default behavior per capability category. <code>DENY_BY_DEFAULT</code> restricts all capabilities in the category—current and future—except those explicitly allowed. When omitted, the default behavior is allow by default.
Conflict resolution	When a capability is denied at one level but explicitly allowed at another, the most specific permission (User > Role > Account) wins.

Prerequisites

Before you configure Deny by Default, verify that the following prerequisites are met.

- **IAM permissions** – You must be a Quick administrator with the following IAM permissions:
 - `quicksight:CreateCustomPermissions`
 - `quicksight:UpdateCustomPermissions`
 - `quicksight:DescribeCustomPermissions`
 - `quicksight:ListCustomPermissions`
 - `quicksight>DeleteCustomPermissions`
 - `quicksight>DeleteAccountCustomPermission`
 - `quicksight>DeleteRoleCustomPermission`
 - `quicksight>DeleteUserCustomPermission`
 - `quicksight:DescribeAccountCustomPermission`
 - `quicksight:DescribeRoleCustomPermission`
 - `quicksight:ListCustomPermissionAssignments`
 - `quicksight:UpdateAccountCustomPermission`
 - `quicksight:UpdateRoleCustomPermission`
 - `quicksight:UpdateUserCustomPermission`
- **Identity configuration** – Your Quick account must be integrated with IAM Identity Center, Active Directory, or configured with Quick managed users.

Note

All API operations use Amazon QuickSight naming conventions. Permission strings use the `quicksight:` prefix.

How capabilities are evaluated

The following rules describe how capability evaluation works when Deny by Default is enabled. The rules are evaluated in order.

1. If a capability belongs to a restricted category (for example, AI) with `DENY_BY_DEFAULT` and is not listed in Capabilities, the user is denied by default. This is the primary effect of Deny by Default.

2. If a capability is explicitly listed in Capabilities with ALLOW, the user is permitted for that specific capability. This overrides the DENY_BY_DEFAULT category default for that capability only. Other capabilities in the same category remain denied unless they are also explicitly set to ALLOW.
3. If a capability is explicitly listed in Capabilities with DENY, the user is denied.
4. If a capability is not listed and does not belong to a restricted category, the user is permitted (allow-by-default behavior is unchanged).

Quick evaluates these rules each time a user accesses a capability, based on the capability's category membership at that time. This is why a restricted category also covers capabilities that are added later.

This means that when Quick launches a new capability in a restricted category, that capability is automatically denied for all users whose profile has DENY_BY_DEFAULT enabled for that category. No administrator action is required. The restriction takes effect on the day the capability launches.

 Note

Custom permission profiles are resolved in this priority order: user-level, then role-level, then account-level (first match wins). A user with a user-level allow-by-default profile is not subject to an account-level Deny by Default profile. Assign Deny by Default profiles at the appropriate level for your requirements.

Supported categories

The following table describes the supported categories for Deny by Default.

Category	Covers
AI	All AI and LLM-powered capabilities in Quick, including chat agents, flows, spaces, knowledge bases, apps AI inference, Q analyses, and Quick desktop AI features.

Note

The category system is modeled using tags. A capability can carry multiple category tags. If a capability is tagged with more than one category and more than one has Deny by Default enabled, the most restrictive setting applies.

Configuring Deny by Default (Quick console)

You configure Deny by Default as part of creating or editing a custom permissions profile. The setting is controlled by the **Restrict capabilities** section on the profile configuration page.

To enable Deny by Default on a custom permissions profile

1. Step 1: Open the custom permissions settings

- a. Open the [Quick console](#).
- b. Choose **Manage Quick**.
- c. In the left navigation, choose **Permissions**, and then choose **Custom permissions**.
- d. Create a new profile by choosing **Create profile**, or edit an existing profile by choosing the actions menu and then **Edit**.

2. Step 2: Configure the restriction

- a. In the **Restrict capabilities** section, turn on the toggle for the category you want to restrict (for example, **Restrict AI capabilities**). Turning on this toggle enables Deny by Default for that category. Any capability in this category that isn't explicitly allowed in the profile is automatically denied for users assigned to this profile.
- b. In the **Capabilities & features** section, explicitly allow any capabilities within the restricted category that you want users to retain access to. Only capabilities you explicitly allow are available. All others in the category, including any new capabilities that Quick launches in the future, are denied.
- c. Review the live preview panel on the right to verify your configuration matches your intent.

3. Step 3: Save the profile

Choose **Create** or **Update** to save the profile.

To remove Deny by Default from a profile, edit the profile and turn off the category toggle in the **Restrict capabilities** section. Capabilities that were previously denied become available to users assigned to the profile.

Configuring Deny by Default (AWS CLI)

You can use the AWS Command Line Interface to create and manage custom permissions profiles with Deny by Default enabled.

The following example creates a custom permissions profile with the AI category set to DENY_BY_DEFAULT, with the ChatAgent capability explicitly allowed.

```
aws quicksight create-custom-permissions \  
--aws-account-id AWSACCOUNTID \  
--custom-permissions-name PERMISSIONNAME \  
--capabilities '{"ChatAgent": "ALLOW"}' \  
--governance '{"DefaultCategoryEffects": {"AI": "DENY_BY_DEFAULT"}}'
```

The following example updates the Deny by Default settings on an existing profile.

```
aws quicksight update-custom-permissions \  
--aws-account-id AWSACCOUNTID \  
--custom-permissions-name PERMISSIONNAME \  
--capabilities '{"ChatAgent": "ALLOW", "Flow": "ALLOW"}' \  
--governance '{"DefaultCategoryEffects": {"AI": "DENY_BY_DEFAULT"}}'
```

Important

UpdateCustomPermissions performs a full replacement. You must send all --capabilities and --governance values, not just the delta. Any capability or setting you omit from the update call is removed from the profile.

The following example describes a profile with Deny by Default enabled.

```
aws quicksight describe-custom-permissions \  
--aws-account-id AWSACCOUNTID \  
--custom-permissions-name PERMISSIONNAME
```

Note

DescribeCustomPermissions returns the Governance field only if the profile was created or updated with Deny by Default settings. Profiles without Deny by Default return only the Capabilities field.

To remove Deny by Default from a profile entirely using the CLI, omit the `--governance` flag on the update call.

Examples**Example 1: Converting an existing profile to Deny by Default**

This example shows how to convert an existing allow-by-default profile that explicitly denies certain AI capabilities to a Deny by Default profile.

Scenario: You have a custom permissions profile that explicitly denies Flow, Automate, and ChatAgent capabilities. All other capabilities are available by default.

Run the following command to view your current profile configuration:

```
aws quicksight describe-custom-permissions \
--aws-account-id AWSACCOUNTID \
--custom-permissions-name "RestrictAI-Finance"
```

The command returns output similar to the following:

```
{
  "CustomPermissions": {
    "CustomPermissionsName": "RestrictAI-Finance",
    "Capabilities": {
      "Flow": "DENY",
      "Automate": "DENY",
      "ChatAgent": "DENY"
    }
  }
}
```

The problem: When Quick launches a new AI capability, it is automatically available to users with this profile because the profile only blocks explicitly listed capabilities. New capabilities are not listed, so they are allowed by default.

The solution: Convert the profile to Deny by Default. When you convert, you invert the logic. Instead of listing capabilities to deny, you list capabilities to allow. Everything not explicitly allowed is denied.

First, determine which AI capabilities you want to allow. In this case, you want users to retain access to Research, Topic, KnowledgeBase, and Space.

Run the following command to update the profile with Deny by Default:

```
aws quicksight update-custom-permissions \  
--aws-account-id AWSACCOUNTID \  
--custom-permissions-name "RestrictAI-Finance" \  
--capabilities '{"Research": "ALLOW", "Topic": "ALLOW", "KnowledgeBase": "ALLOW",  
"Space": "ALLOW"}' \  
--governance '{"DefaultCategoryEffects": {"AI": "DENY_BY_DEFAULT"}}'
```

Result: Now when Quick launches any new AI capability, it is automatically denied for users with this profile. Only Research, Topic, KnowledgeBase, and Space are available. Flow, Automate, ChatAgent, and any future AI capabilities are denied.

Important

Remember that UpdateCustomPermissions performs a full replacement. Include all capabilities you want to set, not just the ones related to the conversion.

Example 2: Setting up Deny by Default for a new account

This example shows how to lock down all AI capabilities from day one for a new Quick account.

Scenario: You are onboarding a new account and want to restrict all AI capabilities until your team evaluates each one individually.

Run the following command to create a profile that denies all AI capabilities by default with no explicit allows:

```
aws quicksight create-custom-permissions \  

```

```
--aws-account-id AWSACCOUNTID \  
--custom-permissions-name "DenyAllAI-NewAccount" \  
--governance '{"DefaultCategoryEffects": {"AI": "DENY_BY_DEFAULT"}}'
```

Run the following command to assign the profile at the account level so it applies to all users:

```
aws quicksight update-account-custom-permission \  
--aws-account-id AWSACCOUNTID \  
--custom-permissions-name "DenyAllAI-NewAccount"
```

Result: All AI capabilities are denied for every user in the account. As you evaluate and approve individual capabilities, you can update the profile to add them to the allow list.

Example 3: Allowing a specific new capability after launch

This example shows how to approve a new capability that Quick has launched after you enabled Deny by Default.

Scenario: Quick launches a new AI capability called NewAIFeature. Your team evaluates it and decides to approve it for users.

First, describe the current profile to get the current state:

```
aws quicksight describe-custom-permissions \  
--aws-account-id AWSACCOUNTID \  
--custom-permissions-name "RestrictAI-Finance"
```

The command returns the following output:

```
{  
  "CustomPermissions": {  
    "CustomPermissionsName": "RestrictAI-Finance",  
    "Capabilities": {  
      "Research": "ALLOW",  
      "Topic": "ALLOW",  
      "KnowledgeBase": "ALLOW",  
      "Space": "ALLOW"  
    },  
    "Governance": {  
      "DefaultCategoryEffects": {  
        "AI": "DENY_BY_DEFAULT"  
      }  
    }  
  }  
}
```

```
    }
  }
}
```

Update the profile to include the new capability in the allow list. You must include all existing capabilities plus the new one, because the update performs a full replacement:

```
aws quicksight update-custom-permissions \
--aws-account-id AWSACCOUNTID \
--custom-permissions-name "RestrictAI-Finance" \
--capabilities '{"Research": "ALLOW", "Topic": "ALLOW", "KnowledgeBase": "ALLOW",
"Space": "ALLOW", "NewAIFeature": "ALLOW"}' \
--governance '{"DefaultCategoryEffects": {"AI": "DENY_BY_DEFAULT"}}'
```

Result: The new capability is now available to users with this profile. All other unlisted AI capabilities remain denied.

Example 4: Multi-level precedence with Deny by Default

This example shows how Deny by Default interacts with the precedence hierarchy when profiles are assigned at multiple levels.

Scenario: You want most users locked down with Deny by Default for AI, but you want authors to have access to more capabilities. A specific data scientist needs full access to all AI capabilities.

Account-level (most restrictive): Create a profile that denies all AI by default with no allows. Assign it at the account level.

```
aws quicksight create-custom-permissions \
--aws-account-id AWSACCOUNTID \
--custom-permissions-name "Account-DenyAllAI" \
--governance '{"DefaultCategoryEffects": {"AI": "DENY_BY_DEFAULT"}}'

aws quicksight update-account-custom-permission \
--aws-account-id AWSACCOUNTID \
--custom-permissions-name "Account-DenyAllAI"
```

Role-level (Author): Create a profile with Deny by Default but with more capabilities allowed for power users. Assign it to the Author role.

```
aws quicksight create-custom-permissions \
```

```
--aws-account-id AWSACCOUNTID \  
--custom-permissions-name "Author-LimitedAI" \  
--capabilities '{"Research": "ALLOW", "Topic": "ALLOW", "ChatAgent": "ALLOW"}' \  
--governance '{"DefaultCategoryEffects": {"AI": "DENY_BY_DEFAULT"}}'\  
  
aws quicksight update-role-custom-permission \  
--role AUTHOR \  
--aws-account-id AWSACCOUNTID \  
--namespace default \  
--custom-permissions-name "Author-LimitedAI"
```

User-level (data scientist): Create an allow-by-default profile with no restrictions. Assign it to the specific user.

```
aws quicksight create-custom-permissions \  
--aws-account-id AWSACCOUNTID \  
--custom-permissions-name "DataScientist-FullAccess"\  
  
aws quicksight update-user-custom-permission \  
--aws-account-id AWSACCOUNTID \  
--namespace default \  
--user-name DATA_SCIENTIST_USERNAME \  
--custom-permissions-name "DataScientist-FullAccess"
```

Result:

- Most users (Readers, Admins without user-level overrides) receive the account-level profile with all AI capabilities denied.
- Authors receive the role-level profile with Research, Topic, and ChatAgent allowed. All other AI capabilities are denied.
- The data scientist receives the user-level profile with no restrictions. They are not subject to the account-level or role-level Deny by Default settings because user-level takes highest precedence.

Troubleshooting

A user can still access a capability I expected to be denied

Verify the following:

- Use the Check permissions feature to verify that the correct profile is assigned to the user.

- Check the precedence hierarchy. A user-level or role-level profile might override your account-level Deny by Default profile.
- Check if the capability is explicitly set to ALLOW in the profile.

Limit profiles

Intended audience: System administrators and Amazon Quick administrators

With Limits Management, you can monitor resource consumption. You can cap per-user usage before account-level service limits are reached. You can govern two resource types: *index storage* and *agent hours*.

The mechanism is straightforward: you create reusable *limit profiles* that define per-user caps, then assign those profiles to individual users, roles, or the entire account as a default. Quick enforces the most specific assignment that applies to each user.

Understanding index storage and agent hours

Limit profiles govern two resource types: index storage and agent hours. Understanding how each is measured helps you set effective per-user caps.

Index storage

Index capacity is measured by the original (raw) file size of documents at their source location before any processing by Quick. Supported source locations include Amazon S3, SharePoint, and Confluence. For full details on how index capacity is allocated, pooled, and purchased, see [Index capacity](#).

Index storage allocation is based on user count and subscription tier and is pooled at the payer-account level. Because the pool is shared, a single heavy user can consume capacity that would otherwise be available to other users. With limit profiles, you can cap individual consumption so that no single user exhausts the shared pool.

Agent hours

Agent hours measure the time consumed by AI-powered features in Quick. The following activities are metered:

- Quick Research – Time from research request submission until the report completes.
- Quick Flows – Runtime while workflows are actively executing, excluding idle and waiting time.
- Quick Automate – Runtime of deployed automations.
- Desktop app – Time spent actively using the AI assistant.
- Custom apps – Runtime of AI-powered custom applications.
- Artifact generation – Time spent generating documents, presentations, and images.

Viewing usage

Index capacity consumption is visible three ways: by user, by knowledge base, and by space. The **Per-user Capacity Overview** table provides an at-a-glance summary.

The **Per-user Capacity Overview** table provides an at-a-glance summary with the following columns.

User

The user's display name.

Role

The user's assigned role (Author or Reader).

Storage usage

Current index storage that the user consumed.

Agent-hours usage

Agent hours that the user consumed in the current billing cycle.

Usage distribution

A breakdown of consumption across knowledge bases and spaces.

User detail side panel

Select a user row to open a side panel that shows the following details:

- Linked limit profiles for each resource type
- Storage consumption compared to the user's effective limit

- Agent-hours consumption for the current billing cycle
- Usage distribution across knowledge bases and spaces

For additional analytics on agent-hours consumption trends, see [Usage metrics](#).

Managing limit profiles

Create a limit profile

Each limit profile requires a name and at least one limit. You can configure the following fields:

- **Name** (required) – A descriptive name for the profile.
- **Description** (optional) – Additional context about the profile's purpose.
- **Storage limit** (optional) – The maximum index storage in GB that the user can consume.
- **Agent hours per month** (optional) – The maximum agent hours the user can consume per billing cycle.

You must set at least one of the two limits (storage or agent hours) when creating a profile.

Assign a limit profile

You can assign a limit profile to:

- An individual user
- A role (Author or Reader)
- The account default (applies to all users who do not have a more specific assignment)

Resolution hierarchy

When multiple assignments apply to a user, the most specific assignment determines the effective limit, in the following priority order:

1. **User-level** – A limit profile assigned directly to a user takes highest priority.
2. **Role-level** – A limit profile assigned to the user's role (Author or Reader) applies if no user-level assignment exists.
3. **Account-level** – The account default profile applies if neither a user-level nor role-level assignment exists.

4. **System default** – The built-in subscription entitlement applies when no admin-configured profile is in effect.

Group-level assignment (assigning a profile to an identity-provider group) is planned for a future release. When available, group-level assignment will slot between user-level and role-level in the resolution hierarchy.

How limits are enforced

As long as a user stays below their effective limit, they can work without interruption.

When a user reaches 100% of a limit:

- **Index storage** – New file uploads and knowledge base ingestion are blocked for that user.
- **Agent hours** – New agent invocations are blocked until the next billing cycle begins.

Existing content is always preserved. Tightening a limit never deletes files or knowledge bases.

Enforcement is global across all AWS Regions. Usage in any Region counts toward the same per-user limit.

End-user visibility

Your users can view their own consumption in the **My usage** widget (available in **My stuff**). The widget shows:

- Agent hours used compared to their monthly limit. This value resets at the start of each billing cycle.
- Index storage capacity consumed compared to their effective limit.

For programmatic management of limit profiles, see the Amazon Quick API Reference.

Governance

With governance features in Quick, you control actions that affect shared assets. Use approval workflows to require review before the approver grants access.

Topics

- [Approval workflows](#)
- [Data loss prevention](#)

Approval workflows

Applies to: Enterprise Edition

Intended audience: System administrators and Amazon Quick administrators

Approval workflow overview

With approval workflows, you require a designated approver group to review and approve certain actions on assets in Amazon Quick before those actions take effect. Use approval workflows when you want a trusted reviewer to validate a sharing decision before the approver grants access. This reduces the risk of unauthorized access to sensitive assets.

Currently, approval workflows support sharing actions. The target user receives access only after the approver approves the request.

Approval workflows support the following asset types:

- Knowledge bases
- Spaces
- Custom chat agents

How it works

Approval workflows are opt-in. Sharing requires approval only after an administrator creates and enables a policy for an asset type.

An approval workflow involves three personas:

Administrator

Creates and manages approval policies.

Requester

Submits share requests that require approval.

Approver

Reviews and acts on pending approval requests.

For administrators: setting up approval policies

As an administrator, you create and manage approval policies in the **Approval Policies** section of the account management console.

To navigate to approval policies

1. Sign in to Quick as an administrator.
2. Choose your account name, and then choose **Manage Account**.
3. In the left navigation pane, choose **Approval Policies**.

To create an approval policy

1. Choose **Create Policy**.
2. Enter a policy name and an optional description.
3. Select the asset types that the policy applies to.
4. Choose one or more approver groups. These are existing identity groups from IAM Identity Center, IAM federation, or Active Directory.
5. In **Assign Policy**, select the user groups whose members must go through the approval workflow when sharing.
6. Choose **Create Policy**.

To manage existing policies, choose a policy to view its details in the side panel. From there, you can edit the policy name, description, asset types, and approver groups. You can also delete policies that are no longer needed.

For requesters: submitting a share request

Approval requirements depend on the sharing action:

Add a new person to an asset

Requires approval.

Upgrade access (for example, Viewer to Owner)

Requires approval.

Downgrade access

Takes effect immediately; no approval required.

Remove access

Takes effect immediately; no approval required.

To submit a share request

1. Locate the asset that you want to share.
2. Choose **Share**.
3. Add a person or group, or change an existing role.
4. If an approval policy is active, an approval request form appears with the following fields:
 - (Required) **Notes** – Context for the approver.
 - (Optional) **Severity** – For example, Low, Medium, or High.
 - (Required) **Approval needed by** – The date by which a decision is needed. This must be a future date.
5. Choose **Send Request**.

What happens after submission

After you submit a request, the following occurs:

- The approver group receives viewer-level access to the asset so they can review it. Quick grants this access when you submit the request and does not remove it automatically afterward. The asset owner removes the approver group manually.
- The request enters *Pending* status.
- The target user does not receive access until the request is approved.

Tracking requests

To track your submitted requests, navigate to **My stuff**, and then choose the **My Tasks** widget. Choose **Submitted By Me**.

Opening a request shows the status (Pending, Approved, or Denied), the asset and target user, your submitted notes, severity, date, and any approver comments or decision history.

For approvers: reviewing and acting on requests

To access pending requests, navigate to **My stuff**, and then choose **My Tasks**. You can view requests under **All** and **Assigned To Me** (requests routed to your approver group).

Before you can act on a request, you must claim it. Choose **Claim Request** to move the request to **Assigned To Me**. This exposes the **Approve** and **Deny** actions.

The access that approvers receive depends on the asset type:

Executable assets (agents)

Execution access to test. The asset runs in the creator's context, so the approver does not gain direct access to underlying data sources.

Content assets (spaces, knowledge bases)

Read access to review content.

After reviewing the asset, choose one of the following actions:

- **Approve** – The target user receives access. The request status changes to Closed – Approved.
- **Deny** – The request is declined. The requester receives reason codes and written feedback. The request status changes to Closed – Denied.

Verifying access after approval

After the approver approves a request, you can verify that Quick granted access correctly.

- **Target user** – The shared asset appears under the relevant section. Refresh the page if it does not appear immediately.
- **Requester** – In **My stuff**, choose **My Tasks**, and then choose **Submitted By Me**. The request shows *Approved* status. The details panel shows the history and timestamp.

- **Administrator** – Check the asset's sharing settings. The audit trail in AWS CloudTrail captures Submit, Approve, Deny, and Revoke actions with user, asset, timestamps, and notes.

Package sharing for custom chat agents

When you share a custom chat agent, you can submit a package share request that includes the agent and its dependencies (knowledge bases, connectors, and spaces) as a single all-or-nothing approval.

- **Approve** – The target user gets the agent and all listed dependencies.
- **Deny** – No access to any component is granted.

Approvers can view the full dependency list on the asset page before deciding.

API reference

For programmatic management of approval policies, see the Amazon Quick API Reference.

Frequently asked questions

Is approval required by default?

No. Approval workflows are opt-in only. No approval is required unless an administrator creates and enables a policy.

Which edition supports approval workflows?

Approval workflows are available in Quick Enterprise edition.

Who can be an approver?

Both Professional and Enterprise users can be approvers. Professional and Enterprise are user subscriptions within Quick Enterprise edition, not separate editions of Quick.

What groups can I use as approver groups?

You can use existing identity groups from IAM Identity Center, IAM federation, or Active Directory.

What happens if a request is denied?

The requester receives reason codes and written feedback. They can revise and resubmit the request.

Is approver access to the asset removed after a decision?

No. The approver group retains viewer-level access. The asset owner removes the approver group manually.

What happens if I delete an approval policy?

In-flight pending requests continue to completion. New share requests for those asset types no longer require approval.

Can a requester cancel a pending request?

Yes. In **My stuff**, choose **My Tasks**, choose **Submitted By Me**, and then choose **Cancel request**.

Are approvers notified of new requests?

Yes. Approvers are notified when new requests are submitted.

Can I audit approval events?

Yes. All approval events (Submit, Approve, Deny, and Revoke) are logged in AWS CloudTrail.

Data loss prevention

Intended audience: System administrators and Amazon Quick administrators

Amazon Quick integrates with Microsoft Purview to enforce your organization's data loss prevention (DLP) policies. After you connect your Microsoft Purview tenant, Quick classifies and protects sensitive files shared through spaces, chat, and knowledge bases. Sensitive data stays within the boundaries that your organization's information governance policies define.

Data loss prevention concepts

Before you configure DLP in Amazon Quick, familiarize yourself with the following concepts.

Sensitivity labels

Sensitivity labels are classifications that you define in your Microsoft Purview tenant to describe the sensitivity level of content – for example, *Public*, *Confidential*, or *Highly Confidential*. You can organize labels hierarchically with parent labels and sub-labels (child labels).

Enforcement actions

Enforcement actions define how Quick handles a file that carries a specific sensitivity label.

- **Block** – Quick rejects the file, and the file can't be shared or uploaded. You receive an error message.
- **Warn** – In interactive capabilities, you see a warning message and can choose to proceed or cancel the upload.
- **Allow** – Quick shares the file without restriction.

Default action

The default action is the enforcement action that Quick applies to any file whose sensitivity label you haven't explicitly mapped to a specific action. You set the default action during configuration. The default action also covers new labels that you publish in Microsoft Purview after setup. Quick governs files that carry those labels right away, so nothing goes unprotected. To give a new label its own action, edit the configuration and map it explicitly.

Provider outage action

The provider outage action determines how Quick handles files when the DLP provider (Microsoft Purview) is temporarily unavailable. You can set it to one of the following actions.

- **Block** – Quick rejects files until the provider is available again.
- **Warn** – Quick permits files through and shows a warning during the outage.
- **Allow** – Quick permits files through without restriction.

Capabilities

Capabilities are the areas within Amazon Quick where Quick applies DLP enforcement.

- **Spaces** – Files that users upload to collaborative workspaces.
- **Chat** – Files that users share through chat conversations.
- **Knowledge bases** – Content synced through SharePoint, OneDrive, and other connectors.

Label inheritance

In the label mapping configuration, you can assign a parent label an explicit action (Block or Warn) or leave it set to the default action. Sub-labels (child labels) inherit their parent label's action. A label that you haven't explicitly mapped follows its mapped parent label's action if one exists. Otherwise, your default action applies.

Prerequisites

Prepare the following before you create a DLP configuration.

Microsoft Purview sensitivity labels

You must already publish your sensitivity labels (for example, *Public*, *Confidential*, and *Highly Confidential*) in your Microsoft Purview or Microsoft 365 tenant. Quick reads these labels live from your tenant.

A Microsoft Entra ID app registration

Register an application in Microsoft Entra ID (Azure AD) that Quick uses to read labels and classify files. Note the **Directory (tenant) ID** and **Application (client) ID**. Both are GUIDs that you need to create a client secret credential. You must grant the app registration the following API permissions.

API permission	Type	Description
UnifiedPolicy.Tenant.Read	Required	Read the unified data-protection policy for the tenant.
SensitivityLabels.Read.All	Required	Read all sensitivity labels defined in the tenant.
Files.Read.All	Optional	Required only if you use knowledge bases backed by SharePoint or OneDrive.

An AWS Secrets Manager secret

Store the Purview credentials in an AWS Secrets Manager secret in the same AWS account as your Quick account. Use the following JSON format for the secret value.

```
{
  "clientId": "abcdef12-3456-7890-abcd-ef1234567890",
  "clientSecret": "<client secret value>",
  "tenantId": "11111111-1111-1111-1111-111111111111"
}
```

Note

Quick stores only the ARN of your secret. Quick reads your credentials at runtime and never displays them in the console, returns them from the API, or writes them to logs.

⚠ Important

Use exactly these three key names: `clientId`, `clientSecret`, and `tenantId`. Quick looks up these keys verbatim, so a renamed or missing key causes validation to fail with a missing-fields error. Store the value as a single JSON object.

Access for Quick to your secret

Sign in to your AWS account as an administrator and open the Quick admin console. Then grant Quick permission to read your Secrets Manager secret.

1. Choose **Permissions**, and then choose **AWS resources**.
2. Select **AWS Secrets Manager** from the list of services.
3. Choose your secret.
4. Choose **Save**.

Secrets encrypted with a customer managed KMS key

If a customer managed KMS key encrypts your Secrets Manager secret, Quick also needs `kms:Decrypt` permission on that key, in addition to `secretsmanager:GetSecretValue`.

⚠ Important

The **Permissions, AWS resources** page can't grant `kms:Decrypt`. Edit the Quick service role directly in IAM to add it. After you edit the role manually, you can no longer manage it from the **AWS resources** page in the admin console.

Add a statement like the following to the role. Replace the account ID, secret name, and key ID with your own.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [ "secretsmanager:GetSecretValue" ],
```

```
"Resource": [
  "arn:aws:secretsmanager:<home-region>:<account-id>:secret:<secret-name>",
  "arn:aws:secretsmanager:<other-region>:<account-id>:secret:<secret-name>"
],
{
  "Effect": "Allow",
  "Action": [ "kms:Decrypt" ],
  "Resource": [ "arn:aws:kms:<other-region>:<account-id>:key/<key-id>" ]
}
```

Replicating your secret across Regions

Quick reads your secret in every AWS Region where it evaluates files, so the secret must exist in each of those Regions. Replicate it by using **Replicate secret to other Regions** in the Secrets Manager console, and make sure the role grants access to every replica ARN.

If a customer managed KMS key doesn't encrypt the secret, replicating it is sufficient. If a customer managed KMS key encrypts the secret, use one of the following approaches.

Option 1: Single-Region keys

1. Replicate the secret to the other Region.
2. Detach the replica from the primary secret so that it becomes standalone.
3. Create a KMS key in the other Region.
4. Attach that key to the standalone secret.
5. Grant `kms:Decrypt` on the new key, as described in [the section called "Secrets encrypted with a customer managed KMS key"](#).

Option 2: Multi-Region key

1. Create a multi-Region key in your home Region.
2. Set the multi-Region key as the encryption key on the secret.
3. Replicate the multi-Region key to the other Region.
4. Replicate the secret to that Region, and select the replicated multi-Region key as its encryption key.

5. Grant kms:Decrypt on the replica key, as described in [the section called "Secrets encrypted with a customer managed KMS key"](#).

Creating a DLP configuration

Sign in to the admin console. Choose **Governance**, choose **Data loss prevention**, and then choose **Create DLP configuration** to open the setup wizard. The wizard has four steps, listed in the navigation pane. The following table describes each step.

Step	Name	Description
1	Provider	Select the DLP provider (Microsoft Purview).
2	Credentials	Name the configuration and connect to AWS Secrets Manager.
3	Label mapping	Scope enforcement and map sensitivity labels to actions.
4	Review	Confirm settings and activate the configuration.

Step 1: Provider

Select **Microsoft Purview** as the DLP provider, and then choose **Continue**.

Step 2: Credentials

Enter the following information:

- **Configuration name** – A descriptive name that the dashboard shows – for example, Knowledge base DLP.
- **Secret ARN** – Paste the ARN of your Secrets Manager secret.
- Choose **Validate** to connect to Purview with the secret and check the required read permissions.

 Note

Each required permission shows a green check when validation succeeds. If a permission is missing or the secret is invalid, Quick flags the issue inline so that you can correct it and retry.

 Important

You can't continue to the next step until validation succeeds. Verify that the app registration has all required API permissions and that the secret ARN is correct before you retry.

Step 3: Label mapping

Map each sensitivity label to an action:

- **Default action** – Choose the action that Quick applies to any label that you don't explicitly map. The options are **Block**, **Warn**, or **Allow**. A conservative starting point is **Block**.
- **Sensitivity labels** – Quick loads the current list of labels from your Purview tenant. For each label, choose its action. Sub-labels inherit their parent's action. Choose **Refresh** if you recently changed labels in Purview and want to pull the latest list.
- **Provider outage action** – Choose what Quick does when Purview is unreachable: **Block** (fail closed – safest), **Warn**, or **Allow** (fail open). For a knowledge base that holds sensitive material, **Block** is the recommended provider outage action.

Choose **Review**.

The following table describes the enforcement actions.

Allow

The file proceeds normally. Quick applies no restrictions.

Warn

The file proceeds, but Quick notifies you in interactive capabilities (Chat and Spaces) if it carries a sensitive label.

Block

Quick rejects the file and doesn't ingest it into the Quick index.

Step 4: Review

Review the summary – the provider, configuration name, authentication method, capabilities, the label-to-action breakdown, the default action, and the provider outage action. Choose the edit link next to any section to return to it.

Use the **Active / Inactive** toggle to set whether Quick enforces the configuration as soon as you create it (the default is **Active**). Quick saves an **Inactive** configuration but doesn't enforce it until you activate it. When you're ready, choose **Create**.

Your configuration now appears as a card on the **Data loss prevention** dashboard. If you leave it **Active**, Quick begins enforcing on new file uploads to your knowledge bases.

How enforcement works

When a file enters a Quick capability that an active DLP configuration protects, the following sequence occurs.

1. A file enters a protected Quick capability – for example, Quick ingests documents during a knowledge base sync.
2. Quick DLP retrieves the file's Microsoft Purview sensitivity label.
3. Quick matches the label against the label-to-action mapping in your configuration.
4. Quick applies the resulting action.
 - **Allow** – The file proceeds normally.
 - **Warn** – The file proceeds, but Quick notifies you in interactive capabilities (Chat and Spaces) if it carries a sensitive label.
 - **Block** – Quick rejects the file.
5. For a label that you haven't explicitly mapped, Quick checks for a mapped parent label. If a mapped parent exists, Quick uses that parent's action. Otherwise, it applies your **default action**. New labels that you publish in Purview after setup are also covered by the default action, so Quick governs them immediately. To give a new label its own action, edit the configuration and map it explicitly.
6. If Quick can't reach Purview, it applies your configured **provider outage action**.

 Tip

For a knowledge base that holds sensitive material, we recommend that you set both the default action and the provider outage action to **Block**. This prevents Quick from ingesting unlabeled files or files that arrive during a Purview outage.

Enforcement by capability

DLP enforcement applies to three capabilities: **Chat**, **Spaces**, and **Knowledge bases**. The same actions apply in all three. What you see, and where Quick records the result, depends on whether Quick scans the file interactively or during a background sync.

Interactive capabilities: Chat and Spaces

Quick evaluates files as you share or upload them, while you wait for the result.

- **Block** – Quick rejects the file, and you receive an error message.
- **Warn** – You see a warning message and can choose to proceed or cancel.
- **Allow** – Quick shares the file without restriction.

Knowledge bases

Quick evaluates files during ingestion, after a sync starts, so no user waits for the outcome. Two consequences follow.

- **There is no warn prompt.** Quick ingests a file that carries a label mapped to **Warn**, and the **Warn** action has no user-visible effect on this capability.
- **Results appear in the Quick Observability report.** To see what DLP did during a knowledge base sync, open the Quick Observability report for that sync. The report shows one status per file.

BLOCKED

Quick didn't ingest the file into the index. A **BLOCKED** status can indicate DLP enforcement or an internal failure. The error message for internal failures is generic.

ADDED

Quick ingested a new file. This status includes files that match **Warn** labels; the report doesn't show them separately.

MODIFIED

Quick updated and re-ingested an existing file. Files that match **Warn** labels appear as **MODIFIED** if the file changed since the last sync.

Testing your configuration

From the configuration's card on the dashboard, choose the **Test** (file-scan) icon. Provide the Amazon S3 URI (for example, `s3://bucket/key`) of a labeled file, and confirm that it returns the expected Allow, Warn, or Block result before you rely on it in production.

Note

The test action performs a dry run using the current label-to-action mapping. It doesn't modify the file or affect any live data.

Managing configurations

From each dashboard card, you can perform the following actions.

- **Edit** (pencil icon) – Change credentials, capabilities, label mappings, the default action, or the provider outage action.
- **Activate / Deactivate** (toggle) – Turn enforcement on or off. Deactivating asks for confirmation, because it stops protection for the covered capabilities.
- **Delete** – Remove the configuration entirely (available from the edit view).

Note

The dashboard card warns you when your Purview tenant has new labels that you haven't mapped yet. Until you map them, they follow your default action.

Limits and validations

The following limits apply to DLP in Amazon Quick.

- **DLP configurations per account** – 10.
- **Active DLP configurations per account** – 1.
- **Maximum file size scanned** – 500 MB. Quick doesn't scan larger files.

Supported file types

Quick scans the file types that Microsoft Purview supports for labeling: Word, Excel, PowerPoint, PDF, Visio, Project, common image formats (JPEG, PNG, TIFF, DNG, PSD), XPS, Power BI (.pbix), .dwfx, and email (.msg, .eml). For the authoritative list, see [supported file types](#) on the Microsoft website.

One distinction matters when you read this list: only file types that Microsoft Purview supports *for labeling* are in scope. Quick doesn't scan files that require Azure Rights Management to decrypt, or file types that apply only to protected labels.

Protected labels

If a file carries a label that has protection enabled, Quick doesn't scan the file and applies your default action instead. Protected labels don't appear in the label-mapping step in the admin console. You can still supply them through the `CreateDlpSetting` API, but the evaluation outcome is the same: the default action applies.

When the default action applies

Beyond labels that you haven't explicitly mapped, Quick falls back to your default action when any of the following is true:

- The file carries no sensitivity label.
- The file type isn't supported (see [the section called "Supported file types"](#)).
- The file exceeds the 500 MB size limit.
- The file is empty (0 bytes).
- The file carries a protected label.

Note

In the public API, the default action is the `unmappedAction` field.

Security best practices

- **Use a dedicated app registration for DLP.** Register a separate Microsoft Entra ID application for Quick DLP rather than reusing an app registration that serves other integrations. A dedicated registration lets you rotate or revoke its credentials independently and keeps its permission scope narrow.
- **Grant only the permissions that DLP needs.** Scope the app registration to `SensitivityLabels.Read.All` and `UnifiedPolicy.Tenant.Read.AddFiles.Read.All` only if you use knowledge bases backed by SharePoint or OneDrive; it isn't required to list or map labels.
- **Keep credentials in Secrets Manager.** Quick stores only the ARN of your secret. Quick reads your credentials at runtime and never displays them in the console, returns them from the API, or writes them to logs.
- **Monitor data loss prevention (DLP) activity.** Quick delivers a `DLP_LOGS` vended log to CloudWatch Logs, Amazon S3, or Firehose. Use it to audit DLP policy changes, including when enforcement was enabled or disabled and which principal made the change (`DLP_SETTING_*` events, status, and `last_updated_by`). You can also identify blocked, warned, or inspection-failed files by filtering on `event_type` and `failure_type`. For setup and the full schema, see [the section called "Monitoring using CloudWatch Logs"](#).

API reference

For programmatic management of DLP settings, see the Amazon Quick API Reference.

Setting up Quick knowledge bases

To set up Quick ingestion knowledge bases, follow the instructions for each connector:

- [the section called "Knowledge base integration"](#)
- [the section called "Knowledge base integration"](#)
- [the section called "Knowledge base integration"](#)
- [the section called "Web Crawler integration"](#)

- [the section called "S3 integration"](#)
- [the section called "Knowledge base integration"](#)

Troubleshooting

The following table lists common issues and how to resolve them.

Validation fails with a permission error

Verify that the app registration has `UnifiedPolicy.Tenant.Read` and `SensitivityLabels.Read.All` granted and admin-consented.

Secret ARN not found

Confirm that the Secrets Manager secret exists in the same AWS account as Quick, and that you granted Quick access under **Permissions, AWS resources**.

The labels list is empty or outdated

Use **Refresh** in Step 3 (Label mapping) to re-fetch the current label list from your Purview tenant.

Files are unexpectedly blocked during a knowledge base sync

Check the Quick Observability report for the sync. A **BLOCKED** status can also indicate an internal failure rather than DLP enforcement. Check whether the file carries a label that you mapped to Block, whether the default action is Block, and the provider outage action if Purview was unreachable during the sync.

Customizations

Using Amazon Quick, you can create a customized experience for people using either the AWS Management Console or Quick consoles embedded in your application.

Currently, different options for customizing Quick are available separately in the console and the Quick API. Following, you can find information about the available options.

The following customization options are currently available:

- You can customize the welcome content Quick provides for new users:
 - You can accept or decline the sample assets. These assets include sample datasets and analyses that are added when a person signs in for the first time.

- You can show or hide default introductory videos. These videos include the animation that displays for new users and also the tutorial videos shown on the Amazon Quick home page.
- You can create and specify a default theme.
- You can customize dashboard report emails, pixel perfect report emails, and alert emails by editing the email template.

Important

All customizations apply only to the AWS Region that you are using in the API or that is selected in the Amazon Quick console.

To check your Region setting, you can use one of the following procedures.

To check your AWS Region on the Amazon Quick console

1. Choose your profile icon to open the menu.
2. View your current AWS Region, listed next to a location icon.
3. (Optional) Choose another AWS Region from the menu to change to that Region. Remember to change back after you are finished with customizations.

To check your AWS Region using the AWS CLI

- On the command line, enter the following command and press Enter to view the current settings.

```
aws configure list
```

To reconfigure your default Region, use the `aws configure` command.

To keep your default Region, you can add the `--region` parameter to most CLI commands.

Amazon Quick brand customization

Amazon Quick allows account admins to customize their application's branding and visual theme to align with their organization's guidelines. This customization includes the following visual elements to create a cohesive look and feel across all non-administrative Amazon Quick console pages, schedules, alerts, and email reports.

- Logo
- Favicon
- Associated alt text for visual assets

The following list shows the different areas customizable theme colors are grouped into.

Brand colors

- **Global navigation bar** colors are applied to the topmost bar in the Amazon Quick UI and include the company logo that is displayed in the standard and embedded Amazon Quick consoles.
- **Application bar** colors are applied to the secondary navigation bar that contains contextual actions.

Interaction colors

- **Accent** colors are applied to interactive elements like buttons, borders, and icons.

Surface colors

- **Primary** colors are applied to high-emphasis surfaces like the homepage background and text.
- **Secondary** colors are applied to practical surfaces like borders, backgrounds, and form fields. Secondary colors are used alongside primary colors.

Status colors

- **Success** colors are applied to success messages.
- **Danger** colors are applied to error messages.
- **Warning** colors are applied to warning messages.
- **Info** colors are applied to informational messages.

Data visualization colors

- **Dimension** colors are used to identify associations between data columns that share the same role.
- **Measure** colors are used to identify metrics or measured values.

Features

- **Visualization** colors are applied to the **Visualization** icon.
- **Insight** colors are applied to the **Insight** icon.
- **Connection** colors are applied to the **Connection** icon.
- **Automation** colors are applied to the **Automation** icon.

Use the following sections to get started with brand customization in Amazon Quick.

Topics

- [Permissions for Amazon Quick brand customization](#)
- [Create a custom brand in Amazon Quick](#)
- [Setting a default theme for Amazon Quick analyses with the Amazon Quick APIs](#)

Permissions for Amazon Quick brand customization

To set up a brand, you must be granted an Admin role through IAM Identity Center or IAM. Admins whose roles are granted to them within Amazon Quick can't create brands. To learn more about integrating your account with IAM Identity Center, see [Configure your Amazon Quick account with IAM Identity Center](#). For information about admin roles and capabilities, see [Understanding Amazon Quick subscriptions and roles](#).

Admin users can only manage brands that are in the same capacity Region as their Amazon Quick account.

The IAM role that you use to create a brand in Amazon Quick must contain `quicksight:*` or granular action permissions to manage brands in the admin console. The following granular permissions are required for admins to work with Amazon Quick brands:

- `quicksight:CreateBrand`

- quicksight:UpdateBrand
- quicksight:DescribeBrand
- quicksight:DescribeBrandPublishedVersion
- quicksight:UpdateBrandPublishedVersion
- quicksight>DeleteBrand
- quicksight:ListBrands
- quicksight:UpdateBrandAssignment
- quicksight:DescribeBrandAssignment
- quicksight>DeleteBrandAssignment

After you confirm that your Admin role contains the required permissions, you can [Create a custom brand](#) in the Amazon Quick admin console.

Create a custom brand in Amazon Quick

Use the following procedure to create a custom brand in Amazon Quick.

1. Open the [Quick console](#).
2. Choose the user icon at the top right, and then choose **Manage Quick**.
3. Choose **Customize application**.
4. On the **Customize application** page that opens, choose **ADD BRAND**. The **Brand settings** page opens.
5. Navigate to the **Brand Info** section.
6. For **Brand name**, enter a name for the brand. The brand name can contain up to 512 characters.
7. (Optional) For **Brand description**, enter a description for the custom brand. The brand description can contain up to 512 characters.
8. Navigate to the **Logo** section.

Logo

Primary

Favicon

Alt text

9. For **Primary**, choose the ellipsis (three dots) next to the primary icon, and then choose **Replace image**.
10. In the **Choose image** pop up that opens, perform one of the following actions:
 - a. Drag and drop image into the **Drag an image here** box.
 - b. Choose **Select a file** to select a file from your computer.
 - c. Enter a public URL or Amazon S3 URI in the text bar.

The image that you choose must be a .jpeg, .png, or .svg format and can't exceed 1MB.

When you are finished choosing an image, choose **Apply**.

11. For **Favicon**, choose the ellipsis (three dots) next to the favicon, and then choose **Replace image**.
12. In the **Choose image** pop up that opens, perform one of the following actions:
 - a. Drag and drop image into the **Drag an image here** box.
 - b. Choose **Select a file** to select a file from your computer.
 - c. Enter a public URL or Amazon S3 URI in the text bar.

The image that you choose must be a .jpeg, .png, or .svg format and can't exceed 1MB.

When you are finished choosing an image, choose **Apply**.

13. (Optional) For **Alt text**, enter alt text to display with the logo. The alt text can contain up to 512 characters.

14. To make changes to the theme colors of the brand, navigate to the **Appearance** pane on the left and choose **Theme**.
15. The **Theme settings** page appears and displays all parts of a Amazon Quick theme that can be customized. The following image shows the configuration settings of the global navigation bar.

16. To change the background color of an area, navigate to the item that you want to change and choose the **Background** color swatch.
17. In the **Custom color** pop up that appears, choose a color from the color gradient or enter a hex code value in the **HEX** bar, and then choose **APPLY**.
18. To change the foreground color of an area, navigate to the item that you want to change and choose the **Foreground** color swatch.
19. In the **Custom color** pop up that appears, choose a color from the color gradient or enter a hex code value in the **HEX** bar, and then choose **APPLY**.
20. When you are finished configuring a custom brand, choose **PUBLISH** to publish and apply the brand customization to all Amazon Quick user accounts. If you don't want to publish the brand, choose **SAVE** to save the brand for later.

When you finish creating a brand in Amazon Quick, the new brand appears in the brands table on the **Customize application** page of the Quick admin console. The **Status** column of the brands table indicates which brand is currently published to the Quick account. To make changes to a custom brand, locate the brand that you want to change in the brands table, choose the ellipsis (three dots) icon in the **Actions** column, and then choose **Publish**, **Edit**, or **Delete**.

Once you publish a brand, it can take up to 10 minutes for the new brand to propagate across all users.

Setting a default theme for Amazon Quick analyses with the Amazon Quick APIs

To set a default theme by using the API

1. Identify the custom theme that you want to use as the default, and locate its theme ID. If you want to use one of the QuickSight starter themes, skip this step.

To get the theme ID of a custom theme, use the [ListThemes](#) API operation for the Region where the theme is. Make sure that the theme is in the same Region with the users or groups that need to use it.

The following example shows a shell script that uses the `list-themes` command in the AWS CLI. It sets the AWS account ID and the AWS Region as variables. If you previously used `aws configure` to set a default Region, adding the `--region` variable to your command overrides your default setting.

```
#declare variables
awsacct1='111122223333'
region='us-west-2'

aws quicksight list-themes \
--region $region \
--aws-account-id $awsacct1 \
--type 'CUSTOM'
```

2. Use the [ListUsers](#) or [ListGroups](#) API operation to collect the Amazon Resource Names (ARNs) for users or groups that need to use the theme as a default. You need only the top-level ARN. If all your users are part of the same group, use the group ARN.

For more information on Amazon Quick ARNs, see [ARN formats](#) in the *Quick API Reference*.

3. If you're using a custom theme, grant access to the theme for the ARNs that you collected in the previous step. If you're using a starter theme, skip this step because all users have access to starter themes.

The following example shows a shell script that uses the [update-theme-permissions](#) command. The `grant-permissions` parameter is shown using shorthand syntax. You can use JSON or YAML instead. For more information, see [Specifying parameter values](#) in the *AWS Command Line Interface User Guide*.

```
#declare variables
awsacct1='111122223333'
namespace='default'
region='us-west-2'
theme-id='bdb844d0-0fe9-4d9d-b520-0fe602d93639' #Find this with list-themes

aws quicksight update-theme-permissions \
```

```
#Specify region if necessary: --region $region \
--aws-account-id $awsacct1 \
--theme-id $theme-id \
--grant-permissions
Principal="arn:aws:quicksight:$region:$awsacct1:group/$namespace/
QuickSight_Group_Name",Actions="quicksight:DescribeTheme","quicksight:ListThemeVersions","
```

4. Assign the theme as the default for the same ARN or ARNs.

```
#declare variables
awsacct1='111122223333'
namespace='default'
region='us-west-2'
theme-id='bdb844d0-0fe9-4d9d-b520-0fe602d93639'

aws quicksight create-account-customization \
#Specify region if necessary: --region $region \
--aws-account-id $awsacct1 \
--namespace $namespace \
--account-customization
DefaultTheme="arn:aws:quicksight:$region:$awsacct1:theme/$theme-id"
```

Currently, there are three starter themes: Classic, Midnight, and Seaside. Their ARNs are the capitalized spelling of their theme name. If you are using a starter theme instead of a custom theme, use one of the following theme ARNs:

- arn:aws:quicksight::aws:theme/CLASSIC
- arn:aws:quicksight::aws:theme/MIDNIGHT
- arn:aws:quicksight::aws:theme/SEASIDE
- arn:aws:quicksight::aws:theme/RAINIER

Chat agent customization in Amazon Quick

When a user account subscribes to Quick, the service automatically creates a system default chat agent. This agent powers the default chat experience, allowing Amazon Quick users to leverage all chat functionalities (such as uploading files to chat, using large language model (LLM) parametric knowledge, and answering from their enterprise data) out of the box. The system default chat agent can be updated in the Amazon Quick agent section by a select set of users who are designated as owners for the agent by the admin.

Amazon Quick uses multiple safety controls for chat interactions in the Amazon Quick web experience. You can configure blocked words and phrases under **Guardrails and safety controls**. For information about built-in safeguards and blocked words and phrases, see [AI guardrails in Amazon Quick](#).

Admins can also configure whether URLs in chat responses appear as clickable hyperlinks or plain text. This setting applies across all chat agents and flows in your instance, allowing you to control how links are presented to users.

Note

Admins can also control permissions for whether users can create and use chat agents and flows. For instructions on how to do that, see [Custom permissions](#).

The following sections outline how to edit the system default agent and configure clickable external links in chat responses.

Topics

- [Grant user permissions to edit system default chat agent](#)
- [Edit system chat agent settings](#)
- [Configure clickable external links in chat responses](#)

Grant user permissions to edit system default chat agent

The system default chat agent can be edited by users the admin designates as owners to this agent in the admin console. The following procedure shows you how to grant admin permissions to a user so that they can edit the system default agent.

To grant permissions to edit system default agent

1. Log in to the Amazon Quick console.
2. Select **Manage Quick** from the Amazon Quick admin console.
3. From the admin console left navigation menu, select **Account**, and then select **Manage assets**.
4. In **Manage assets**, select **Chat agents**.
5. Select **My Assistant** from the list of chat agents shown. Then, from the **Actions** menu, select **Share**.

6. In the **Share assets** modal, use the **User or Group** search bar to find the user or group you want to designate as owners for the system agent.
7. Then, from **Permissions**, choose **Owner**. Then, select **Share**.

Edit system chat agent settings

To customize your system chat agent, users designated as owners need to login to Amazon Quick and visit the agent library page. Admins can directly access this page by clicking on the **Go to agent** link in admin console under **Chat agent customization**. Once in Amazon Quick, follow these steps to edit your system default chat agent's properties. You can preview and test how your system agent works as you configure it.

To update system chat agent settings

1. Log in to the Amazon Quick console.
 2. Select **Manage Quick** from the Amazon Quick admin console.
 3. From the admin console left navigation menu, select **Customization**, and then select **Chat agent customization**.
 4. In **Chat agent customization**, in **System chat agent**, select **Go to chat agent**.
 5. In the **My Assistant** page, in **Configure chat agent**, customize the following sections:
 - a. In **Chat agent persona**, configure your chat agent's personality, identity, tone, and response style. For detailed information about agent customization options, see [Working with chat agents](#) in the *Amazon Quick User Guide*.
-  **Note**
- This agent powers default chat interactions across all users of this account with chat feature access. Ensure that your instructions (e.g. identity and response style) work well for all users of this account.
- b. In **Reference documents**, upload files that remain active in your chat agent's memory to guide all interactions. For detailed information about file upload options, see [Working with chat agents](#) in the *Amazon Quick User Guide*.

Note

Since this agent is meant for broad use, this is a place to upload enterprise-level response templates and guides.

The system default agent isn't linked to specific knowledge sources, actions, or spaces to ensure it works for all users regardless of their access permissions. This setting can't be changed.

6. In **Customization**, configure details to help recognize the chat agent. For detailed information about customization options, see [Working with chat agents](#) in the *Amazon Quick User Guide*.

Configure clickable external links in chat responses

Admins can configure whether URLs in chat agent responses appear as clickable hyperlinks. The following procedure shows you how to enable clickable hyperlinks for all chat agents in your Amazon Quick instance.

To enable clickable external links

1. Log in to the Amazon Quick console.
2. Select **Manage Quick** from the Amazon Quick admin console.
3. From the admin console left navigation menu, select **Customization**, and then select **Chat agent customization**.
4. Under **Clickable external links**, turn the toggle on.

Using the Amazon Quick analytics dashboard

Analytics in Amazon Quick provides insights into how users interact with your instance across all features and capabilities. The analytics dashboard delivers the data-driven insights you need to make informed decisions about security, performance, and user experience.

Note

The analytics dashboard is only available for IAM administrators.

The Amazon Quick analytics system captures detailed usage metrics from chat conversations, space interactions, flow executions, action invocations, research activities, automations, and custom agent usage. This comprehensive data collection enables you to understand not just what users are doing, but how effectively they're leveraging Quick to accomplish their goals while maintaining security and compliance standards.

You can use analytics to:

- Monitor user adoption and engagement across all Quick features
- Identify potential issues and monitor system health through available analytics
- Analyze user feedback and satisfaction trends to improve the user experience
- Understand resource utilization patterns and identify your most valuable content
- Make data-driven decisions about feature deployment, training needs, and resource allocation
- Monitor security-related events such as blocked messages and failed queries

Topics

- [Analytics access and permissions](#)
- [Analytics dashboard overview](#)
- [Accessing the analytics dashboard](#)
- [Understanding analytics metrics](#)
- [Analytics limitations](#)

Analytics access and permissions

Access to analytics in Amazon Quick is controlled by user roles and permissions to ensure data security and privacy. Currently, only IAM administrators have access to the analytics dashboard.

To access the analytics dashboard, you need the following permission:
quicksight:QuickSuiteUsageMetrics

User type	Analytics capabilities
IAM administrators	• View all analytics data for the entire instance • Access detailed query and response data • Monitor team adoption and engagement metrics

Important

If you have analytics access, you can view detailed query text, failed-query content, and the full conversation context associated with negative feedback. Grant analytics access only to authorized administrators, and apply your organization's data-handling and incident-response policies to analytics review workflows.

Analytics dashboard overview

The Amazon Quick analytics dashboard is organized into several key sections that provide different perspectives on your instance usage and security events:

Dashboard filters and controls

The analytics dashboard provides filtering options to focus on specific data:

- **Agent filter** – Select from two available options: "All Agents" to see aggregate data across all agents, or "My Assistant (System Agent)" to view system agent metrics
- **Date range picker** – Choose different time periods to analyze trends and patterns

Active user metrics

Track how users interact with your Amazon Quick instance over time.

This section displays user activity metrics including:

- **Active users** – Daily, weekly, and monthly active user counts with trend comparisons
- **Usage trends** – Growth patterns and engagement changes over time
- **Feature adoption** – Usage distribution across chat, spaces, flows, and other features

Use these metrics to understand user adoption patterns and identify engagement opportunities.

Chat agent and asset metrics

Monitor chat usage patterns and user feedback to understand engagement with conversational features and identify areas for improvement.

Conversation analytics

This section provides insights into chat usage including:

- **Total conversations** – Number of chat sessions initiated
- **Total queries** – Number of messages sent by users
- **Average queries per user** – Engagement depth metrics
- **Average queries per conversation** – Conversation length patterns displayed in a time-series chart showing trends over months
- **Conversations, queries, and active users chart** – Interactive line chart displaying total conversations, total queries, and active users trends over time with monthly granularity

These metrics help optimize chat experiences and identify usage trends.

User feedback analytics

Track user satisfaction to continuously improve system quality.

This section displays user feedback data including:

- **Positive feedback** – Thumbs up interactions and trends
- **Negative feedback analysis** – Thumbs down interactions with detailed reasons and breakdown by category
- **Customer feedback trend chart** – Time-series visualization showing positive vs. negative feedback patterns over months
- **Query scope selection chart** – Analytics showing how users select different query scopes, with breakdowns by "All Resources Selected", "No Resources Selected", and "Specific Resources"
- **Feedback trends** – Satisfaction changes over time with 3-month historical data
- **Thumbs down details** – View specific queries that received negative feedback, including the full conversation context and user-provided reasons
- **Thumbs down reason breakdown** – Detailed categorization of negative feedback reasons to identify common issues and improvement areas

Leverage feedback data to enhance user satisfaction and system performance.

Query issue analysis

Identify and resolve query problems to improve system performance.

The query issue analysis section helps you identify and resolve problems:

- **Issue percentage breakdown** – View the percentage of queries that failed by issue type
- **Failed query details** – See the actual query text from users, ordered by most recent, with issue type classification
- **Unanswered queries section** – Dedicated analytics for queries that received no response, helping identify system gaps and user needs
- **Full conversation context** – Click on any failed query to see the complete conversation leading up to the issue
- **Issue trends** – Track how query issues change over time to identify patterns

Use this analysis to proactively address system issues and improve user experience.

Asset creation and usage

Monitor resource utilization to optimize content and feature adoption.

This section provides insights into resource utilization including:

- **Assets created** – New spaces, agents, flows, actions, research, and automations
- **Assets used** – Active resource engagement
- **Number of users by asset type chart** – Horizontal bar chart showing user distribution across different asset types including Actions, Automations, Chat, Custom Agents, Flows, Research, and Spaces
- **Most used assets** – Most popular content and tools (spaces, agents, actions, flows, research)

Use these insights to guide content strategy and resource allocation decisions.

Automations, flows, and research agent hours usage

Monitor agent hours usage to manage subscription limits and optimize resource allocation across different subscription tiers.

This section includes the following tabs:

- **Automation and Flows Agent hours** – Provides insights into agent hours consumed by automations and flows
- **Research Agent hours** – Provides insights into agent hours consumed by research activities

Agent hours consumption metrics include:

- **Total Professional hours** – Agent hours consumed by Professional tier users
- **Total Enterprise hours** – Agent hours consumed by Enterprise tier users
- **Additional hours** – Overage hours used beyond included monthly allocations
- **Hours used by subscription type chart** – Horizontal bar chart showing user distribution by percentage of included hours consumed (25-49%, 50-74%, 75-99%, >100%) for both Enterprise (4hrs/mo) and Professional (2hrs/mo) tiers
- **Additional agent hours used by week** – Weekly trend chart showing additional hours consumed by Enterprise users after exceeding their included hours

Use these metrics to understand user adoption patterns and identify engagement opportunities.

Accessing the analytics dashboard

You can access the analytics dashboard from the Amazon Quick console if you have the appropriate permissions.

To access the analytics dashboard

1. Log in to the Amazon Quick console.
2. From the left navigation menu, select **Analytics**, and then select **Amazon Quick Usage Metrics**.

The analytics dashboard opens, displaying an overview of your instance usage and available analytics.

3. Use the date picker to specify the time interval for the graphs. You can choose from the following preset intervals:
 - **Last week** – This interval starts from the previous Sunday at 00:00 and goes until the following Sunday at 00:00 in the UTC time zone.
 - **This week** – This interval starts on Monday at 00:00 and goes until 00:00 today as per the timezone relevant for the primary region of the Amazon Quick account.

- **Last month** – This interval begins on the 1st day of the last month at 00:00 and ends on the first day of this month at 00:00 in the UTC time zone.
- **This month** – This interval begins on the 1st day of this month at 00:00 and goes until 00:00 today in the UTC time zone.

Note

If you don't see the Analytics option in the navigation menu, contact your instance administrator to request access.

Understanding analytics metrics

The analytics dashboard displays various metrics that help you understand usage patterns, performance, and security events. The following sections explain key metrics in detail.

User activity metrics

User activity metrics help you understand how many people are actively using your Amazon Quick instance:

- **Daily active users** – Number of unique users who sent at least one message in a given day
- **Weekly active users** – Number of unique users who sent at least one message in the current week starting from Monday
- **Monthly active users** – Number of unique users who sent at least one message in the current month starting from the 1st day of the month

Note

Active user metrics are based on chat interactions and may not reflect all types of Quick usage.

Security monitoring metrics

Security monitoring metrics help you track potential security issues and policy enforcement:

- **Blocked messages** – Messages blocked by guardrails for safety, policy, or content violations

- **Failed messages** – Messages that encountered errors, with specific error codes for troubleshooting

Analytics limitations

The following limitations apply to Amazon Quick analytics:

- Analytics primarily covers chat interactions and may not capture all types of Quick usage
- Data processing may have a delay of up to 24 hours
- Historical data availability depends on when analytics was first enabled
- Some metrics may be aggregated to protect individual user privacy
- Analytics data retention follows your instance's data retention policies
- Detailed query and response data is only available to instance administrators

Note

For comprehensive monitoring beyond chat interactions, consider using CloudWatch metrics and logs in conjunction with the analytics dashboard. For more information, see [Monitoring Quick](#).

AWS security in Quick

Amazon Quick provides a secure platform that enables you to distribute dashboards and insights to tens of thousands of users, with multiple-region availability and built-in redundancy.

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that is built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The [shared responsibility model](#) describes this as security *of* the cloud and security *in* the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. The effectiveness of our security is regularly tested and verified by third-party auditors as part of the

[AWS compliance programs](#). To learn about the compliance programs that apply to Quick, see [AWS Services in Scope by Compliance Program](#).

- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors, including the sensitivity of your data, your organization's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Amazon Quick. The following topics show you how to configure Amazon Quick to meet your security and compliance objectives. You also learn how to use other AWS services that can help you to monitor and secure your Amazon Quick resources.

Amazon Quick enables you to manage your users and content using a comprehensive set of security features. These include role-based access control, Microsoft Active Directory integration, AWS CloudTrail auditing, single sign-on using AWS Identity and Access Management (IAM) and third-party solutions, private VPC subnets, and data backup. Amazon Quick can also support FedRAMP, HIPAA, PCI DSS, ISO, and SOC compliance to help you meet industry-specific or regulatory requirements.

AI and agent security in Amazon Quick

Amazon Quick includes AI capabilities that read content, take actions, and run automated workflows. These capabilities introduce properties that differ from traditional BI features. Use this page to understand what makes these capabilities different, how to apply the available controls, and where those controls have limits. For the corresponding security checklist, see [Security in Quick](#).

What makes these capabilities different

Three properties distinguish the AI and agent capabilities from traditional features such as dashboards and datasets.

- **The assistant reads content your users did not author** – Knowledge bases, web search, third-party research providers, and connectors all supply content that originates outside your organization. Any content from outside your trust boundary is a potential source of adversarial input. For the full list of content sources, see [Two-condition model for adversarial content risk](#).
- **The assistant can take actions with effects outside the service** – Through connectors, Model Context Protocol (MCP) server tools, and web search queries, the assistant can cause changes in external systems. For the full inventory of outbound paths, see [Outbound connections and data egress in Amazon Quick](#).
- **Some capabilities run without a person watching** – Automated workflows execute on a schedule or in response to events, without an interactive user session. This changes how you evaluate the risk of each action. For more information, see [Autonomy and identity](#).

None of these properties is unique to Amazon Quick. They are common across AI-powered services. Together, they mean that the same security review you apply to a traditional dashboard does not fully address the risk profile of an agent or automated workflow.

Two-condition model for adversarial content risk

The risk of acting on adversarial content requires two conditions to be present at the same time:

1. The assistant can read content from outside your trust boundary.
2. The assistant can take a consequential action.

Narrowing either condition reduces your exposure. A trust boundary is the set of content sources that you consider safe and under your control. Any content that enters the assistant's context from outside that boundary is untrusted by definition.

Read surface

The following sources can supply content to the assistant's context. Each is a point where content you did not author can enter.

- Knowledge base and index retrieval (including bring-your-own-index from Amazon Q Business)

- Files uploaded to spaces
- Files uploaded in chat
- Web search results
- Third-party research provider data
- Content returned by connectors
- Content returned by remote MCP server tools

Retained context also contributes to the read surface. Past conversations and, on Quick Desktop, entities extracted from connected data sources persist across sessions and can inform later responses. For more information, see [Memory and retained context](#).

Not all of these sources carry equal risk. Files uploaded by your own users in chat are within your trust boundary. Content returned by a web search query to the open internet is not. Evaluate each source against your trust boundary when you review your configuration.

Action surface

The following paths allow the assistant to cause effects outside Amazon Quick. Each is a point where a consequential action can occur.

- On-demand actions through third-party and AWS service connectors
- Automated workflow actions through service-level connectors
- Remote MCP server tool invocations
- Web search queries (send context externally)
- Quick Apps bridge API calls (sandboxed)
- Code execution on Quick Desktop (file effects on the user's machine, within configured folder permissions; other code execution surfaces are sandboxed without external reach)
- Scheduled agent execution

For the complete inventory of outbound paths, including what data can leave through each one and who controls it, see [Outbound connections and data egress in Amazon Quick](#).

Autonomy and identity

Amazon Quick supports two invocation models with different security characteristics. The same connector or action carries different risk depending on which model invokes it.

On-demand actions

On-demand actions are user-initiated and interactive. They authenticate with the individual user's personal credentials and act as the invoking user. Each on-demand action is bounded by that user's connector permissions, and a person is present in the session when it executes.

Automated workflows

Automated workflows are scheduled or event-triggered and non-interactive. They authenticate at service level rather than as an individual user. Because they use service-level authentication, they are not bounded by an individual user's connector permissions and they run unattended.

The consequence for your review is that an automated workflow can reach any resource the service-level credential permits, regardless of which user created the workflow. No interactive session is present to observe what happens during execution. An action can carry limited risk when you invoke it on demand. The same action can carry broader risk when an automated workflow invokes it with service-level reach.

Adding a review step

To add a review step to an automated workflow, use the human-in-the-loop task center. For workflows where you want a person to approve an action before it executes, the task center pauses execution and collects approval before the workflow continues. For more information, see [Human-in-the-loop task center](#).

Human oversight

You can apply human approval gates at five points in the lifecycle of AI and agent capabilities. Together, they form a layered model for human oversight.

1. **Capability approval (Deny by Default)** – New AI capabilities in a restricted category are denied on launch until an administrator explicitly allows them. This gate applies before a capability is available to any user. For more information, see [Deny by Default](#).
2. **Build-time consent (Apps integration consent)** – When the Apps agent adds an integration to an app (connector, space, dashboard visual, or AI inference), it prompts the author for approval. The published app never includes unapproved integrations, and app viewers inherit the approved integration scope rather than broader access. For more information, see [Integration consent model](#).
3. **Share approval (Flows)** – Custom permissions control which users can review and approve flow sharing requests, and whether creators can share flows without approval. Administrators

configure these capabilities through custom permissions profiles. For more information, see [Custom permissions](#).

4. **Runtime review (human-in-the-loop task center)** – For workflows where you want a person to approve an action before it executes, the human-in-the-loop task center pauses execution and collects approval. This gate is optional and per-workflow. For more information, see [Human-in-the-loop task center](#).
5. **Per-action user control (Desktop, Preview)** – On Quick Desktop, each system tool can be enabled or disabled individually and supports a three-tier permission model – **Full Access**, **Read Only**, and **Ask Each Time** – with granularity for each operation. **Full Access** runs operations without prompting for confirmation. **Ask Each Time** confirms every operation. This places an approval decision in your hands at the moment of each action, for the tools you have enabled. For more information, see [Access levels](#) and [Managing permissions](#).

Where a per-action prompt applies, it is a user-configurable choice. On Desktop, you set a tool to **Ask Each Time** to confirm every operation, or to **Full Access** to run without prompting. In the web experience, on-demand actions execute when you trigger them, and automated workflows are non-interactive by design – the gates at capability, build, and share time do the work there.

Per-action confirmation is therefore available but not universal. It depends on the surface and on how you configure each tool.

For an automated workflow running unattended, no interactive session exists to confirm anything. For those workflows, the review effort belongs at approval time, when you evaluate what the automation can reach and what it can do.

Controls and limits for AI and agent capabilities

Amazon Quick provides the following controls relevant to AI and agent capabilities. Each control is described together with its limits.

Retrieval permission enforcement

For knowledge bases with document-level access control list (ACL) support enabled, Amazon Quick enforces synchronized document permissions on every retrieval. Supported integrations include Amazon S3, Google Drive, Microsoft SharePoint, Atlassian Confluence Cloud, and Microsoft OneDrive. If Amazon Quick cannot evaluate document permissions for a query, it returns no documents rather than unfiltered results.

Limit – ACL enforcement applies only to knowledge bases created with ACL support. Knowledge bases created without ACL support do not enforce document-level permissions. ACL configuration is permanent and cannot be changed after creation. For more information, see [Best practices for managing ACLs in knowledge bases](#).

Custom permissions and deny by default

Custom permissions restrict the capabilities available to each role. They cannot grant capabilities that a user does not already have. The most specific level wins: user-level overrides role-level, which overrides account-level. The deny-by-default option for the AI capability category restricts all AI capabilities, current and future, so that new capabilities are denied on launch day until you explicitly allow them.

Limit – Custom permissions require an Enterprise subscription. They scope down access but cannot extend it. For more information, see [Custom permissions](#) and [Deny by Default](#).

Organization-level controls and their limits

Custom permissions apply at the account level, and an administrator of that account can change them. If you manage many accounts with AWS Organizations, you can add organization-level controls that individual account administrators cannot override. These controls act on AWS API operations and account sign-up. Understand what they reach and what they do not.

- **Restrict who signs up for Quick** – A service control policy (SCP) controls which accounts, editions, and identity types can create a Quick subscription, so new accounts cannot start a subscription outside your approved set. For more information, see [Using service control policies to restrict Amazon Quick sign-up options](#).
- **Restrict the management API operations** – An SCP denies the Quick API operations that create and manage agents, flows, spaces, and knowledge bases. Where the policy applies, principals cannot create those resources through the AWS Command Line Interface, the AWS SDKs, or CloudFormation.
- **Restrict AI feature availability with custom permissions, not SCPs** – SCPs act on AWS API operations and account sign-up. They do not control which AI features a user sees or can use within the product. To restrict AI features for your users, use custom permissions with the deny-by-default option for the AI capability category. For more information, see [Deny by Default](#).

Limit – Each control enforces a different layer. An SCP controls account sign-up and API-based management across your organization, and no account administrator can override it. Custom

permissions control which AI features your users can use, and an account administrator can change them. To detect a custom permissions change, record the Quick management API operations with AWS CloudTrail and review them. For more information, see [Incident response, logging, and monitoring in Amazon Quick](#).

Tool and connector supply chain

Tools reach the AI assistant only through integrations that an administrator creates. MCP integrations require an Enterprise subscription. The integration model restricts the transport and discovery path for external tools.

- Only remote MCP servers are supported. Local studio connections are not supported.
- During connection, Amazon Quick discovers and registers the tools that the MCP server provides. After discovery completes, each tool is listed as an action that you can review and turn on. Tools do not become available automatically.
- You can connect to private MCP servers through a VPC connection that has network access to the server.
- Administrators can restrict individual connectors through custom permissions. Each connector supports three permissions: **Create and Update action**, **Share action**, and **Use action**. For more information, see [Custom permissions](#).

For more information about configuring an MCP integration, see [Model Context Protocol \(MCP\) integration](#).

Limit – Authentication options vary by connector type. For remote MCP servers, agent-to-agent connectors, and generic HTTP connectors, connecting without authentication is a selectable option. The integrity of a connection depends on how it is configured. The service does not evaluate the trustworthiness of a third-party MCP server or the behavior of the tools it exposes. That assessment is yours to make.

Guardrail screening and blocked words

Built-in content safety screening checks user requests for harmful content, including hate speech, insults, sexual content, violence, and misconduct. These checks also assess user requests for prompt attacks. You can configure up to 50 blocked words and phrases that Amazon Quick checks against both user requests and generated responses.

Limit – These controls help reduce risk. However, they do not replace your responsibility to configure access, permissions, agents, flows, and data sources for your use case. Blocked-word

checks use exact-match string comparison, not semantic analysis, and are limited to 50 entries of up to 36 characters each. Blocked-word checks apply only to chat agents and flows in the Amazon Quick web experience. For more information, see [AI guardrails in Amazon Quick](#).

Code execution isolation

The AI assistant can write and run Python code on four surfaces. Each surface runs code in a sandboxed environment designed to contain the code's effects. The surfaces differ in where code runs and what it can reach.

- **Quick Desktop** – Code runs in an OS-level sandbox (macOS Seatbelt or Windows AppContainer) on the user's machine. File access inside the sandbox follows the folder permissions the user configures, and a persistent namespace carries variables across code runs within a conversation. Pre-installed Python packages only; package installation (`pip install`) is not supported. For more information, see [Code execution](#).
- **Web experience chat** – Code runs in an isolated, service-managed sandbox with no internet access. Outbound network requests from the sandbox fail. The sandbox does not persist beyond the conversation.
- **Automated workflows (Quick Automate)** – Code actions and custom agent code run within a restricted Python environment. Code actions are not the path for reaching external systems: external API calls belong to REST API integrations, and file system or database access belongs to the appropriate integrations. For more information, see [the section called "Code"](#).
- **Office extensions** – The assistant creates and executes code within the Office application sandbox (Outlook, Excel, Word, and PowerPoint). For more information, see [Connect Amazon Quick to your existing tools with extensions](#).

The Execute code locally capability in custom permissions restricts code execution in Quick Desktop for the users a profile applies to. Extension capabilities, including code execution within Office applications, can be restricted through extension access controls. For more information, see [Custom permissions](#) and [Extension access](#).

Limit – On Desktop, the sandbox always has access to the system temporary directories regardless of the configured folder permissions. On Desktop, the persistent namespace means data loaded by an earlier code run remains available to later code runs in the same conversation. Sandboxing contains what code can reach; it does not evaluate what the code does with content already in the conversation context. Review generated code output like any other assistant output.

Logging and audit coverage

AWS CloudTrail records API-level activity (who did what). Vended logs record conversational content (what was said and what was responded). Together, they provide after-the-fact visibility into AI and agent activity.

Limit – Logging does not prevent any action. It provides visibility after the fact. The service does not include real-time alerting; you must configure CloudWatch alarms separately if you need near-real-time notification. Vended chat logs do not capture the content of source documents that retrieval returns. For more information, see [Incident response, logging, and monitoring in Amazon Quick](#).

Limits stated plainly

The following limitations apply to the AI and agent capabilities in Amazon Quick:

- **Screening reduces risk but does not replace configuration** – Built-in screening and guardrails help reduce risk. They do not replace your responsibility to configure access, permissions, agents, flows, and data sources for your use case.
- **No universal human review requirement** – Human review is not a system-wide requirement for actions. Per-action confirmation is available where a tool is configured for it (on Desktop, through the **Ask Each Time** access level), and the human-in-the-loop task center is available for workflows where you choose to add a review step. However, on-demand actions in the web experience execute immediately, and automated workflows execute without user intervention.
- **Authentication options vary by connector type** – The authentication methods available depend on the connector type. For remote MCP servers, agent-to-agent connectors, and generic HTTP connectors, connecting without authentication is a selectable option.

Memory and retained context

Chat memory personalizes responses by remembering your preferences, context, and past interactions. Chat agents reference stored information to provide more relevant responses without you repeating information in every conversation. For more information, see [Memory and response personalization](#).

On Quick Desktop, a My Context surface provides a Knowledge graph tab that shows entities and relationships extracted from connected data sources, and a Memory tab that shows facts, procedures, and patterns learned from conversations. For more information, see [My context](#).

Why retained context matters for security

Retained context is part of the read surface described in [Two-condition model for adversarial content risk](#). Unlike a single conversation, retained context persists across sessions. Information that the assistant remembers from a past interaction can influence responses and actions in a future session.

Controls

- **Isolation** – Memories are specific to the individual user and are not shared with other users.
- **User control** – You can review your chat memory through **Conversation History**. On Desktop, you can additionally manage whether Quick learns from your conversations, searches your conversation history, and extracts entities from connected services. You can also view, edit, and delete individual memories. For more information, see [Privacy controls](#).
- **Full reset (Desktop)** – The **Clear all data** option irreversibly removes all conversations, knowledge graph data, saved credentials, and user preferences. For more information, see [Clearing all data](#).
- **Administrator control** – Custom permissions include capabilities that restrict building and managing engrams (profiles of a user's writing style and patterns) and creating and accessing knowledge memory in Quick Desktop. For more information, see [Custom permissions](#).
- **No training** – Quick does not use your conversations, files, or personal context to train or improve AI models.

Limitations

- Chat memory is not supported for accounts configured with AWS KMS customer managed keys. An organization that requires customer managed keys does not get chat memory. For more information, see [Memory and response personalization](#).
- Quick Desktop is in Preview. The My Context surface, the Knowledge graph tab, the ability to view, edit, and delete individual memories, and the **Clear all data** option are Desktop features. In the web experience, you review chat memory through **Conversation History**. Confirm which controls are available on the surface you deploy rather than assuming parity between Desktop and web.

Where to go next

- [Security in Quick](#) – The security checklist with actionable practices for configuring Amazon Quick.

- [Outbound connections and data egress in Amazon Quick](#) – The complete inventory of outbound paths, what data can leave through each, and who controls it.
- [AI guardrails in Amazon Quick](#) – Built-in content safety screening and administrator-configured blocked words.
- [Custom permissions](#) – Role-based capability restriction and deny-by-default governance.
- [Best practices for managing ACLs in knowledge bases](#) – Document-level access control for knowledge bases, including fail-closed retrieval behavior.

Data protection in Amazon Quick

The AWS [shared responsibility model](#) applies to data protection in Amazon Quick. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. You are also responsible for the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see [Data Privacy FAQ](#). For information about data protection in Europe, see the [General Data Protection Regulation \(GDPR\) Center](#).

For data protection purposes, we recommend that you protect AWS account credentials and set up individual users with AWS IAM Identity Center or AWS Identity and Access Management (IAM). That way, each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We require TLS 1.2 and recommend TLS 1.3.
- Set up API and user activity logging with AWS CloudTrail. For information about using CloudTrail trails to capture AWS activities, see [Working with CloudTrail trails](#) in the *AWS CloudTrail User Guide*.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-3 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see [Federal Information Processing Standard \(FIPS\) 140-3](#).

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form text fields such as a **Name** field. This includes when you work with Amazon Quick or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form text fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Amazon Quick does not use customer data for training or improving underlying LLMs.

For information about safety controls for AI-powered chat interactions, see [AI guardrails in Amazon Quick](#).

Topics

- [Data encryption in Amazon Quick](#)
- [Inter-network traffic privacy in Amazon Quick](#)
- [Outbound connections and data egress in Amazon Quick](#)
- [User lifecycle and data handling in Amazon Quick](#)

Data encryption in Amazon Quick

Amazon Quick uses the following data encryption features:

- Encryption at rest
- Encryption in transit
- Key management

You can find more details about data encryption at rest and data encryption in transit in the following topics. For more information about key management in Amazon Quick, see [Encrypting your Amazon Quick data with AWS Key Management Service customer managed keys](#).

Topics

- [Encryption at rest](#)
- [Encryption in transit](#)

Encryption at rest

Amazon Quick securely stores your Amazon Quick metadata. This includes the following:

- Amazon Quick user data, including Amazon Quick user names, email addresses, and passwords. Amazon Quick administrators can view user names and emails, but each user's password is completely private to each user.
- Minimal data necessary to coordinate user identification with your Microsoft Active Directory or identity federation implementation (Federated Single Sign-On (IAM Identity Center) through Security Assertion Markup Language 2.0 (SAML 2.0)).
- Data source connection data.
- Amazon Quick encrypts your data source credentials (username and password) and OAuth tokens with your default customer managed KMS key when one is registered with Amazon Quick. Amazon Quick re-encrypts credentials and tokens with the current default customer managed KMS key each time you update the credential or refresh an OAuth token. If you do not register a default customer managed KMS key, Amazon Quick encrypts this information with a service-managed key.
- Names of your uploaded files, data source names, and data set names.
- Statistics that Amazon Quick uses to populate machine learning (ML) insights.
- Data indexed to support Amazon Q in Quick. This includes the following:
 - Topics
 - Metadata related to your dashboards
 - Your first index capacity purchase
 - Your first chat
 - Your first space creation
 - Your first knowledge base creation

Important

Quick protects data indexed to support Amazon Q with the Amazon Q data key. That key is set the first time Amazon Q data is created in your account and cannot be changed afterward. To use a customer managed KMS key for Amazon Q data, register it as your account default key before creating any Amazon Q data. For more information, see [Amazon Q data key](#) and [Customer managed KMS key scope](#).

Amazon Quick securely stores your Amazon Quick data. This includes the following:

- When no customer managed KMS key applies, data at rest in SPICE is encrypted using hardware block-level encryption with keys that AWS owns and manages. For information about using a customer managed KMS key with SPICE datasets, see [Customer managed KMS key scope](#).
- When no customer managed KMS key applies, other data at rest is encrypted with a service-managed key. This includes the following:
 - Sample values for filters.
 - User feedback on chat responses, including optional free-text comments. User feedback is not encrypted with your customer managed KMS key or the Amazon Q data key.

Report artifacts (including email reports) can be encrypted with your default customer managed KMS key when one is registered. For more information, see [Customer managed KMS key scope](#).

- Amazon Quick encrypts cached query results at rest. Amazon Quick caches query results from a SPICE dataset that your customer managed KMS key protects under that same key, and encrypts other cached results with a service-managed key.

When you delete a user, Amazon Quick permanently deletes that user's metadata. What happens to the assets that the user owned, and to data such as the user's conversation history, depends on how the user is removed. For more information, see [User lifecycle and data handling in Amazon Quick](#).

When you unsubscribe from Amazon Quick, all of your Amazon Quick data is completely and permanently deleted. This includes all metadata, any data you have in SPICE, and Amazon Q data, including the Quick index. This deletion is immediate; there is no retention period during which the data can be recovered.

Encryption in transit

Amazon Quick supports encryption for all data transfers. This includes transfers from the data source to SPICE, or from SPICE to the user interface. However, encryption isn't mandatory. For some databases, you can choose whether transfers from the data source are encrypted or not. Amazon Quick secures all encrypted transfers by using Secure Sockets Layer (SSL).

Inter-network traffic privacy in Amazon Quick

To use Amazon Quick, users need access to the internet. They also need access to a compatible browser or a mobile device with the Amazon Quick mobile app installed. They don't need access to the data sources they want to analyze. This access is handled inside Amazon Quick. User

connections to Amazon Quick are protected through the use of SSL. So that users can access Amazon Quick, allow access to HTTPS and Web Sockets Secure (wss://) protocol.

You can use a Microsoft AD connector and single sign-on (IAM Identity Center) in a corporate network environment. You can further restrict access through the identity provider. Optionally, you can also use MFA.

Amazon Quick accesses data sources by using connection information supplied by the data source owner in Amazon Quick. Connections are protected both between Amazon Quick and on-premises applications and between Amazon Quick and other AWS resources within the same AWS Region. For connections to any source, the data source must allow connections from Amazon Quick.

Traffic between service and on-premises clients and applications

You have two connectivity options between your private network and AWS:

- An AWS Site-to-Site VPN connection. For more information, see [What is AWS site-to-site VPN?](#)
- An Direct Connect connection. For more information, see [What is AWS direct connect?](#)

If you are using AWS API operations to interact with Amazon Quick through the network, clients must support Transport Layer Security (TLS) 1.2 or later. Clients must also support cipher suites with Perfect Forward Secrecy (PFS), such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Diffie-Hellman Ephemeral (ECDHE). Most modern systems such as Java 7 and later support these modes. You must sign requests using an access key ID and a secret access key that are associated with an IAM principal, or you can use the [AWS Security Token Service \(STS\)](#) to generate temporary security credentials to sign requests.

Traffic between AWS resources in the same region

An Amazon Virtual Private Cloud (Amazon VPC) endpoint for Amazon Quick is a logical entity within a VPC that allows connectivity only to Amazon Quick. The VPC routes requests to Amazon Quick and routes responses back to the VPC. For more information, see the following:

- [VPC endpoints](#) in the *Amazon VPC User Guide*
- [Connecting to a Amazon VPC with Amazon Quick](#)

Outbound connections and data egress in Amazon Quick

Stored customer data in Amazon Quick does not leave its AWS Region. The documented exceptions are AI inference processed within a defined geography (cross-Region inference) and the outbound paths that you or your administrator enables. Every path described on this page is either off by default or requires explicit configuration before data can leave the service boundary.

For related guidance on evaluating these paths before you enable them, see [Security in Quick](#).

Code execution is not an outbound path in the web experience. Python code that the AI assistant writes and runs in web chat executes in an isolated sandbox with no internet access. Automation code actions run in a restricted Python environment. External API calls belong to REST API integrations, which are connectors described on this page. For more information, see [Code execution isolation](#).

The following table summarizes each outbound path, the data that can leave, and the control that enables it.

Outbound path	Data that can leave	What enables it
Connectors	Conversational context, user requests, and structured parameters sent to the connected third-party or AWS service	Administrator creates and configures the connector, selects authentication method and scopes; individual connectors can be restricted through custom permissions
Remote MCP servers	Tool invocation parameters derived from conversational context	Administrator creates the MCP integration (Enterprise subscription required)
Web search	Queries derived from user requests sent to external web search providers	Administrator enables web search for the organization
Third-party research providers	Research queries derived from the research objective	Administrator sets up each integration individually and shares it with authorized users; premium providers require a

Outbound path	Data that can leave	What enables it
		provisioned license; the Research custom permission removes all providers for a profile
Quick Apps (public access)	App content rendered to anonymous internet viewers	App owner enables public sharing (Free and Plus accounts only)
Embedding	Dashboard visuals, analytics, and generative BI content rendered in an external web application	Administrator or developer configures embedding with IAM API calls and domain allowlisting (Enterprise required)
Exports and downloads	Dashboard data (PDF, CSV), research reports, analysis data	User-initiated; administrator can restrict through custom permissions
Log and metric delivery	Chat conversations, user feedback, agent hours, index storage usage, knowledge base file sync results	Administrator configures delivery destinations (CloudWatch Logs, Amazon S3, Firehose)
Cross-Region inference	Inference inputs and outputs move between Regions within a defined geography	Automatic platform behavior; no outbound destination for you to review or restrict

Connectors

Connectors create secure connections between Amazon Quick and third-party or AWS services. After an administrator configures a connector, it sends conversational context, user requests, and structured parameters to the target service.

- **What triggers it** – On-demand connectors execute when a user initiates them. Automated workflow connectors execute on a schedule or in response to an event, without user interaction.
- **Who controls it** – An administrator creates and configures each connector, choosing the authentication method (managed OAuth, custom user OAuth, API key, or service-to-service) and the scopes granted. A user can invoke only the connectors that an administrator shares with that

user. Administrators can additionally restrict individual connectors through custom permissions. Each connector supports three permissions: **Create and Update action**, **Share action**, and **Use action**. Custom permissions profiles apply at the user, role, or account level. The most specific level takes precedence. For more information, see [Custom permissions](#).

- **What to verify** – Before enabling a connector, verify the authentication method and OAuth scopes granted, whether the connector is shared broadly or narrowly, whether it is on-demand or automated, and what the service-level authorization permits. The credential you configure defines the connector's reach into the connected system. The connector can act on whatever the granted scopes and the service-level authorization permit, and nothing more.

For more information about action types, see [On-demand actions](#) and [Automated workflows](#). For details on authentication methods, see [Authentication methods](#).

Remote MCP servers

With remote Model Context Protocol (MCP) server integrations, the AI assistant can invoke tools that those servers provide. When the assistant invokes a tool, it sends tool invocation parameters derived from conversational context to the MCP server endpoint.

- **What triggers it** – The AI assistant selects a tool during a user-initiated or automated conversation. During connection, Amazon Quick discovers and registers the tools that the MCP server provides. After discovery completes, each tool is listed as an action that you can review and turn on.
- **Who controls it** – An administrator creates the MCP integration in the console. The integration specifies the endpoint URL, the connection type (public internet or private VPC), and the authentication method. You need an Enterprise subscription. Administrators can restrict individual MCP connectors through custom permissions. Each connector supports three permissions: **Create and Update action**, **Share action**, and **Use action**. For more information, see [Custom permissions](#).
- **Transport restriction** – MCP integration supports remote servers only. Local stdio connections are not supported. An MCP integration cannot invoke a process running on a local machine.
- **What to verify** – Before enabling an MCP integration, verify whether authentication is enabled (unauthenticated access is a selectable option), the OAuth scope if user authentication is selected, the network path (public internet or private VPC), and what tools the server exposes. Confirm that only the tools required for the intended use case are turned on.

For more information, see [Model Context Protocol \(MCP\) integration](#).

Web search

When web search is enabled, Amazon Quick sends queries derived from user requests to external web search providers. The assistant uses web search automatically in chat and research sessions to gather information from publicly available online sources.

- **What triggers it** – The assistant selects web search during a user-initiated chat or research session. You can turn off web search for individual queries.
- **Who controls it** – An administrator enables or disables web search for the organization. When web search is enabled, you can turn it off for each query. Web search queries route through designated AWS Regions based on the account's primary Region.
- **What to verify** – Before enabling web search, determine whether your use case requires external web data and understand how queries route across Regions.

For more information, see [Admin controls](#).

For more information about cross-Region routing for web search, see [Cross-Region calls for web search](#).

Third-party research providers

Amazon Quick Research integrates with third-party data providers such as FactSet, IDC, and S&P Global. When a user runs a research session, the agent determines which providers to use based on relevance to the research objective and sends queries to those providers.

- **What triggers it** – The research agent selects providers automatically based on relevance. Users choose which provider categories to include for each research session.
- **Who controls it** – Access to third-party research providers is layered across multiple controls. An administrator sets up each integration individually and shares it only with the users who need access. Unshared integrations are unavailable. Premium providers (FactSet, IDC, S&P Global Energy, S&P Global Market Intelligence) additionally require an administrator-provisioned license. If you don't provision a license, those providers stay unavailable. The Research capability in custom permissions removes access to Research – and therefore all third-party providers – for a given profile. Restricting the "Use internet to enhance results" capability separately removes web-based search in chat agents and Research.

- **What to verify** – Verify that each third-party data integration is shared only with authorized users. For premium providers, verify that licenses are provisioned only where needed. For public providers, verify that your acceptable-use policies permit sending research queries to external sources. Use the Research capability in custom permissions to remove Research entirely for profiles that must not reach any external provider. For more information about custom permissions, see [Custom permissions](#).

For more information, see [Using third party data in Amazon Quick Research](#) and [Select research materials](#).

Quick Apps and public access

Quick Apps run inside a security sandbox that blocks direct external network access. All communication with external systems goes through the secure bridge API or a registered connector. When an app owner enables public sharing, app content renders to anonymous internet viewers who have no identity, no integrations, and are rate-limited.

- **What triggers it** – The app owner creates and publishes an app. Anonymous viewers access it through a public URL.
- **Who controls it** – The app owner controls sharing and public access settings. Public access is available only to Free and Plus accounts. The sandbox is platform-enforced and blocks app code from making direct HTTP requests to external servers or loading external resources.
- **What to verify** – Before making an app public, verify that public viewers have no access to integrations, that usage counts against the owner's quota, and that the sandbox restrictions meet your security requirements.

For more information, see [Security and sandbox in apps in Quick](#).

Embedding

Embedding renders Amazon Quick dashboard visuals, analytics, and generative BI content in an external web application. Domain allowlisting controls where embedded content can render. Row-level security (RLS) and column-level security (CLS) are enforced for embedded viewers.

- **What triggers it** – An administrator or developer configures embedding through IAM API calls. End users then access the embedded content in the host application.

- **Who controls it** – An Enterprise subscription is required. The administrator or developer configures the AllowedDomains parameter to limit which domains can host embedded content. The IAM policy condition AllowedEmbeddingDomains provides additional restriction.
- **What to verify** – Before enabling embedding, verify that every domain in the allowlist is controlled by your organization, that RLS and CLS are configured for the underlying datasets, and that you have an Enterprise subscription.

For more information, see [Embedding Amazon Quick Sight analytics into your applications](#).

Exports and downloads

Users can export dashboard data as PDF or CSV files, download research reports, and export analysis data. Exported data goes to the user's local device or, for scheduled email reports, to the configured email delivery destination.

- **What triggers it** – A user initiates an export or download action in the console.
- **Who controls it** – An administrator can restrict export capabilities through custom permissions. For example, you can disable access to the export-to-PDF option on analyses and dashboards. An Enterprise subscription is required for custom permissions.
- **What to verify** – No single consolidated export-security configuration exists. Verify whether export capabilities are restricted through custom permissions for the relevant roles, whether scheduled email reports are limited to intended recipients, and whether your compliance requirements impose constraints on where exported data can be stored.

For more information about restricting capabilities, see [Custom permissions](#).

Log and metric delivery

Use log and metric delivery to send data from Amazon Quick to destinations that you control. Unlike the other paths on this page, data goes to your own AWS infrastructure rather than to a third party. Log types include chat conversations, user feedback, agent and research hours, index storage usage, and knowledge base file sync results.

Sensitive data in chat logs

Chat logs can contain sensitive or personally identifiable data.

- **What triggers it** – An administrator configures delivery. After configuration, delivery is continuous or scheduled.
- **Who controls it** – An administrator configures the delivery destination (CloudWatch Logs, Amazon S3, or Firehose). IAM permissions are required to set up delivery. When a destination uses a customer managed KMS key, the key policy must allow the delivery service principal.
- **What to verify** – Before configuring log delivery, verify the encryption and access policies at the destination, the retention policies at the destination, and that personnel with access to the destination understand that chat logs can contain sensitive data.

For more information, see [Monitoring Amazon Quick using CloudWatch Logs](#).

Cross-Region inference

Cross-Region inference is processing within a defined geography, not customer-enabled egress. It is included on this page to prevent confusion, because it involves data moving between Regions. However, it differs from every other path described on this page. There is no customer-chosen destination. No data reaches a third party. Data stays on the AWS network, and stored data remains in the primary Region.

- **What moves** – Inference inputs (prompts) and outputs (results) can move outside of the primary Region during processing. All data is transmitted encrypted across the AWS secure network.
- **What triggers it** – Amazon Quick automatically selects the optimal Region within a defined geography to process inference requests. You do not initiate or schedule this routing.
- **Who controls it** – Cross-Region inference is not a customer-configurable outbound path. Inference is processed within the Regions that make up your geography, no data reaches a third party, and stored data remains in your primary Region. Because there is no outbound destination, there is no destination for you to approve or restrict. You cannot disable cross-Region inference. Instead, verify which geography your Region belongs to. Confirm that the geography boundary satisfies your data residency requirements.
- **Boundaries** – Cross-Region inference requests stay within the AWS Regions that are part of the geography where the data originally resides. Stored data remains only in the primary Region.

For more information, see [Cross-Region inference for Australia, Japan, Europe, and the United States](#).

User lifecycle and data handling in Amazon Quick

What happens to a user's data and assets in Amazon Quick depends on how the user is removed. This page describes the three removal paths and their effect on a user's assets. It also covers the cleanup steps you must complete as an administrator.

Topics

- [How users are removed](#)
- [What is deleted immediately](#)
- [Assets with multiple owners](#)
- [Orphaned assets](#)
- [Deactivation compared with deletion](#)
- [Account termination](#)
- [Conversations and Amazon Q data](#)
- [When access ends](#)

How users are removed

How a user is removed determines what happens to the assets they owned. The following table describes the three removal paths.

Removal path	Access	What happens to the user's assets
Console deletion by an administrator	Ends when the user is deleted.	The administrator chooses whether to transfer the user's assets to another user or delete them. If no transfer user is chosen, assets owned solely by the deleted user are deleted, and assets that have other owners remain available to those owners with the deleted user removed from their permissions.

Removal path	Access	What happens to the user's assets
DeleteUser API operation	Ends when the user is deleted.	No asset cleanup runs. The user's assets are neither transferred nor deleted; they remain in the account without an owner until an administrator transfers them.
Removal from a directory group (IAM Identity Center or Active Directory)	The user can no longer sign in.	No asset cleanup runs automatically. Amazon Quick detects the removal and lists the user in the Inactive users list on the Manage users page, where an administrator can review them and apply the same transfer-or-delete choice as console deletion. Until an administrator acts, the user's assets remain in the account. This detection applies only to IAM Identity Center and Active Directory.

To complete cleanup, administrators use the asset management console to transfer assets owned by a departed user, and review users removed from IAM Identity Center or Active Directory on the **Manage users** page, where those users appear in the **Inactive users** list. For the console deletion procedure, see [Deleting a Amazon Quick user account](#). To transfer assets that no longer have an owner, see [Amazon Quick asset management](#). For users removed from IAM Identity Center or Active Directory, see [Deleting Enterprise accounts](#).

The Inactive users list applies to directory-federated users only

Amazon Quick detects removed users and populates the **Inactive users** list only for accounts that federate through IAM Identity Center or Active Directory. Users that you create directly in Amazon Quick, including IAM federation users, are managed at the user

level, so Amazon Quick does not detect their removal from an external identity provider. Remove these users with console deletion or the `DeleteUser` API operation, and transfer or delete their assets as part of that removal.

If your knowledge bases use document-level access control lists (ACLs), also update the ACL configuration to remove the departing user, and refresh the affected knowledge bases. User removal does not update knowledge base ACLs. For more information, see [Best practices for managing ACLs in knowledge bases](#).

What is deleted immediately

When you delete a user through any path, Amazon Quick permanently deletes the user's metadata, including their profile and role membership.

Assets with multiple owners

Amazon Quick never deletes an asset that has more than one owner when a user is removed. Amazon Quick removes the departed user from the asset's permissions, and the asset remains available to its other owners.

Orphaned assets

No user can access assets that remain in the account without an owner – for example, after deletion with the `DeleteUser` API operation, or after identity-provider removal that is pending administrator review – until you transfer them. Use the asset management console to find and transfer assets that a departed user owned. For more information, see [Amazon Quick asset management](#).

Deactivation compared with deletion

Deactivating a user revokes the user's access but leaves the user's assets associated with them. Deactivation occurs, for example, when you remove the user from the IAM Identity Center or Active Directory group that grants Amazon Quick access. Reactivating the user restores their access to those assets. Deletion is permanent.

A user who is removed from IAM Identity Center or Active Directory appears in the **Inactive users** list on the **Manage users** page and remains there until an administrator removes them.

A user who is deleted but not deactivated can sign in again as a new user, without access to their previous assets.

For more information, see [Deactivating user accounts](#).

Account termination

Unsubscribing from Amazon Quick permanently deletes all of your Amazon Quick data, including all metadata, any data in SPICE, and Amazon Q data. For more information about account settings, see [Account details in Amazon Quick](#). For how unsubscribing affects the Amazon Q data key, see [Amazon Q data key](#).

Conversations and Amazon Q data

A user's chat conversations are private to that user. When you delete or deprovision a user, Amazon Quick does not transfer their conversation history to any other user, and you can't access it through the application.

Deleting a user does not immediately delete the user's conversation history. Amazon Quick retains conversations, messages, and chat file attachments on a rolling 30-day window measured from activity, and then permanently deletes them. Users can delete their own conversations at any time. When you unsubscribe from Amazon Quick, Amazon Quick permanently deletes all Amazon Q data, including conversation history.

Amazon Quick does not delete feedback that a user submitted when that user is deleted. Amazon Quick retains analytics data according to your instance's data retention policies.

When access ends

Removing or deleting a user prevents new sign-ins to Amazon Quick. Amazon Quick also denies requests from the user's existing sessions after the change takes effect, which can take up to five minutes.

Incident response, logging, and monitoring in Amazon Quick

Intended audience: System administrators and Amazon Quick administrators

Amazon Quick provides multiple monitoring and audit signals that address different aspects of security, operations, and compliance. Each signal has distinct coverage, latency, retention, and access-control characteristics.

- **CloudTrail** – Records supported Amazon Quick and Amazon Quick Sight API operations and a documented set of non-API events, such as dashboard views and user-management actions. For chat conversations and feedback, use CloudWatch vended logs.
- **CloudWatch vended logs** – Deliver chat conversations, user feedback, agent hours usage, index storage usage, and knowledge base file sync results to destinations that you control. Configure vended log delivery shortly after enabling Amazon Quick.
- **CloudWatch metrics** – Provide near-real-time operational metrics and support CloudWatch alarms.
- **Amazon Quick analytics** – Provide usage, adoption, feedback, and selected security-related insights to IAM administrators.
- **Feature-specific reports** – Provide operational detail for the feature that produces them, such as knowledge base sync reports.
- **Amazon EventBridge** – CloudTrail events route to Amazon EventBridge on a best-effort basis. You can create rules that match Amazon Quick events and route them to targets such as Lambda functions, Amazon SNS topics, or Amazon SQS queues for automated response.

Use these sources together when you design monitoring and incident-response procedures. Before you rely on a signal for compliance, detection, or investigation, confirm that it covers the event you intend to track.

The following table helps you choose the right signal for your monitoring need.

To answer	Use	More information
Who performed an administrative or API action, from where, and when	CloudTrail	Monitoring Amazon Quick using CloudTrail
Who viewed a dashboard, or which non-API events occurred	CloudTrail non-API events	Tracking non-API events by using CloudTrail logs
Which API calls occurred for AI features (flows, agents, automations, connectors)	CloudTrail (management and data events)	Monitoring Amazon Quick using CloudTrail; Logging Amazon Quick data events in CloudTrail

To answer	Use	More information
What users asked and what Quick answered	CloudWatch vended logs (CHAT_LOGS)	Monitoring Amazon Quick using CloudWatch Logs
How users rated responses and why	Vended logs (FEEDBACK_LOGS) or analytics	Monitoring Amazon Quick using CloudWatch Logs ; Using the Amazon Quick analytics dashboard
Whether a document synced into a knowledge base, and why it failed or was skipped	Vended logs (KB_FILE_SYNC_LOGS) or console sync reports	Monitoring Amazon Quick using CloudWatch Logs ; Sync reports and observability
Whether a specific user can access a specific synced document	Sync report ACL verification	Sync reports and observability
Index storage per knowledge base or Space	Vended logs (INDEX_USAGE_LOGS) or CloudWatch metrics	Monitoring Amazon Quick using CloudWatch Logs ; Monitoring Amazon Quick using CloudWatch metrics
Operational health: load times, ingestion failures, connector errors, SPICE capacity	CloudWatch metrics and alarms	Monitoring Amazon Quick using CloudWatch metrics
Adoption, engagement, feedback trends, agent-hours consumption	Analytics dashboard	Using the Amazon Quick analytics dashboard

Use the following checklist to configure monitoring for your environment:

1. Create a CloudTrail trail for the AWS accounts and AWS Regions that require audit logging.
2. Configure CloudWatch vended log delivery shortly after enabling Amazon Quick AI features.

3. When vended-log destinations use a customer managed AWS KMS key, allow `delivery.logs.amazonaws.com` in the key policy.
4. Chat logs can contain sensitive or personally identifiable data. Filter this information at subscription setup, or apply CloudWatch Logs data-protection masking policies.
5. Configure CloudWatch alarms on operational metrics and map them to your incident-response procedures.
6. Grant `quicksight:QuickSuiteUsageMetrics` (analytics access) only to authorized administrators.
7. Revalidate your monitoring design when you enable a new Amazon Quick capability.

- [Monitoring Amazon Quick using CloudTrail](#)
- [Monitoring Amazon Quick using CloudWatch metrics](#)

Monitoring Amazon Quick using CloudWatch Logs

You can use [Amazon CloudWatch Logs](#) to deliver chat conversations, user feedback, agent hours usage, and index storage usage in Amazon Quick for you to analyze. These logs can be delivered to multiple destinations, such as CloudWatch, Amazon S3, or Amazon Data Firehose (standard rates apply).

Important

Set up vended log delivery shortly after enabling Amazon Quick AI features. Logs are not retroactive – you only receive events that occur after delivery is configured.

The following are examples of tasks you can complete with logs from Amazon Quick:

- Identify common user queries and pain points by reviewing the chat message content.
- Monitor the quality of responses by looking at metrics like `feedbackReason`.
- Understand user sentiment and satisfaction by analyzing the feedback data, including comments and usefulness ratings.
- Generate custom dashboards and reports to track key metrics and trends over time.

- Identify and analyze cases where the chat returned no answer or the user query was blocked.
- Monitor agent hours usage.
- Track index storage usage across knowledge bases and Spaces.
- Track knowledge base sync operations and identify document crawl or indexing failures.

Important

Logs from conversations might include sensitive or personally identifiable data passed in the chats. You can filter out this information from your logs when setting up logs subscription. Or you can mask this data on your logs using CloudWatch Logs masking policies. For more information, see [Help protect sensitive log data with masking](#).

Supported log destinations

Amazon Quick can deliver logs to the following destinations:

- **Amazon CloudWatch Logs** – For real-time monitoring and analysis
- **Amazon S3** – For long-term storage and batch processing
- **Amazon Data Firehose** – For streaming analytics and data transformation

Supported log types

Amazon Quick supports the following log types. You specify one of these values as the `logType` when you create a delivery source.

- **CHAT_LOGS** – Chat conversation interactions, including the user message, system response, and status.
- **FEEDBACK_LOGS** – User feedback on chat responses, such as usefulness ratings and reasons.
- **AGENT_HOURS_LOGS** – Agent hours usage for each agent.
- **AGENT_METADATA_LOGS** – Lifecycle events for chat agents, such as creation, updates, and deletion.
- **INDEX_USAGE_LOGS** – Per-source index storage metrics for knowledge bases and Spaces.
- **KB_FILE_SYNC_LOGS** – Per-document knowledge base sync status, including crawl and indexing failures.

- DLP_LOGS – Data loss prevention enforcement decisions and configuration changes.

Prerequisites

Before you can enable logging, make sure that you have the following:

- An active Amazon Quick instance with Enterprise or Professional subscriptions
- Appropriate IAM permissions to configure log delivery
- A destination configured for your logs (CloudWatch Logs, Amazon S3 bucket, or Firehose)

Configure logging

To enable logging for Amazon Quick chat and feedback, configure IAM permissions, create a delivery source and destination, and verify log delivery.

Topics

- [Set up IAM permissions](#)
- [Configure log subscription](#)
- [Verify log delivery](#)

Set up IAM permissions

To set up CloudWatch Logs for Amazon Quick, use the following IAM policy examples to grant the necessary permissions.

```
{
  "Version": "2012-10-17"
  ,
  "Statement": [{
    "Sid": "QuicksightLogDeliveryPermissions",
    "Effect": "Allow",
    "Action": "quicksight:AllowVendedLogDeliveryForResource",
    "Resource": "arn:aws:quicksight:region:account-id:account/account-id"
  }]
}
```

You must also allow the `delivery.logs.amazonaws.com` service principal in your customer managed AWS KMS key policy.

```
{
  "Effect": "Allow",
  "Principal": {
    "Service": "delivery.logs.amazonaws.com"
  },
  "Action": [
    "kms:GenerateDataKey",
    "kms:Decrypt"
  ],
  "Resource": "*",
  "Condition": {
    "StringLike": {
      "kms:EncryptionContext:SourceArn": "arn:partition:logs:region:account-id:*"
    }
  }
}
```

Configure log subscription

For example IAM policies with all the required permissions for your specific logging destination, see [Enable logging from AWS services](#) in the *Amazon CloudWatch Logs User Guide*.

Create a delivery source with the [PutDeliverySource](#) CloudWatch Logs API operation. Give the delivery source a name and for `resourceArn`, specify the ARN of your application. For `logType`, specify one of the supported log types (see [the section called “Supported log types”](#)).

```
{
  "logType": "CHAT_LOGS",
  "name": "my-quick-suite-delivery-source",
  "resourceArn": "arn:aws:quicksight:your-region:your-account-id:account/account-id"
}
```

```
{
  "logType": "FEEDBACK_LOGS",
  "name": "my-quick-suite-delivery-source",
  "resourceArn": "arn:aws:quicksight:your-region:your-account-id:account/account-id"
}
```

```
{
  "logType": "AGENT_HOURS_LOGS",
  "name": "my-quick-suite-delivery-source",
```

```
"resourceArn": "arn:aws:quicksight:your-region:your-account-id:account/account-id"
}
```

```
{
  "logType": "INDEX_USAGE_LOGS",
  "name": "my-quick-index-usage-delivery-source",
  "resourceArn": "arn:aws:quicksight:your-region:your-account-id:account/account-id"
}
```

```
{
  "logType": "KB_FILE_SYNC_LOGS",
  "name": "my-quick-kb-file-sync-delivery-source",
  "resourceArn": "arn:aws:quicksight:your-region:your-account-id:account/account-id"
}
```

```
{
  "logType": "AGENT_METADATA_LOGS",
  "name": "my-quick-agent-metadata-delivery-source",
  "resourceArn": "arn:aws:quicksight:your-region:your-account-id:account/account-id"
}
```

```
{
  "logType": "DLP_LOGS",
  "name": "my-quick-dlp-delivery-source",
  "resourceArn": "arn:aws:quicksight:your-region:your-account-id:account/account-id"
}
```

To enable user conversation logging with the CloudWatch Logs API operations, you call the `PutDeliverySource`, `PutDeliveryDestination`, and `CreateDelivery` API operations.

Note

Vended-log delivery is per Region. Each delivery captures only the activity that occurs in the Region specified by the `resourceArn` in `PutDeliverySource`. To receive logs from multiple Regions, configure a separate delivery in each Region.

Verify log delivery

After you configure log delivery, verify that logs are being delivered to your destination:

- **Verify the setup:** Verify the list of deliveries that have been created in the account by using the `DescribeDeliveries` API in CloudWatch Logs.
- **CloudWatch Logs:** Check the specified log group for new log streams.
- **Amazon S3:** Monitor your bucket for new log files.
- **Firehose:** Verify data is flowing through your delivery stream.

Log schema and format

Each Amazon Quick log type has its own schema. The field names, including the log type and account identifiers, vary by log type – for example, chat and feedback logs use `logType` and `accountId`, while other log types use `log_type` and `account_id`. The fields for each log type are listed in the following sections.

Chat logs

Chat logs capture conversation interactions:

Note

Temporary conversations that are excluded from history and memory are still delivered to chat logs. Each record includes the `user_arn` and `user_type` of the user who initiated the conversation.

- `user_arn` – Amazon Quick user ARN associated with the event
- `user_type` – Amazon Quick user type associated with the event (for example, `ADMIN_PRO`)
- `status_code` – Status of the chat request (for example, `success`, `request_blocked`, `no_answer_found`)
- `conversation_id` – Unique ID for the user conversation
- `system_message_id` – System-generated message ID
- `message_scope` – Scope of the message (for example, `all_resources`, `specific_resources`, `no_resources`)
- `user_message_id` – Unique ID of the user message
- `user_message` – User message in the conversation

- `agent_id` – Unique ID of the chat agent, or `SYSTEM` for the default agent
- `flow_id` – Unique ID of the Amazon Quick Flow, or `-` if not a flow invocation
- `system_text_message` – System response in the conversation
- `user_selected_resources` – List of resources selected by user
- `action_connectors` – List of connectors available in the conversation
- `cited_resource` – List of cited resources
- `file_attachment` – List of files attached by user
- `resource_arn` – Resource ARN of your Amazon Quick account
- `event_timestamp` – Timestamp of the event
- `logType` – `CHAT_LOGS`
- `accountId` – AWS account ID

The following is an example of chat logs:

```
{
  "user_arn": "arn:aws:quicksight:us-east-1:111122223333:user/default/johndoe",
  "user_type": "ADMIN_PRO",
  "status_code": "success",
  "conversation_id": "c11ba72c-ff18-4213-9686-1952bb547c19",
  "system_message_id": "42a37690-1804-442b-8368-3d34570dd2cd",
  "message_scope": "all_resources",
  "user_message_id": "5ec45e03-bf22-40c7-b32a-d69eb015f86b",
  "user_message": "What is in this document?",
  "agent_id": "SYSTEM",
  "flow_id": "-",
  "system_text_message": "Here is a summary of the attached document.",
  "user_selected_resources": [{"resourceId": "ALL", "resourceType": "space"}],
  "action_connectors": [{"actionConnectorId": "quicksuite-documentation"},
{"actionConnectorId": "quicksuite-websearch"}],
  "cited_resource": [{"citedResourceType": "document", "citedResourceId": null,
"citedResourceName": "example-document.html"}],
  "file_attachment": [{"fileAttachmentType": "html", "fileAttachmentName": "example-
document.html"}],
  "resource_arn": "arn:aws:quicksight:us-east-1:111122223333:account/111122223333",
  "event_timestamp": 1787185484508,
  "logType": "CHAT_LOGS",
  "accountId": "111122223333"
```

```
}
```

Feedback logs

Feedback logs capture user feedback on chat responses:

- `user_arn` – Amazon Quick user ARN associated with the event
- `user_type` – Amazon Quick user type associated with the event (for example, `ADMIN_PRO`)
- `status_code` – Status of the event delivery
- `conversation_id` – Unique ID of the conversation
- `system_message_id` – System generated message ID
- `user_message_id` – Unique ID of user message
- `feedback_type` – Type of feedback (for example, `Not Useful`, `Useful`)
- `feedback_reason` – Feedback reason selected by the user
- `feedback_details` – (Optional) Additional details provided by the user
- `resource_arn` – Resource ARN of your Amazon Quick account
- `event_timestamp` – Timestamp of the event
- `logType` – `FEEDBACK_LOGS`
- `accountId` – AWS account ID

The following is an example of feedback logs:

```
{
  "user_arn": "arn:aws:quicksight:us-east-1:111122223333:user/default/johndoe",
  "user_type": "ADMIN_PRO",
  "status_code": "success",
  "conversation_id": "c11ba72c-ff18-4213-9686-1952bb547c19",

```

Agent hours logs

This log type captures the usage logs for different agents within your Quick account:

- `user_arn` – Amazon Quick user ARN associated with the event
- `subscription_type` – Subscription tier of the user. Values: ENTERPRISE, PROFESSIONAL.
- `reporting_service` – The Quick surface that consumed agent hours. Current values include FLOW, AUTOMATION, and RESEARCH. New values might appear as additional Quick features begin metering agent hours.
- `usage_group` – Whether the usage is covered by the subscription entitlement or billed as overage. Values:
 - Included – Usage within the daily entitlement grant for the subscription tier. No incremental charge.
 - Extra – Overage beyond the daily grant. Billed on consumption.
- `usage_hours` – Decimal value indicating the agent hours consumed for this record
- `service_resource_arn` – ARN of the resource that consumed the hours (for example, a flow, automation, or research session)
- `resource_arn` – Resource ARN of your Amazon Quick account
- `event_timestamp` – Timestamp of the event
- `logType` – AGENT_HOURS_LOGS
- `accountId` – AWS account ID

The following is an example of Agent Hours logs:

```
{
  "user_arn": "arn:aws:quicksight:us-east-1:111122223333:user/default/johndoe",
  "subscription_type": "ENTERPRISE",
  "reporting_service": "RESEARCH",
  "usage_group": "Included",
  "usage_hours": 0.0928,
  "service_resource_arn": "arn:aws:quicksight::111122223333:research/a11b2bbc-
c123-3abc-a12b-12a34b5c678d",
  "resource_arn": "arn:aws:quicksight:us-east-1:111122223333:account/111122223333",
  "event_timestamp": 1787183715000,
  "logType": "AGENT_HOURS_LOGS",
}
```

```
"accountId": "111122223333"  
}
```

Agent metadata logs

Agent metadata logs capture lifecycle events for chat agents, including creation, updates, permission changes, and deletion. One record is emitted per agent operation:

- `user_arn` – Amazon Quick user ARN associated with the event.
- `event_name` – The agent lifecycle operation. Values include `CreateAgent`, `UpdateAgent`, `DeleteAgent`, `UpdateAgentPermissions`, and others as new operations are added.
- `event_version` – Schema version of the log record.
- `agent_id` – UUID of the agent.
- `agent_arn` – Full ARN of the agent.
- `agent_name` – Display name of the agent.
- `agent_status` – Current status of the agent (for example, `ACTIVE`).
- `request_id` – Request identifier for the operation.
- `description` – Agent description text.
- `spaces` – JSON array of spaces attached to the agent.
- `permissions_granted` – Permissions added in this operation.
- `permissions_revoked` – Permissions removed in this operation.
- `permissions_state` – Current permissions after the operation.
- `update_action` – The update action performed.
- `version` – Agent version number.
- `icon_id` – Icon identifier for the agent.
- `magic_builder_query` – The natural language query used to create the agent via the builder.
- `instructions` – Agent instructions.
- `failed_to_add_spaces` – Spaces that could not be attached.
- `failed_to_remove_spaces` – Spaces that could not be detached.
- `draft_discarded` – Whether a draft was discarded.
- `custom_prompt_input` – Custom prompt input configured for the agent.
- `welcome_message` – Welcome message shown to users of the agent.
- `starter_prompts` – Starter prompts suggested to users of the agent.

- `resource_arn` – Resource ARN of your Amazon Quick account.
- `event_timestamp` – Timestamp of the event.
- `log_type` – `AGENT_METADATA_LOGS`.
- `account_id` – AWS account ID.

Note

The `custom_prompt_input`, `welcome_message`, and `starter_prompts` fields contain sensitive content. When you configure a customer managed AWS KMS key for delivery, these fields are encrypted. Without a key, they are delivered in cleartext.

The following is an example of an agent metadata log for a `CreateAgent` event:

```
{
  "user_arn": "arn:aws:quicksight:us-east-1:111122223333:user/default/johndoe",
  "event_version": "1.0",
  "event_name": "CreateAgent",
  "agent_id": "12345678-90ab-cdef-1234-567890abcdef",
  "request_id": "fedcba98-7654-3210-fedc-ba9876543210",
  "agent_arn": "arn:aws:quicksight:us-east-1:111122223333:agent/12345678-90ab-cdef-1234-567890abcdef",
  "agent_name": "Project Status Assistant",
  "agent_status": "ACTIVE",
  "description": "An agent that helps track project status and find relevant documentation.",
  "spaces": "[{\"Arn\": \"arn:aws:quicksight:us-east-1:111122223333:space/11112222-3333-4444-5555-666677778888\"}]",
  "resource_arn": "arn:aws:quicksight:us-east-1:111122223333:account/111122223333",
  "event_timestamp": 1787185396000,
  "log_type": "AGENT_METADATA_LOGS",
  "account_id": "111122223333"
}
```

Index usage logs

Index usage logs capture per-source storage metrics for knowledge bases and Spaces. Events are published whenever a change occurs (created, updated, synced, or deleted):

- `user_arn` – Amazon Quick user ARN associated with the event

- `consumed_index_size` – Total size (in bytes) consumed by the entire index
- `source_type` – Type of source: SPACE or KB
- `source_name` – Display name of the Space or knowledge base
- `source_arn` – Full ARN of the source
- `consumed_source_size` – Size (in bytes) consumed by this individual source
- `consumed_source_doc_count` – Number of documents in this source
- `resource_arn` – Resource ARN of your Amazon Quick account
- `event_timestamp` – Timestamp of the event
- `log_type` – INDEX_USAGE_LOGS
- `account_id` – AWS account ID

The following is an example of index usage logs:

```
{
  "account_id": "111122223333",
  "event_timestamp": 1774911984257,
  "log_type": "INDEX_USAGE_LOGS",
  "user_arn": "arn:aws:quicksight::111122223333:user/default/user",
  "resource_arn": "arn:aws:quicksight:us-west-2:111122223333:account/111122223333",
  "consumed_index_size": 500000,
  "source_type": "SPACE",
  "source_name": "my-space",
  "source_arn": "arn:aws:quicksight:us-west-2:111122223333:space/2744af89-31b2-423b-93a2-69b0cd0d7fa1",
  "consumed_source_size": 244436,
  "consumed_source_doc_count": 2
}
```

 Note

Events are published per source on change. Not all sources emit events every day. To reconstruct the current state, use the most recent event per `source_arn`.

For information about building dashboards and running queries against index usage logs, see [the section called “Monitor index storage usage”](#).

Knowledge base file sync logs

Knowledge base file sync logs capture per-document sync status events. One log record is emitted per document per sync run:

- `document_id` – Original document identifier such as a URL or file path.
- `document_title` – Document title.
- `document_status` – Terminal document status. Values: ADDED, MODIFIED, UNMODIFIED, DELETED, SKIPPED, FAILED.
- `sync_result` – High-level availability result. Values: AVAILABLE or UNAVAILABLE.
- `sync_id` – Sync job execution ID.
- `data_source_id` – Identifier of the data source that the knowledge base is connected to.
- `source_uri` – Source URL of the document.
- `error_message` – Error description when status is FAILED or SKIPPED.
- `error_mitigation` – Actionable guidance for resolving the error.
- `error_type` – Error code when status is FAILED or SKIPPED.
- `knowledge_base_id` – UUID of the knowledge base that produced the log.

The following table describes the `document_status` values and their corresponding `sync_result`.

<code>document_status</code>	<code>sync_result</code>	Meaning
ADDED	AVAILABLE	New document successfully indexed
MODIFIED	AVAILABLE	Existing document re-indexed with changes
UNMODIFIED	AVAILABLE	Document content unchanged, no re-indexing needed
DELETED	UNAVAILABLE	Document removed from index
SKIPPED	UNAVAILABLE	Document filtered during crawl, such as by robots.txt or size limit
FAILED	UNAVAILABLE	Document failed during crawl or indexing

The following example shows a successful knowledge base file sync log where a document was added to the knowledge base:

```
{
  "resource_arn": "arn:aws:quicksight:us-west-2:111122223333:account/111122223333",
  "event_timestamp": 1781296858575,
  "log_type": "KB_FILE_SYNC_LOGS",
  "account_id": "111122223333",
  "document_id": "https://docs.aws.amazon.com/quick/latest/userguide/monitoring-
cloudwatch-logs.html",
  "document_title": "Monitoring Amazon QuickSight usage using CloudWatch Logs",
  "document_status": "ADDED",
  "sync_result": "AVAILABLE",
  "sync_id": "86a70a9a-cad9-4fc6-8881-e3909c8954d2",
  "data_source_id": "56225744-18bc-4373-a91f-861dd1c3d566",
  "source_uri": "https://docs.aws.amazon.com/quick/latest/userguide/monitoring-
cloudwatch-logs.html",
  "knowledge_base_id": "b0bd0a47-8095-439d-9dff-c64bd5fe3fa3"
}
```

The following example shows a skipped document log where crawling was skipped due to a validation error:

```
{
  "resource_arn": "arn:aws:quicksight:us-west-2:111122223333:account/111122223333",
  "event_timestamp": 1781296492951,
  "log_type": "KB_FILE_SYNC_LOGS",
  "account_id": "111122223333",
  "document_id": "https://docs.aws.amazon.com/quick/latest/userguide/blocked-
page.html",
  "document_title": "Blocked Page",
  "document_status": "SKIPPED",
  "sync_result": "UNAVAILABLE",
  "sync_id": "86a70a9a-cad9-4fc6-8881-e3909c8954d2",
  "data_source_id": "56225744-18bc-4373-a91f-861dd1c3d566",
  "source_uri": "https://docs.aws.amazon.com/quick/latest/userguide/blocked-
page.html",
  "error_message": "This URL wasn't crawled because crawling isn't allowed by its
robots.txt file.",
  "error_mitigation": "Contact the website administrator for assistance.",
  "error_type": "VALIDATION_ERROR",
  "knowledge_base_id": "b0bd0a47-8095-439d-9dff-c64bd5fe3fa3"
}
```

```
}
```

DLP logs

Data loss prevention (DLP) logs capture DLP activity: the enforcement decision for each scanned file, and changes to your DLP configurations. Use them to audit policy changes and to monitor enforcement. The specific event is identified by `event_type`.

Every `DLP_LOGS` record includes these common fields:

- `resource_arn` – Resource ARN of your Amazon Quick account
- `event_timestamp` – Unix epoch time in milliseconds
- `log_type` – `DLP_LOGS`
- `account_id` – AWS account ID
- `event_type` – The DLP event: `DLP_FILE_BLOCKED`, `DLP_FILE_WARNED`, `DLP_INSPECTION_FAILED`, `DLP_SETTING_CREATED`, `DLP_SETTING_UPDATED`, or `DLP_SETTING_DELETED`
- `request_id` – Unique identifier for the event
- `user_arn` – Amazon Quick user ARN associated with the event (system for service-initiated events)

Enforcement events (`DLP_FILE_BLOCKED`, `DLP_FILE_WARNED`, `DLP_INSPECTION_FAILED`) add these fields:

- `dlp_job_id` – Unique ID of the DLP scan job
- `dlp_setting_id` – ID of the DLP configuration that evaluated the file
- `policy_action` – Enforcement action applied (`BLOCK`, `WARN`)
- `file_name` – Name of the scanned file (customer content; see the note that follows)
- `file_size` – Size of the scanned file, in bytes
- `failure_type` – (`DLP_INSPECTION_FAILED` only) Category of the failure, for example `CUSTOMER_ERROR`
- `policy_message` – (`DLP_FILE_WARNED` and `DLP_INSPECTION_FAILED`) The warning message shown to the user, or the reason the inspection failed

Configuration events (DLP_SETTING_CREATED, DLP_SETTING_UPDATED, DLP_SETTING_DELETED) add these fields:

- `dlp_setting_id` – ID of the DLP configuration
- `dlp_setting_name` – Display name of the configuration
- `status` – Configuration status (ACTIVE, INACTIVE) – reflects whether enforcement is enabled or disabled
- `provider_type` – DLP provider (for example, MICROSOFT_PURVIEW)
- `auth_type` – Provider authentication type (for example, CLIENT_SECRET)
- `provider_outage_mode` – Action applied when the provider is unavailable (for example, BLOCK)
- `unmapped_action` – Default action for files with no mapped label (for example, BLOCK)
- `last_updated_by` – ARN of the principal that made the change
- `changes` – (DLP_SETTING_UPDATED only) The fields that changed

The following is an example of a blocked file event:

```
{
  "resource_arn": "arn:aws:quicksight:us-east-1:111122223333:account/111122223333",
  "event_timestamp": 1786510225000,
  "log_type": "DLP_LOGS",
  "account_id": "111122223333",
  "event_type": "DLP_FILE_BLOCKED",
  "request_id": "422518600001076813548728842",
  "dlp_setting_id": "dlp-config-prod-01",
  "dlp_job_id": "dlpjob-internal-1c5e20d9-8af4-4ad9-95ee-18c34cd62c76",
  "policy_action": "BLOCK",
  "file_name": "confidential.docx",
  "file_size": 64,
  "user_arn": "arn:aws:quicksight:us-east-1:111122223333:user/default/johndoe"
}
```

The following is an example of an inspection failed event:

```
{
  "resource_arn": "arn:aws:quicksight:us-east-1:111122223333:account/111122223333",
  "event_timestamp": 1786488697000,
  "log_type": "DLP_LOGS",
```

```

"account_id": "111122223333",
"event_type": "DLP_INSPECTION_FAILED",
"request_id": "421276000001518855116675749",
"dlp_setting_id": "dlp-config-prod-01",
"dlp_job_id": "dlpjob-internal-f25e8e10-d831-4479-8f0d-e32d7b12b123",
"policy_action": "BLOCK",
"failure_type": "CUSTOMER_ERROR",
"policy_message": "The QuickSight service role for SECRETS_MANAGER access is not
configured. Verify your account's QuickSight service role setup.",
"file_name": "confidential.docx",
"file_size": 64,
"user_arn": "system"
}

```

The following is an example of a configuration updated event:

```

{
  "resource_arn": "arn:aws:quicksight:us-east-1:111122223333:account/111122223333",
  "event_timestamp": 1786492367000,
  "log_type": "DLP_LOGS",
  "account_id": "111122223333",
  "event_type": "DLP_SETTING_UPDATED",
  "request_id": "327788200001887837483925731",
  "dlp_setting_id": "dlp-config-prod-01",
  "dlp_setting_name": "Production DLP policy",
  "status": "ACTIVE",
  "provider_type": "MICROSOFT_PURVIEW",
  "auth_type": "CLIENT_SECRET",
  "provider_outage_mode": "BLOCK",
  "unmapped_action": "BLOCK",
  "last_updated_by": "arn:aws:sts::111122223333:assumed-role/DlpAdmin/jane",
  "changes": { "unmapped_action": { "old": "WARN", "new": "BLOCK" } },
  "user_arn": "system"
}

```

Note

The `file_name` field is customer content. When you configure a customer managed AWS KMS key for delivery, this field is encrypted. Without a key, Quick delivers it in cleartext.

Security considerations

- **Encryption** – Use customer-managed AWS KMS keys for sensitive data.
- **Access control** – Implement least-privilege IAM policies.
- **Data retention** – Configure appropriate retention policies for your compliance requirements.

Monitoring Amazon Quick using CloudTrail

Amazon Quick is integrated with AWS CloudTrail. This service provides a record of actions taken by a user, role, or an AWS service in Amazon Quick. CloudTrail captures API calls for Amazon Quick as events. The calls captured include some calls from the console and all code calls to API operations. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for Amazon Quick. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in **Event history**. Using the information collected by CloudTrail, you can determine who made a request to Amazon Quick and when. You can also identify the source IP address, the specific request, and other details.

Note

CloudTrail records supported Amazon Quick API operations and the non-API events documented on this page. When you examine event samples, event records include selected metadata such as account ID, resource ID, and user identity. For chat conversations and feedback, use [Monitoring Amazon Quick using CloudWatch Logs](#). For the full signal-by-capability model, see [Incident response, logging, and monitoring in Amazon Quick](#).

Amazon Quick publishes operational metrics to CloudWatch, and you can create CloudWatch alarms on those metrics. For more information, see [Creating alarms with the Amazon CloudWatch console](#). To alert on individual CloudTrail events, you can develop a custom solution that processes CloudTrail logs.

Amazon Quick service status can be viewed on the [Service Health Dashboard](#).

By default, CloudTrail encrypts the log files it delivers to your bucket using [Amazon S3-managed encryption keys \(SSE-S3\)](#). For a directly manageable security layer, you can instead use [AWS KMS-managed keys \(SSE-KMS\)](#) for your CloudTrail log files. SSE-KMS encrypts the log files but not the digest files. Digest files are encrypted with [Amazon S3-managed encryption keys \(SSE-S3\)](#).

To learn more about CloudTrail, including how to configure and enable it, see the [AWS CloudTrail User Guide](#).

Topics

- [Logging Amazon Quick operations with AWS CloudTrail](#)
- [Discovering Amazon Quick events in your trail](#)

- [Logging Amazon Quick data events in CloudTrail](#)
- [Tracking non-API events by using CloudTrail logs](#)

Logging Amazon Quick operations with AWS CloudTrail

Intended audience: System administrators

CloudTrail is enabled on your AWS account when you create the account. When supported event activity occurs in Amazon Quick, that activity is recorded in a CloudTrail event along with other AWS service events in **Event history**. You can view, search, and download recent events in your AWS account. For more information, see [Viewing Events with CloudTrail Event History](#).

For an ongoing record of events in your AWS account, including events for Amazon Quick, create a trail. A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all . The trail logs events from all Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following:

- [Overview for Creating a Trail](#)
- [CloudTrail Supported Services and Integrations](#)
- [Configuring Amazon SNS Notifications for CloudTrail](#)
- [Receiving CloudTrail Log Files from Multiple Regions](#) and [Receiving CloudTrail Log Files from Multiple Accounts](#)
- [Cross-Account CloudTrail Logging](#) in the AWS Lake Formation Developer Guide – This topic includes instructions for including principal identities in cross-account CloudTrail logs.

Amazon Quick supports logging the following actions as events in CloudTrail log files:

- Whether the request was made with root or AWS Identity and Access Management user credentials
- Whether the request was made with temporary security credentials for an IAM role or federated user
- Whether the request was made by another AWS service

For more information on user identity, see the [CloudTrail userIdentity Element](#).

By default, each Amazon Quick log entry contains the following information:

- **userIdentity** – User identity
- **eventTime** – Event time
- **eventID** – Event ID
- **readOnly** – Read only
- **awsRegion** – AWS Region
- **eventSource (quicksight)** – Source of the event (Amazon Quick)
- **eventType (AwsServiceEvent)** – Event type (AWS service event)
- **recipientAccountId (customer AWS account)** – Recipient account ID (Customer AWS account)

Some events include a `userIdentity.invokedBy` field set to `quicksight.amazonaws.com`. This indicates that the event was triggered by the Amazon Quick service on behalf of the account rather than by a direct user action. You can use this field to distinguish user-initiated operations from service-internal calls when analyzing your trail.

 Note

CloudTrail displays the user identity as unknown for users that were provisioned directly by Amazon Quick (legacy provisioning). Users authenticated through IAM Identity Center

appear as `IdentityCenterUser` with full `onBehalfOf` details in the `userIdentity` element.

Discovering Amazon Quick events in your trail

Amazon Quick adds new event names as features launch and evolve. The non-API events listed below represent a subset of what your trail captures. To discover all Amazon Quick events in your account, query your trail for `eventSource: quicksight.amazonaws.com` and inspect the `eventName` values. Event names follow a consistent pattern: the operation name (such as `CreateFlow` or `UpdateAgent`) matches the feature it relates to.

Example: Amazon Quick log file entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the `BatchCreateUser` action.

```
{
  "eventVersion": "1.11",
  "userIdentity": {
    "type": "Root",
    "principalId": "123456789012",
    "arn": "arn:aws:iam::123456789012:root",
    "accountId": "123456789012",
    "userName": "test-username"
  },
  "eventTime": "2017-04-19T03:16:13Z",
  "eventSource": "quicksight.amazonaws.com",
  "eventName": "BatchCreateUser",
  "awsRegion": "us-west-2",
  "requestParameters": null,
  "responseElements": null,
  "eventID": "e7d2382e-70a0-3fb7-9d41-a7a913422240",
  "readOnly": false,
  "eventType": "AwsServiceEvent",
```

```
"recipientAccountId":"123456789012",
"serviceEventDetails":
{
  "eventRequestDetails":
  {
    "users":
    {
      "test-user-11":
      {
        "role":"USER"
      },
      "test-user-22":
      {
        "role":"ADMIN"
      }
    }
  },
  "eventResponseDetails":
  {
    "validUsers":[
    ],
    "InvalidUsers":[
      "test-user-11",
      "test-user-22"
    ]
  }
}
```

Logging Amazon Quick data events in CloudTrail

In addition to management events, Amazon Quick supports CloudTrail data events for selected resource types. Data events are off by default. Enable them through advanced event selectors on your trail.

The following Amazon Quick resource types support data events:

Resource type	Event name	Availability
AWS::Quicksight::ActionConnector	InvokeAction	Generally available

Resource type	Event name	Availability
AWS::QuickSight::Flow	–	Generally available
AWS::QuickSight::FlowSession	–	Generally available
AWS::QuickSight::Companion	–	Varies by Region
AWS::QuickSight::CompanionAccess	–	Varies by Region
AWS::QuickSight::Namespaces	–	Varies by Region

Important

Data-event resource-type availability varies by account and AWS Region. If a resource type is not supported in your Region, the `put-event-selectors` call returns an error for that type. Build one `put-event-selectors` call that includes only the resource types supported in your Region, and omit unsupported types from that call.

Note

The casing of Quicksight compared with QuickSight in resource type ARNs is intentional and varies by resource type. Use the exact casing shown above when configuring event selectors.

Enabling data events

Use advanced event selectors to enable data events. Include a management-events selector to retain management event logging:

```
aws cloudtrail put-event-selectors \
```

```
--trail-name your-trail-name \
--region us-east-1 \
--advanced-event-selectors '[
  { "Name": "All management events",
    "FieldSelectors": [ { "Field": "eventCategory", "Equals": ["Management"] } ] },
  { "Name": "Quick connector data events",
    "FieldSelectors": [
      { "Field": "eventCategory", "Equals": ["Data"] },
      { "Field": "resources.type", "Equals":
["AWS::Quicksight::ActionConnector"] } ] },
  { "Name": "Quick flow data events",
    "FieldSelectors": [
      { "Field": "eventCategory", "Equals": ["Data"] },
      { "Field": "resources.type", "Equals": ["AWS::QuickSight::Flow"] } ] },
  { "Name": "Quick flow session data events",
    "FieldSelectors": [
      { "Field": "eventCategory", "Equals": ["Data"] },
      { "Field": "resources.type", "Equals": ["AWS::QuickSight::FlowSession"] } ] }
]'
```

Add selectors for `AWS::Quicksight::Companion`, `AWS::Quicksight::CompanionAccess`, and `AWS::QuickSight::Namespace` if supported in your Region.

InvokeAction data event

When a user or flow invokes a connector, CloudTrail records an `InvokeAction` data event. This event captures the following information:

- Caller identity, including `onBehalfOf.userId` and `endUserArn`
- The `actionConnectorId` and `actionId` of the invoked action
- The outcome: `invokeActionStatus` and `httpStatusCode`
- `readOnly`: `false` (always)
- `eventCategory`: `Data`, `managementEvent`: `false`
- Resource type: `AWS::Quicksight::ActionConnector`

⚠ Important

InvokeAction does not include the action's input parameters (such as an email recipient, subject, or body) or any approval decision. Use CloudWatch vended logs for conversation content.

ℹ Note

The `readOnly` field is always `false` for action connector invocations, including read-only actions such as listing emails. To distinguish read from write operations, filter by `actionId` rather than the `readOnly` field.

The following example shows an InvokeAction data event for a successful email action:

```
{
  "eventVersion": "1.11",
  "userIdentity": {
    "type": "IdentityCenterUser",
    "accountId": "111122223333",
    "onBehalfOf": {
      "userId": "a1b2c3d4-e5f6-7890-abcd-ef1234567890",
      "identityStoreArn": "arn:aws:identitystore::111122223333:identitystore/d-1234567890"
    }
  },
  "eventTime": "2026-08-19T20:26:36Z",
  "eventSource": "quicksight.amazonaws.com",
  "eventName": "InvokeAction",
  "awsRegion": "us-east-1",
  "sourceIPAddress": "203.0.113.1",
  "requestParameters": {
    "awsAccountId": "111122223333",
    "actionConnectorId": "52bde8f0-3de5-4e3d-9283-222f81a9fc4f",
    "actionId": "SendUserEmail",
    "endUserArn": "arn:aws:quicksight:us-east-1:111122223333:user/default/johndoe"
  },
  "responseElements": {
    "invokeActionStatus": "SUCCESS",
    "invokeActionOutput": {
```

```
        "httpInvokeActionOutput": {
            "httpStatusCode": "200"
        }
    },
    "readOnly": false,
    "resources": [
        {
            "accountId": "111122223333",
            "type": "AWS::Quicksight::ActionConnector",
            "ARN": "arn:aws:quicksight:us-east-1:111122223333:action-connector/52bde8f0-3de5-4e3d-9283-222f81a9fc4f"
        }
    ],
    "eventType": "AwsApiCall",
    "managementEvent": false,
    "eventCategory": "Data"
}
```

Tracking non-API events by using CloudTrail logs

The following non-API events are captured in your CloudTrail trail:

User management

- **CreateAccount** – Create Account
- **BatchCreateUser** – Create User
- **BatchResendUserInvite** – Invite User
- **UpdateGroups** – Update Groups

This event works with Enterprise edition only.

- **UpdateSpiceCapacity** – Update SPICE Capacity
- **DeleteUser** – Delete User
- **Unsubscribe** – Unsubscribe User

Subscription

- **CreateSubscription** – Create Subscription
- **UpdateSubscription** – Update Subscription
- **DeleteSubscription** – Delete Subscription

Dashboard

- **GetDashboard** – Get Dashboard
- **CreateDashboard** – Create Dashboard
- **UpdateDashboard** – Update Dashboard
- **UpdateDashboardAccess** – Update Dashboard Access
- **DeleteDashboard** – Delete Dashboard

Analysis

- **GetAnalysis** – Get Analysis
- **CreateAnalysis** – Create Analysis
- **UpdateAnalysisAccess** – Update Analysis Access
- **UpdateAnalysis** – Update Analysis
 - **RenameAnalysis** – Rename Analysis
 - **CreateVisual** – Create Visual
 - **RenameVisual** – Rename Visual
 - **DeleteVisual** – Delete Visual

- **DeleteAnalysis** – Delete Analysis

Data source

- **CreateDataSource** – Create Data Source
 - **FlatFile** – Flat file
 - **External** – External
 - **S3** – S3
 - **ImportS3ManifestFile** – S3 Manifest File
 - **Presto** – Presto
 - **RDS** – RDS
 - **Redshift** – Redshift (manual)
- **UpdateDataSource** – Update Data Source
- **DeleteDataSource** – Delete Data Source

Data set

- **CreateDataSet** – Create Data Set
 - **CustomSQL** – Custom SQL
 - **SQLTable** – SQL Table
 - **File** – CSV or XLSX
- **UpdateDataSet** – Update SQL Join Dataset

- **DeleteDataSet** – Delete Dataset
- **Querydatabase** – During a dataset refresh, query data source.

Monitoring Amazon Quick using CloudWatch metrics

Amazon Quick sends metrics to Amazon CloudWatch in the AWS/QuickSight namespace. These metrics cover dashboards, visuals, dataset ingestions, SPICE capacity, knowledge base indexing, connectors, and automations. Use them to observe availability and performance, and to create alarms for your Amazon Quick environment.

For more information about using Amazon CloudWatch, see the [Amazon CloudWatch User Guide](#).

Accessing Quick metrics in Amazon CloudWatch

Use the following procedure to access Amazon Quick metrics in Amazon CloudWatch.

To access Amazon Quick metrics in CloudWatch

1. Sign in to the AWS account that's associated with your Amazon Quick account.
2. In the upper-left corner of the AWS Management Console home page, choose **Services**, and then choose **CloudWatch**.
3. In the navigation pane, choose **Metrics**, **All metrics**, **QuickSight**.

Topics

- [Graph metrics with the Amazon CloudWatch console](#)
- [Creating alarms with the Amazon CloudWatch console](#)
- [Metrics](#)
- [Aggregate metrics](#)
- [Aggregate SPICE metrics](#)
- [Dimensions](#)

Graph metrics with the Amazon CloudWatch console

You can also use the Amazon CloudWatch console to graph metric data generated by Quick. For more information, see [Graphing metrics](#) in the *Amazon CloudWatch User Guide*.

Creating alarms with the Amazon CloudWatch console

You can create a Amazon CloudWatch alarm that monitors CloudWatch metrics for your Quick assets. When the metric reaches a threshold that you specify, CloudWatch automatically sends you a notification. For examples, see [Creating Amazon CloudWatch alarms](#) in the *Amazon CloudWatch User Guide*.

Metrics

The AWS/QuickSight namespace includes the following metrics for monitoring traffic and latency of your Amazon Quick assets.

Topics

- [Per-dashboard metrics](#)
- [Per-dataset ingestion metrics](#)
- [Per-visual metrics](#)
- [Per-unstructured dataset metrics](#)
- [Per-connector metrics](#)
- [Per-automation metrics](#)

Per-dashboard metrics

The following metrics track dashboard view counts and load times. You can find these metrics under the AWS/QuickSight/Dashboard Metrics group in CloudWatch.

Metric	Description	Dimension	Unit
DashboardViewCount	The number of times that a dashboard has been viewed. This number includes all access patterns such as web, mobile, and embedded. The most useful statistic for this metric is SUM, which	DashboardId	Count

Metric	Description	Dimension	Unit
	represents the total number of dashboard views during a set period of time.		
DashboardViewLoadTime	The amount of time that it takes for a Amazon Quick dashboard to load. The measurement begins when a user reaches the Amazon Quick dashboard and ends when all of the dashboard's visuals finish rendering. The most useful statistic for this metric is AVERAGE, which represents the average load time of a Quick dashboard during a set period of time.	DashboardId	Millisecond

Per-dataset ingestion metrics

The following metrics track ingestions for specific [SPICE](#) datasets. You can find these metrics under the AWS/QuickSight/Ingestion Metrics group in CloudWatch.

Metric	Description	Dimension	Unit
IngestionErrorCount	The number of failed ingestions.	DatasetId	Count

Metric	Description	Dimension	Unit
	The most useful statistic for this metric is SUM, which represents the total number of failed ingestions during a set period of time.		
IngestionInvocationCount	The number of ingestions that have been initiated. This includes scheduled and manual ingestions that are initiated through the console and the Amazon Quick API operations. The most useful statistic for this metric is SUM, which represents the total number of ingestions initiated during a set period of time.	DatasetId	Count

Metric	Description	Dimension	Unit
IngestionLatency	The time period between the initiation of an ingestion to the completion of the ingestion. The most useful statistic for this metric is AVERAGE, which represents the average runtime of ingestions during a set period of time.	DatasetId	Second
IngestionRowCount	The number of successful row ingestions. The most useful statistic for this metric is SUM, which represents the total amount of data ingested during a set period of time.	DatasetId	Count

Per-visual metrics

The following metrics track the load times and error counts of individual visuals on a Amazon Quick dashboard. You can find these metrics under the AWS/QuickSight/Visual Metrics group in CloudWatch.

Metric	Description	Dimension	Unit
VisualLoadTime	The time that it takes for a Amazon Quick visual to receive the necessary query data for an initial paint of the visual. This includes the round-trip query time from the client, to the Amazon Quick service, and then back to client. The most useful statistic for this metric is AVERAGE, which represents the average load time of a visual during a set period of time.	- DashboardId - SheetId - VisualId	Millisecond
VisualLoadErrorCount	The number of times that a Amazon Quick visual fails to complete a data query for the initial paint. Any error that occurs during a visual's loading period is included in this metric. The most useful statistic for this metric is SUM, which	- DashboardId - SheetId - VisualId	Count

Metric	Description	Dimension	Unit
	represents the total number of failed visual loads during a set period.		

Per-unstructured dataset metrics

The following metrics track document statistics and indexing status for Amazon Quick unstructured datasets. You can find these metrics under the AWS/QuickSight/QuickInstanceId group in CloudWatch.

Metric	Description	Dimension	Unit
QuickIndexDocumentCount	The number of documents in the unstructured Quick index.	- KnowledgeBaselId - QuickInstanceId	Count
QuickIndexExtractedTextSize	The extracted text size of the unstructured Quick index.	- KnowledgeBaselId - QuickInstanceId	Bytes
QuickIndexPurchaseInMB	The amount of storage that has been purchased for the unstructured Quick index.	- KnowledgeBaselId - QuickInstanceId	MB
QuickIndexCapacityConsumedRawFileSizeInGB	The raw file size consumed by the unstructured Quick index.	QuickInstanceId	GB
QuickIndexCapacityRawFileSizeLimitInGB	The raw file size limit of the unstructured Quick index.	QuickInstanceId	GB

Metric	Description	Dimension	Unit
DocumentsCrawled	The number of uploaded documents crawled in the unstructured Quick index.	- KnowledgeBaseld - QuickInstanceId	Count
DocumentsIndexed	The number of documents indexed in the unstructured Quick index.	- KnowledgeBaseld - QuickInstanceId	Count
DocumentsDeleted	The number of documents deleted from the unstructured Quick index.	- KnowledgeBaseld - QuickInstanceId	Count
DocumentsModified	The number of documents modified in the unstructured Quick index.	- KnowledgeBaseld - QuickInstanceId	Count
DocumentsFailedToIndex	The number of documents that failed to index in the unstructured Quick index.	- KnowledgeBaseld - QuickInstanceId	Count
ExtractedTextSize	The total text size extracted during a connector level sync in the unstructured Quick index.	- KnowledgeBaseld - QuickInstanceId	MB

Per-connector metrics

The following metrics track the number of invocations made to Quick connectors. You can find these metrics under the AWS/QuickSight namespace in CloudWatch.

Metric	Description	Dimension	Unit
ActionInvocationCount	The number of times a connector was invoked.	- ActionConnectorId - ActionConnectorType - ActionId	Count
ActionInvocationError	The number of times a connector failed to invoke.	- ActionConnectorId - ActionConnectorType - ActionId - InvokeErrorCode	Count

Per-automation metrics

The following metrics track automation run counts and duration. You can find these metrics under the AWS/QuickSight namespace in CloudWatch.

Metric	Description	Dimension	Unit
TotalAutomationRunCount	The total number of automation runs initiated. The most useful statistic for this metric is SUM, which represents the total number of automation runs during a set period of time.	AutomationId	Count

Metric	Description	Dimension	Unit
SuccessfulAutomationRunCount	The number of automation runs that completed successfully. The most useful statistic for this metric is SUM, which represents the total number of successful runs during a set period of time.	AutomationId	Count
FailedAutomationRunCount	The number of automation runs that failed. The most useful statistic for this metric is SUM, which represents the total number of failed runs during a set period of time.	AutomationId	Count

Metric	Description	Dimension	Unit
StoppedAutomationRunCount	The number of automation runs that were stopped before completion. The most useful statistic for this metric is SUM, which represents the total number of stopped runs during a set period of time.	AutomationId	Count
AutomationRunDuration	The elapsed time of an automation run from start to completion. The most useful statistic for this metric is AVERAGE, which represents the average duration of automation runs during a set period of time.	AutomationId	Seconds

Aggregate metrics

The AWS/QuickSight namespace includes the following aggregate metrics for monitoring traffic and latency of your Amazon Quick assets.

Topics

- [Aggregate dashboard metrics](#)
- [Aggregate ingestion metrics](#)

- [Aggregate visual metrics](#)
- [Aggregate unstructured dataset metrics](#)
- [Aggregate connector metrics](#)

Aggregate dashboard metrics

The following metrics track view counts and load times of all dashboards in a Amazon Quick account and region. You can find these metrics under the AWS/QuickSight/Aggregate Metrics group in CloudWatch.

Metric	Description	Unit
DashboardViewCount	The number of times that all Amazon Quick dashboards have been viewed across the entire Amazon Quick account in the region. This number is an aggregate that includes all access patterns such as web, mobile, and embedded. The most useful statistic for this metric is SUM, which represents the total number of Amazon Quick dashboard views during a set period of time.	Count
DashboardViewLoadTime	The amount of time that it takes for all Amazon Quick dashboards to load. The measurement begins when a user navigates to the Amazon Quick dashboard and ends when all of the dashboard's visuals finish rendering.	Millisecond

Metric	Description	Unit
	The most useful statistic for this metric is AVERAGE, which represents the average load time of all Amazon Quick dashboard during a set period of time.	

Aggregate ingestion metrics

The following metrics track all ingestions associated with a Amazon Quick account and AWS Region. You can find these metrics under the AWS/QuickSight/Aggregate Metrics group in CloudWatch.

Metric	Description	Unit
IngestionErrorCount	The number of failed ingestions. The most useful statistic for this metric is SUM, which represents the total number of failed ingestion during a set period.	Count
IngestionInvocationCount	The number of ingestion s that have been initiated. This includes scheduled and manual ingestions that are initiated through the console and the Amazon Quick API operations. The most useful statistic for this metric is SUM, which represents the total number	Count

Metric	Description	Unit
	of ingestions initiated during a set period of time.	
IngestionLatency	The time period between the initiation of an ingestion to the completion of the ingestion. The most useful statistic for this metric is AVERAGE, which represents the average runtime of ingestions during a set period of time.	Second
IngestionRowCount	The number of successful row ingestions. The most useful statistic for this metric is SUM, which represents the total amount of data ingested during a set period of time.	Count

Aggregate visual metrics

The following metrics track load times and error counts of all visuals on a dashboard and in a Amazon Quick account in a Region. You can find these metrics under the AWS/QuickSight/Aggregate Metrics group for CloudWatch.

Metric	Description	Unit
VisualLoadTime	The time that it takes for all Amazon Quick visuals to receive the necessary query data for an initial paint of the visuals. This includes the	Millisecond

Metric	Description	Unit
	round-trip query time from the client, to the Amazon Quick service, and then back to the client. The most useful statistic for this metric is AVERAGE, which represents the average load time of all visuals during a set period of time.	
VisualLoadErrorCount	The number of times that all Amazon Quick visuals that belong to the Amazon Quick account fail to complete a data query for an initial paint. The most useful statistic for this metric is SUM, which represents the total number of failed visuals during a set period.	Count

Aggregate unstructured dataset metrics

The following metrics track all unstructured dataset metrics within a Amazon Quick account in a Region. You can find these metrics under the AWS/QuickSight/Aggregate Metrics group for CloudWatch.

Metric	Description	Unit
QuickIndexDocumentCount	The number of documents in the unstructured Quick index. The most useful statistic for this metric is SUM, which	Count

Metric	Description	Unit
	represents the total number of documents added to your index during a set period of time.	
QuickIndexExtractedTextSize	The extracted text size of the unstructured Quick index. The most useful statistic for this metric is SUM, which represents the total size of all text across all documents in your index.	Bytes
QuickIndexPurchasedInMB	The amount of storage that has been purchased for the unstructured Quick index. The most useful statistic for this metric is SUM, which represents the total size of purchased storage in MB across your index.	MB
QuickIndexCapacity ConsumedRawFileSizeInGB	The raw file size consumed by the unstructured Quick index. The most useful statistic for this metric is SUM, which represents the total raw file size consumed across your index in GB.	GB

Metric	Description	Unit
QuickIndexCapacityRawFileSizeLimitInGB	The raw file size limit of the unstructured Quick index. The most useful statistic for this metric is SUM, which represents the total raw file size limit across your index in GB.	GB
DocumentsCrawled	The number of uploaded documents crawled in the unstructured Quick index. The most useful statistic for this metric is SUM, which represents the total number of documents crawled in your index.	Count
DocumentsIndexed	The number of documents indexed in the unstructured Quick index. The most useful statistic for this metric is SUM, which represents the total number of documents indexed.	Count

Metric	Description	Unit
DocumentsDeleted	The number of documents deleted from the unstructured Quick index. The most useful statistic for this metric is SUM, which represents the total number of documents deleted from your index.	Count
DocumentsModified	The number of documents modified in the unstructured Quick index. The most useful statistic for this metric is SUM, which represents the total number of documents modified in your index.	Count
DocumentsFailedToIndex	The number of documents that failed to index in the unstructured Quick index. The most useful statistic for this metric is SUM, which represents the total number of documents that failed to index.	Count

Metric	Description	Unit
ExtractedTextSize	The total text size extracted during a connector level sync in the unstructured Quick index. The most useful statistic for this metric is SUM, which represents the total size of documents extracted during a connector level sync.	MB

Aggregate connector metrics

The following metrics track all Quick connector invocations associated with a Amazon Quick account in an AWS Region. You can find these metrics under the AWS/QuickSight/Aggregate Metrics group for CloudWatch.

Metric	Description	Unit
ActionInvocationCount	The number of connector invocations made. The most useful statistic for this metric is SUM, which represents the total number of connector invocations initiated during a set period of time.	Count
ActionInvocationError	The number of failed connector invocations. The most useful statistic for this metric is SUM, which represents the total number of connector invocations that	Count

Metric	Description	Unit
	failed during a set period of time.	

Aggregate SPICE metrics

Use the following metrics to monitor SPICE consumption and avoid reaching the consumption limit that can cause ingestions to fail. CloudWatch stores statistics for up to 15 months, so you can access historical information to better understand the consumption trends of your Amazon Quick account. You can find these metrics in the `AWS/QuickSight/Aggregate Metrics` group for CloudWatch.

Metric	Description	Unit
SPICECapacityLimitInMB	This value represents the provisioned SPICE capacity at a specific point in time. This metric refreshes when an update of 1 MB or more in consumed or purchased capacity is made.	MegaBytes
SPICECapacityConsumedInMB	This value represents the consumed SPICE capacity at a specific point in time. This metric refreshes when an update of 1 MB or more in consumed or purchased capacity is made.	MegaBytes

Dimensions

The following table lists Quick metric dimensions that appear in Amazon CloudWatch.

Dimension	Description
DashboardId	The public ID of a Quick dashboard. You can use the <code>ListDashboards</code> API operation to see a list of every dashboard in your Amazon Quick account. For more information, see ListDashboards in the <i>Amazon Quick API Reference</i>.
DatasetId	The public ID of a Quick dataset. You can use the <code>ListDataSets</code> API operation to see a list of every dataset in your Amazon Quick account. For more information, see ListDataSets in the <i>Amazon Quick API Reference</i>.
SheetId	The public ID of a Quick sheet.
VisualId	The public ID of a Quick visual.
KnowledgeBaseId	The public ID of a Quick knowledge base.
QuickInstanceId	The public ID of the Quick instance.
ActionConnectorId	The public ID of the Quick connector.
ActionConnectorType	The type of the Quick connector.
ActionId	The public ID of the Quick Action.
InvokeErrorCode	The error code related to a failed Quick Action Connector invocation.

Compliance validation for Amazon Quick

Third-party auditors assess the security and compliance of Amazon Quick as part of multiple AWS compliance programs. Amazon Quick, across its web, desktop, and mobile clients, is in scope for the following programs:

- Federal Risk and Authorization Management Program (FedRAMP)
- Health Insurance Portability and Accountability Act (HIPAA)
- Payment Card Industry Data Security Standard (PCI DSS)
- System and Organization Controls (SOC) 1, SOC 2, and SOC 3
- International Organization for Standardization (ISO) 9001, ISO 27001, ISO 27018, and ISO 27019
- Cloud Computing Compliance Criteria Catalogue (C5) from the German Federal Office for Information Security (BSI)
- Health Information Trust Alliance Common Security Framework (HITRUST CSF)

When a program lists Quick as in scope, the audits and assessments for that program include the service. In-scope status does not make your own workloads compliant. Under the [shared responsibility model](#), you configure Quick and manage your data to meet the requirements that apply to you.

Compliance programs that include Quick

The following programs include Quick. For each program, use the linked AWS page to confirm the current status, the authorized AWS Regions, and any program details before you rely on the program for your own workloads.

FedRAMP

Quick is in scope for the FedRAMP program. To confirm the current authorization status and the authorized AWS Regions, see [AWS services in scope for FedRAMP](#). You remain responsible for meeting the FedRAMP requirements that apply to your workloads.

HIPAA eligibility

Quick is a HIPAA Eligible Service. This eligibility applies across the Quick web, desktop, and mobile clients, subject to the shared responsibility model and your configuration. To process, store, or transmit protected health information (PHI), you must have an AWS Business Associate

Addendum (BAA) in place. You must also configure the service according to your obligations. To confirm current eligibility, see the [HIPAA Eligible Services Reference](#). For more information about using AWS to build HIPAA workloads, see [HIPAA Overview](#).

PCI DSS

Quick is in scope for the Payment Card Industry Data Security Standard (PCI DSS). To confirm the current status, see [AWS services in scope for PCI DSS](#). You are responsible for the security of the cardholder data that you handle in the service.

SOC reports

Quick is in scope for the AWS System and Organization Controls (SOC) reports, including SOC 1, SOC 2, and SOC 3. To confirm the current status and download the reports that describe the AWS controls, see [AWS services in scope for SOC](#).

ISO 9001, ISO 27001, ISO 27018, and ISO 27019

Quick is in scope for the ISO 9001, ISO 27001, ISO 27018, and ISO 27019 standards. ISO 27018 is the code of practice for protecting personal data in the cloud. To confirm the current status and review the certifications, see [ISO 27001 Overview](#) and the [AWS services in scope by compliance program](#) page.

BSI C5

Quick is in scope for the AWS Cloud Computing Compliance Criteria Catalogue (BSI C5). To confirm the current status, see [AWS services in scope for BSI C5](#).

HITRUST CSF

Quick is in scope for the HITRUST Common Security Framework (CSF). To confirm the current status, see [AWS services in scope for HITRUST CSF](#).

Verifying current reports and scope

Program scope and audit reports change over time. To confirm the status that applies to you, use the following AWS resources.

- To download third-party audit reports, use AWS Artifact. For more information, see [Downloading reports in AWS Artifact](#).
- For the most current list of AWS services in scope of specific compliance programs, see [AWS services in scope by compliance program](#). For general information, see [AWS compliance programs](#).

Your compliance responsibilities

Your compliance responsibility when you use Amazon Quick depends on the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. Use the following AWS resources to help you meet your obligations:

- [Security and compliance quick start guides](#) – These deployment guides discuss architectural considerations and provide steps for deploying security- and compliance-focused baseline environments on AWS.
- [AWS compliance resources](#) – This collection of workbooks and guides might apply to your industry and location.
- [AWS Config](#) – This AWS service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- [AWS Security Hub CSPM](#) – This AWS service provides a comprehensive view of your security state within AWS that helps you check your compliance with security industry standards and best practices.

Resilience in Amazon Quick

Quick is built by AWS and runs on AWS-managed infrastructure. It takes full advantage of the high availability features provided by AWS.

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

Because Amazon Quick is an AWS-managed application, all patches and updates are applied by AWS as needed.

For more information about AWS Regions and Availability Zones, see [AWS global infrastructure](#).

Infrastructure security in Amazon Quick

Intended audience: Amazon Quick administrators

Quick is delivered as a web application, hosted on dedicated Amazon EC2 hosts, separate from AWS virtual private clouds (VPCs). Instead of deploying Amazon Quick on your own hosts, you access the Amazon Quick service through Regional public endpoints. Amazon Quick accesses data sources over a secured internet connection from Regional endpoints. To access data sources that are located inside a corporate network, configure the network to allow access from one of the Amazon Quick public IP address blocks. We recommend that you consider using a VPC (a virtual network dedicated to your AWS account).

For more information, see the following:

- [Global Infrastructure: The Most Extensive, Reliable, and Secure Global Cloud Infrastructure](#)
- [AWS Regions, websites, IP address ranges, and endpoints](#)
- [Connecting to a Amazon VPC with Amazon Quick](#)

As a managed service, Quick is protected by the AWS global network security procedures that are described in the [Amazon Web Services: Overview of Security Processes](#) paper.

If you use AWS published API calls to access Amazon Quick through the network, clients must support Transport Layer Security (TLS) 1.2 or later. Clients must also support cipher suites with perfect forward secrecy (PFS) such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Ephemeral Diffie-Hellman (ECDHE). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an AWS Identity and Access Management (IAM) principal. Or you can use the [AWS Security Token Service](#) (AWS STS) to generate temporary security credentials to sign requests.

You can call these API operations from any network location, but Amazon Quick does support resource-based access policies, which can include restrictions based on the source IP address. You can also use Amazon Quick policies to control access from specific Amazon Virtual Private Cloud (Amazon VPC) endpoints or specific VPCs. Effectively, this isolates network access to a given Amazon Quick resource from only the specific VPC within the AWS network. For more information on using Amazon Quick in a VPC, see [Connecting to a Amazon VPC with Amazon Quick](#).

Security in Quick

Amazon Quick provides a number of security features to consider as you develop and implement your own security policies. The following best practices are general guidelines and don't represent a complete security solution. Because these best practices might not be appropriate or sufficient for your environment, treat them as helpful considerations rather than prescriptions.

For more information about how your data is protected, including the statement that customer data is not used for training or improving underlying LLMs, see [Data protection in Amazon Quick](#).

For a conceptual explanation of how AI and agent capabilities change the risk analysis for Quick, including the two-condition model for adversarial content risk, see [AI and agent security in Amazon Quick](#).

Decide before you deploy – The following decisions are irreversible or difficult to change after initial configuration. Make them deliberately before you create resources or onboard users.

Register encryption keys before you create resources – Quick encrypts all data at rest by default. For more information, see [Encryption at rest](#). The following decision is about whether you or AWS controls the keys. If you require control of the encryption keys that protect your data, register a customer managed KMS key as the account default *before* you create resources. Two key paths matter:

- **Account default key** – Participating resource types select the account default key when data is written. Changing the default affects future writes but does not re-encrypt existing content.
- **Amazon Q data key** – Set once, the first time Amazon Q data is created in the account, from the default key registered at that moment. You cannot change this key afterward. For more information, see [Amazon Q data key](#).
- **Research resources** – A Research resource associates a key at creation. A Research resource created without a key association cannot be moved to one later.

Customer managed KMS key support requires an Enterprise subscription. For the full list of participating resource types, see [Customer managed KMS key scope](#).

Choose your identity model – Choose deliberately among IAM Identity Center, Active Directory, IAM federation, and Quick local users. Provisioning and offboarding behavior differ by model. In particular, Quick detects inactive users and populates the **Inactive users** list. This detection applies only to accounts that federate through IAM Identity Center or Active Directory. For more information, see [User lifecycle and data handling in Amazon Quick](#).

Select the knowledge base access model at creation – For supported integrations, decide at creation whether a knowledge base is access control list (ACL) aware. Document-level ACL configuration is permanent. You cannot turn on ACLs for a knowledge base created without ACL support, and you cannot turn them off after you turn them on. To change ACL configuration, create a new knowledge base with your desired setting from the start.

- **Supported integrations** – Amazon S3, Google Drive, Microsoft SharePoint, Atlassian Confluence Cloud, and Microsoft OneDrive.
- **Sharing and retrieval are separate controls** – Knowledge base sharing determines who can use the knowledge base. For ACL-aware knowledge bases, source-document ACLs further limit which indexed documents each authorized user can retrieve. Review both controls before granting access.
- **Fail-closed behavior** – If Quick cannot evaluate document permissions for a query, it returns no documents rather than unfiltered results.
- **Sync cadence** – Quick synchronizes identity and document-permission changes on the knowledge base refresh schedule, which is every 24 hours by default. Configure a shorter schedule when your access-change requirements demand it.
- **Shared email addresses** – If multiple Quick users share the same email address within a namespace, the system denies access to everyone using that shared email.
- **ACL resolution scope** – Quick resolves all ACLs within the namespace of the knowledge base creator.
- **Email recycling** – If your organization reassigns an email address before the next ACL refresh and the previous holder never used Quick for chat, temporary access leakage is possible. Update ACLs and refresh the knowledge base before reassigning the email.
- **Research incompatibility** – Knowledge bases with document-level ACLs enabled are not compatible with Quick Research.

For more information, see [Best practices for managing ACLs in knowledge bases](#).

Restrict access – After your account is configured, restrict access to the minimum required for each role.

Apply least privilege – Assign Quick roles that match each user's responsibilities. Use custom permissions profiles to further scope down the default capabilities available to a role. Custom permissions can only restrict. They cannot grant capabilities a user does not already have. When you assign profiles at multiple levels, the most specific level wins: user-level overrides role-level, which overrides account-level. Custom permissions require an Enterprise subscription. For more information, see [Custom permissions](#).

For BI workloads, supplement permissions with row-level security, column-level security, and run-as roles to limit data access at query time.

Deny by default for AI capabilities – If your organization has model-risk or change-approval requirements, restrict the AI capability category so that new AI capabilities are denied on launch day until you explicitly allow them. Without this restriction, every new AI capability that Quick ships is automatically available to all users upon release. For more information, see [Deny by Default](#).

Configure AI guardrails – Built-in content safety screening applies automatically to chat interactions. You can further configure up to 50 blocked words and phrases that Quick checks against both user requests and generated responses. For more information, see [AI guardrails in Amazon Quick](#).

Match oversight to how the action runs – Quick supports two invocation models with different security characteristics. Match your review depth to the autonomy and consequence of each model.

- **On-demand actions** – User-initiated, interactive, and authenticated with the individual user's personal credentials. Each action runs as the invoking user and is bounded by that user's connector permissions. For more information, see [On-demand actions](#).
- **Automated workflows** – System-level, scheduled or event-triggered, non-interactive, and authenticated at service level. An automated workflow authenticates at service level. It does not act as an individual user, is not bounded by that user's connector permissions, and runs unattended. Give automated workflows closer scrutiny during review. For more information, see [Automated workflows](#).
- **Restricting autonomous execution** – If unattended execution is not acceptable for some or all users, use the following custom permissions capabilities to restrict it:
 - **Automate** – Prevents restricted users from creating, updating, or running automations.
 - **Flows** – Restricts creating, updating, sharing, and running flows.
 - **Triggers** – Restricts all trigger capabilities, including inbound email triggers and Quick event triggers.

Apply these restrictions in an account-level profile to restrict unattended execution across the entire account. For more information, see [Custom permissions](#).

- **Adding a review step** – For workflows where a human review step is appropriate, use the human-in-the-loop task center to pause execution and collect approval before the workflow continues. For more information, see [Human-in-the-loop task center](#).

Treat retrieved and external content as untrusted – The risk of acting on adversarial content requires two conditions: the assistant can read content from outside your trust boundary, and it can take a consequential action. Narrowing either side reduces exposure.

- **Read surface** – Content from the following sources enters the assistant's context: knowledge base and index retrieval, files uploaded to spaces and chat, web search, third-party research providers, and content returned by connectors.
- **Action surface** – Limit the connectors, actions, and outbound paths available to each role. A narrower action scope reduces the consequence of any single compromised input.
- **Built-in screening** – Built-in safety checks screen user requests, including requests that contain prompt attacks. Pair this screening with narrow action scope rather than relying on screening alone. For more information, see [AI guardrails in Amazon Quick](#).

Restrict network access – Use IP and VPC endpoint rules to control which networks can reach Quick through web, embedded, and mobile access. Rule types include CIDR blocks (IPv4), VPC IDs, and VPC endpoint IDs. You can add up to 100 IP and VPC endpoint rules combined. These rules are global and apply to all AWS Regions. Rule changes can take up to 10 minutes to take effect. IP and VPC endpoint rules require an Enterprise subscription.

IP and VPC endpoint rules do *not* restrict access to the public API. To restrict API access, use IAM policy conditions. For more information, see [Turning on Internet Protocol \(IP\) and VPC endpoint restrictions in Amazon Quick](#).

Transfer ownership before you offboard – Assets left in the account without an owner become inaccessible to every user. Transfer ownership of connectors, agents, and automations before you remove a user from the account.

- **Review orphaned assets** – Periodically review connectors, agents, and automations whose owners have left your organization. For more information, see [Orphaned assets](#).
- **Review dormant connections** – Managed OAuth refresh tokens carry a 90-day lifecycle. Use this cadence as a trigger to review whether each connection is still needed, and remove connections that are no longer in use.
- **Plan for the full lifecycle** – For detailed guidance on user removal and its effects, see [User lifecycle and data handling in Amazon Quick](#).

Review what leaves – Each outbound path is customer-enabled, and each connection has its own authentication and data-access characteristics. Review each path as a potential egress channel before you turn it on.

Require authentication on every connection – The authentication options available depend on the connector type. Some connector types allow connecting without authentication, including remote Model Context Protocol (MCP) servers, agent-to-agent connectors, and generic HTTP connectors. Confirm that every connection requires authentication before you enable it.

- **User-level OAuth** – Each user authenticates individually and acts as themselves. Prefer user-level authentication where the connector supports it, because the impact of a misconfigured connection is limited to a single user's access scope.
- **Shared client-credentials connection** – A single set of credentials is shared across all users of the connector. Every user of that connector inherits its reach and access scope. Scope shared credentials narrowly and review what they grant.
- **Per-connector restriction** – You can restrict individual connectors for Create and Update, Share, and Use through custom permissions, so a connector can be enabled for a narrow set of users rather than everyone. For more information, see [Custom permissions](#).

For more information about the available authentication methods, see [Authentication methods](#).

Review each outbound path before enabling it – Before you enable an outbound capability, verify that the destination and the data that can flow to it meet your organization's requirements. Outbound paths include connectors, remote MCP servers, web search, third-party research providers, public apps, embedding, and export destinations. For per-path detail on what data can leave, what triggers it, who controls it, and what to verify, see [Outbound connections and data egress in Amazon Quick](#).

Configure observability – Configure monitoring and logging before you onboard users at scale. Use the following signals together when you design monitoring and incident-response procedures. Before you rely on a signal for compliance, detection, or investigation, confirm that it covers the event you intend to track.

- **CloudTrail** – Records supported API operations and a documented set of non-API events such as dashboard views and user-management actions. CloudTrail does not capture chat conversation content or user feedback. For those signals, use CloudWatch vended logs. For more information, see [Monitoring Amazon Quick using CloudTrail](#).

- **CloudWatch vended logs** – Five log types deliver conversational and operational data to destinations you control (Amazon CloudWatch Logs, Amazon S3, or Firehose):
 - Chat conversations (CHAT_LOGS)
 - User feedback (FEEDBACK_LOGS)
 - Agent and research hours (AGENT_HOURS_LOGS)
 - Index storage usage (INDEX_USAGE_LOGS)
 - Knowledge base file sync (KB_FILE_SYNC_LOGS)

Vended logs do not flow by default. Configure delivery shortly after you enable Quick AI features so that you do not lose early interaction data. For more information, see [Monitoring Amazon Quick using CloudWatch Logs](#).

- **CloudWatch metrics and alarms** – Near-real-time operational metrics cover dashboards, visuals, dataset ingestions, unstructured datasets, connectors, and SPICE capacity. You can create CloudWatch alarms that send notifications when a metric reaches a threshold that you specify. For more information, see [Monitoring Amazon Quick using CloudWatch metrics](#).
- **Analytics dashboard** – Provides usage, adoption, and feedback insights for IAM administrators. Access requires the `quicksight:QuickSuiteUsageMetrics` permission. The analytics dashboard can expose detailed query text, failed-query content, and the full conversation context associated with negative feedback. Grant analytics access only to authorized administrators. For more information, see [Using the Amazon Quick analytics dashboard](#).
- **Feature-specific reports** – Some features produce their own operational reports, such as knowledge base sync reports that document per-file sync status.

You control retention for all externalized signals. Set destination retention policies to match your compliance requirements. CloudTrail event history retains 90 days of management events by default. CloudWatch Logs, Amazon S3, and Firehose destination retention follows the policies you configure at each destination. For more information, see [Incident response, logging, and monitoring in Amazon Quick](#).

CloudTrail records metadata (who, when, what operation) but not the message body or response content. CloudWatch vended chat logs capture user messages and system responses but not source document content. The analytics dashboard exposes conversation context only in the scope of negative feedback review. If your compliance model requires a signal not listed here, verify coverage before assuming it exists.

Data source connectivity – The following practices help you connect securely to data sources.

Use VPC connections for private sources – Use a virtual private cloud (VPC) connection for data in AWS data sources and for data in on-premises servers without public connectivity. For AWS sources, Quick uses an elastic network interface for secure, private communication with data sources in a VPC. For on-premises sources, use Direct Connect or AWS Site-to-Site VPN to create a secure, private link. VPC connections require an Enterprise subscription. For more information, see [Managing VPC connection in Amazon Quick](#).

Encrypt database connections with SSL – Use SSL to connect to your databases, especially if you are using public networks. Using SSL with Quick requires certificates signed by a publicly recognized certificate authority (CA).

Configure firewall rules for user and data access – To allow users to access Quick, allow access to HTTPS and WebSockets Secure (wss://) protocol. To allow Quick to reach a database on a non-AWS server, change that server's firewall configuration to accept traffic from the applicable Quick IP address range. For more information, see [Network and database configuration requirements](#).

AWS managed policies for Amazon Quick

To add permissions to users, groups, and roles, it is easier to use AWS managed policies than to write policies yourself. It takes time and expertise to [create IAM customer managed policies](#) that provide your team with only the permissions they need. To get started quickly, you can use our AWS managed policies. These policies cover common use cases and are available in your AWS account. For more information about AWS managed policies, see [AWS managed policies](#) in the *IAM User Guide*.

AWS services maintain and update AWS managed policies. You can't change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (users, groups, and roles) where the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services do not remove permissions from an AWS managed policy, so policy updates won't break your existing permissions.

Additionally, AWS supports managed policies for job functions that span multiple services. For example, the **ReadOnlyAccess** AWS managed policy provides read-only access to all AWS services and resources. When a service launches a new feature, AWS adds read-only permissions for new operations and resources. For a list and descriptions of job function policies, see [AWS managed policies for job functions](#) in the *IAM User Guide*.

Topics

- [AWS managed policy: AWSQuickSightElasticsearchPolicy](#)
- [AWS managed policy: AWSQuickSightOpenSearchPolicy](#)

AWS managed policy: AWSQuickSightElasticsearchPolicy

This information is provided for backward compatibility only. The AWSQuickSightOpenSearchPolicy AWS managed policy replaces the AWSQuickSightElasticsearchPolicy AWS managed policy.

Previously, you used the AWSQuickSightElasticsearchPolicy AWS managed policy to provide access to Amazon Elasticsearch Service resources from Amazon Quick. Starting on or after September 7, 2021, Amazon Elasticsearch Service is renamed to Amazon OpenSearch Service.

Wherever you are using AWSQuickSightElasticsearchPolicy, you can update to the new AWS managed policy that's called AWSQuickSightOpenSearchPolicy. You can attach the policy to your IAM entities. Amazon Quick also attaches the policy to a service role that allows Amazon Quick to perform actions on your behalf. AWSQuickSightElasticsearchPolicy is still available and as of August 31, 2021, had the same permissions as the new policy. However, AWSQuickSightElasticsearchPolicy is no longer kept up-to-date with latest changes.

This policy grants read-only permissions that allow access to OpenSearch (previously known as Elasticsearch) resources from Amazon Quick.

Permissions details

This policy includes the following permissions:

- **es** – Allows principals to use `es:ESHttpGet` to access your OpenSearch (previously known as Elasticsearch) domains, cluster settings, and indices. This is required to use the search service from Amazon Quick.

- `es` – Allows principals to use `es:ListDomainNames` to list your OpenSearch (previously known as Elasticsearch) domains. This is required to initiate access of the search service from Amazon Quick.
- `es` – Allows principals to use `es:DescribeElasticsearchDomain` to search your OpenSearch (previously known as Elasticsearch) domains. This is required to use the search service from Amazon Quick.
- `es` – Allows principals to use `es:ESHttpPost` and `es:ESHttpGet` with your OpenSearch (previously known as Elasticsearch) domains. This is required to use a SQL plugin with read-only access to the search service domains from Amazon Quick.

For information on the contents of this IAM policy, see [AWSQuickSightElasticsearchPolicy](#) in the IAM console.

AWS managed policy: AWSQuickSightOpenSearchPolicy

Use the `AWSQuickSightOpenSearchPolicy` AWS managed policy to provide access to Amazon OpenSearch Service resources from Amazon Quick. `AWSQuickSightOpenSearchPolicy` replaces `AWSQuickSightElasticsearchPolicy`. As of August 31, 2021, this policy had the same permissions as the legacy policy, `AWSQuickSightElasticsearchPolicy`. For now, you can use them interchangeably. For the long term, we recommend updating your policy usage to `AWSQuickSightOpenSearchPolicy`.

You can attach `AWSQuickSightOpenSearchPolicy` to your IAM entities. Amazon Quick also attaches this policy to a service role that allows Amazon Quick to perform actions on your behalf.

This policy grants read-only permissions that allow access to OpenSearch resources from Amazon Quick.

Permissions details

This policy includes the following permissions:

- `es` – Allows principals to use `es:ESHttpGet` to access your OpenSearch domains, cluster settings, and indices. This is required to use Amazon OpenSearch Service from Amazon Quick.
- `es` – Allows principals to use `es:ListDomainNames` to list your OpenSearch domains. This is required to initiate access of Amazon OpenSearch Service from Amazon Quick.

- `es` – Allows principals to use `es:DescribeElasticsearchDomain` and `es:DescribeDomain` to search your OpenSearch domains. This is required to use Amazon OpenSearch Service from Amazon Quick.
- `es` – Allows principals to use `es:ESHttpPost` and `es:ESHttpGet` with your OpenSearch domains. This is required to use a SQL plugin with read-only access to Amazon OpenSearch Service domains from Amazon Quick.

For information on the contents of this IAM policy, see [AWSQuickSightOpenSearchPolicy](#) in the IAM console.

AWS managed policy: AWSQuickSightSageMakerPolicy

Use the `AWSQuickSightSageMakerPolicy` AWS managed policy to provide access to Amazon SageMaker AI resources from Amazon Quick.

You can attach `AWSQuickSightSageMakerPolicy` to your IAM entities. Amazon Quick also attaches this policy to a service role that allows Amazon Quick to perform actions on your behalf.

This policy grants read-only permissions that allow access to Amazon SageMaker AI resources from Amazon Quick.

To view the `AWSQuickSightSageMakerPolicy`, see [AWSQuickSightSageMakerPolicy](#) in the [AWS Managed Policy reference](#).

Permissions details

This policy includes the following permissions:

- `sagemaker` – .
- `s3` – Allows principals to use `s3:GetObject` on all Amazon S3 buckets that start with the prefix `arn:aws:s3:::sagemaker.*` to access data stored in SageMaker AI default buckets. This is required to load models shared from Amazon SageMaker AI Canvas to the default Amazon SageMaker AI Canvas Amazon S3 bucket.
- `s3` – Allows principals to use `s3:PutObject` to export objects into an Amazon S3 bucket. This is required to support existing datasets from Amazon Quick to Amazon SageMaker AI Canvas to build predictive models.
- `s3` – Allows principals to use `s3:ListBucket` to allow Amazon Quick to validate an existing Amazon SageMaker AI Canvas bucket in Amazon S3. This is required to allow the export of data from Amazon Quick to Amazon SageMaker AI Canvas to build predictive models.

- `s3` – Allows principals to use `s3:GetObject` on all Amazon Quick– owned Amazon S3 buckets that start with the prefix `arn:aws:s3:::quicksight-ml`. This is required to allow Amazon Quick to access the predictions that are generated by Amazon SageMaker AI Canvas. The generated predictions can be appended to a Amazon Quick dataset.
- `sagemaker` – Allows principals to use `sagemaker:CreateTransformJob`, `sagemaker:DescribeTransformJob`, and `sagemaker:StopTransformJob` to perform SageMaker AI transform jobs on your behalf. This is required for Amazon Quick to request predictions from SageMaker AI models that can be appended to a Amazon Quick dataset.
- `sagemaker` – Allows principals to use `sagemaker:ListModels` to list your SageMaker AI models. This is required to allow generated SageMaker AI models to appear in Amazon Quick.

AWS managed policy: AWSQuickSightAssetBundleExportPolicy

Use the `AWSQuickSightAssetBundleExportPolicy` AWS managed policy to perform asset bundle export operations. You can attach `AWSQuickSightAssetBundleExportPolicy` to your IAM entities.

This policy grants read-only permissions that allow access to Amazon Quick asset resources. To view the details of this policy, see [AWSQuickSightAssetBundleExportPolicy](#) in the AWS Managed Policy reference.

This policy includes the following permissions:

- `quicksight` – Allows principals to use `quicksight:Describe*` and `quicksight:List*` to find and fetch Amazon Quick assets and their corresponding permissions.
- `quicksight` – Allows principals to use `quicksight:ListTagsForResource` to fetch tags of Amazon Quick assets.
- `quicksight` – Allows principals to list, execute, and get the status of an Asset bundle export job. This policy uses the `quicksight:ListAssetBundleExportJob`, `StartAssetBundleExportJob`, and `quicksight:DescribeAssetBundleExportJob` permissions.

AWS managed policy: AWSQuickSightAssetBundleImportPolicy

Use the `AWSQuickSightAssetBundleImportPolicy` AWS managed policy to perform asset bundle import operations. This managed policy does not grant permissions for any run-as-role functionality with the `iam:passrole` that is required for some VPC connection and `DataSource`

operations. This policy also does not grant access to retrieve objects from a users Amazon S3 bucket.

You can attach the `AWSQuickSightAssetBundleImportPolicy` to your IAM entities. This policy grants read and write permissions that allow access to Amazon Quick resources. To view the details of this policy, see [AWSQuickSightAssetBundleImportPolicy](#) in the AWS Managed Policy reference.

This policy includes the following permissions:

- `quicksight` – Allows principals to use `quicksight:Describe*` and `quicksight:List*` to detect changes in the Amazon Quick assets and their permissions.
- `quicksight` – Allows principals to use `quicksight:Create*` and `quicksight:Update*` to make changes to the Amazon Quick assets and permissions from the supplied asset bundle.
- `quicksight` – Allows principals to use `quicksight:ListTagsForResource`, `quicksight:TagResource`, and `quicksight:UntagResource` to update the tags of Amazon Quick assets.
- `quicksight` – Allows principals to list, execute, and get the status of an Asset bundle import job. This policy uses the `quicksight:ListAssetBundleImportJob`, `quicksight:StartAssetBundleImportJob`, and `quicksight:DescribeAssetBundleImportJob` permissions.

Amazon Quick updates to AWS managed policies

View details about updates to AWS managed policies for Amazon Quick since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the [Amazon Quick Document History](#) page.

Change	Description	Date
AWSQuickSightAssetBundleExportPolicy – New policy	Amazon Quick added new permissions to simplify Asset bundle export operations.	March 27, 2024
AWSQuickSightAssetBundleImportPolicy – New policy	Amazon Quick added new permissions to simplify Asset bundle import operations.	March 27, 2024

Change	Description	Date
AWSQuickSageMakerPolicy – Update to an existing policy	Amazon Quick added new permissions to allow integration with Amazon SageMaker AI Canvas.	July 25, 2023
AWSQuickSightElasticsearchPolicy – Update to an existing policy	Amazon Quick added new permissions to provide access to Amazon OpenSearch Service resources.	September 08, 2021
AWSQuickSightOpenSearchPolicy – New policy	Amazon Quick added a new policy to allow access to Amazon OpenSearch Service resources from Quick.	September 08, 2021
Amazon Quick started tracking changes	Amazon Quick started tracking changes for its AWS managed policies.	August 2, 2021

Ask questions, explore data, and get insights with chat in Amazon Quick

You can use Amazon Quick chat to ask questions, interact with your Quick resources, and accomplish tasks using multiple agentic workflows using natural language. When you ask a question, Quick chat analyzes the data it has access to to generate comprehensive responses.

Quick chat provides you with the following capabilities.

Topics

- [Welcome message](#)
- [Suggested prompts](#)
- [Expand and collapse modes](#)
- [Agent picker](#)
- [Scoping response generation to specific data](#)
- [Chatting with datasets](#)
- [Chatting with Topics](#)

- [Amazon Quick chat explanations](#)

Welcome message

When you log in, Amazon Quick chat displays a welcome message.

Suggested prompts

To help you get started on interacting with your resources in chat, Amazon Quick displays suggested prompts you can use to learn more about Amazon Quick features. Use these to get started on your tasks. Once you select a prompt, Amazon Quick guides you step-by-step through the information it needs from you to complete the task.

Note

Suggested prompts are system generated for the system agent; you can't customize them. For custom agents, suggested prompts can be created and customized by the agent builder or owner.

Expand and collapse modes

To help enhance your productivity and streamline your chat interactions, Amazon Quick offers two separate chat window display modes:

- **Collapse mode** – The default chat window display. Use for easy access to chat from within all Amazon Quick contexts.
- **Expand mode** – Access chat in an expanded view. Use this mode to work in the chat window without any distractions.

You can open up the chat interface at any time by selecting the chat bubble icon from the top right navigation menu. You can also exit out of the chat at any time by selecting the cancel icon from the top navigation menu.

Agent picker

Chat agents in Amazon Quick are conversational assistants that help users explore data, analyze information, and take actions. You can pick any agent you've created to use during chat, or use the system agent **My Assistant** for your conversations.

To learn more about agents, see [Working with agents](#).

Scoping response generation to specific data

When you use Amazon Quick, you can define what data you want your chat responses generated from using data filters. Data filters enable you to customize your chat's expertise area. The data available to your agent depends on whether it is bound to specific Amazon Quick knowledge and integrations, or if it's unbounded (not connected to specific Amazon Quick resources).

By default, an agent has knowledge of all your Amazon Quick resources and its underlying large language model (LLM). While using chat, you can select between the following knowledge modes:

- **All data and apps** – Amazon Quick will use all available knowledge sources (including spaces, dashboards, datasets, topics, knowledge bases, action integrations, and LLM knowledge) to generate a response to your prompts.
- **General knowledge** – Amazon Quick will only use LLM knowledge to generate responses to your prompts. It won't use any knowledge from Amazon Quick resources.
- **Specific data and apps** – Chat with a specific or multiple spaces, dashboards, datasets, topics, knowledge bases, or actions. To choose specific resources, select **Choose resource**.

An agent with pre-defined knowledge, on the other hand, only has knowledge of existing Amazon Quick resources already linked to it, and its underlying LLM knowledge. While chatting with an agent with pre-defined knowledge, you get the following knowledge modes:

- **Pre-defined knowledge** – Amazon Quick will use only the Amazon Quick resource knowledge linked to the agent, and LLM knowledge, to generate responses. You can't change this setting.
- **Additional data and apps** – Chat with a specific or multiple spaces, dashboards, datasets, topics, or knowledge bases and actions. To choose specific resources, select **Choose resource**.

Chatting with datasets

You can chat with your datasets in Amazon Quick to ask questions and get insights from your data using natural language. To get started, you need to first create a dataset. For more information, see [Creating datasets](#).

Amazon Quick chat supports the following dataset types:

- SPICE datasets
- Direct Query datasets against Amazon Redshift, Athena, Aurora PostgreSQL, and Amazon S3 Tables

 Note

Direct Query datasets against other data sources are not yet supported for chat.

For SPICE datasets, the size limit of 2 TB and 2 billion rows applies when chatting with the dataset.

Chatting with Topics

You can chat with your Topics in Amazon Quick to ask natural language questions that span multiple datasets. When you select a Topic as your data context in chat, the LLM-powered chat agent uses the defined relationships, dataset enrichment metadata, and custom instructions to generate cross-dataset SQL queries and return unified answers.

To chat with a Topic, use the data filter to select **Specific data and apps** and choose your Topic from the list. Or navigate to the Topic and choose the chat icon.

The chat agent traverses relationships across datasets, identifying which tables contain the relevant columns, constructing SQL with appropriate joins, and returning a unified answer. You can view the generated SQL in the Explanation panel to verify the correct datasets and joins were used.

Amazon Quick chat supports the following Topic types:

- **New Topics (multi-dataset)** – The LLM-powered chat agent generates cross-dataset SQL with runtime joins. It can produce inner joins, left joins, outer joins, unions, and subqueries based on your defined relationships and custom instructions.
- **Legacy Topics** – The legacy ML-based fuzzy search model selects one dataset from the Topic and queries only that single dataset. Cross-dataset queries are not supported.

For more information about creating and configuring Topics, see [Working with Amazon Quick Sight Topics](#).

Web search

Amazon Quick comes with built-in web search capability. Amazon Quick chat automatically searches both your connected data sources and the web, providing comprehensive answers from either or both sources as needed. You can turn web search off for any query by clicking the globe icon in the chat panel. Any content retrieved from the web is appropriately cited in the final response.

Note

Web search is available to users only if it has been enabled by admin.

Upload files and chat

You can upload documents into Amazon Quick chat and ask Amazon Quick chat to summarize or analyze data based on the content of the uploaded documents.

When you start a new conversation, you can upload new files, choose from a saved list of recent documents, or drag and drop files directly into the conversation.

You can upload up to 20 files at one time with the following size limits:

- 10 MB for images (.jpeg, .png)
- 10 MB for spreadsheet files (.csv, .xls, .xlsx)
- 50 MB for other supported formats

Supported file types include:

- Word (.docx)
- Excel (.xls, .xlsx)
- PowerPoint (.ppt, .pptx)
- PDF (.pdf)
- images (.jpeg, .png)
- text files (.csv, .txt, .rtf, .md)
- Outlook (.msg)

- structured data files (.json, .yaml, .xml, .vtt, and common code files)

The total parsed content for all files combined has to be under 665,000 characters.

Note

If your files exceed the file count and character count limits, you can upload them to a [space](#) instead.

Documents uploaded through the chat interface are deleted with the associated conversation after 90 days of inactivity.

Note

Audio and video files are not supported as file uploads.

Actions

Amazon Quick actions boost productivity by allowing you to perform relevant tasks in supported third-party services from your Amazon Quick chat interface, like sending an email using Microsoft Outlook, or creating a PagerDuty incident. You can invoke any actions configured and available to you from your Amazon Quick chat interface. To select an action, use the action application from the data scoping filter and select the third party application you want to perform actions in. Then, choose the action you want to perform from the available actions. The system checks if you have authorization to perform the action before performing it.

To learn more about actions, see [Actions in Amazon Quick](#).

Flows

Use Amazon Quick flows to create shortcuts for everyday, repetitive tasks you perform while chatting in Amazon Quick. For example, if you find yourself using Amazon Quick chat to create and copy edit product launch descriptions, you can use Amazon Quick flows to generate an application that takes your draft content as input, and generates a polished draft—after content, style, and grammar review—as output.

You can run a flow directly from chat within a conversation. Within a single conversation, you can talk to a chat agent as well as run a flow.

To learn more about flows, see [Flows in Amazon Quick](#).

Memory and response personalization

Memory in Amazon Quick chat helps personalize your conversations by remembering your preferences, context, and past interactions. Chat agents can reference this stored information to provide more personalized and contextually relevant responses without you needing to repeat information in every conversation, enabling more relevant and tailored responses over time.

When you interact with chat agents in Amazon Quick, you can provide your preferences including:

- Response style and format
- Frequently accessed Dashboards, Spaces, integrations, and other Amazon Quick assets
- Context about your role and responsibilities
- Common tasks and workflows you perform

This information is securely stored and fetched to enhance your future interactions with chat agents. Memories are specific to you and are not shared with other users. To get the most value from memory in chat, follow the best practices below:

- **Be explicit about your preferences** – Clearly state your preferences, priorities, and context when you want the chat agent to remember them. For example, "I prefer reports in table format" or "I work on the marketing team".
- **Provide relevant context** – Share information about your role, responsibilities, and common tasks to help chat agents understand your needs better.
- **Update your preferences** – As your priorities change, inform the chat agent about updates to ensure the stored information remains current and relevant.
- **Review and refine** – If responses don't align with your expectations, provide feedback and clarify your preferences to improve future interactions.

You maintain control over your memory data. You can review chat memory by going to **Conversation History** and clicking on **View Memories**.

 Note

Chat memory has the following limitations:

- Chat memory isn't supported for accounts configured with [AWS KMS customer managed keys](#).

Source citations

Amazon Quick chat responses provide in-text source citations in a numbered list. To view the source for a response, choose the number at the end of the sentence. The dialog box shows the title, URL, and a snippet from the source that was used to generate the response. Choose the URL to view the source document.

To view the full list of sources, choose **Sources** at the end of the response. You can use the source list to fact-check the response, or for deeper analysis.

Copy responses

You can copy and save the responses for later review and analysis. To copy a response, choose the copy icon at the end of the response.

Provide feedback

You can provide direct feedback about the responses you received from Amazon Quick chat by using the thumbs-up or thumbs-down button. Your feedback is used to help address technical issues in the web experience.

If you select the thumbs-down button, you can choose from the following feedback options:

- **Inaccurate, not factually correct**
- **Incomplete answer**
- **Didn't understand my question**
- **Issue with sources**
- **Too wordy**

- **Offensive or unsafe language**
- **Other**

You can also copy conversation details from the feedback window for further troubleshooting.

Artifact panel

An *artifact* in Amazon Quick is defined as any Amazon Quick generated content produced using Amazon Quick's underlying large language model's (LLM) generative capabilities, for example: contracts, email drafts, social media posts, tables, interactive charts, code blocks, or any Amazon Quick visuals.

Amazon Quick stores any artifacts it generates as responses during chat in an artifact panel. You can access any artifacts created during your chat by selecting **View more** from below the artifact in chat.

You can download artifacts as text, CSV, code files, Word documents, Excel spreadsheets, PowerPoint presentations, PDFs, and infographics. Saving artifacts to a Space is not currently supported.

For more information about creating and downloading documents and visuals, see [Document and visual creation](#).

Conversation management

Amazon Quick stores conversations for up to 90 days, and you can access them in the left navigation pane. You can perform the following tasks to manage your conversations:

- **Start new conversation** – Choose **+** from the chat controls menu to start a new conversation.
- **View conversation history** – Choose the clock icon to view all conversation history for the last 90 days. You can filter conversation history to specific agents.

Note

Searching, saving, renaming, and sharing conversations with other users is not supported.

Response events

For every natural language prompt Amazon Quick chat receives, it generates real-time processing steps while the request is being fulfilled. These steps can be viewed as part of **Response events** during response generation, and are also accessible once Amazon Quick has finished generating a response. Response events vary based on the chat interaction you're having (whether you're chatting with a file you've uploaded or with a Amazon Quick resource) and capture any rewrites to your response before it's finalized. A response event also includes the system generated identifiers for your conversation—you can copy and save the information for troubleshooting..

Explanations

When you chat with dashboards and datasets, each answer includes an Explanation that shows how the model arrived at each numerical claim, including the data sources, assumptions, filters, calculations, and SQL queries that the model used. Instead of manually verifying each answer by finding the original source and re-creating the logic, you can directly see the model's assumptions at the click of a button.

When you open an Explanation, you can see the following components:

- **Found data in** – Displays the dashboards, sheets, or datasets where the insight came from.
- **Filters** – Lists dashboard filter values that were used to arrive at the answer.
- **Assumptions** – Unpacks any large language model (LLM)-derived definitions from either the data directly or from world knowledge.
- **Calculation explained** – Shows any calculations that the model performed to arrive at the answer, presented in both natural language and as a math formula.
- **Generated SQL** (datasets only) – Displays the specific SQL query that produced each numerical claim.

For more information and examples, see [the section called “Chat explanations”](#).

Contextual awareness

Amazon Quick chat is context aware. It registers the Amazon Quick resource you're interacting with and scopes your chat automatically to the resource. This way, when you start chatting, the resource you're interacting with is already included as a knowledge source for your chat.

If you navigate to a specific Amazon Quick resource during an on-going chat, and that resource supports chat, Amazon Quick chat will automatically register your new context and ask you whether you want to chat with the specific resource you have navigated to. If you want to continue chatting in the mode you're in, you can choose to **Ignore** the message. Or you can choose **Yes** to focus your chat on the specific resource you're interacting with. If you do so, Amazon Quick automatically scopes your chat interactions to the resource in context.

Managing your preferences in Amazon Quick

User Preferences in Amazon Quick gives you control over how Quick looks, feels, and works for you. You can customize your chat experience, set a default chat agent, personalize how Quick interacts with you, and manage your memories — all from a single settings modal.

Customizing your chat experience

You can set your default chat panel to open in either expanded or collapsed mode. By default, Quick automatically remembers your last used setting. For example, if you expand the chat panel during a session, Quick updates your default so the panel opens expanded the next time you return. You can also manually set your preferred default at any time from the Preferences modal.

Setting your default chat agent

You can choose a preferred chat agent that greets you each time you open Quick. In addition to selecting a default agent, you can pre-select a default knowledge scope for My Assistant. The available knowledge scope options are:

- **All data and apps** – Quick searches across all your connected data sources and applications.
- **General knowledge** – Quick responds using general knowledge only, without searching your connected data.
- **Specific data and apps** – Quick searches only the data sources and applications you specify.

Your selected agent and knowledge scope are applied automatically each time you start a new conversation.

Personalizing your experience

You can let Quick know what to call you and share your area of focus at work. Quick uses this context to personalize responses and make your experience more relevant to your role and responsibilities.

Managing your memories

You can view and manage your memories directly from Preferences. Memories are insights that Quick learns from your conversations to personalize future interactions. From the Memories section, you can:

- View all saved memories.
- Search for specific memories.
- Delete individual memories.
- Delete all memories at once.

Accessing User Preferences

To access and configure your preferences:

1. Go to the top-right corner of the Amazon Quick homepage.
2. Choose your account name.
3. Select **Preferences** from the dropdown menu.
4. Make your changes across any of the available sections.
5. Choose **Save** to apply your changes, or choose **Cancel** to discard them.

Amazon Quick chat explanations

In Amazon Quick, when you chat with dashboards and datasets, each answer includes an Explanation that shows how the model arrived at each numerical claim, including the data sources, assumptions, filters, calculations, and SQL queries that the model used. Instead of manually verifying each answer by finding the original source and re-creating the logic, you can directly see the model's assumptions at the click of a button.

Chat with your dashboards

When you chat with your dashboard data, open the Explanation to see which dashboards and sheets were selected. You can also see which filters were applied. This helps you validate whether the answer matches your intent.

For example, suppose you open your "Test Drive Conversion" dashboard and ask "what electric car models have an almost perfect satisfaction score but a low conversion rate?" You want to see if some cars test drive well but don't result in a sale. You open the Explanation and check the Assumptions section. Chat defined "electric car model" by using the vehicle model naming terminology. It searched for names that ended with "E" (electric) or "SE" (sport electric). Although that might be correct in most cases, the best field to ensure accuracy is "vehicle_fueltype". You type that directly in the chat: "use the vehicle fuel type for identifying electric cars." You then open the refreshed and correct Explanation.

ⓘ Explanation

×

📄 Data point 1

“Table describing electric vehicle models with satisfaction scores and conversion rates”

^

Found data in

Test Drive Performance and Conversi...

4 filters ^

Vehicle & Engagement Analysis

Modified

Existing

Categorical

status equals: all

customer_role equals: all

country equals: all

vehicle_fueltype equals: all

Assumptions

- *'electric car models'* → identified models ending with ' E', ' SE', or containing 'SE ALL4'
- *'satisfaction score'* → mapped to *avg_satisfaction* column from 'Average Customer Satisfaction by Vehicle Model' visual
- *'conversion rate'* → calculated from *lead_to_offer* column in 'Lead Conversion by Vehicle Model' visual

Calculations explained

Retrieved satisfaction scores from the 'Average Customer Satisfaction by Vehicle Model' visual and conversion data from the 'Lead Conversion by Vehicle Model' visual on the Vehicle & Engagement Analysis sheet. Identified electric models by filtering for model names ending in ' E' or ' SE' or containing 'SE ALL4'. Calculated conversion rate for each model by dividing the count of test drives that converted (*lead_to_offer* = true) by total test drives and multiplying by 100.

▼ Calculation

📄 Data point 2

▼

Explanation

Data point 1

"Table describing all 6 electric car models with satisfaction and conversion metrics"

Found data in

Test Drive Performance and Conversi...
4 filters ^

Vehicle & Engagement Analysis

Modified Existing

Categorical

status equals: all customer_role equals: all

country equals: all vehicle_fueltype equals: ELECTRIC

Assumptions

- 'electric car models' → filtered column *vehicle_fueltype* to *ELECTRIC*
- 'satisfaction' → used column *feedback_rating* from visual 'Average Customer Satisfaction by Vehicle Model'
- 'conversion rate' → calculated from column *lead_to_offer* from visual 'Lead Conversion by Vehicle Model'

Calculations explained

Filtered the Vehicle & Engagement Analysis sheet to show only electric vehicles using the *vehicle_fueltype* filter. Retrieved satisfaction scores from the 'Average Customer Satisfaction by Vehicle Model' visual and conversion data from the 'Lead Conversion by Vehicle Model' visual. Calculated conversion rate for each model by dividing the count of converted test drives by total test drives and multiplying by 100.

Data point 2

"The average satisfaction across electric models is **2.991106** and the average conversion rate is **34.779935%**."

Data point 3

"MINI Aceman E — Satisfaction of **3.279070** (2nd highest) but conversion of only **34.285714%**, just below the electric average. Despite 105 test drives

Explanation components

- Found data in** – Displays the dashboards and corresponding sheets where the insight came from.
- Filters** – Lists dashboard filter values that were used to arrive at the answer.

- **Assumptions** – Unpacks any large language model (LLM)-derived definitions from either the data directly (like referencing agent instructions) or from world knowledge.
- **Calculation explained** – Shows any calculations that the model performed to arrive at the answer, presented in both natural language and as a math formula.

Chat with your datasets

When you chat directly with your datasets, you can see the SQL queries that are generated. Use these queries to verify that the model understood your intent. In the car dealer example, suppose you ask "what's the no-show rate, and which car model struggles with it the most?"

- **Found data in** – Displays the datasets where the insight came from.
- **Assumptions** – Unpacks any LLM-derived definitions from either the data directly (like referencing dataset-level descriptive metadata) or from world knowledge.
- **Calculation explained** – Shows any calculations that the model performed to arrive at the answer, presented in both natural language and as a math formula.
- **Generated SQL** – Displays the specific SQL query that produced each numerical claim.

🔍 Explanation

💬 Data point 1

"Out of **2,000** total test drives, **338** were no-shows — giving an overall no-show rate of **16.90%**."

Found data in

 VBS_test_drives

Assumptions

- '*no-show rate*' → filtered column *status* to 'NO_SHOW' and calculated percentage

Calculations explained

Queried the VBS_test_drives dataset to count total test drives (2,000) and those with status 'NO_SHOW' (338), then calculated the percentage: 338 divided by 2,000 equals 16.90%.

^ Calculation

$$\text{No-Show Rate} = \frac{338}{2,000} \times 100 = 16.90\%$$

^ SQL query

```
SELECT
  COUNT(*) AS total,
  SUM(
    CASE
      WHEN "status" = 'NO_SHOW' THEN 1
      ELSE 0
    END
  ) AS no_shows,
  ROUND(
    100.0 * SUM(
      CASE
        WHEN "status" = 'NO_SHOW' THEN 1
        ELSE 0
      END
    ) / COUNT(*),
    2
  ) AS no_show_rate_pct
FROM
  "VBS_test_drives"
```

Document and visual creation with Amazon Quick

Quick can create professional-quality documents and business visuals from natural language requests. You can create and edit Word documents, Excel spreadsheets, PowerPoint presentations, PDFs, infographics, and other business visuals directly within Quick. Describe what you need, and Quick produces a downloadable file that you can use immediately or refine further.

Document and visual creation is available in the following Quick features:

- **Quick chat** — Create and edit documents and visuals through conversational requests. For more information, see [the section called “Creating documents and visuals in chat”](#).

Topics

- [Supported document and visual types](#)
- [How document and visual creation works](#)
- [Creating documents and visuals in chat](#)
- [Editing existing documents](#)
- [Working with uploaded files](#)
- [Using templates](#)
- [Previewing and downloading](#)
- [Business visual creation](#)
- [Brand theming](#)
- [Best practices](#)
- [Limitations](#)

Supported document and visual types

Quick supports creating the following document and visual types:

Word documents (.docx)

Create professional reports, proposals, contracts, and other text-based documents. Quick generates formatted documents with styles, tables, images, charts, headers, footers, and tables of contents.

Excel spreadsheets (.xlsx)

Create spreadsheets with formulas, charts, conditional formatting, and multiple worksheets. Quick supports dashboards, financial models, data analysis workbooks, trackers, and data exports.

PowerPoint presentations (.pptx)

Create slide decks with professional themes, layouts, charts, speaker notes, and visual elements. Quick can create presentations from scratch or from an existing template.

PDF documents (.pdf)

Create formatted PDF documents with styled pages, tables, headers, footers, and page numbers.

Business visuals (.png)

Create visual infographics, posters, diagrams, and charts from natural language descriptions.

How document and visual creation works

When you request a document or visual, Quick uses an AI-powered process to interpret your request and produce the file. The process works as follows:

1. You describe the document you want to create using natural language. For example, *"Create a quarterly sales report in Excel with charts showing revenue by region."*
2. Quick determines the appropriate document type and generates the file using specialized document creation tools.
3. As the document is being built, you see real-time progress updates describing each step of the generation process.
4. When the document creation is complete, you can preview it in a dedicated panel to review the content and format.
5. If everything looks good in the preview, you can download the document. If you need to make edits and refine the content further, you can add comments to specific sections of the document and regenerate the document with the feedback included. For broader changes that apply across the document, you can also use chat to give feedback and suggested changes.

You can also upload files to use as input for document generation. For example, you can upload a CSV file and ask Quick to create an Excel dashboard from the data, or upload a Word document and ask for specific edits.

Creating documents and visuals in chat

You can create documents and business visuals directly in Quick chat by describing what you need.

Create a new document or visual

1. Open Quick chat.
2. (Optional) Upload any input files that you want to use as source data. You can upload spreadsheets (.csv, .xls, .xlsx), documents (.docx), presentations (.pptx), PDFs, and JSON files.
3. Describe the document you want to create. Be specific about the content, structure, formatting, and any analytical requirements. See the following section for examples.
4. Quick generates the document and displays progress updates as it works. When the document is ready, it appears in a preview panel.
5. Choose **Download** to save the file to your device.

Example prompts

The following examples demonstrate the range of documents and visuals you can create, from simple documents to complex multi-sheet financial models.

Financial modeling (Excel)

"Our company is evaluating whether to build a new distribution center or lease additional warehouse space. Create an Excel model comparing the total cost of ownership for building versus leasing over 10 years. Include an assumptions sheet with construction costs, lease rates, annual escalation percentages, maintenance costs, and discount rate that I can adjust. Create a 10-year cash flow projection for each scenario with NPV and IRR calculations. Add a break-even analysis sheet and a conclusion page comparing the two options with charts."

This produces a multi-sheet workbook with an editable assumptions page, year-by-year cash flow projections for each scenario, Excel formulas that update when you change inputs, and a conclusion sheet with comparison charts and financial metrics.

Data-driven presentation (PowerPoint)

"Using the attached quarterly sales CSV, create a board-ready PowerPoint presentation. Include an executive summary slide with key metrics, regional breakdowns with bar charts, a year-over-year trend analysis with line charts, and a final slide with strategic recommendations. Use a dark professional theme with our company colors (navy and gold)."

Upload your data file alongside the prompt. Quick extracts the data, builds the charts, and applies the requested theme across all slides.

Contract document (Word)

"Create a professional services agreement in Word. Include sections for scope of work, payment terms with a milestone schedule table, intellectual property rights, confidentiality, termination clauses, and limitation of liability. Add a signature block at the end. Use formal legal formatting with numbered sections and sub-sections."

This produces a structured legal document with proper heading hierarchy, numbered clauses, formatted tables, and signature blocks.

Operational dashboard (Excel)

"Create a project management dashboard in Excel. Include a summary sheet with KPI cards for budget utilization, schedule variance, and resource allocation. Add a task tracker sheet with status columns that use conditional formatting (green for on track, yellow for at risk, red for blocked). Add a Gantt-style timeline sheet and a risk register with severity scoring formulas."

This produces a multi-sheet workbook with conditional formatting, formulas that calculate status indicators, and charts that visualize project health.

Research report (Word with data)

"Using the attached PDF research paper and the CSV dataset, create a Word report that summarizes the key findings, includes a methodology section, presents the data in formatted tables with alternating row shading, and adds charts showing the main trends. Include a table of contents and an executive summary at the top."

Upload both files with your prompt. Quick reads the PDF content and CSV data, then produces a formatted report that synthesizes both sources with embedded charts and tables.

Visual infographic

"Create an infographic showing the global impact of renewable energy adoption. Include statistics on solar and wind capacity growth over the last decade, a world map highlighting top adopting

countries, and a comparison of energy costs between renewable and fossil fuel sources. Use a clean, modern design with a green and white color palette."

This produces a visually designed infographic with data visualizations, geographic elements, and styled typography. Because no source data is uploaded with this prompt, the statistics shown are illustrative. You can refine the values by providing a data file or describing updates in chat.

Editing existing documents

You can edit documents that Quick has previously created, or upload your own files for editing. Quick preserves the existing formatting and structure while applying your requested changes. For most document types, you can upload your own files for editing. See individual document types below for details.

Edit an existing document

1. In Quick chat, upload the document you want to edit, or continue a conversation where a document was previously generated.
2. Describe the changes you want to make. For example:
 - *"Change all the heading colors to dark blue."*
 - *"Add a new column called Status to the first table."*
 - *"Update the title slide to say Q1 2026 Results."*
3. Quick applies the edits and produces an updated version of the document.

The following editing capabilities are supported for each document type.

Word (.docx)

- *Text replacement* — Replace words or phrases throughout the document. Example: *"Change all instances of 2025 to 2026."*
- *Formatting changes* — Update fonts, colors, sizes, and styles. Example: *"Make all Heading 1 text dark blue and 16pt."*
- *Section management* — Add, remove, or reorder sections. Example: *"Move the Conclusions section to before the Appendix."*

- *Table modifications* — Add rows, columns, or update cell values. Example: *"Add a Status column to the project tracking table."*
- *Headers and footers* — Add or update page headers, footers, and page numbers. Example: *"Add a footer with the company name and page numbers."*

Excel (.xlsx)

- *Cell updates* — Modify values, formulas, and number formats. Example: *"Update the Q4 revenue figure in cell B5 to \$3.5M."*
- *Chart additions* — Add or modify charts and visualizations. Example: *"Add a bar chart comparing revenue across all quarters."*
- *Worksheet management* — Add new sheets or restructure existing ones. Example: *"Add a Summary sheet with totals from each regional sheet."*
- *Formatting* — Update styles, conditional formatting, and layout. Example: *"Apply alternating row colors and bold the header row."*

PowerPoint (.pptx)

- *Content updates* — Change text, titles, and bullet points. Example: *"Update the title slide to say Q1 2026 Results."*
- *Layout changes* — Modify slide layouts and visual elements. Example: *"Change slide 3 to a two-column layout with the chart on the right."*
- *Data modifications* — Update chart data and table content. Example: *"Update the sales chart with the new figures from the uploaded spreadsheet."*
- *Slide management* — Add, remove, or reorder slides. Example: *"Add a new slide after the introduction with a team overview."*

Infographics (.png)

Infographic editing applies to visuals that were created in the current conversation. You can request changes to a previously generated infographic without uploading a separate file.

- *Text changes* — Update titles, labels, and descriptions. Example: *"Change the title to Global Warming Trends."*
- *Visual updates* — Modify colors, layout, and styling. Example: *"Make the background blue and increase the font size of the statistics."*

Note

PDF documents cannot be edited in place. To modify a PDF, Quick extracts the content and creates a new PDF with your requested changes.

Working with uploaded files

You can upload files to use as input when creating documents and visuals. Quick reads the content of your uploaded files and uses it to produce the requested output.

Common use cases include:

- Uploading a CSV or JSON file and creating an Excel dashboard or report from the data
- Uploading a PDF and converting its content into a Word document or presentation
- Uploading multiple source files and creating a consolidated summary document
- Uploading a PowerPoint template and creating a new presentation that matches its visual style

Supported input file types:

- Spreadsheets: .csv, .xls, .xlsx
- Documents: .docx, .pdf
- Presentations: .pptx
- Data files: .json
- Brand assets: .svg (for logos used with brand theming)

Using templates

You can upload an existing file as a template so that Quick creates new content that matches the original's visual design, branding, and formatting. Template support varies by document type, with PowerPoint offering the most comprehensive template cloning workflow. This is useful when your organization has standardized document styles that you want to maintain across new documents.

PowerPoint templates

PowerPoint has the most comprehensive template support. When you upload a .pptx file and ask Quick to create a new presentation using it as a template, Quick does the following:

1. Inspects the template to discover slide layouts, shape names, theme fonts, and theme colors.
2. Classifies the template slides by type, such as title or cover slides, section dividers, and content slides.
3. Clones the template slides that best match each section of your new content. Cloning preserves backgrounds, brand colors, decorative elements, icons, and images from the original template.
4. Fills in your new content by replacing text in the cloned slides while keeping the visual design intact.

The result is a new presentation with your content that looks like it was built by hand using the original template.

To use a PowerPoint template:

1. Upload your .pptx template file in Quick chat.
2. Describe the new presentation you want to create. Mention that you want to use the uploaded file as a template. For example:
 - *"Using this template, create a 12-slide presentation about our 2026 product roadmap."*
 - *"Create a quarterly business review deck using this template and the attached CSV data."*
3. Quick generates the presentation using the template's visual design and your new content.

PowerPoint templates work best when the template contains a variety of slide layouts, such as title slides, content slides with text placeholders, and section dividers. Quick selects the most appropriate layout for each slide in the new presentation based on the content.

Excel templates

When you upload an existing .xlsx file as a template, Quick clones the workbook and preserves its formatting, formulas, and structure. It then populates the cloned workbook with your new data while keeping the original styling intact.

This is useful for:

- Recurring reports that use the same layout each period, such as monthly financial statements or quarterly dashboards
- Standardized workbooks with pre-built formulas, conditional formatting, and data validation rules that you want to reuse with new data
- Branded spreadsheets with specific header styles, color schemes, and chart formatting

To use an Excel template, upload your .xlsx file and describe what data to populate. For example: *"Using this template, fill in the revenue sheet with the data from the attached CSV and update the dashboard charts."*

Word templates

Word documents do not have a dedicated template cloning workflow. However, you can achieve a similar result by uploading an existing .docx file and asking Quick to edit it with new content. When editing, Quick preserves the original formatting, styles, headers, footers, and structure while applying your requested changes.

For example, if your organization has a branded report template with specific fonts, colors, and section layouts, you can upload it and ask: *"Replace the placeholder content in this report template with the following project details..."*

For new Word documents created from scratch, Quick applies professional formatting with configurable styles. You can specify fonts, colors, and layout preferences in your prompt to match your organization's standards.

Previewing and downloading

When Quick creates a document or visual, it appears in a preview panel. You can access the preview panel by choosing **View more** from below the item in chat.

From the preview panel, you can:

- Preview the created document or visual
- Download it to your device
- Continue editing by sending follow-up messages in chat

The following download formats are supported:

Type	Download format
Word documents	.docx
Excel spreadsheets	.xlsx
PowerPoint presentations	.pptx
PDF documents	.pdf
Infographics and business visuals	.png

Business visual creation

Quick can create business visuals like infographics, charts, and data visualizations. You can turn insights into shareable images for presentations and reports, or generate professional graphics for business communication.

Business visuals are available in two ways:

Standalone infographics and visuals

You can create standalone business visuals by describing what you need in Quick chat. Quick produces a professionally designed image that you can download and share. These visuals are ideal for:

- Data-driven infographics that summarize key metrics and trends
- Comparison charts and diagrams for stakeholder communication
- Visual summaries for executive briefings and team updates
- Process diagrams and workflow visualizations

Example prompts:

- *"Create an infographic comparing our Q1 and Q2 performance metrics with charts showing revenue growth, customer acquisition, and retention rates."*

- *"Create a visual summary of our three-year strategic roadmap with milestones and key deliverables for each phase."*
- *"Using the attached CSV, create a data visualization showing regional sales distribution with a map and supporting bar charts."*

You can also edit previously created visuals by describing the changes you want. For example: *"Change the color scheme to blue and white and update the title to say H1 2026 Results."*

Visuals embedded in documents

When creating Word documents, PowerPoint presentations, or PDFs, you can request that Quick include generated visuals within the document. These embedded visuals include:

- Background images and hero visuals for presentation title slides and section dividers
- Illustrations and concept visuals for reports and proposals
- Custom icons and decorative elements with transparent backgrounds
- Data charts and visualizations created from your uploaded data

To include visuals in a document, mention them in your prompt. For example:

- *"Create a PowerPoint presentation about our product launch with generated hero images on the title and section divider slides."*
- *"Create a Word proposal with an illustrated cover page and concept visuals for each solution section."*

Note

Each visual takes a few seconds to generate. For best results, limit visual generation requests to a few images per document.

Brand theming

You can apply your organization's brand identity to created documents and visuals by providing theme assets. When brand theme files are available, Quick automatically applies your brand colors and logos.

Brand theming supports the following asset types:

- Theme configuration files that define brand colors
- Logo files in SVG format

To apply brand theming, upload your theme configuration file (JSON format) and SVG logo assets in Quick chat alongside your document request. The theme configuration file defines your brand colors as hex values. Quick detects the theme files and applies your brand colors and logos to the generated output.

 Note

Brand theming for business visuals and infographics supports brand colors and logos. Typography and additional brand image assets are not included in theme configuration but can be provided as file uploads in chat.

Brand theming is available for all document and visual types, including Word documents, Excel spreadsheets, PowerPoint presentations, PDFs, and infographics.

Best practices

Follow these best practices to get the best results:

- **Be specific in your requests.** Include details about the content, structure, formatting, and any specific requirements. For example, instead of "Create a report," try "Create a Word report with an executive summary, three data sections with tables, and a conclusion."
- **Provide source data when possible.** Upload CSV, Excel, or JSON files so that Quick can use real data instead of generating placeholder content.
- **Iterate on your documents.** Start with a first draft and then request specific edits in follow-up messages. This is often more effective than trying to specify everything in a single request.
- **Specify the document type.** Mention the file format you want (Word, Excel, PowerPoint, PDF) in your request to ensure Quick generates the correct document type.
- **Use templates for consistent styling.** When creating presentations, upload an existing .pptx template to maintain consistent visual styling across your organization.

Limitations

The following limitations apply to document and visual creation in Quick:

- When you provide source data, Quick uses it exactly as given and does not fabricate additional data points. When no source data is provided, Quick can generate illustrative values such as common assumptions or sample inputs for models and templates. For editable document types (Word, Excel, PowerPoint), these values are clearly presented as defaults that you can modify directly in the downloaded file. For infographics (PNG), you can request changes by describing the updates you want in chat.
- PDF documents cannot be edited in place. To modify a PDF, Quick extracts the content and recreates the document.
- Complex formatting or highly customized layouts may require multiple iterations to achieve the desired result.
- Saving generated documents to a Space is not currently supported.

Create, customize, and deploy AI-powered chat agents in Amazon Quick

Chat agents in Amazon Quick help users explore data, analyze information, and take actions. Users can interact with chat agents using the Quick chat interface. Chat agents provide assistance through open-ended conversations supported by specific goals, sources of knowledge, and any connected tools. Chat agents can evolve from simple question-answering interfaces to more advanced functions that orchestrate complex workflows.

You can use chat agents to:

- Generate content and provide answers through natural language conversations
- Analyze and summarize information from connected spaces, dashboards, topics, datasets, and uploaded files
- Invoke actions to perform predefined steps for consistent, repeatable outcomes

Note

To learn more about chatting using chat agents, see [Using Amazon Quick chat](#).

Topics

- [Chat agent types](#)
- [Amazon Quick user interaction with chat agents](#)
- [Amazon Quick user permissions for chat agents](#)
- [Custom permissions for chat agents](#)
- [System chat agent](#)
- [Custom chat agents](#)
- [Chat agent context sources and best practices](#)
- [Use a chat agent](#)

Chat agent types

Amazon Quick supports two types of chat agents:

- **System chat agent** – This chat agent ("My assistant") is automatically available to all users by default. The system chat agent serves as a base planner with no inherent data or actions of its own—it dynamically accesses resources available to each user during chat time, allowing it to be tailored to individual user permissions and available content. Admin users control system chat agent settings by assigning specific users as owners so they can customize its persona and other settings.

The system chat agent is enabled with all chat capabilities, including file upload functionality, LLM knowledge access, toxicity and other guardrails, web search. It also includes chat data scoping mechanisms that provide access to spaces, topics, dashboards, knowledge bases, and actions based on user permissions.

- **Custom chat agents** – These chat agents can be created and customized to specific use cases by users with chat agent creation capabilities in Amazon Quick, and shared with anyone. Admins can choose to restrict specific users and groups from creating custom chat agents, while still allowing users to use chat agents via chat. Chat agents return responses scoped to content that their invoking users have permissions to.

Custom chat agents can interact with Amazon Quick resources in the following ways:

- **Preconfigured with resources** – These chat agents use only the configured resources (for example, spaces as knowledge sources, connectors as tools) when looking for answers or orchestrating actions as their default behavior. While chatting, users can attach additional resources as per their need or invoke actions directly. For example, chat agents configured with only spaces containing files can't take actions by default unless users explicitly invoke them. Similarly, chat agents configured with only actions rely on LLM knowledge unless users attach a space or dashboard for enterprise-specific answers. However, users may attach additional spaces or directly invoke other actions they may have access to within the chat interface.
- **Not opinionated at build time** – These chat agents are not initially configured with resources when they are built (spaces, or connectors, or both). Chat determines the resource boundary for the chat agent. For example, if no space is configured for the chat agent, chat will default to all spaces or LLM knowledge until the user makes a change. If no connectors are configured for the chat agent, during chat, all actions a user has access to will be available to the agent until user makes a resource selection that doesn't include actions.

User resource selection during chat affects chat agent behavior. If a user selects a space, the chat agent will only answer with data within that space and take actions available within that space (if it is not opinionated at build time). If a user selects a dashboard, topic, or knowledge base, the chat agent will only answer from that source and not take any actions since the focus is changed to a specific data source. Users are expected to select all relevant resources within chat for comprehensive assistance.

 Note

The system chat agent is an unopinionated chat agent by design. If you want chat agents to access all actions irrespective of data focus, configure chat agents with connectors.

Amazon Quick user interaction with chat agents

The following table shows what you can do with chat agents in the admin console versus as a Amazon Quick user. For more information on which roles can access these features, refer to the [Amazon Quick pricing](#) document.

Access Level	Capabilities
Admin Console	- Assign owners for the system chat agent and custom chat chat agents using Manage assets - Control whether users can create chat agents using Custom permissions - Configure instance-wide blocked words and phrases for all chat agents
Amazon Quick user	- Create and maintain custom chat agents (with appropriate permissions) - Configure chat agent personality and response styles and provide reference documents to inform its behavior - Link chat agents with spaces (with dashboards, datasets, topics) as their knowledge source to look for answers - Attach connectors to use as tools

Access Level	Capabilities
	• Share chat agents with specific users and teams • Interact with chat agents through conversations • Analyze data with chat agent assistance • Receive permissions-aware responses from chat agents

Amazon Quick user permissions for chat agents

What you can do with a chat agent also depends on the permissions you're assigned for it. There are two permission types that users can be assigned:

- **Owner** – Owners can edit, share, and delete the chat agent.
- **Viewer** – Viewers can view and use the chat agent.

 Note

If you don't have access to a linked resource as either a viewer or owner, resources added to the chat agent by another owner appear as "Resource unavailable". You can delete these resources as an owner, but you cannot list or add them because resource-level sharing is required.

Quick admins must give users the permission to create chat agents. For information on which roles can create chat agents, refer to the [Amazon Quick pricing](#) documentation. For information on how to provide access to these features, see [Custom permissions](#) in the Quick Admin Guide.

The following table outlines how user permissions determine what you can do with a Amazon Quick chat agent:

Permissions type	Permissions
Owners	• Can access and configure agent behavior (agent persona settings, reference documents) and resources (space and connectors) • Can customize chat agent details like title, description, and suggested prompts to improve usability

Permissions type	Permissions
	• Can share chat agents with users and groups • Can delete the chat agent
Viewers	• Can't customize the chat agent's details • Can receive responses based on the permissions they have to resources

Custom permissions for chat agents

By default, Amazon Quick enables all new features available for the Amazon Quick account, so that users can access them immediately based on their subscription. You can use [custom permissions](#) to restrict specific features. As an admin, when you create a custom permissions profile, you can create two types of restrictions for chat agents:

- You can completely disable all chat agent functionality for users, including chatting with the default agent, chatting with custom agents, and creating new agents. This can be done by restricting the **Chat agent** capability.
- You can also specifically restrict the ability to create agents without impacting chat with agents. This can be done by creating a custom permission profile and restricting only the feature **Create chat agents**.

Note

If you want your users to be able to chat using the system agent but don't want them to create chat agents, restrict their chat agent creation abilities only.

Agent permissions in Amazon Quick can be configured in various combinations to meet your organization's needs. To help you understand how to configure permissions, the following section provides a use-case driven approach that groups common scenarios:

Use case scenario	What users can do
Agent with all capabilities	• Chat with all default and custom chat agents

Use case scenario	What users can do
(No restrictions on chat agents, spaces, knowledge bases, actions, or flows)	• Create and customize new chat agents • Connect chat agents to spaces, knowledge bases, and actions • Trigger flows from the chat window from existing conversation with a chat agent • Share chat agents with other users • Use all chat features and integrations
Chat-only access to agents (Agent capabilities enabled, but chat agent creation restricted)	• Chat with existing default and shared custom chat agents • Can't create new custom chat agents • Can't edit or update custom chat agents • Full access to chat interface and chat agent library
Limited access to other capabilities (Chat agents enabled, but specific capabilities restricted)	• Chat with system and custom agents but with reduced functionality • Can't attach knowledge bases, spaces, or actions to an agent's configuration, or select these resources during chat • If spaces restricted: Agents configured with spaces will fall back to LLM knowledge only. Users can't view or select spaces in the chat resource selector • If knowledge bases restricted: Users can't select knowledge bases to use in chat. Any knowledge bases present in spaces either attached to the agent or selected by user during chat won't be used to generate responses • If actions restricted: Users can't attach actions to agents or invoke actions from chat. Any actions preconfigured with agents won't be used to execute tasks • If flows restricted: Chat won't show flows anymore, so users can't invoke flows while chatting with an agent

Use case scenario	What users can do
No chat agent access (Agent capabilities completely restricted)	• Can't view or access any chat agents • Agent library and navigation are hidden • Can still access and create other Amazon Quick resources, such as creating spaces for file sharing with teams or flows for structured interactions (as long as those capabilities are not also restricted)

System chat agent

The Amazon Quick system chat agent is automatically created when you sign up for Quick. It serves as the primary interface for all users to interact with their data and perform various tasks within the Quick environment. It comes equipped with default guardrails.

Ownership of the system chat agent is managed by the Quick admin. Admins can disable chatting with chat agents including the system chat agent using [custom permissions](#). If enabled, users with non-admin roles (authors and readers) can view, list, invoke, and use the Quick chat chat agent. Its responses are filtered based on user permissions to assets.

The Quick system chat agent is set to use all chat features out of the box with minimal customization required. While these features are also available to custom chat agents, they must be configured during chat agent creation. The system chat agent includes:

- Default persona as the Quick assistant, with professional tone and response style
- File upload in chat capability enabled
- Large language model (LLM) knowledge chat enabled
- Uses default guardrails configured for chat in admin console
- Access to all spaces, topics, dashboards, knowledge bases, and actions based on user permissions
- Web search capabilities

To learn how to customize a system chat agent as an Admin owner, see [Managing chat agent customization](#). To learn how to control access to the system chat chat agent, see [Manage assets](#).

Custom chat agents

Custom chat agents enable Amazon Quick users to create tailored conversational interfaces for specific business needs. Unlike the system chat agent, which is available to all users with chat permissions by default, custom chat agents can be selectively shared and configured by authorized users.

Users with chat agent creation capabilities can customize the chat agent's personality, response style, and capabilities through a natural language interface, or through the agent builder configuration flow. These users can also configure these chat agents with specific knowledge sources (like spaces) and workflows (like actions) while maintaining control over sharing and access permissions for each of those resources separately. Or, chat agents can be left unlinked for general purpose use which allows end users to use the agent with all or some of their resources.

Quick admins must give users the permission to create chat agents. For information on which roles can create chat agents, refer to the [Amazon Quick pricing](#) documentation. For information on how to provide or restrict access to these features, see [Custom permissions](#) in the Quick Admin Guide.

Create and preview custom chat agents

You can create custom chat agents in Amazon Quick from the **Chat agents** menu on the Amazon Quick home page. You can preview and test your chat agent as you build it. When you create a custom chat agent, you are assigned as its owner by default. The following procedure outlines how to create a custom chat agent.

Using natural language

To create a custom chat agent using a natural language prompt

1. Log in to the Amazon Quick console.
2. From the left navigation menu, select **Chat agents**, and then select **Create chat agent**.
3. In **New chat agent**, do the following:
 - a. In the text input box, enter a natural language description for what kind of chat agent you want to create. This is the prompt Amazon Quick will use you create your chat agent. You can use the suggested sample instructions on the page to create your chat agent as well.
 - b. Then, select **Generate**. Selecting **Generate** takes the instruction or goal provided and expands it into chat agent instructions and configurations. It also scans the user's available resources (spaces and action connectors) and finds the most relevant matches based on the chat agent intent provided. The expanded builder UI is opened with these configurations for the user to review, customize, test, and launch.
4. On the **Configure chat agent** page, make sure your chat agent has the right settings and customize your chat agent further. Click on **Update preview** to ensure all changes are saved before you try out the chat agent in preview.
5. When you're ready, select **Launch chat agent** to publish your custom chat agent to the chat agent library and use it in chat.

Note

- Until you select **Launch chat agent**, your chat agent is not available in the chat agent library. If you exit the creation process without launching, the preview version will be deleted and the chat agent won't be saved.
- When you launch a chat agent, it remains private by default. The chat agent only becomes available in other users' libraries after you share it. Once shared, subsequent edits and launches will publish changes to the same chat agent for all users who have access.

Using builder view directly

To create a custom chat agent using builder mode

1. Log in to the Amazon Quick console.
2. From the left navigation menu, select **Chat agents**, and then select **Create chat agent**.
3. In **Agent Creator**, select **Skip**. This opens up the chat agent configuration page from which you can build and customize your chat agent.
4. Add a name for your custom chat agent. This is the name that your chat agent will be identified by.
5. (Optional) Add a description for your custom chat agent that helps users understand the purpose of the chat agent.
6. (Optional) Select an icon for your chat agent.
7. In **Configure chat agent**, customize the following sections:
 - a. In **AGENT PERSONA**, configure your chat agent's personality, identity, tone, and response style:
 - For **Agent identity** – Define the identity of your chat agent. For example, you can give it instructions on what its name and personality are. Amazon Quick will use defaults if left blank.
 - For **Persona instructions** – Add instructions on how your chat agent interacts with users during chat. For example, you can define what your chat agent's primary tasks are. Amazon Quick uses these to customize your chat agent's persona.
 - b. In **Communication style**, for **Pick a response style preset** – Choose a response style. You can choose between the following response style presets or add custom instructions:
 - **Executive** – Optimized for high-level business communication and strategic insights.
 - **Technical** – Optimized for detailed technical explanations and technical problem-solving.
 - **Creative** – Standard configuration for general-purpose interactions.

Each preset has the following settings:

- For **Tone** – Add a natural language prompt to define your agent's tone. Amazon Quick will use it to customize your chat agent's persona.
- For **Response format** – Add a natural language prompt to define your chat agent's response style. Amazon Quick will use it to customize your chat agent's response style. Define the format of your chat agent's responses, for example: "Use bullet points for lists longer than 3 items".
- For **Length** – Specify the length of your chat agent's responses. Define the length of your chat agent's responses, for example: "Keep answers under 100 words".

When you choose a preset to use, Amazon Quick auto-populates the **Tone**, **Response format**, and **Length** instructions for your chat agent's responses based on the style chosen. You can further customize the existing prompts using natural language, or create new ones.

- c. In **Reference documents**, upload files that remain active in your chat agent's memory to guide all interactions. For more information about how reference documents work with other context types, see [Types of agent context](#).
 - Select **Upload files** or drag and drop your documents to attach files that will guide your chat agent's responses.
 - You can attach documents of .pdf, .txt, .html, .md, .csv, .doc or .docx format. Upto 100,000 characters of text will be extracted and accepted from documents uploaded.

8. (Optional) In **Knowledge sources**, choose between the following options:

- Continue without linking knowledge sources
 - Your chat agent will generate responses from large language model (LLM) knowledge and all Amazon Quick resources the interacting user has access to. You can choose to select a specific knowledge source to focus on during chat. Choose this if you want to create a general purpose chat agent.
- To link specific existing spaces
 - Select **Link**.
 - From the **Link spaces** modal, select the spaces you want to link to your chat agent, and then select **Link**.

The system displays a success message to denote successful linking.

If you link a chat agent to a knowledge source, your chat agent will generate responses from large language model (LLM) knowledge and data from linked resources only. You can add up to 1 more knowledge source to this chat agent as temporary context during chat.

- To create and link a new space
 - Select **Create**.
 - From the **Create space** window that opens, select the assets you want to add to your space and then select **Create**.

If you link a chat agent to a knowledge source, your chat agent will generate responses from large language model (LLM) knowledge and data from linked resources only. You can add up to 1 more knowledge source to this chat agent as temporary context during chat.

 Note

For more information on creating and using spaces, see [Working with spaces in Amazon Quick](#).

The system displays a success message to denote successful space creation. Return to the chat agent creation window.

- In the chat agent creation window, from **Knowledge sources** select **Link**.
- From the **Link spaces** modal, select the space you just created, and then select **Link**.

The system displays a success message to denote successful linking.

9. (Optional) In **Actions**, for **Actions** – Choose between the following options:

- To link specific existing actions
 - Select **Link**.
 - From the **Link action connectors** modal, select the action connectors you want to link to your chat agent, and then select **Next**.
 - In **Actions** select the actions you want to add and then select **Link**.

The system displays a success message to denote successful linking.

- To create a connector and link new actions
 - Select **Create**.
 - From the **Actions** home page, select **New action**.
 - From the **New action** window, for **Sources** select the connector you want to add and then select **Next**.
 - In **Actions** review the actions available and then select **Next**.
 - In **Connection details**, enter the connection details needed and select **Add**.

 Note

For more information on creating and using connectors, see [Actions in Amazon Quick](#).

The system displays a success message to denote successful action addition. Return to the chat agent creation window.

- In the chat agent creation window, from **Actions** select **Link**.
- From the **Link action connectors** modal, select the action connector you just created, and then select **Link**.

The system displays a success message to denote successful linking.

10. In **Customization**, do the following:

- a. For **Welcome message** – Add a welcome message for your chat agent to display to your end user.
- b. For **Suggested prompts** – Add example prompts as conversation starters to inform your end users of the chat agents capabilities.

11. Select **Launch chat agent** to create your custom chat agent.

 Note

- Until you select **Launch chat agent**, your chat agent is not available in the chat agent library. If you exit the creation process without launching, the preview version will be deleted and the chat agent won't be saved.

- When you launch a chat agent, it remains private by default. The chat agent only becomes available in other users' libraries after you share it. Once shared, subsequent edits and launches will publish changes to the same chat agent for all users who have access.

Share custom chat agents

When you create a chat agent, you are assigned as its owner by default. You can choose to share a chat agent you own with other Amazon Quick users using the following permissions:

- *Owner* permissions – User can edit, share, use, and delete the chat agent.
- *Viewer* permissions – User can view and use the chat agent.

You can also define access permissions for a chat agent globally, granting all users access to a chat agent and then defining more granular access permissions for specific users and groups.

The following procedure shows you how to share and assign permissions to chat agents.

To share custom chat agents

1. Log in to the Amazon Quick console.
2. From the left navigation menu, select **Chat agents**
3. Then, from the **Actions** column for the chat agent you want to share, select the menu icon, and then select **Share**.
4. In the **Share chat agent** modal that opens, enter the user or group name you want to share the chat agent with. When the user or group name appears, select it. Repeat the action for all groups or users you want to share the chat agent with. The modal displays the users and groups you're adding.
5. Assign permissions and access information for each user or group you're sharing your chat agent with using the dropdown next to the user or group name. You can assign one of two roles:
 - **Owner** – User can edit, share, and delete the chat agent.
 - **Viewer** – User can view and use the chat agent.
6. Select **Share**.

Embed custom chat agents

You can embed a custom chat agent in an external website or application so that users can interact with it outside of the Amazon Quick console. To embed a chat agent, you must first allow the hosting domain in the Amazon Quick admin settings, and then generate the embed code from the chat agent's share options.

Embedding a chat agent involves two steps:

1. **Allow the hosting domain** – A Amazon Quick admin must add the domain (and optionally its subdomains) where the embedded chat agent will be hosted to the domain allow list.
2. **Generate the embed code** – The chat agent owner or an authorized user generates the embed code from the chat agent's share options.

Allow a domain for embedded chat agents

Before you can embed a chat agent on an external website, a Amazon Quick admin must add the hosting domain to the allow list. You must be a Amazon Quick admin to complete this procedure. This ensures that only approved domains can host embedded chat agents.

To allow a domain for embedding

1. Log in to the Amazon Quick console.
2. Choose the profile icon.
3. Choose **Manage account**.
4. In the navigation pane under **Security**, choose **Manage domains**.
5. In the **Domain** field, enter the domain name where you want to host the embedded chat agent (for example, `https://example.com`).
6. (Optional) Select **Include subdomains** to allow embedded chat agents on all subdomains of the specified domain.
7. Choose **Add**.

The domain now appears in the list of allowed domains. You can edit or delete existing domains by choosing the edit or delete icons next to each domain in the list.

Generate the embed code for a chat agent

After you allow the hosting domain, you can generate the embed code for a chat agent.

To generate the embed code for a chat agent

1. Log in to the Amazon Quick console.
2. From the navigation pane, choose **Chat agents**.
3. From the **Actions** column for the chat agent you want to embed, choose the menu icon, and then choose **Edit**.
4. In the chat agent editor, choose **Share**.
5. In the share options, choose **Share via embed**.
6. Copy the provided embed code and paste it into the HTML of your website or application where you want the chat agent to appear.

The embedded chat agent is now available on your website. Users who visit the page can interact with the chat agent directly.

Update custom chat agents

You can update custom chat agents in Amazon Quick from the **Agents** menu on the Amazon Quick home page. The following procedure outlines how to do so.

Note

You can preview how your chat agent customizations updates perform, as you are configuring the chat agent, in the preview chat interface. Make sure to select **Update preview** before testing a change. Once all changes are tested in preview, select **Launch** to publish the changes to the chat agent currently in use.

To update a custom chat agent

1. Log in to the Amazon Quick console.
2. From the left navigation menu, select **Chat agents**

3. Then, from the **Actions** column for the chat agent you want to share, select the menu icon, and then select **Edit**. This creates a preview version of your chat agent to update and test before publishing.
4. In the **Edit agent**, update your chat agent settings, and then select **Launch**.

Manage access to a custom chat agent

If you're the owner of a chat agent, you can choose to change the user access permissions for a chat agent. You can also remove user and group access to a chat chat agent. The following procedure shows how.

To manage access to custom chat agents

1. Log in to the Amazon Quick console.
2. From the left navigation menu, select **Chat agents**
3. Then, from the **Actions** column for the chat agent you want to share, select the menu icon, and then select **Share**.
4. In the **Share chat agent** modal that opens, select the user and group you want to change permissions for. When the user or group name appears, select it and change the permissions. Repeat the action for all groups or users you want to change permissions for. The modal displays the users and group permissions you're changing. You can take the following three actions:
 - Change to **Owner** – User can edit, share, and delete the chat agent.
 - Change to **Viewer** – User can view and use the chat agent.
 - **Remove access** – Remove user or group access to a chat agent.

Note

You can also define access permissions to a chat agent globally, granting all users access to a chat agent and then defining more granular access permissions for specific users and groups. To do so, choose **Settings** and then use **Global settings** to turn this feature on or off.

5. Select **Share**.

View chat agents

You can view a list of the chat agents you have created or have access to. The following procedure shows how.

To view custom chat agents

1. Log in to the Amazon Quick console.
2. From the left navigation menu, select **Chat agents**
3. The chat agents you have created or have access to will be displayed on the **Chat agents** home page.

View chat agent details

You can view the details of chat agents that are either created by you or shared with you, including all spaces and actions attached to each chat agent.

To view chat agent details

1. Log in to the Amazon Quick console.
2. From the left navigation menu, select **Chat agents**
3. Then, from the list of chat agents, from the **Name** column, click on the name of the chat agent you want to view details for. A detail modal will open.

Note

You can also view chat agent details by navigating to the **Actions** column for the chat agent you want to share, selecting the menu icon, and then selecting **View chat agent details**.

4. In the chat agent details modal that opens, you will see the following details:
 - a. **Description** – The description for the chat agent.
 - b. **Instruction summary** – A summary of the instructions defined for the chat agent.
 - c. **Created by** – Details on whether the chat agent was created by you or someone else.
 - d. **Last modified** – The time the chat agent was last modified.
 - e. Under **Capabilities**:

- **Knowledge** – The knowledge sources the chat agent is either attached to or has access to. If your chat agent is linked to a space, you'll be able to see which space it is linked to.
- **Actions** – The actions that the chat agent is attached or has access to. You can also view this by clicking on **info** next to the agent name in the chat UI agent selector.

Duplicate custom chat agents

You can duplicate existing custom chat agents without building a chat agent from scratch. Users can duplicate chat agents from the list page using the **Duplicate** action button. When you duplicate a chat agent, Amazon Quick creates a new chat agent with name format "[Original name] (copy)", which you can edit. All fields and configurations from the original chat agent are copied to the new version of the chat agent. Once duplicated, you can assign custom user access permissions to the duplicated chat agent and share it.

The following procedure outlines how to duplicate chat agents.

To duplicate custom chat agents

1. Log in to the Amazon Quick console.
2. From the left navigation menu, select **Chat agents**
3. Then, from the **Actions** column for the chat agent you want to share, select the menu icon, and then select **Duplicate**.

You will be redirected to a chat agent duplication modal with prepopulated fields.

4. Make any changes you need to, including adding the right user and group permissions, and linking it to the assets you want and then select **Launch** to launch your duplicated chat agent.

Delete chat agents

You can delete a Amazon Quick chat agent you own. The following procedure shows you how.

To delete a custom chat agent

1. Log in to the Amazon Quick console.
2. From the left navigation menu, select **Chat agents**

3. Then, from the **Actions** column for the chat agent you want to share, select the menu icon, and then select **Delete**.

Chat agent context sources and best practices

When creating custom chat agents in Amazon Quick, you have multiple options to influence chat agent behavior and frame chat agent workflows. The way you configure chat agent context and instructions significantly impacts how your chat agent performs and responds to user interactions. Understanding when to use instructions, reference documents, and spaces is crucial for creating effective chat agents that meet your specific business needs and deliver consistent, reliable results. The following sections outline how to best use chat agent context and knowledge for your use case.

Topics

- [Types of agent context](#)

Types of agent context

Amazon Quick provides three distinct methods for configuring chat agent behavior, each serving different purposes in chat agent development. Understanding how each method processes content and when to use them forms the foundation of effective chat agent configuration.

The three context types available in Amazon Quick are:

- **Persona instructions** – High-level guidance that Amazon Quick enhances using generative AI
- **Reference documents** – Documents that provide exact instructions and remain active in the chat agent's memory
- **Spaces** – Collections of searchable Amazon Quick resources and documents from which chat agents retrieve information to answer questions

The following section details what these are and the best practices of using them.

Topics

- [Chat agent persona instructions](#)
- [Chat agent reference documents](#)
- [Chat agents and spaces](#)

Chat agent persona instructions

You provide chat agent persona instructions in the **Persona instructions** field when you create your custom chat agent. These persona instructions are refined using generative AI to ensure that it works with all the chat features and the resources configured for the chat agent. This approach is ideal when you want the system to build upon your foundational direction. When you use persona instructions, Amazon Quick uses generative AI to interpret and expand your persona instructions in the backend, augment simple guidance with additional context and capabilities, optimize the prompt for better chat agent performance, and enhance effectiveness through AI-driven improvements.

Use persona instructions to:

- Provide high level guidance on behavior and goals, which are enhanced by Amazon Quick AI to customize agent responses
- Instruct how to leverage reference documents for detailed interactions
- Provide general guidance on use of spaces and connectors in its responses

This approach works best for general-purpose chat agents and exploratory use cases where you want to benefit from AI assistance in chat agent design.

Note

The AI enhancement process may modify your original wording and structure to improve chat agent performance. Critical guidelines that must remain unchanged should be placed in reference documents instead.

Chat agent reference documents

Reference documents provide specific process and response templates that the chat agents need to follow. These reference documents are part of the chat agent's permanent context and go hand-in-hand with persona instructions and response style to inform its overall behavior.

Reference documents provide complete control over chat agent behavior by preserving your content exactly as written. This approach is essential when precision and consistency are paramount. When you upload reference documents, Amazon Quick preserves precise wording and

specific instructions, maintains exact formatting and structure, provides direct control over chat agent behavior, and ensures consistency across all interactions.

Use reference documents when you need:

- Exact control where precise wording and specific instructions must be preserved
- Brand consistency with specific tone, terminology, or response formats
- Complex workflows with multi-step processes that must follow exact sequences
- Predictable behavior with consistent responses across all interactions

Supported file formats:

- .pdf, .txt, .html, .md – Instructions, templates, and guidelines
- .csv – Reference data, lookup tables, and examples
- .doc, .docx – Detailed process documentation

You can attach upto 10 files of total size 50 MB as reference documents. Amazon Quick extracts text from these documents and applies a 100K character limit after processing.

File prioritization and behavior

- Behavioral frameworks and reference data from files remain active even when users attach alternative content.
- Response templates may be temporarily adjusted if users provide conflicting formatting instructions.

Reference documents serve as the chat agent's operating manual, providing the behavioral framework that remains constant across all user interactions with the chat agent.

Chat agents and spaces

Spaces provide dynamic, searchable knowledge repositories that chat agents query during conversations to retrieve specific information. When you link spaces to chat agents, Amazon Quick chat agents look for answers within the space to generate responses. Spaces excel at managing organizational knowledge that evolves over time, allowing multiple team members to contribute

and update information while maintaining appropriate security boundaries through Amazon Quick's permission system.

Use spaces with chat agents for:

- Enabling chat agents to search and retrieve current business data
- Providing chat agents access to organizational knowledge repositories
- Allowing chat agents to respect existing permission boundaries
- Connecting chat agents to collaborative document collections
- Giving chat agents access to regularly updated information
- Enabling chat agents to query live dashboards and datasets

Spaces function as the chat agent's dynamic knowledge layer, enabling real-time access to organizational information while maintaining security boundaries and collaborative workflows.

Use a chat agent

You can use a Amazon Quick chat agent to ask questions and to accomplish your tasks. When you ask a question, the chat agent analyzes the latest approved data shared with you to generate a comprehensive response.

You can ask complex questions in plain language and get a detailed response. You can also use a Quick chat agent to perform tasks for you, such as draft an email message, create a ticket, or use flows.

To use custom chat agents

1. Log in to the Quick console.
2. From the left navigation menu, select **Chat agents**
3. Then, from the **Actions** column for the chat agent you want to share, select the menu icon, and then select **Chat**.

This will open a chat interface that you use to interact with your chat agent.

You can interact with a chat agent in the following ways:

- View and access example prompts to demonstrate possible questions and tasks

- Get contextual responses from organizational data sources
- Continue or start new conversations
- Analyze data, including summarization and comparative analysis
- Take actions like scheduling meetings and creating tickets
- View source citations to responses with clickable numbered references
- Upload files
- View conversation history

** Tip**

You can also use your chat agents while automating your routine tasks with Quick Flows. For more information, see [Chat agent](#).

To learn more about chatting using chat agents, see [Using Amazon Quick chat](#).

Organize, collaborate, and share resources with spaces in Amazon Quick

A space in Amazon Quick is a collection of data and Quick resources scoped for a particular team or domain. You can use spaces to aggregate and organize files, dashboards, topics, knowledge bases, and application actions into a unified and customizable knowledge center for your team. Spaces integrate seamlessly with Quick agents for contextual conversations and are designed to scale across personal, team, and cross-team use cases.

Spaces allow your team to get the most relevant results from conversational agents and other AI tools inside Quick by grounding the results with only data relevant for your task or domain. Multiple people on the team can contribute to the knowledge inside a space; this reduces data silos and streamline information discovery. Spaces also serve as a data layer for apps in Amazon Quick applications. For more information, see [Build web applications with apps in Amazon Quick](#).

Note

Quick resources added to a space respect user access permissions. If a user can't access a resource outside a space, they won't be able to access it inside a space. Files uploaded to a space are always available to everyone with access to the space.

You can use spaces to accomplish tasks like:

- Aggregating and sharing customer feedback, allowing any team member to ask questions and get summaries
- Onboarding new team members with team documents, manuals, and processes
- Analyzing hundreds of annual reports
- Summarizing and search for action items from audio meeting recordings

Amazon Quick user interactions with spaces

The following table shows how each user type in Amazon Quick interacts with spaces.

User type	Capabilities
Administrators	• Control whether users with space creation capabilities can create spaces
Author Pro and Reader Pro users	• Create and maintain spaces • Add topics, dashboards, datasets, knowledge bases, and application actions to spaces • Upload files directly into spaces • Attach an agent to a space • Interact with space data through chat • Share spaces

Amazon Quick user permission for spaces

What you can do with a space also depends on the permissions you're assigned for it. There are two permission types that users can be assigned:

- **Owner** – Owners can create, edit, share, and delete a space.
- **Viewer** – Viewers can view ask questions, and download files from spaces.

The following table outlines how user permissions determine what you can do with a Amazon Quick space:

Permissions type	Permissions
Owners	• Create a space

Permissions type	Permissions
	• Upload files to a space • Share spaces with others • Link and unlink Amazon Quick resources (topics, dashboards, datasets, knowledge bases, and application actions) to a space • Delete a space As an owner, you can designate another user co-owner of a space. If you do so, the user can undertake all post-creation management actions an owner can.
Viewers	• Download files uploaded into a space • Ask questions from data inside space • Use a specific space as context for an agent • Search for a space by name • Access a space using a direct URL • View a preset list sample questions to help get started on using the space

Understanding file upload status

When you upload files, you should see the following status messages:

Uploading

Files are being uploaded into your computer.

Processing

Files are being processed.

Text ready

The text content of the document is ready to be queried. However, the document's images and tables are still processing.

Ready

The text and media of the document has been processed.

Deleting

The document is being deleted.

Limitations of spaces

The following list outlines the limitations of spaces:

- A space can't contain other spaces.
- Users can't access Amazon Quick resources (topics, dashboards) in a space if they don't have access to the resource outside it. Sharing a space doesn't automatically give access to users to assets within it.
- If an Amazon Quick resource is linked to a space is deleted outside the space, users of the space won't get notified of the deletion. Deleted assets will only display a message indicating unavailability.
- Files uploaded to spaces will be rejected if your index data storage capacity is full. Reach out to your system administrator if this happens.
- Files uploaded to a space must be one of the following formats: .html, .xhtml, .txt, .pdf, .csv, .tsv, .xml, .json, .md, .rtf, .xslt, .eml, .vtt, .docx, .dotx, .docm, .dotm, .ppt, .pptx, .pptm, .ppsm, .ppsx, .xlsx, .xls, .xlsm, .xltx, .xltm, .c, .h, .cpp, .hpp, .cs, .java, .py, .go, .rb, .scala, .m, .sql, .clj, .mp3, .wav, .m4a, .flac, .ogg, .mp4, .mov, .m4v.
- File uploads are limited to 500 MB for PDF, Word, and PowerPoint files, and 50 MB for all other supported file types.
- Spaces support up to 10,000 files (compared to 20 files in regular chat conversations), as long as the total space storage is less than 10 GB.
- You can add at most 20 resources of a specific resource type (dashboard, topic, knowledge base, or action) to a space.

Creating a space

You can create spaces in Amazon Quick from the **Spaces** menu on the Quick home page. You can directly add files to your space or connect existing resources to it when you create it. If you upload a file that exceeds the file size limits, or is of an unsupported file type, Quick displays an error and asks you to try again. When you create a space, you are assigned as its owner by default. The following procedure outlines how to create a space.

To create a space

1. Log in to the Quick console.
2. From the left navigation menu, select **Spaces**, and then select **Create space**.
3. On the space creation page that opens, do the following:
 - a. (Optional) Enter a name for your space.
 - b. (Optional) Enter a description for your space.
 - c. Select **Add knowledge** to begin adding content to your space.

From the dropdown menu, you can select from available resource types including **Dashboards**, **Topics**, **Knowledge bases**, **Actions**, and **File uploads**.

Note

You can preview a resource before you choose to add it by clicking on its name.

After you finish adding resources, **Space knowledge** displays a list of all assets and files added to your space.

After your space is created, you can select the sparkle icon from the top left corner of the screen and start interacting with your space using any available agent.

Managing a space

You can perform the following actions for spaces.

Topics

- [Viewing a list of spaces](#)
- [Editing a space](#)
- [Adding knowledge to a space](#)
- [Viewing a list of content inside a space](#)
- [Using a space](#)
- [Sharing a space](#)
- [Deleting a space](#)
- [Removing knowledge from a space](#)
- [Adding data from external sources into your space](#)
- [Adding application actions to a space](#)

Viewing a list of spaces

You can view a list of spaces created by—or shared with—you.

To view a list of spaces

1. Log in to the Amazon Quick console.
2. From the left navigation menu, select **Spaces**.

You will see a list of spaces displayed. The list also displays the name, description, owner, and last modified date for each space. You can search for a space, and filter for recent spaces.

Editing a space

You can edit an Amazon Quick space. When you edit a space, you can perform the following actions:

- Edit space description and space name
- Add and delete any files and link or unlink any resources (dashboards, topics, knowledge bases, and application actions) that you've added.

To edit a space

1. Log in to the Amazon Quick console.

2. From the left navigation menu, select **Spaces**.
3. In **Spaces**, select the space you want to edit.
4. Inside the space, do any of the following:
 - a. To edit **Space name** or **Space description** , double click on the name or description field. Then, select the edit icon to update the description.
 - b. In the **All knowledge** section, select **Add knowledge** to add new content.
 - c. In **Amazon Quick resources** – Link and unlink resources as needed.

Adding knowledge to a space

You can add knowledge—files and Amazon Quick resources—to a space after it's been created.

To add knowledge to an existing space

1. Log in to the Amazon Quick console.
2. From the left navigation menu, select **Spaces**, and then select your space from the list of spaces displayed.
3. Select **Add knowledge** to begin adding content to your space.

From the dropdown menu, you can select from available resource types including **Dashboards**, **Topics**, **Knowledge bases**, **Actions**, and **File uploads**.

Note

You can preview a resource before you choose to add it by clicking on its name.

After you finish adding resources, **Space knowledge** displays a list of all resources and files added to your space.

Viewing a list of content inside a space

You can view a list of content inside a space.

To view a list of content within a space

1. Log in to the Amazon Quick console.

2. From the left navigation menu, select **Spaces**.
3. Select the name of the space whose content you want to view from the list of spaces.

On the space detail page, you will see the **Space knowledge** section displaying a list of files uploaded and resources linked to the space.

Using a space

After you finish creating your space and adding knowledge to it, you can start interacting with it through agents. You can interact with an agent while in a space in the following ways:

- Interact with a space using any agent

Note

When you switch between spaces or open up a space during an on-going chat Amazon Quick detects your space and focuses your agent to it.

- Interact with a specific knowledge source within a space using an agent

To use an agent to chat with a space

1. Log in to the Amazon Quick console.
2. Then, do one of the following:
 1. From the left navigation menu, select **Spaces**.
 2. In **Spaces**, select the space name.
 3. In the space that opens, start chatting with your data using the chat interface.
 1. Use the sparkle chat icon to open the chat interface.
 2. From the resource selector menu, select **All resources**, and then select **Choose a resource**.
 3. From the **Add a resource** menu, from **Spaces**, select the space you want to chat with. Then, start chatting.

Sharing a space

You can share a space with any other Amazon Quick user. When you share a space with a user, you must also choose the permission levels that user has to the space—whether owner or viewer.

To share a space

1. Log in to the Amazon Quick console.
2. From the left navigation menu, select **Spaces**, and select the name of the space you want to share. The space should open.
3. From the top right corner of your space menu, select **Share**
4. In the **Share space** modal that opens, add the users and groups you want. Choose the permissions type for each user and group you add.

Note

You can also share a space from the space home page. Locate the space you want to share, select the menu icon in the **Actions**, and then select **Share**. In the **Share space** modal that opens, add users and groups and set their permissions.

Deleting a space

You can delete a Amazon Quick space. Deleting a space deletes all files associated with the space. Deleting a space unlinks assets associated with the space without deleting the assets. You can only delete a space you own.

To delete a space

1. Log in to the Amazon Quick console.
2. From the left navigation menu, select **Spaces**, and select the name of the space you want to share. The space should open.
3. From the top right corner of your space menu, select **Delete**, and then select **Delete** from the modal that opens.

Note

You can also delete a space from the space home page. Locate the space you want to delete, select the menu icon in the **Actions**, and then select **Delete**. In the **Delete space** modal that opens, select **Delete**.

Removing knowledge from a space

You can remove knowledge (remove files and unlink assets) from a space. When you remove files, they are removed from the Amazon Quick index in which they are stored. When you remove an asset, it unlinks it from the space without deleting it from the Amazon Quick system.

To remove knowledge from an existing space

1. Log in to the Amazon Quick console.
2. From the left navigation menu, select **Spaces**, and then select your space from the list of spaces displayed.
3. In the **Space knowledge** section:
 - a. In **Files uploaded** – From the **Actions** menu select **Delete**.
 - b. In **Amazon Quick resources** – From the **Actions** menu select **Remove from this space**.

Adding data from external sources into your space

You can pull in data from Google Drive, OneDrive, Confluence, SharePoint, web pages, and Amazon S3 into your spaces to expand the context of your chat and research agents.

To add data from external sources

1. Create a space and give it a name.
2. Select the **Knowledge bases** section in the space knowledge list.
3. Select **Add knowledge bases**.
4. In **All knowledge bases** you will see application data integrations that were created for you by others in your organization. You can select one to pull into your space, or create a new one.

Note

To learn how to create a knowledge base, refer to [Working with integrations](#).

Adding application actions to a space

You can use application actions to read and write data to external SaaS applications and MCP servers from within a space. When you add actions to a space, only those actions will be considered when you select the space as your chat context.

Note

Only authors can create connectors.

To use actions in a space

1. Create a space and give it a name.
2. Select the **Actions** section in the space knowledge list.
3. Select **Add action**.
4. Select **All actions**, and choose an action that others have created in your organization.

Note

To learn how to create a connector, refer to [Working with integrations](#).

Visualize, analyze, and share data with analyses, dashboards, and reports in Amazon Quick Sight

Amazon Quick Sight is a comprehensive business intelligence service that enables you to transform raw data into meaningful insights through interactive visualizations, dashboards, and reports. Whether you're connecting to databases, preparing datasets, creating analyses, or sharing dashboards with stakeholders, Amazon Quick Sight provides the tools you need to make data-driven decisions.

Note

Amazon Quick Sight is available only for Amazon Quick accounts provisioned through the AWS Management Console. It is not available for Free or Plus accounts created at aws.com/quick.

This section covers the complete Amazon Quick Sight workflow, from initial data connection through final report sharing. You'll learn how to connect to various data sources, prepare and transform your data, create compelling visualizations, build interactive dashboards, and leverage generative BI capabilities to accelerate your analytics workflow. Each topic builds upon the previous one, providing a comprehensive guide to maximizing your use of Amazon Quick Sight's powerful features.

Topics

- [Key concepts](#)
- [Connecting to data in Amazon Quick Sight](#)
- [Refreshing data in Amazon Quick Sight](#)
- [Preparing data in Amazon Quick Sight](#)
- [Analyses and reports: Visualizing data in Amazon Quick Sight](#)
- [Sharing and subscribing to data in Amazon Quick Sight with dashboards and reports](#)
- [Exploring interactive dashboards in Amazon Quick Sight](#)
- [Gaining insights with machine learning \(ML\) in Amazon Quick Sight](#)
- [Generative BI with Quick Sight](#)
- [Troubleshooting Amazon Quick Sight](#)

- [Developing with Amazon Quick Sight](#)

Key concepts

The following terms are used throughout this section.

Data source

A connection to an external data repository such as a database, data warehouse, cloud service, or file. Data sources provide the raw data for your analyses.

Data preparation

The process of transforming data for use in an analysis. This includes filtering data, renaming fields, changing data types, adding calculated fields, and creating SQL queries to refine data.

Dataset

A prepared collection of data ready for use in analyses and dashboards. Datasets can be stored in SPICE for fast performance or queried directly from the source.

SPICE

SPICE (Super-fast, Parallel, In-memory Calculation Engine) is the in-memory engine that Quick Sight uses for high-performance analytics. SPICE speeds up analytical queries on imported data so you don't need to retrieve data from the source every time you change an analysis or update a visual.

Analysis

The workspace for creating data visualizations. Each analysis contains a collection of visualizations that you arrange and customize on one or more sheets.

Visual

A graphical representation of data such as a chart, graph, or table. All visuals begin in AutoGraph mode, which automatically selects the best visualization type for the fields you select.

Sheet

A page within an analysis that displays a set of visualizations and insights. You can add multiple sheets to an analysis and configure them to work independently or together.

Dashboard

The published version of an analysis. You share dashboards with other Quick users and control what they can do with the data.

Connecting to data in Amazon Quick Sight

People in many different roles use Amazon Quick Sight to help them do analysis and advanced calculations, design data dashboards, embed analytics, and make better-informed decisions. Before any of that can happen, someone who understands your data needs to add it to a [Quick Sight dataset](#). Quick Sight supports direct connections and uploads from a variety of [data sources](#).

Capabilities and use cases

Amazon Quick Standard edition capabilities

After your data is available in Quick Standard edition, you can do the following:

- Transform the dataset with field formatting, hierarchies, data type conversions, and calculations.
- Create one or more data analyses based on your newly created dataset.
- Share your analysis with other people so they can help design it.
- Add charts, graphs, more datasets, and multiple pages (called sheets) to your data analysis.
- Create visual appeal with customized formatting and themes.
- Make them interactive by using parameters, controls, filters, and custom actions.
- Combine data from multiple data sources, and then build new hierarchies for drilling down and calculations only available during analytics, like aggregations, window functions, and more.
- Publish your analysis as an interactive data dashboard.
- Share the dashboard so other people can use the dashboard, even if they don't use the analysis that it's based on.
- Add more data to create more analyses and dashboards.

Amazon Quick Enterprise edition capabilities

After your data is available in Quick Enterprise edition, you can do different things depending on your role. If you can build datasets, design analyses, and publish dashboards, you can do all of the things people using Standard edition can do.

In addition, these are some examples of additional tasks that you can do:

- Create analyses that use Quick Sight insights, including machine learning (ML) powered insights for forecasting, anomaly and outlier detection, and key driver identification.
- Design narrative insights with text, colors, images, and calculations.
- Add data from virtual private clouds (VPCs) and on-premises data sources, with data encryption at rest.
- Control access in datasets by adding row and column level security.
- Refresh imported datasets every hour.
- Share emailed reports.

Application development

If you develop applications or use the AWS SDKs and AWS Command Line Interface (AWS CLI), you can do the following and more:

- Add embedded analytics and embedded interactive dashboards to websites and applications.
- Use API operations to manage data sources and datasets.
- Refresh imported data more frequently by using the data ingestion API operations.
- Script, transfer, and make templates from analyses and dashboards by using API operations.
- Programmatically assign people to security roles based on settings managed by system administrators.

Administrative functions in Quick

If you perform administrative functions in Quick, you can do the following and more:

- Manage security with shared folders to organize your teams' work and help them collaborate using dashboards, analytics, and datasets.
- Add Quick Sight to your VPC to enable access to data in VPC and on-premises data sources.
- Protect sensitive data with finely grained access control to AWS data sources.
- Manually assign people to the Quick author security role so they can prepare datasets, design analytics, and publish data dashboards at a fixed cost per month.
- Manually assign people to the Quick reader security role so they can securely interact with published data dashboards on a pay-per-session basis.

Dashboard subscription

If you subscribe to dashboards, you can do the following:

- Use and subscribe to interactive dashboards designed by your team of experts.

- Enjoy a simplified uncluttered interface.
- View dashboard snapshots in email.
- Focus on making decisions with the data at your fingertips.

After you connect to or import data, you create a dataset to shape and prepare data to share and reuse. You can view your available datasets on the **Data** page, which you reach by choosing **Data** on the Amazon Quick Sight start page. You can view available data sources and create a new dataset on the **Create a Data Set** page, which you reach by choosing **Create** then **New dataset** on the **Data** page.

Topics

- [Supported data sources](#)
- [Connect to your data with integrations and datasets](#)
- [Connecting to data catalogs in Amazon Quick](#)
- [Data source quotas](#)
- [Supported data types and values](#)
- [Working with datasets](#)
- [Working with data sources in Amazon Quick Sight](#)

Supported data sources

Amazon Quick Sight supports a variety of data sources that you can use to provide data for analyses. The following data sources are supported.

Connecting to relational data

You can use any of the following relational data stores as data sources for Amazon Quick Sight:

- Amazon Athena
- Amazon Aurora
- AWS Glue Data Catalog can be accessed using AWS Glue data catalog compatible services, such as Athena or Redshift Spectrum
- Amazon OpenSearch Service
- Amazon Redshift
- Amazon Redshift Spectrum

- Amazon S3
- Amazon S3 Analytics
- Amazon S3 Tables
- Apache Impala
- Apache Spark 2.0 or later
- AWS IoT Analytics
- Databricks (E2 Platform only) on Spark 1.6 or later, up to version 3.0
- Exasol 7.1.2 or later
- Google BigQuery
- MariaDB 10.0 or later
- Microsoft SQL Server 2012 or later
- MySQL 5.7 or later

 Note

Effective October 2023, the MySQL community has deprecated support for MySQL version 5.7. This means that Amazon Quick Sight will no longer support new features, enhancements, bug fixes, or security patches for MySQL 5.7. Support for existing query workload will take place at a best effort basis. Quick Sight customers can still use MySQL 5.7 datasets with Quick Sight, but we encourage customers to upgrade their MySQL databases (DB) to major version 8.0 or higher. To see the statement provided by Amazon RDS, see [Amazon RDS Extended Support opt-in behavior is changing. Upgrade your Amazon RDS for MySQL 5.7 database instances before February 29, 2024 to avoid potential increase in charges.](#)

Amazon RDS has updated their security settings for Amazon RDS MySQL 8.3. Any connections from Quick Sight to Amazon RDS MySQL 8.3 are SSL-enabled by default. This is the only option available for MySQL 8.3. connections.

TLS 1.2 for MySQL connections requires MySQL version 5.7.28 or higher. For MySQL versions below 5.7.28, Quick Sight falls back to TLS 1.1. If your security requirements mandate TLS 1.2, ensure your MySQL or Aurora MySQL database is running version 5.7.28 or higher.

- Oracle 12c or later
- PostgreSQL 9.3.1 or later

Note

SCRAM based authentication to PostgreSQL from Amazon Quick Sight is supported for the following connectors: RDS hosted PostgreSQL, Aurora PostgreSQL, and Vanilla PostgreSQL. If the appropriate PostgreSQL engine version is used, and the correct configurations in PostgreSQL for SCRAM are set up, no additional configurations are needed in Quick Sight. If you are still experiencing issues establishing a SCRAM authentication to PostgreSQL from Quick Sight, please create a support ticket.

- Presto 0.167 or later
- Snowflake
- Starburst
- Trino
- Teradata 14.0 or later
- Timestream

Note

You can access additional data sources not listed here by linking or importing them through supported data sources.

Amazon Redshift clusters, Amazon Athena databases, and Amazon RDS instances must be in AWS. Other database instances must be in one of the following environments to be accessible from Amazon Quick Sight:

- Amazon EC2
- Local (on-premises) databases
- Data in a data center or some other internet-accessible environment

For more information, see [Infrastructure security in Amazon Quick](#).

Importing file data

You can use files in Amazon S3 or on your local (on-premises) network as data sources. Quick Sight supports files in the following formats:

- CSV and TSV – Comma-delimited and tab-delimited text files
- ELF and CLF – Extended and common log format files
- JSON – Flat or semistructured data files
- XLSX – Microsoft Excel files

Quick Sight supports UTF-8 file encoding, but not UTF-8 (with BOM).

Files in Amazon S3 that have been compressed with zip, or gzip (www.gzip.org), can be imported as-is. If you used another compression program for files in Amazon S3, or if the files are on your local network, remove compression before importing them.

JSON data

Amazon Quick Sight natively supports JSON flat files and JSON semistructured data files.

You can either upload a JSON file or connect to your Amazon S3 bucket that contains JSON data. Amazon Quick Sight automatically performs schema and type inference on JSON files and embedded JSON objects. Then it flattens the JSON, so you can analyze and visualize application-generated data.

Basic support for JSON flat-file data includes the following:

- Inferring the schema
- Determining data types
- Flattening the data
- Parsing JSON (JSON embedded objects) from flat files

Support for JSON file structures (.json) includes the following:

- JSON records with structures
- JSON records with root elements as arrays

You can also use the `parseJson` function to extract values from JSON objects in a text file. For example, if your CSV file has a JSON object embedded in one of the fields, you can extract a value from a specified key-value pair (KVP). For more information on how to do this, see [parseJson](#).

The following JSON features aren't supported:

- Reading JSON with a structure containing a list of records
- List attributes and list objects within a JSON record; these are skipped during import
- Customizing upload or configuration settings
- `parseJSON` functions for SQL and analyses
- Error messaging for invalid JSON
- Extracting a JSON object from a JSON structure
- Reading delimited JSON records

You can use the `parseJson` function to parse flat files during data preparation. This function extracts elements from valid JSON structures and lists.

The following JSON values are supported:

- JSON object
- String (double quoted)
- Number (integer and float)
- Boolean
- NULL

Software as a service (SaaS) data

Quick Sight can connect to a variety of Software as a Service (SaaS) data sources either by connecting directly or by using Open Authorization (OAuth).

SaaS sources that support direct connection include the following:

- Jira
- ServiceNow

SaaS sources that use OAuth require that you authorize the connection on the SaaS website. For this to work, Quick Sight must be able to access the SaaS data source over the network. These sources include the following:

- Adobe Analytics
- GitHub
- Salesforce

You can use reports or objects in the following editions of Salesforce as data sources for Amazon Quick Sight:

- Enterprise Edition
- Unlimited Edition
- Developer Edition

Local data sources

To connect to on premises data sources, you need to add your data sources and a Quick-specific network interface to Amazon Virtual Private Cloud (Amazon VPC). When configured properly, a VPC based on Amazon VPC resembles a traditional network that you operate in your own data center. It enables you to secure and isolate traffic between resources. You define and control the network elements to suit your requirements, while still getting the benefit of cloud networking and the scalable infrastructure of AWS.

For detailed information, see [Infrastructure security in Amazon Quick](#).

Connect to your data with integrations and datasets

You can connect Amazon Quick Sight to different types of data sources. This includes data residing in Software-as-a-Service (SaaS) applications, flat files stored in Amazon S3 buckets, data from third-party services like Salesforce, and query results from Athena. Use the following examples to learn more about the requirements for connecting to specific data sources.

Creating a dataset using Amazon Athena data

Use the following procedure to create a new dataset that connects to Amazon Athena data or to Athena Federated Query data.

To connect to Amazon Athena

1. Begin by creating a new dataset. Choose **Data** from the navigation pane at left.
2. Choose **Create**, then choose **New dataset**.
3. a. To use an existing Athena connection profile (common), choose the card for the existing data source that you want to use. Choose **Select**.

Cards are labeled with the Athena data source icon and the name provided by the person who created the connection.

- b. To create a new Athena connection profile (less common), use the following steps:
 1. Choose **New data source**, then choose the **Athena** data source card.
 2. Choose **Next**.
 3. For **Data source name**, enter a descriptive name.

4. For **Athena workgroup**, choose your workgroup.
 5. Choose **Validate connection** to test the connection.
 6. Choose **Create data source**.
 7. (Optional) Select an IAM role ARN for queries to run as.
4. On the **Choose your table** screen, do the following:
- a. For **Catalog**, choose one of the following:
 - If you are using Athena Federated Query, choose the catalog you want to use.
 - Otherwise, choose **AwsDataCatalog**.
 - b. Choose one of the following:
 - To write a SQL query, choose **Use custom SQL**.
 - To choose a database and table, choose your catalog that contains your databases from the dropdown under **Catalog**. Then, choose a database from the dropdown under **Database** and choose a table from the **Tables** list that appears for your database.
- If you don't have the right permissions, you receive the following error message: "You don't have sufficient permissions to connect to this dataset or run this query." Contact your Quick administrator for assistance. For more information, see [Authorizing connections to Amazon Athena](#).
5. Choose **Edit/preview data**.
 6. Create a dataset and analyze the data using the table by choosing **Visualize**. For more information, see [Analyses and reports: Visualizing data in Amazon Quick Sight](#).

Using Amazon OpenSearch Service with Amazon Quick Sight

Following, you can find how to connect to your Amazon OpenSearch Service data using Amazon Quick Sight.

Creating a new Quick Sight data source connection for OpenSearch Service

Following, you can find how to connect to OpenSearch Service

Before you can proceed, Amazon Quick Sight needs to be authorized to connect to Amazon OpenSearch Service. If connections aren't enabled, you get an error when you try to connect. A Quick Sight administrator can authorize connections to AWS resources.

To authorize Quick Sight to initiate a connection to OpenSearch Service

1. Open the menu by clicking on your profile icon at top right, then choose **Manage Quick**. If you don't see the **Manage Quick** option on your profile menu, ask your Amazon Quick administrator for assistance.
2. Choose **Security & permissions, Add or remove**.
3. Enable the option for **OpenSearch**.
4. Choose **Update**.

After OpenSearch Service is accessible, you create a data source so people can use the specified domains.

To connect to OpenSearch Service

1. Begin by creating a new dataset. Choose **Data** from the navigation pane at left, then choose **Create and New Dataset**.
2. Choose the **Amazon OpenSearch** data source card.
3. For **Data source name**, enter a descriptive name for your OpenSearch Service data source connection, for example OpenSearch Service ML Data. Because you can create many datasets from a connection to OpenSearch Service, it's best to keep the name simple.
4. For **Connection type**, choose the network you want to use. This can be a virtual private cloud (VPC) based on Amazon VPC or a public network. The list of VPCs contains the names of VPC connections, rather than VPC IDs. These names are defined by the Quick administrator.
5. For **Domain**, choose the OpenSearch Service domain that you want to connect to.
6. Choose **Validate connection** to check that you can successfully connect to OpenSearch Service.
7. Choose **Create data source** to proceed.
8. For **Tables**, choose the one you want to use, then choose **Select** to continue.
9. Do one of the following:
 - To import your data into the Quick Sight in-memory engine (called SPICE), choose **Import to SPICE for quicker analytics**. For information about how to enable importing OpenSearch data, see [Authorizing connections to Amazon OpenSearch Service](#).
 - To allow Quick Sight to run a query against your data each time you refresh the dataset or use the analysis or dashboard, choose **Directly query your data**.

To enable autorefresh on a published dashboard that uses OpenSearch Service data, the OpenSearch Service dataset needs to use a direct query.

10. Choose **Edit/Preview** and then **Save** to save your dataset and close it.

Managing permissions for OpenSearch Service data

The following procedure describes how to view, add, and revoke permissions to allow access to the same OpenSearch Service data source. The people that you add need to be active users in Quick Sight before you can add them.

To edit permissions on a data source

1. Choose **Data** at left, then scroll down to find the data source card for your Amazon OpenSearch Service connection. An example might be `US Amazon OpenSearch Service Data`.
2. Choose the **Amazon OpenSearch** dataset.
3. On the dataset details page that opens, choose the **Permissions** tab.

A list of current permissions appears.

4. To add permissions, choose **Add users & groups**, then follow these steps:
 - a. Add users or groups to allow them to use the same dataset.
 - b. When you're finished adding everyone that you want to add, choose the **Permissions** that you want to apply to them.
5. (Optional) To edit permissions, you can choose **Viewer** or **Owner**.
 - Choose **Viewer** to allow read access.
 - Choose **Owner** to allow that user to edit, share, or delete this Quick Sight dataset.
6. (Optional) To revoke permissions, choose **Revoke access**. After you revoke someone's access, they can't create new datasets from this data source. However, their existing datasets still have access to this data source.
7. When you are finished, choose **Close**.

Adding a new Quick Sight dataset for OpenSearch Service

After you have an existing data source connection for OpenSearch Service, you can create OpenSearch Service datasets to use for analysis.

To create a dataset using OpenSearch Service

1. From the start page, choose **Data, Create, New dataset**.
2. Scroll down to the data source card for your OpenSearch Service connection. If you have many data sources, you can use the search bar at the top of the page to find your data source with a partial match on the name.
3. Choose the **Amazon OpenSearch** data source card, and then choose **Create data set**.
4. For **Tables**, choose the OpenSearch Service index that you want to use.
5. Choose **Edit/Preview**.
6. Choose **Save** to save and close the dataset.

Adding OpenSearch Service data to an analysis

After you have an OpenSearch Service dataset available, you can add it to a Quick Sight analysis. Before you begin, make sure that you have an existing dataset that contains the OpenSearch Service data that you want to use.

To add OpenSearch Service data to an analysis

1. Choose **Analyses** at left.
2. Do one of the following:
 - To create a new analysis, choose **New analysis** at right.
 - To add to an existing analysis, open the analysis that you want to edit.
 - Choose the pencil icon near at top left.
 - Choose **Add data set**.
3. Choose the OpenSearch Service dataset that you want to add.

For information on using OpenSearch Service in visualizations, see [Limitations for using OpenSearch Service](#).

4. For more information, see [Working with analyses](#).

Limitations for using OpenSearch Service

The following limitations apply to using OpenSearch Service datasets:

- OpenSearch Service datasets support a subset of the visual types, sort options, and filter options.
- To enable autorefresh on a published dashboard that uses OpenSearch Service data, the OpenSearch Service dataset needs to use a direct query.
- Multiple subquery operations aren't supported. To avoid errors during visualization, don't add multiple fields to a field well, use one or two fields per visualization, and avoid using the **Color** field well.
- Custom SQL isn't supported.
- Crossdataset joins and self joins aren't supported.
- Calculated fields aren't supported.
- Text fields aren't supported.
- The "other" category isn't supported. If you use an OpenSearch Service dataset with a visualization that supports the "other" category, disable the "other" category by using the menu on the visual.

Creating a dataset using Amazon S3 files

To create a dataset using one or more text files (.csv, .tsv, .clf, or .elf) from Amazon S3, create a manifest for Quick Sight. Quick Sight uses this manifest to identify the files that you want to use and to the upload settings needed to import them. When you create a dataset using Amazon S3, the file data is automatically imported into [SPICE](#).

You must grant Quick Sight access to any Amazon S3 buckets that you want to read files from. For information about granting Quick Sight access to AWS resources, see [Configuring Amazon Quick Sight access to AWS data sources](#).

Topics

- [Supported formats for Amazon S3 manifest files](#)
- [Creating Amazon S3 datasets](#)
- [Datasets using S3 files in another AWS account](#)

Supported formats for Amazon S3 manifest files

You use JSON manifest files to specify files in Amazon S3 to import into Quick Sight. These JSON manifest files can use either the Quick Sight format described following or the Amazon Redshift format described in [Using a manifest to specify data files](#) in the *Amazon Redshift Database Developer Guide*. You don't have to use Amazon Redshift to use the Amazon Redshift manifest file format.

If you use an Quick Sight manifest file, it must have a .json extension, for example `my_manifest.json`. If you use an Amazon Redshift manifest file, it can have any extension.

If you use an Amazon Redshift manifest file, Quick Sight processes the optional mandatory option as Amazon Redshift does. If the associated file isn't found, Quick Sight ends the import process and returns an error.

Files that you select for import must be delimited text (for example, .csv or .tsv), log (.clf), or extended log (.elf) format, or JSON (.json). All files identified in one manifest file must use the same file format. Plus, they must have the same number and type of columns. Quick Sight supports UTF-8 file encoding, but not UTF-8 with byte-order mark (BOM). If you are importing JSON files, then for `globalUploadSettings` specify `format`, but not `delimiter`, `textqualifier`, or `containsHeader`.

Make sure that any files that you specify are in Amazon S3 buckets that you have granted Quick Sight access to. For information about granting Quick Sight access to AWS resources, see [Configuring Amazon Quick Sight access to AWS data sources](#).

Manifest file format for Quick Sight

Quick Sight manifest files use the following JSON format.

```
{
  "fileLocations": [
    {
      "URIs": [
        "uri1",
        "uri2",
        "uri3"
      ]
    },
    {
      "URIPrefixes": [
```

```
        "prefix1",
        "prefix2",
        "prefix3"
    ]
  },
  "globalUploadSettings": {
    "format": "JSON",
    "delimiter": ",",
    "textqualifier": "'",
    "containsHeader": "true"
  }
}
```

Use the fields in the `fileLocations` element to specify the files to import, and the fields in the `globalUploadSettings` element to specify import settings for those files, such as field delimiters.

The manifest file elements are described following:

- **fileLocations** – Use this element to specify the files to import. You can use either or both of the URIs and `URIPrefixes` arrays to do this. You must specify at least one value in one or the other of them.
- **URIs** – Use this array to list URIs for specific files to import.

Quick Sight can access Amazon S3 files that are in any AWS Region. However, you must use a URI format that identifies the AWS Region of the Amazon S3 bucket if it's different from that used by your Quick account.

URIs in the following formats are supported.

URI format	Example	Comments
<code>https://s3.amazonaws.com/<bucket name>/<file name></code>	<code>https://s3.amazonaws.com/amzn-s3-demo-bucket/data.csv</code>	
<code>s3://<bucket name>/<file name></code>	<code>s3://amzn-s3-demo-bucket/data.csv</code>	

URI format	Example	Comments
<code>https://<bucket name>.s3.amazonaws.com/<file name></code>	<code>https://<i>amzn-s3-demo-bucket</i>.s3.amazonaws.com/<i>data.csv</i></code>	
<code>https://s3-<region name>.amazonaws.com/<bucket name>/<file name></code>	<code>https://<i>s3-us-east-1.amazonaws.com</i> /<i>amzn-s3-demo-bucket</i> /<i>data.csv</i></code>	This URI type identifies the AWS Region for the Amazon S3 bucket.
<code>https://<bucket name>.s3-<region name>.amazonaws.com/<file name></code>	<code>https://<i>amzn-s3-demo-bucket</i>.s3-us-east-1.amazonaws.com/<i>data.csv</i></code>	This URI type identifies the AWS Region for the Amazon S3 bucket.

- **URIPrefixes** – Use this array to list URI prefixes for S3 buckets and folders. All files in a specified bucket or folder are imported. Quick Sight recursively retrieves files from child folders.

Quick Sight can access Amazon S3 buckets or folders that are in any AWS Region. Make sure to use a URI prefix format that identifies the S3 bucket's AWS Region if it's different from that used by your Quick account.

URI prefixes in the following formats are supported.

URI prefix format	Example	Comments
<code>https://s3.amazonaws.com/<bucket name>/</code>	<code>https://s3.amazonaws.com/amzn-s3-demo-bucket/</code>	
<code>https://s3.amazonaws.com/<bucket name>/<folder name1>/(<folder name2>/etc.)</code>	<code>https://s3.amazonaws.com/amzn-s3-demo-bucket/folder1/</code>	
<code>s3://<bucket name></code>	<code>s3://amzn-s3-demo-bucket/</code>	

URI prefix format	Example	Comments
<code>s3://<bucket name>/<folder name1>/(<folder name2>/etc.)</code>	<code>s3://amzn-s3-demo-bucket/folder1/</code>	
<code>https://<bucket name>.s3.amazonaws.com</code>	<code>https://amzn-s3-demo-bucket.s3.amazonaws.com</code>	
<code>https://s3-<region name>.amazonaws.com/<bucket name>/</code>	<code>https://s3-your-region-for-example-us-east-2.amazonaws.com/amzn-s3-demo-bucket /</code>	This URIPrefix type identifies the AWS Region for the Amazon S3 bucket.
<code>https://s3-<region name>.amazonaws.com/<bucket name>/<folder name1>/(<folder name2>/etc.)</code>	<code>https://s3-us-east-1.amazonaws.com/amzn-s3-demo-bucket /folder1/</code>	This URIPrefix type identifies the AWS Region for the Amazon S3 bucket.
<code>https://<bucket name>.s3-<region name>.amazonaws.com</code>	<code>https://amzn-s3-demo-bucket.s3-us-east-1.amazonaws.com</code>	This URIPrefix type identifies the AWS Region for the Amazon S3 bucket.

- **globalUploadSettings** – (Optional) Use this element to specify import settings for the Amazon S3 files, such as field delimiters. If this element is not specified, Quick Sight uses the default values for the fields in this section.

⚠ Important

For log (.clf) and extended log (.elf) files, only the **format** field in this section is applicable, so you can skip the other fields. If you choose to include them, their values are ignored.

- **format** – (Optional) Specify the format of the files to be imported. Valid formats are **CSV**, **TSV**, **CLF**, **ELF**, and **JSON**. The default value is **CSV**.
- **delimiter** – (Optional) Specify the file field delimiter. This must map to the file type specified in the **format** field. Valid formats are commas (,) for .csv files and tabs (\t) for .tsv files. The default value is comma (,).
- **textqualifier** – (Optional) Specify the file text qualifier. Valid formats are single quote ('), double quotes (\"). The leading backslash is a required escape character for a double quote in JSON. The default value is double quotes (\"). If your text doesn't need a text qualifier, don't include this property.
- **containsHeader** – (Optional) Specify whether the file has a header row. Valid formats are **true** or **false**. The default value is **true**.

Manifest file examples for Quick Sight

The following are some examples of completed Quick Sight manifest files.

The following example shows a manifest file that identifies two specific .csv files for import. These files use double quotes for text qualifiers. The **format**, **delimiter**, and **containsHeader** fields are skipped because the default values are acceptable.

```
{
  "fileLocations": [
    {
      "URIs": [
        "https://yourBucket.s3.amazonaws.com/data-file.csv",
        "https://yourBucket.s3.amazonaws.com/data-file-2.csv"
      ]
    }
  ],
  "globalUploadSettings": {
    "textqualifier": "\""
  }
}
```

```
}
}
```

The following example shows a manifest file that identifies one specific .tsv file for import. This file also includes a bucket in another AWS Region that contains additional .tsv files for import. The `textqualifier` and `containsHeader` fields are skipped because the default values are acceptable.

```
{
  "fileLocations": [
    {
      "URIs": [
        "https://s3.amazonaws.com/amzn-s3-demo-bucket/data.tsv"
      ]
    },
    {
      "URIPrefixes": [
        "https://s3-us-east-1.amazonaws.com/amzn-s3-demo-bucket/"
      ]
    }
  ],
  "globalUploadSettings": {
    "format": "TSV",
    "delimiter": "\t"
  }
}
```

The following example identifies two buckets that contain .clf files for import. One is in the same AWS Region as the Quick account, and one in a different AWS Region. The `delimiter`, `textqualifier`, and `containsHeader` fields are skipped because they are not applicable to log files.

```
{
  "fileLocations": [
    {
      "URIPrefixes": [
        "https://amzn-s3-demo-bucket1.your-s3-url.com",
        "s3://amzn-s3-demo-bucket2/"
      ]
    }
  ],
  "globalUploadSettings": {
```

```
    "format": "CLF"
  }
}
```

The following example uses the Amazon Redshift format to identify a .csv file for import.

```
{
  "entries": [
    {
      "url": "https://amzn-s3-demo-bucket.your-s3-url.com/myalias-test/file-to-import.csv",
      "mandatory": true
    }
  ]
}
```

The following example uses the Amazon Redshift format to identify two JSON files for import.

```
{
  "fileLocations": [
    {
      "URIs": [
        "https://yourBucket.s3.amazonaws.com/data-file.json",
        "https://yourBucket.s3.amazonaws.com/data-file-2.json"
      ]
    }
  ],
  "globalUploadSettings": {
    "format": "JSON"
  }
}
```

Creating Amazon S3 datasets

To create an Amazon S3 dataset

1. Check [Data source quotas](#) to make sure that your target file set doesn't exceed data source quotas.
2. Create a manifest file to identify the text files that you want to import, using one of the formats specified in [Supported formats for Amazon S3 manifest files](#).
3. Save the manifest file to a local directory, or upload it into Amazon S3.

4. On the Quick start page, choose **Data**.
5. On the **Data** page, choose **Create** then **New dataset**.
6. Choose the Amazon S3 icon and then choose **Next**.
7. For **Data source name**, enter a description of the data source. This name should be something that helps you distinguish this data source from others.
8. For **Upload a manifest file**, do one of the following:
 - To use a local manifest file, choose **Upload**, and then choose **Upload a JSON manifest file**. For **Open**, choose a file, and then choose **Open**.
 - To use a manifest file from Amazon S3, choose **URL**, and enter the URL for the manifest file. To find the URL of a pre-existing manifest file in the Amazon S3 console, navigate to the appropriate file and choose it. A properties panel displays, including the link URL. You can copy the URL and paste it into Quick Sight.
9. Choose **Connect**.
10. To make sure that the connection is complete, choose **Edit/Preview data**. Otherwise, choose **Visualize** to create an analysis using the data as-is.

If you choose **Edit/Preview data**, you can specify a dataset name as part of preparing the data. Otherwise, the dataset name matches the name of the manifest file.

To learn more about data preparation, see [Preparing data in Amazon Quick Sight](#).

Creating datasets based on multiple Amazon S3 files

You can use one of several methods to merge or combine files from Amazon S3 buckets inside Quick Sight:

- **Combine files by using a manifest** – In this case, the files must have the same number of fields (columns). The data types must match between fields in the same position in the file. For example, the first field must have the same data type in each file. The same goes for the second field, and the third field, and so on. Quick Sight takes field names from the first file.

The files must be listed explicitly in the manifest. However, they don't have to be inside the same Amazon S3 bucket.

In addition, the files must follow the rules described in [Supported formats for Amazon S3 manifest files](#).

For more details about combining files using a manifest, see [Creating a dataset using Amazon S3 files](#).

- **Merge files without using a manifest** – To merge multiple files into one without having to list them individually in the manifest, you can use Athena. With this method, you can simply query your text files, like they are in a table in a database. For more information, see the post [Analyzing data in Amazon S3 using Athena](#) in the Big Data blog.
- **Use a script to append files before importing** – You can use a script designed to combine your files before uploading.

Datasets using S3 files in another AWS account

Use this section to learn how to set up security so you can use Quick Sight to access Amazon S3 files in another AWS account.

For you to access files in another account, the owner of the other account must first set Amazon S3 to grant you permissions to read the file. Then, in Quick Sight, you must set up access to the buckets that were shared with you. After both of these steps are finished, you can use a manifest to create a dataset.

Note

To access files that are shared with the public, you don't need to set up any special security. However, you still need a manifest file.

Topics

- [Setting up Amazon S3 to allow access from a different Quick account](#)
- [Setting up Quick Sight to access Amazon S3 files in another AWS account](#)

Setting up Amazon S3 to allow access from a different Quick account

Use this section to learn how to set permissions in Amazon S3 files so they can be accessed by Quick Sight in another AWS account.

For information on accessing another account's Amazon S3 files from your Quick Sight account, see [Setting up Quick Sight to access Amazon S3 files in another AWS account](#). For more information

about S3 permissions, see [Managing access permissions to your Amazon S3 resources](#) and [How do I set permissions on an object?](#)

You can use the following procedure to set this access from the S3 console. Or you can grant permissions by using the AWS CLI or by writing a script. If you have a lot of files to share, you can instead create an S3 bucket policy on the `s3:GetObject` action. To use a bucket policy, add it to the bucket permissions, not to the file permissions. For information on bucket policies, see [Bucket policy examples](#) in the *Amazon S3 Developer Guide*.

To set access from a different Quick account from the S3 console

1. Get the email address of the AWS account email that you want to share with. Or you can get and use the canonical user ID. For more information on canonical user IDs, see [AWS account identifiers](#) in the *AWS General Reference*.
2. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
3. Find the Amazon S3 bucket that you want to share with Quick Sight. Choose **Permissions**.
4. Choose **Add Account**, and then enter an email address, or paste in a canonical user ID, for the AWS account that you want to share with. This email address should be the primary one for the AWS account.
5. Choose **Yes** for both **Read bucket permissions** and **List objects**.

Choose **Save** to confirm.

6. Find the file that you want to share, and open the file's permission settings.
7. Enter an email address or the canonical user ID for the AWS account that you want to share with. This email address should be the primary one for the AWS account.
8. Enable **Read object** permissions for each file that Quick Sight needs access to.
9. Notify the Quick user that the files are now available for use.

Setting up Quick Sight to access Amazon S3 files in another AWS account

Use this section to learn how to set up Quick Sight so you can access Amazon S3 files in another AWS account. For information on allowing someone else to access your Amazon S3 files from their Quick account, see [Setting up Amazon S3 to allow access from a different Quick account](#).

Use the following procedure to access another account's Amazon S3 files from Quick Sight. Before you can use this procedure, the users in the other AWS account must share the files in their Amazon S3 bucket with you.

To access another account's Amazon S3 files from Quick Sight

1. Verify that the user or users in the other AWS account gave your account read and write permission to the S3 bucket in question.
2. Choose your profile icon, and then choose **Manage Quick Sight**.
3. Choose **Security & permissions**.
4. Under **Quick Sight access to AWS services**, choose **Manage**.
5. Choose **Select S3 buckets**.
6. On the **Select Amazon S3 buckets** screen, choose the **S3 buckets you can access across AWS** tab.

The default tab is named **S3 buckets linked to Quick Sight account**. It shows all the buckets your Quick account has access to.

7. Do one of the following:
 - To add all the buckets that you have permission to use, choose **Choose accessible buckets from other AWS accounts**.
 - If you have one or more Amazon S3 buckets that you want to add, enter their names. Each must exactly match the unique name of the Amazon S3 bucket.

If you don't have the appropriate permissions, you see the error message "We can't connect to this S3 bucket. Make sure that any S3 buckets you specify are associated with the AWS account used to create this Quick account." This error message appears if you don't have either account permissions or Quick Sight permissions.

Note

To use Amazon Athena, Quick Sight needs to access the Amazon S3 buckets that Athena uses.

You can add them here one by one, or use the **Choose accessible buckets from other AWS accounts** option.

8. Choose **Select buckets** to confirm your selection.

9. Create a new dataset based on Amazon S3, and upload your manifest file. For more information Amazon S3 datasets, see [Creating a dataset using Amazon S3 files](#).

Creating a dataset using Amazon S3 Tables

You can use Amazon S3 Tables as a data source to create datasets in Quick Sight. Amazon S3 Tables stores data as Apache Iceberg tables, enabling you to query your data lake directly from Quick Sight without setting up an intermediate query layer.

You can use Amazon S3 Tables datasets in the following query modes:

- **Direct Query** – Query your Amazon S3 Tables data directly without importing it.
- **SPICE** – Import your Amazon S3 Tables data into SPICE for faster performance.

Configuring Amazon S3 Tables resource permissions (admin)

Before authors can create datasets from Amazon S3 Tables, an admin must configure resource permissions.

To configure Amazon S3 Tables resource permissions

1. Log in as an admin user.
2. Choose the people icon in the top right, and then choose **Manage QuickSuite** to open the admin page.
3. Choose the **AWS Resources** card to open the resource permissions page.
4. Choose **Use QuickSuite-managed role (default)** so that Quick manages the related IAM role and permissions for you.
5. Select **Amazon S3 Tables**. All available S3 table buckets in your current Region are displayed.
6. Select the S3 table buckets that you want to allow authors to use, and then choose **Finish**.
7. Choose **Save**.

After you save, a new IAM role named `aws-quicksight-s3-tables-role-v0` is created with permissions to read the selected S3 table buckets.

Creating a data source for an Amazon S3 table bucket

To create an Amazon S3 Tables data source

1. From the left navigation pane, choose **Data**, and then choose the **Data sources** tab.
2. Choose **Create data source**.
3. Choose the **Amazon S3 Tables** card.
4. Enter the ARN of the S3 table bucket and a name for the data source, and then choose **Create data source**.

After a few seconds, the data source appears in your data sources list.

Creating a dataset from an Amazon S3 Tables data source

To create a dataset using Amazon S3 Tables

1. From the left navigation pane, choose **Data**, and then choose the **Datasets** tab.
2. Choose **Create dataset**.
3. Select the Amazon S3 Tables data source that you want to use.
4. Select the namespace of the S3 table that you want to use, and then select the table.
5. Choose **Direct Query** or **SPICE** mode based on your use case.
6. Choose **Edit/Preview data** to transform your data in the same way you would for other data sources. After all transformations are defined, choose **Save and publish** to save the dataset.

Note

Amazon S3 Tables datasets support a maximum of 2 billion rows.

For information about supported AWS Regions, see [Supported AWS Regions](#).

Creating a data source using Apache Spark

You can connect directly to Apache Spark using Quick Sight, or you can connect to Spark through Spark SQL. Using the results of queries, or direct links to tables or views, you create data sources in Quick Sight. You can either directly query your data through Spark, or you can import the results of your query into [SPICE](#).

Before you use Quick Sight with Spark products, you must configure Spark for Quick Sight.

Quick Sight requires your Spark server to be secured and authenticated using LDAP, which is available to Spark version 2.0 or later. If Spark is configured to allow unauthenticated access, Quick Sight refuses the connection to the server. To use Quick Sight as a Spark client, you must configure LDAP authentication to work with Spark.

The Spark documentation contains information on how to set this up. To start, you need to configure it to enable front-end LDAP authentication over HTTPS. For general information on Spark, see [the Apache spark website](#). For information specifically on Spark and security, see [Spark security documentation](#).

To make sure that you have configured your server for Quick Sight access, follow the instructions in [Network and database configuration requirements](#).

Using Databricks in Quick Sight

Use this section to learn how to connect from Quick Sight to Databricks.

To connect to Databricks

1. Begin by creating a new dataset. Choose **Data** from the navigation pane at left.
2. Choose **Create** then **New Dataset**.
3. Choose the **Databricks** data source card.
4. For **Data source name**, enter a descriptive name for your Databricks data source connection, for example Databricks CS. Because you can create many datasets from a connection to Databricks, it's best to keep the name simple.
5. For **Connection type**, select the type of network you're using.
 - **Public network** – if your data is shared publicly.
 - **VPC** – if your data is inside a VPC.

Note

If you're using VPC, and you don't see it listed, check with your administrator.

6. For **Database server**, enter the **Hostname of workspace** specified in your Databricks connection details.

7. For **HTTP Path**, enter the **Partial URL for the spark instance** specified in your Databricks connection details.
8. For **Port**, enter the **port** specified in your Databricks connection details.
9. For **Username** and **Password**, enter your connection credentials.
10. To verify the connection is working, click **Validate connection**.
11. To finish and create the data source, click **Create data source**.

Adding a new Quick Sight dataset for Databricks

After you have an existing data source connection for Databricks data, you can create Databricks datasets to use for analysis.

To create a dataset using Databricks

1. Choose **Data** at left, then scroll down to find the data source card for your Databricks connection. If you have many data sources, you can use the search bar at the top of the page to find your data source with a partial match on the name.
2. Choose the **Databricks** data source card, and then choose **Create data set**.
3. To specify the table you want to connect to, first select the Catalog and Schema you want to use. Then, for **Tables**, select the table that you want to use. If you prefer to use your own SQL statement, select **Use custom SQL**.
4. Choose **Edit/Preview**.
5. (Optional) To add more data, use the following steps:
 - a. Choose **Add data** at top right.
 - b. To connect to different data, choose **Switch data source**, and choose a different dataset.
 - c. Follow the UI prompts to finish adding data.
 - d. After adding new data to the same dataset, choose **Configure this join** (the two red dots). Set up a join for each additional table.
 - e. If you want to add calculated fields, choose **Add calculated field**.
 - f. To add a model from SageMaker AI, choose **Augment with SageMaker**. This option is only available in Quick Enterprise edition.
 - g. Clear the check box for any fields that you want to omit.
 - h. Update any data types that you want to change.

6. When you are done, choose **Save** to save and close the dataset.

Quick Sight Administrator's guide to connecting Databricks

You can use Amazon Quick Sight to connect to Databricks on AWS. You can connect to Databricks on AWS whether you signed up for through AWS Marketplace or through the Databricks website.

Before you can connect to Databricks, you create or identify existing resources that the connection requires. Use this section to help you gather the resources you need to connect from Quick Sight to Databricks.

- To learn how to obtain your Databricks connection details, see [Databricks ODBC and JDBC connections](#).
- To learn how to obtain your Databricks credentials—personal access token or user name and password—for authentication, see [Authentication requirements](#) in the [Databricks documentation](#).

To connect to a Databricks cluster, you need `Can Attach To` and `Can Restart` permissions. These permissions are managed in Databricks. For more information, see [Permission Requirements](#) in the [Databricks documentation](#).

- If you are setting up a private connection for Databricks, you can learn more about how to configure a VPC for use with Quick Sight, see [Connecting to a VPC with Amazon Quick Sight](#) in the Quick Sight documentation. If the connection isn't visible, verify with a system administrator that the network has open [inbound endpoints for Amazon Route 53](#). The hostname of a Databricks workspace uses a public IP, there needs to be DNS TCP and DNS UDP inbound and outbound rules to allow traffic on DNS port 53, for the Route 53 security group. An administrator needs to create a security group with 2 inbound rules: one for DNS(TCP) on port 53 to the VPC CIDR and one for DNS(UDP) for port 53 to the VPC CIDR.

For Databricks-related details if you are using PrivateLink instead of a public connection, see [Enable AWS PrivateLink](#) in the [Databricks documentation](#).

Creating a dataset using Google BigQuery

Note

When Quick Sight uses and transfers information that is received from Google APIs, it adheres to the [Google API Services User Data Policy](#).

Google BigQuery is a fully managed serverless data warehouse that customers use to manage and analyze their data. Google BigQuery customers use SQL to query their data without any infrastructure management.

Creating a data source connection with Google BigQuery

Prerequisites

Before you start, make sure that you have the following. These are all required to create a data source connection with Google BigQuery:

- **Project ID** – The project ID that is associated with your Google account. To find this, navigate to the Google Cloud console and choose the name of the project that you want to connect to Quick Sight. Copy the project ID that appears in the new window and record it for later use.
- **Dataset Region** – The Google region that the Google BigQuery project exists in. To find the dataset region, navigate to the Google BigQuery console and choose **Explorer**. Locate and expand the project that you want to connect to, then choose the dataset that you want to use. The dataset region appears in the pop-up that opens.
- **Google account login credentials** – The login credentials for your Google account. If you don't have this information, contact your Google account administrator.
- **Google BigQuery Permissions** – To connect your Google account with Quick Sight, make sure that your Google account has the following permissions:
 - BigQuery Job User at the Project level.
 - BigQuery Data Viewer at the Dataset or Table level.
 - BigQuery Metadata Viewer at the Project level.

For information about how to retrieve the previous prerequisite information, see [Unlock the power of unified business intelligence with Google Cloud BigQuery and Quick Sight](#).

Use the following procedure to connect your Quick account with your Google BigQuery data source.

To create a new connection to a Google BigQuery data source from Quick Sight

1. Open the [Quick console](#).
2. From the left navigation pane, choose **Data**.
3. Choose **Create** then choose **New Dataset**
4. Choose the **Google BigQuery** tile.
5. Add the data source details that you recorded in the prerequisites section earlier:
 - **Data source name** – A name for the data source.
 - **Project ID** – A Google Platform project ID. This field is case sensitive.
 - **Dataset Region** – The Google cloud platform dataset region of the project that you want to connect to.
6. Choose **Sign in**.
7. In the new window that opens, enter the login credentials for the Google account that you want to connect to.
8. Choose **Continue** to grant Quick Sight access to Google BigQuery.
9. After you create the new data source connection, continue to [Step 4](#) in the following procedure.

Adding a new Quick Sight dataset for Google BigQuery

After you create a data source connection with Google BigQuery, you can create Google BigQuery datasets for analysis. Datasets that use Google BigQuery can only be stored in SPICE.

To create a dataset using Google BigQuery

1. Open the [Quick console](#).
2. From the start page, choose **Data**.
3. Choose **Create**, then **New Dataset**
4. Choose the **Google BigQuery** tile, and then choose **Create dataset**.
5. For **Tables**, do one of the following:

- Choose the table that you want to use.
 - Choose **Use custom SQL** to use your own personal SQL statement. For more information about using custom SQL in Quick Sight, see [Using SQL to customize data](#).
6. Choose **Edit/Preview**.
 7. (Optional) In the **Data prep** page that opens, you can add customizations to your data with calculated fields, filters, and joins.
 8. When you are finished making changes, choose **Save** to save and close the dataset.

Creating a dataset using a Google Sheets data source

Google Sheets is a web-based spreadsheet application that enables users to create, edit, and collaborate on data in real time. With its comprehensive set of functions and formulas, it serves as a powerful data source for business intelligence and analytics. Users can organize, analyze, and share insights efficiently, while its seamless collaboration features make it an ideal platform for teams working on data-driven projects.

Admin configuration in Amazon Quick

Amazon Quick administrators need to perform a one-time setup to enable Google Sheets as a data source. For detailed instructions and important considerations, see [the blog](#).

Creating a dataset using a Google Sheets data source

Use the following procedure to create a dataset using a Google Sheets data source.

To create a dataset using a Google Sheets data source

1. From the Quick start page, choose **Datasets**.
2. On the **Datasets** page, choose **New Dataset**.
3. Choose **Google Sheets**.
4. Enter a name for the data source, and then choose **Connect**.
5. When redirected to Google's sign-in page, do the following:
 - a. Enter your Google account credentials, and then choose **Next**.
 - b. Review the permissions to authorize your AWS account to connect with Google Sheets, and then choose **Continue**.

6. In the **Choose your table** menu, locate your data. The menu displays all folders, subfolders, sheets, and tabs from your Google account. To display the tabs, select a sheet from the displayed list.
7. Select the tab you want to work with.
8. Choose **Edit/Preview data** to navigate to the Data preparation page. Choose **Add data** to include any additional tabs.
9. Configure the join, and then select **Publish & visualize** to analyze your Google Sheets data with Quick Sight.

Note

- This connector supports only SPICE functionality.
- If your OAuth token expires (visible in the ingestion error report or when creating a new dataset), reauthorize by choosing **Edit** on the data source and updating it.

Creating a dataset using an Apache Impala data source

Apache Impala is a high-performance massively parallel processing (MPP) SQL query engine designed to run natively on Apache Hadoop. Use the procedure below to establish a secure connection between Quick Sight and Apache Impala.

All traffic between Quick Sight and Apache Impala is encrypted using SSL. Quick Sight supports standard username and password authentication for Impala connections.

To establish a connection, you'll need to configure SSL settings in your Impala instance, prepare your authentication credentials, set up the connection in Quick Sight using your Impala server details, and validate the connection to ensure secure data access.

To create a dataset using an Apache Impala data source

1. On the Quick start page, choose **Data**.
2. On the **Data** page, choose **Create**.
3. Choose **Data source**.
4. Choose **Impala**, then choose **Next**.
5. Enter a name for the data source.

6. For public connections:
 - a. Enter connection details for **Database server**, **HTTP Path**, **Port**, **Username**, and **Password**.
 - b. Once the validation is successful, choose **Create data source**.
7. For private connections:
 - Coordinate with your administrator to set up a VPC connection before entering connection details.

You or your administrator can [configure the VPC connection in Quick](#). SSL is enabled by default to ensure secure data transmission. If you encounter connection validation errors, please verify your connection and VPC details.

If issues persist, consult your administrator to confirm that your Certificate Authority is included in Quick Sight's [approved list of certificates](#).
8. In the **Choose your table** menu, you can either:
 - a. Choose a specific schema or table, then choose **Select**.
 - b. Choose **Use custom SQL** to write your own SQL query.
9. After completing your selection, you will be redirected to the data preparation page. Make any adjustments to your data, then choose **Publish & visualize** to analyze your Impala data in Quick Sight.

 Note

This connector supports:

- Username and password authentication
- Public and private connections
- Table discovery and custom SQL queries
- Full data refresh during ingestion
- SPICE storage only

Creating a dataset using a Microsoft Excel file

To create a dataset using a Microsoft Excel file data source, upload an .xlsx file from a local or networked drive. The data is imported into [SPICE](#).

For more information about creating new Amazon S3 datasets using Amazon S3 data sources, see [Creating a dataset using an existing Amazon S3 data source](#) or [Creating a dataset using Amazon S3 files](#).

To create a dataset based on an excel file

1. Check [Data source quotas](#) to make sure that your target file doesn't exceed data source quotas.
2. On the Quick start page, choose **Data**.
3. On the **Data** page, choose **Create** then **New dataset**.
4. Choose **Upload a file**.
5. In the **Open** dialog box, choose a file, and then choose **Open**.

A file must be 1 GB or less to be uploaded to Quick Sight.

6. If the Excel file contains multiple sheets, choose the sheet to import. You can change this later by preparing the data.

7.

Note

On the following screens, you have multiple chances to prepare the data. Each of these takes you to the **Prepare Data** screen. This screen is the same one where you can access after the data import is complete. It enables you to change the upload settings even after the upload is complete.

Choose **Select** to confirm your settings. Or you can choose **Edit/Preview data** to prepare the data immediately.

A preview of the data appears on the next screen. You can't make changes directly to the data preview.

8. If the data headings and content don't look correct, choose **Edit settings and prepare data** to correct the file upload settings.

Otherwise, choose **Next**.

9. On the **Data Source Details** screen, you can choose **Edit/Preview data**. You can specify a dataset name in the **Prepare Data** screen.

If you don't need to prepare the data, you can choose to create an analysis using the data as-is. Choose **Visualize**. Doing this names the dataset the same as the source file, and takes you to the **Analysis** screen. To learn more about data preparation and excel upload settings, see [Preparing data in Amazon Quick Sight](#).

Note

If at anytime you want to make changes to the file, such as adding a new field, you must make the change in Microsoft Excel and create a new dataset using the updated version in Quick Sight. For more information about possible implications of changing datasets, see [Things to consider when editing datasets](#).

Creating a data source using Presto

Presto (or PrestoDB) is an open-source, distributed SQL query engine, designed for fast analytic queries against data of any size. It supports both nonrelational and relational data sources. Supported nonrelational data sources include the Hadoop Distributed File System (HDFS), Amazon S3, Cassandra, MongoDB, and HBase. Supported relational data sources include MySQL, PostgreSQL, Amazon Redshift, Microsoft SQL Server, and Teradata.

For more information about Presto, see the following:

- [Introduction to presto](#), a description of Presto on the AWS website.
- [Creating a presto cluster with Amazon elastic MapReduce \(EMR\)](#) in the *Amazon EMR Release Guide*.
- For general information on Presto, see the [Presto documentation](#).

The results of the queries that you run through the Presto query engine can be turned into Quick Sight datasets. Presto processes the analytic queries on the backend databases. Then it returns results to the Quick Sight client. You can directly query your data through Presto, or you can import the results of your query into SPICE.

Before you use Quick Sight as a Presto client to run queries, make sure that you configure data source profiles. You need a data source profile in Quick Sight for each Presto data source that you want to access. Use the following procedure to create a connection to Presto.

To create a new connection to a presto data source from Amazon Quick Sight (console)

1. On the Amazon Quick Sight start page, choose **Data** at left.
2. Choose **Create** then **New dataset**.
3. Choose the **Presto** tile.

Note

In most browsers, you can use Ctrl-F or Cmd-F to open a search box and enter **presto** to locate it.

4. Add the settings for the new data source:
 - **Data source name** – Enter a descriptive name for your data source connection. This name appears in the **Existing data sources** section at the bottom of the **Data sets** screen.
 - **Connection type** – Choose the connection type that you need to use to connect to Presto.

To connect through the public network, choose **Public network**.

If you use a public network, your Presto server must be secured and authenticated using Lightweight Directory Access Protocol (LDAP). For information on configuring Presto to use LDAP, see [LDAP authentication](#) in the Presto documentation.

To connect through a virtual private connection, choose the appropriate VPC name from the **VPC connections** list.

If your Presto server allows unauthenticated access, AWS requires that you connect to it securely by using a private VPC connection. For information on configuring a new VPC, see [Configuring VPC connections in Amazon Quick Sight](#).

- **Database server** – The name of the database server.
- **Port** – The port that the server using to accept incoming connections from Amazon Quick Sight
- **Catalog** – The name of the catalog that you want to use.

- **Authentication required** – (Optional) This option only appears if you choose a VPC connection type. If the Presto data source that you're connecting to doesn't require authentication, choose **No**. Otherwise, keep the default setting (**Yes**).
- **Username** – Enter a user name to use to connect to Presto. Quick Sight applies the same user name and password to all connections that use this data source profile. If you want to monitor Quick Sight separately from other accounts, create a Presto account for each Quick Sight data source profile.

The Presto account that you use needs be able to access to the database and run SELECT statements on at least one table.

- **Password** – The password to use with the Presto user name. Amazon Quick Sight encrypts all credentials that you use in data source profile. For more information, see [Data encryption in Amazon Quick](#).
 - **Enable SSL** – SSL is enabled by default.
5. Choose **Validate connection** to test your settings.
 6. After you validate your settings, choose **Create data source** to complete the connection.

Using Snowflake with Amazon Quick Sight

Snowflake is an AI data cloud platform that provides data solutions from data warehousing and collaboration to data science and generative AI. Snowflake is an [AWS Partner](#) with multiple AWS accreditations that include AWS ISV Competencies in Generative AI, Machine Learning, Data and Analytics, and Retail.

Amazon Quick Sight offers multiple ways to connect to Snowflake: with your Snowflake login credentials, with OAuth client credentials, or with three-legged OAuth (3LO) using end-user identities. Use the following sections to learn about these methods of connection.

Topics

- [Creating an Quick Sight data source connection to Snowflake with login credentials](#)
- [Creating an Quick Sight data source connection to Snowflake with OAuth client credentials](#)
- [Creating an Quick Sight data source connection to Snowflake with three-legged OAuth \(3LO\)](#)

Creating an Quick Sight data source connection to Snowflake with login credentials

Use this section to learn how to create a connection between Quick Sight and Snowflake with your Snowflake login credentials. All traffic between Quick Sight and Snowflake is enabled by SSL.

To create a connection between Quick Sight and Snowflake

1. Open the [Quick console](#).
2. From the left navigation pane, choose **Data**, then choose **Create**, then choose **New Dataset**.
3. Choose the **Snowflake** data source card.
4. In the pop up that appears, enter the following information:
 - a. For **Data source name**, enter a descriptive name for your Snowflake data source connection. Because you can create many datasets from a connection to Snowflake, it's best to keep the name simple.
 - b. For **Connection type**, choose the type of network that you're using. Choose **Public network** if your data is shared publicly. Choose **VPC** if your data is located inside a VPC. To configure a VPC connection in Quick Sight, see [Managing VPC connection in Amazon Quick](#).
 - c. For **Database server** enter the hostname specified in your Snowflake connection details.
5. For **Database name and Warehouse**, enter the respective Snowflake database and warehouse that you want to connect.
6. For **Username** and **Password**, enter your Snowflake credentials.

After you have successfully created a data source connection between your Quick Sight and Snowflake accounts, you can begin [Creating datasets](#) that contain Snowflake data.

Creating an Quick Sight data source connection to Snowflake with OAuth client credentials

You can use OAuth client credentials to connect your Quick Sight account with Snowflake through the [Quick Sight APIs](#). *OAuth* is a standard authorization protocol that is often utilized for applications that have advanced security requirements. When you connect to Snowflake with OAuth client credentials, you can create datasets that contain Snowflake data with the Quick Sight APIs and in the Quick Sight UI. For more information about configuring OAuth in Snowflake, see [Snowflake OAuth overview](#).

Quick Sight supports the `client_credentials` OAuth grant type. OAuth client credentials is used to obtain an access token for machine-to-machine communication. This method is suitable

for scenarios where a client needs to access resources that are hosted on a server without the involvement of a user.

In the client credentials flow of OAuth 2.0, there are several client authentication mechanisms that can be used to authenticate the client application with the authorization server. Quick Sight supports client credentials based OAuth for Snowflake for the following two mechanisms:

- **Token (Client secrets-based OAuth):** The secret-based client authentication mechanism is used with the client credentials to grant flow in order to authenticate with authorization server. This authentication scheme requires the `client_id` and `client_secret` of the OAuth client app to be stored in Secrets Manager.
- **X509 (Client private key JWT-based OAuth):** The X509 certificate key-based solution provides an additional security layer to the OAuth mechanism with client certificates that are used to authenticate instead of client secrets. This method is primarily used by private clients who use this method to authenticate with the authorization server with strong trust between the two services.

Quick Sight has validated OAuth connections with the following Identity providers:

- OKTA
- PingFederate

Storing OAuth credentials in Secrets Manager

OAuth client credentials are meant for machine-to-machine use cases and are not designed to be interactive. To create a datasource connection between Quick Sight and Snowflake, create a new secret in Secrets Manager that contains your credentials for the OAuth client app. The secret ARN that is created with the new secret can be used to create datasets that contain Snowflake data in Quick Sight. For more information about using Secrets Manager keys in Quick Sight, see [Using AWS Secrets Manager secrets instead of database credentials in Quick](#).

The credentials that you need to store in Secrets Manager are determined by the OAuth mechanism that you use. The following key/value pairs are required for X509-based OAuth secrets:

- `username`: The Snowflake account username to be used when connecting to Snowflake
- `client_id`: The OAuth client ID
- `client_private_key`: The OAuth client private key

- `client_public_key`: The OAuth client certificate public key and its encrypted algorithm (for example, `{"alg": "RS256", "kid", "cert_kid"}`)

The following key/value pairs are required for token-based OAuth secrets:

- `username`: The Snowflake account username to be used when connecting to Snowflake
- `client_id`: The OAuth client ID
- `client_secret`: the OAuth client secret

Storing token-based OAuth credentials is optional

For token-based OAuth, storing these credentials in Secrets Manager is optional. Instead of creating a secret and passing its ARN, you can pass the `username`, `client_id`, and `client_secret` as inline credentials in the `CreateDataSource` request.

Creating a Snowflake OAuth connection with the Quick Sight APIs

After you create a secret in Secrets Manager that contains your Snowflake OAuth credentials and have connected your Quick account to Secrets Manager, you can establish a data source connection between Quick Sight and Snowflake with the Quick Sight APIs and SDK. The following example creates a Snowflake data source connection using token OAuth client credentials.

```
{
  "AwsAccountId": "AWSACCOUNTID",
  "DataSourceId": "UNIQUEDATASOURCEID",
  "Name": "NAME",
  "Type": "SNOWFLAKE",
  "DataSourceParameters": {
    "SnowflakeParameters": {
      "Host": "HOSTNAME",
      "Database": "DATABASENAME",
      "Warehouse": "WAREHOUSENAME",
      "AuthenticationType": "TOKEN",
      "DatabaseAccessControlRole": "snowflake-db-access-role-name",
      "OAuthParameters": {
        "TokenProviderUrl": "oauth-access-token-endpoint",
        "OAuthScope": "oauth-scope",
```

```

        "IdentityProviderResourceUri" : "resource-uri",
        "IdentityProviderVpcConnectionProperties" : {
            "VpcConnectionArn": "IdP-VPC-connection-ARN"
        }
    },
    "VpcConnectionProperties": {
        "VpcConnectionArn": "VPC-connection-ARN-for-Snowflake"
    }
    "Credentials": {
        "SecretArn": "oauth-client-secret-ARN"
    }
}

```

For more information about the CreateDataSource API operation, see [CreateDataSource](#).

Once the connection between Quick Sight and Snowflake is established and a data source is created with the Quick Sight APIs or SDK, the new data source is displayed in Quick Sight. Quick Sight authors can use this data source to create datasets that contain Snowflake data. Tables are displayed based on the role used in the DatabaseAccessControlRole parameter that is passed in a CreateDataSource API call. If this parameter is not defined when the data source connection is created, the default Snowflake role is used.

After you have successfully created a data source connection between your Quick Sight and Snowflake accounts, you can begin [Creating datasets](#) that contain Snowflake data.

Creating an Quick Sight data source connection to Snowflake with three-legged OAuth (3LO)

Quick Sight supports three-legged OAuth (3LO) with end-user identities for Snowflake.

Administrator setup: Client application configuration

The Quick Sight account administrator must configure a client application before authors can create 3LO data sources. Complete the following steps:

1. In the Quick Sight console, choose **Manage Account**. Under **Security**, choose **Manage OAuth Client Applications**.
2. Choose **Add OAuth client application** and provide the following information:
 - a. Config ID
 - b. OAuth client application name

- c. Authentication type
 - d. Client ID
 - e. Client secret
 - f. Token endpoint URL
 - g. Authorization endpoint URL
 - h. OAuth scopes
 - i. VPC connection ARN (optional)
 - j. Data source type (select **SNOWFLAKE**)
3. Choose **Add** to save the client application.

Author setup: Creating a 3LO data source

After the administrator configures the client application, authors can create a Snowflake data source with 3LO authentication.

1. Open the [Quick console](#).
2. Choose **Datasets**, then choose **New dataset** to open the **Create Data Source** page.
3. Choose **Snowflake**.
4. Choose **3LO** as the authentication method.
5. Enter the required connection information.
6. Choose **Create data source**.

Using Starburst with Amazon Quick Sight

Starburst is a full-featured data lake analytics service built on top of a massively parallel processing (MPP) query engine, Trino. Use this section to learn how to connect from Amazon Quick Sight to Starburst. All traffic between Quick Sight and Starburst is enabled by SSL. If you're connecting to Starburst Galaxy, you can get the necessary connection details by logging in to your Starburst Galaxy account, then choose **Partner Connect** and then **Quick Sight**. You should be able to see information, such as hostname and port. Amazon Quick Sight supports basic username and password authentication to Starburst.

Quick Sight offers two ways to connect to Starburst: with your Starburst login credentials or with OAuth client credentials. Use the following sections to learn about both methods of connection.

Topics

- [Creating an Quick Sight data source connection to Starburst with login credentials](#)
- [Creating an Quick Sight data source connection to Starburst with OAuth client credentials](#)

Creating an Quick Sight data source connection to Starburst with login credentials

1. Begin by creating a new dataset. From the left navigation pane, choose **Data**, then choose **Create**, then choose **New Dataset**.
2. Choose the **Starburst** data source card.
3. Select the Starburst product type. Choose **Starburst Enterprise** for on-prem Starburst instances. Choose **Starburst Galaxy** for managed instances.
4. For **Data source name**, enter a descriptive name for your Starburst data source connection. Because you can create many datasets from a connection to Starburst, it's best to keep the name simple.
5. For **Connection type**, select the type of network you're using. Choose **Public network** if your data is shared publicly. Choose **VPC** if your data is inside a VPC. To configure a VPC connection in Amazon Quick Sight, see [Configuring the VPC connection in Amazon Quick Sight](#). This connection type is not available for Starburst Galaxy.
6. For **Database server** enter the hostname specified in your Starburst connection details.
7. For **Catalog**, enter the catalog specified in your Starburst connection details.
8. For **Port**, enter the port specified in your Starburst connection details. Defaults to 443 for Starburst Galaxy.
9. For **Username** and **Password**, enter your Starburst connection credentials.
10. To verify the connection is working, choose **Validate connection**.
11. To finish and create the data source, choose **Create data source**.

Note

Connectivity between Amazon Quick Sight and Starburst was validated using Starburst version 420.

After you have successfully created a data source connection between your Quick Sight and Starburst accounts, you can begin [Creating datasets](#) that contain Starburst data.

Creating an Quick Sight data source connection to Starburst with OAuth client credentials

You can use OAuth client credentials to connect your Quick Sight account with Starburst through the [Quick Sight APIs](#). *OAuth* is a standard authorization protocol that is often utilized for applications that have advanced security requirements. When you connect to Starburst with OAuth client credentials, you can create datasets that contain Starburst data with the Quick Sight APIs and in the Quick Sight UI. For more information about configuring OAuth in Starburst, see [OAuth 2.0 authentication](#).

Quick Sight supports the `client_credentials` OAuth grant type. OAuth client credentials is used to obtain an access token for machine-to-machine communication. This method is suitable for scenarios where a client needs to access resources that are hosted on a server without the involvement of a user.

In the client credentials flow of OAuth 2.0, there are several client authentication mechanisms that can be used to authenticate the client application with the authorization server. Quick Sight supports client credentials based OAuth for Starburst for the following two mechanisms:

- **Token (Client secrets-based OAuth):** The secret-based client authentication mechanism is used with the client credentials to grant flow in order to authenticate with authorization server. This authentication scheme requires the `client_id` and `client_secret` of the OAuth client app to be stored in Secrets Manager.
- **X509 (Client private key JWT-based OAuth):** The X509 certificate key-based solution provides an additional security layer to the OAuth mechanism with client certificates that are used to authenticate instead of client secrets. This method is primarily used by private clients who use this method to authenticate with the authorization server with strong trust between the two services.

Quick Sight has validated OAuth connections with the following Identity providers:

- OKTA
- PingFederate

Storing OAuth credentials in Secrets Manager

OAuth client credentials are meant for machine-to-machine use cases and are not designed to be interactive. To create a datasource connection between Quick Sight and Starburst, create a new secret in Secrets Manager that contains your credentials for the OAuth client app. The secret ARN

that is created with the new secret can be used to create datasets that contain Starburst data in Quick Sight. For more information about using Secrets Manager keys in Quick Sight, see [Using AWS Secrets Manager secrets instead of database credentials in Quick](#).

The credentials that you need to store in Secrets Manager are determined by the OAuth mechanism that you use. The following key/value pairs are required for X509-based OAuth secrets:

- `username`: The Starburst account username to be used when connecting to Starburst
- `client_id`: The OAuth client ID
- `client_private_key`: The OAuth client private key
- `client_public_key`: The OAuth client certificate public key and its encrypted algorithm (for example, `{"alg": "RS256", "kid", "cert_kid"}`)

The following key/value pairs are required for token-based OAuth secrets:

- `username`: The Starburst account username to be used when connecting to Starburst
- `client_id`: The OAuth client ID
- `client_secret`: the OAuth client secret

Creating a Starburst OAuth connection with the Quick Sight APIs

After you create a secret in Secrets Manager that contains your Starburst OAuth credentials and have connected your Quick account to Secrets Manager, you can establish a data source connection between Quick Sight and Starburst with the Quick Sight APIs and SDK. The following example creates a Starburst data source connection using token OAuth client credentials.

```
{
  "AwsAccountId": "AWSACCOUNTID",
  "DataSourceId": "DATASOURCEID",
  "Name": "NAME",
  "Type": "STARBURST",
  "DataSourceParameters": {
    "StarburstParameters": {
      "Host": "STARBURST_HOST_NAME",
      "Port": "STARBURST_PORT",
      "Catalog": "STARBURST_CATALOG",
      "ProductType": "STARBURST_PRODUCT_TYPE",
      "AuthenticationType": "TOKEN",
      "DatabaseAccessControlRole": "starburst-db-access-role-name",
```

```

    "OAuthParameters": {
      "TokenProviderUrl": "oauth-access-token-endpoint",
      "OAuthScope": "oauth-scope",
      "IdentityProviderResourceUri" : "resource-uri",
      "IdentityProviderVpcConnectionProperties" : {
        "VpcConnectionArn": "IdP-VPC-connection-ARN"
      }
    },
    "VpcConnectionProperties": {
      "VpcConnectionArn": "VPC-connection-ARN-for-Starburst"
    },
    "Credentials": {
      "SecretArn": "oauth-client-secret-ARN"
    }
  }
}

```

For more information about the CreateDataSource API operation, see [CreateDataSource](#).

Once the connection between Quick Sight and Starburst is established and a data source is created with the Quick Sight APIs or SDK, the new data source is displayed in Quick Sight. Quick Sight authors can use this data source to create datasets that contain Starburst data. Tables are displayed based on the role used in the DatabaseAccessControlRole parameter that is passed in a CreateDataSource API call. If this parameter is not defined when the data source connection is created, the default Starburst role is used.

After you have successfully created a data source connection between your Quick Sight and Starburst accounts, you can begin [Creating datasets](#) that contain Starburst data.

Creating a data source and data set from SaaS sources

To analyze and report on data from software as a service (SaaS) applications, you can use SaaS connectors to access your data directly from Quick Sight. The SaaS connectors simplify accessing third-party application sources using OAuth, without any need to export the data to an intermediate data store.

You can use either a cloud-based or server-based instance of a SaaS application. To connect to an SaaS application that is running on your corporate network, make sure that Quick Sight can access the application's Domain Name System (DNS) name over the network. If Quick Sight can't access the SaaS application, it generates an unknown host error.

Here are examples of some ways that you can use SaaS data:

- Engineering teams who use Jira to track issues and bugs can report on developer efficiency and bug burndown.
- Marketing organizations can integrate Quick Sight with Adobe Analytics to build consolidated dashboards to visualize their online and web marketing data.

Use the following procedure to create a data source and dataset by connecting to sources available through Software as a Service (SaaS). In this procedure, we use a connection to GitHub as an example. Other SaaS data sources follow the same process, although the screens—especially the SaaS screens—might look different.

To create a data source and dataset by connecting to sources through SaaS

1. On the Quick start page, choose **Data**.
2. On the **Data** page, choose **Create** then choose **New dataset**.
3. Choose the icon that represents the SaaS source that you want to use. For example, you might choose Adobe Analytics or GitHub.

For sources using OAuth, the connector takes you to the SaaS site to authorize the connection before you can create the data source.

4. Choose a name for the data source, and enter that. If there are more screen prompts, enter the appropriate information. Then choose **Create data source**.
5. If you are prompted to do so, enter your credentials on the SaaS login page.
6. When prompted, authorize the connection between your SaaS data source and Quick Sight.

The following example shows the authorization for Quick Sight to access the GitHub account for the Quick Sight documentation.

Note

Quick Sight documentation is now available on GitHub. If you want to make changes to this user guide, you can use GitHub to edit it directly.

(Optional) If your SaaS account is part of an organizational account, you might be asked to request organization access as part of authorizing Quick Sight. If you want to do this, follow the prompts on your SaaS screen, then choose to authorize Quick Sight.

7. After authorization is complete, choose a table or object to connect to. Then choose **Select**.
8. On the **Finish data set creation** screen, choose one of these options:
 - To save the data source and dataset, choose **Edit/Preview data**. Then choose **Save** from the top menu bar.
 - To create a dataset and an analysis using the data as-is, choose **Visualize**. This option automatically saves the data source and the dataset.

You can also choose **Edit/Preview data** to prepare the data before creating an analysis. This opens the data preparation screen. For more information about data preparation, see [Preparing dataset examples](#).

The following constraints apply:

- The SaaS source must support REST API operations for Quick Sight to connect to it.
- If you are connecting to Jira, the URL must be public address.
- If you don't have enough [SPICE](#) capacity, choose **Edit/Preview data**. In the data preparation screen, you can remove fields from the dataset to decrease its size or apply a filter that reduces the number of rows returned. For more information about data preparation, see [Preparing dataset examples](#).

Creating a dataset from Salesforce

Use the following procedure to create a dataset by connecting to Salesforce and selecting a report or object to provide data.

To create a dataset using Salesforce from a report or object

1. Check [Data source quotas](#) to make sure that your target report or object doesn't exceed data source quotas.
2. On the Quick start page, choose **Data**.
3. On the **Data** page, choose **Create** then **New dataset**.
4. Choose the **Salesforce** icon.
5. Enter a name for the data source and then choose **Create data source**.
6. On the Salesforce login page, enter your Salesforce credentials.

7. For **Data elements: contain your data**, choose **Select** and then choose either **REPORT** or **OBJECT**.

 Note

Joined reports aren't supported as Quick Sight data sources.

8. Choose one of the following options:
 - To prepare the data before creating an analysis, choose **Edit/Preview data** to open data preparation. For more information about data preparation, see [Preparing dataset examples](#).
 - Otherwise, choose a report or object and then choose **Select**.
9. Choose one of the following options:
 - To create a dataset and an analysis using the data as-is, choose **Visualize**.

 Note

If you don't have enough [SPICE](#) capacity, choose **Edit/Preview data**. In data preparation, you can remove fields from the dataset to decrease its size or apply a filter that reduces the number of rows returned. For more information about data preparation, see [Preparing dataset examples](#).

- To prepare the data before creating an analysis, choose **Edit/Preview data** to open data preparation for the selected report or object. For more information about data preparation, see [Preparing dataset examples](#).

 Note

The Salesforce connector is not supported in embedded console deployments where users authenticate through namespace isolation. The OAuth authentication flow requires direct Amazon Quick Sight console access to complete the sign-in process.

Using Trino with Amazon Quick Sight

Trino is a massively parallel processing (MPP) query engine built to quickly query data lakes with petabytes of data. Use this section to learn how to connect from Amazon Quick Sight to Trino. All

traffic between Amazon Quick Sight and Trino is enabled by SSL. Amazon Quick Sight supports basic username and password authentication to Trino.

Creating a data source connection for Trino

1. Begin by creating a new dataset. From the left navigation pane, choose **Data**. Choose **Create** then **New Dataset**.
2. Choose the **Trino** data source card.
3. For **Data source name**, enter a descriptive name for your Trino data source connection. Because you can create many datasets from a connection to Trino, it's best to keep the name simple.
4. For **Connection type**, select the type of network you're using. Choose **Public network** if your data is shared publicly. Choose **VPC** if your data is inside a VPC. To configure a VPC connection in Amazon Quick Sight, see [Configuring the VPC connection in Amazon Quick Sight](#).
5. For **Database server**, enter the hostname specified in your Trino connection details.
6. For **Catalog**, enter the catalog specified in your Trino connection details.
7. For **Port**, enter the port specified in your Trino connection details.
8. For **Username** and **Password**, enter your Trino connection credentials.
9. To verify the connection is working, choose **Validate connection**.
10. To finish and create the data source, choose **Create data source**.

Adding a new Amazon Quick Sight dataset for Trino

After you go through the [data source creation process](#) for Trino, you can create Trino datasets to use for analysis. You can create new datasets from a new or an existing Trino data source. When you are creating a new data source, Amazon Quick Sight immediately takes you to creating a dataset, which is step 3 below. If you're using an existing data source to create a new dataset, start from step 1 below.

To create a dataset using a Trino data source, see the following steps.

1. From the start page, choose **Data**. Choose **Create** then **New dataset**.
2. Choose the Trino data source you created.
3. Choose **Create data set**.
4. To specify the table you want to connect to, choose a schema. If you don't want to choose a schema, you can also use your own SQL statement.

5. To specify the table you want to connect to, first select the **Schema** you want to use. For **Tables**, choose the table that you want to use. If you prefer to use your own SQL statement, select **Use custom SQL**.
6. Choose **Edit/Preview**.
7. (Optional) To add more data, use the following steps:
8. Choose **Add data** in the top right.
9. To connect to different data, choose **Switch data source**, and choose a different dataset.
10. Follow the prompts to finish adding data.
11. After adding new data to the same dataset, choose **Configure this join** (the two red dots). Set up a join for each additional table.
12. If you want to add calculated fields, choose **Add calculated field**.
13. Clear the check box for any fields that you want to omit.
14. Update any data types that you want to change.
15. When you are done, choose **Save** to save and close the dataset.

Note

Connectivity between Quick Sight and Trino was validated using Trino version 410.

Creating a dataset using a local text file

To create a dataset using a local text file data source, identify the location of the file, and then upload it. The file data is automatically imported into [SPICE](#) as part of creating a dataset.

To create a dataset based on a local text file

1. Check [Data source quotas](#) to make sure that your target file doesn't exceed data source quotas.

Supported file types include .csv, .tsv, .json, .clf, or .elf files.

2. On the Quick start page, choose **Data**.
3. Choose **Create** then **New dataset**.
4. Choose **Upload a file**.
5. In the **Open** dialog box, browse to a file, select it, and then choose **Open**.

A file must be 1 GB or less to be uploaded to Quick Sight.

6. To prepare the data before creating the dataset, choose **Edit/Preview data**. Otherwise, choose **Visualize** to create an analysis using the data as-is.

If you choose the former, you can specify a dataset name as part of preparing the data. If you choose the latter, a dataset with the same name as the source file is created. To learn more about data preparation, see [Preparing data in Amazon Quick Sight](#).

Using Amazon Timestream data with Amazon Quick Sight

Following, you can find how to connect to your Amazon Timestream data using Amazon Quick Sight. For a brief overview, see the [Getting started with Amazon Timestream and Amazon QuickSight](#) video tutorial on YouTube.

Creating a new Amazon Quick Sight data source connection for a Timestream database

Following, you can find how to connect to Amazon Timestream from Amazon Quick Sight.

Before you can proceed, Amazon Quick Sight needs to be authorized to connect to Amazon Timestream. If connections aren't enabled, you get an error when you try to connect. A Quick Sight administrator can authorize connections to AWS resources. To authorize, open the menu by clicking on your profile icon at top right. Choose **Manage QuickSight, Security & permissions, Add or remove**. Then enable the check box for Amazon Timestream, then choose **Update** to confirm. For more information, see [Configuring Amazon Quick Sight access to AWS data sources](#).

To connect to Amazon Timestream

1. Begin by creating a new dataset. Choose **Data** from the navigation pane at left.
2. Choose **Create** then **New Dataset**.
3. Choose the Timestream data source card.
4. For **Data source name**, enter a descriptive name for your Timestream data source connection, for example US Timestream Data. Because you can create many datasets from a connection to Timestream, it's best to keep the name simple.
5. Choose **Validate connection** to check that you can successfully connect to Timestream.
6. Choose **Create data source** to proceed.
7. For **Database**, choose **Select** to view the list of available options.
8. Choose the one you want to use, then choose **Select** to continue.

9. Do one of the following:

- To import your data into Quick Sight's in-memory engine (called SPICE), choose **Import to SPICE for quicker analytics**.
- To allow Quick Sight to run a query against your data each time you refresh the dataset or use the analysis or dashboard, choose **Directly query your data**.

If you want to enable autorefresh on a published dashboard that uses Timestream data, the Timestream dataset needs to use a direct query.

10. Choose **Edit/Preview** and then **Save** to save your dataset and close it.

11. Repeat these steps for the number of concurrent direct connections to Timestream that you want to open in a dataset. For example, let's say you want to use four tables in a Quick Sight dataset. Currently, Quick Sight datasets connect to only one table at a time from a Timestream data source. To use four tables in the same dataset, you need to add four data source connections in Quick Sight.

Managing permissions for Timestream data

The following procedure describes how to view, add, and revoke permissions to allow access to the same Timestream data source. The people that you add need to be active users in Quick Sight before you can add them.

To edit permissions on a dataset

1. Choose **Data** at left, then scroll down to find the dataset for your Timestream connection. An example might be **US Timestream Data**.
2. Choose the **Timestream** dataset to open it.
3. On the dataset details page that opens, choose the **Permissionstab**.

A list of current permissions appears.

4. To add permissions, choose **Add users & groups**, then follow these steps:
 - a. Add users or groups to allow them to use the same dataset.
 - b. When you're finished adding everyone that you want to add, choose the **Permissions** that you want to apply to them.
5. (Optional) To edit permissions, you can choose **Viewer** or **Owner**.

- Choose **Viewer** to allow read access.
 - Choose **Owner** to allow that user to edit, share, or delete this Quick Sight data source.
6. (Optional) To revoke permissions, choose **Revoke access**. After you revoke someone's access, they can't create edit, share, or delete the dataset.
 7. When you are finished, choose **Close**.

Adding a new Quick Sight dataset for Timestream

After you have an existing data source connection for Timestream data, you can create Timestream datasets to use for analysis.

Currently, you can use a Timestream connection only for a single table in a dataset. To add data from multiple Timestream tables in a single dataset, create an additional Quick Sight data source connection for each table.

To create a dataset using Amazon Timestream

1. Choose **Data** at left, then scroll down to find the data source card for your Timestream connection. If you have many data sources, you can use the search bar at the top of the page to find your data source with a partial match on the name.
2. Choose the **Timestream** data source card, and then choose **Create data set**.
3. For **Database**, choose **Select** to view a list of available databases and choose the one that you want to use.
4. For **Tables**, choose the table that you want to use.
5. Choose **Edit/Preview**.
6. (Optional) To add more data, use the following steps:
 - a. Choose **Add data** at top right.
 - b. To connect to different data, choose **Switch data source**, and choose a different dataset.
 - c. Follow the UI prompts to finish adding data.
 - d. After adding new data to the same dataset, choose **Configure this join** (the two red dots). Set up a join for each additional table.
 - e. If you want to add calculated fields, choose **Add calculated field**.
 - f. To add a model from SageMaker AI, choose **Augment with SageMaker**. This option is only available in Amazon Quick Enterprise edition.

- g. Clear the check box for any fields that you want to omit.
 - h. Update any data types that you want to change.
7. When you are done, choose **Save** to save and close the dataset.

Adding Timestream data to an analysis

Following, you can find how to add an Amazon Timestream dataset to a Quick Sight analysis. Before you begin, make sure that you have an existing dataset that contains the Timestream data that you want to use.

To add Amazon Timestream data to an analysis

1. Choose **Analyses** at left.
2. Do one of the following:
 - To create a new analysis, choose **New analysis** at right.
 - To add to an existing analysis, open the analysis that you want to edit.
 - Choose the pencil icon near at top left.
 - Choose **Add data set**.
3. Choose the Timestream dataset that you want to add.

For more information, see [Working with analyses](#).

Connecting to data catalogs in Amazon Quick

Note

Data catalog integration is in Preview for Amazon Quick and is subject to change. Preview features are not typically recommended for critical or production workloads.

Amazon Quick data catalog integration connects Quick to upstream data catalogs such as AWS Glue Data Catalog and Databricks Unity Catalog. The integration provides an AI-powered agentic experience that helps data curators (authors such as analysts and business intelligence engineers) rapidly discover relevant tables, bulk-create DirectQuery datasets and topics, and automatically inherit semantic definitions from their catalogs. By reusing the metadata that already exists in your

catalog, you can go from a business question to production-ready dashboards and AI-powered Q&A in a fraction of the time, not weeks.

In Quick, a connected catalog is represented as a data source. To access a catalog data source, navigate to the **Create Data Source** page and select the catalog connector for your environment.

Benefits of data catalog integration

Data catalog integration provides the following benefits:

- **Accelerated asset curation** – Data curators (authors) use a conversational AI agent to discover tables that match their business needs, create datasets in bulk, and build multi-dataset topics in a single flow. These datasets are DirectQuery representations of your catalog assets, not copies of your data. The upstream catalog remains the source of truth. This significantly reduces the time required to deliver governed analytics to business users.
- **Semantic inheritance** – Table and column descriptions, and primary and foreign key relationships (where available), are automatically inherited from the upstream catalog. This eliminates manual recreation of business context and ensures consistency with your catalog as the single source of truth.
- **Focused context boundaries** – In enterprise environments with thousands of tables, the agentic experience helps authors define a curated subset of catalog assets relevant to their line of business. These curated datasets and topics provide a focused data boundary that improves the accuracy of AI-generated answers in Q&A and enables deterministic, reliable dashboards.
- **Always-fresh data** – All datasets created through the catalog integration use DirectQuery, so data is queried at the source with no duplication or staleness.
- **Governance inheritance** – Optionally enable identity propagation to enforce per-user data permissions defined in your upstream catalog at query time, without recreating row-level security (RLS) or column-level security (CLS) rules in Quick.
- **Combined enterprise context** – After you establish a context boundary with datasets and topics, Quick can combine catalog data with other enterprise knowledge sources such as Slack conversations, Outlook emails, and Google Drive documents. This unified context enables AI agents to deliver more comprehensive insights across structured and unstructured data.

Supported catalogs

The following table lists the supported catalogs and their capabilities in this preview.

Supported catalogs and capabilities

Catalog	Capability	What it enables	Authentication
AWS Glue Data Catalog	Agentic discovery, bulk create, semantic inheritance	AI-powered discovery and dataset creation from Glue metadata, with automatic inheritance of table and column descriptions	Service role or AWS IAM Identity Center
AWS Glue Data Catalog	Trusted identity propagation (TIP)	Per-user data permissions enforcement through AWS IAM Identity Center and Lake Formation	AWS IAM Identity Center
Databricks Unity Catalog	Agentic discovery, bulk create, semantic inheritance	AI-powered discovery and dataset creation from Unity Catalog metadata, with automatic inheritance of descriptions and relationships	Personal Access Token (PAT) or OAuth 3LO
Databricks Unity Catalog	Identity propagation (3LO)	Per-user data permissions enforcement through Databricks OAuth	OAuth 3LO

The agentic catalog experience

After you connect to a supported catalog, data curators (authors) can choose **Explore data** on the data source to launch the agentic experience. The AI agent guides you through the following steps in a conversational flow:

1. **Discover** – Describe your use case in natural language. The agent uses catalog metadata, including table and column descriptions, data quality scores, and lineage, to recommend the most relevant tables. For example: *"I am a supply chain analyst looking to enable Q&A for my logistics managers. They need to track carrier on-time delivery performance and shipping costs across distribution centers."*
2. **Create** – After you verify the recommended assets, create all relevant datasets in bulk within the same conversational flow. These datasets are DirectQuery representations of your catalog assets — the upstream catalog remains the source of truth. We recommend that you create datasets only for your intended use cases to maintain a focused context boundary.

3. **Relationships and topics** – Once datasets are created, the agent inherits relationships from the upstream catalog (where available) and can recommend additional inferred relationships. The agent then creates a multi-dataset topic that spans your selected assets.
4. **Semantic inheritance** – Table and column descriptions are automatically inherited from the upstream catalog onto the created datasets. This metadata provides the business context that AI agents in Quick need to generate accurate, grounded answers for your end users.

Important

The agentic experience is AI-powered. Authors should review all agent recommendations, including discovered tables, inferred relationships, and inherited descriptions, before proceeding.

Behavior of created datasets

Datasets created through the agentic catalog experience have the following characteristics:

- **Semantics inherited indicator** – Created datasets display a **Semantics inherited** badge to show that definitions come from the upstream catalog.
- **DirectQuery** – All datasets use DirectQuery mode by default. Data is always queried at the source with no duplication.
- **Sync semantics** – Choose **Sync semantics** on a dataset to refresh table and column definitions from the upstream catalog at any time. This ensures the catalog remains the single source of truth for metadata.
- **Flexibility** – You can edit these datasets to switch to SPICE or add transformations in Quick. However, after you do so, semantic sync is no longer available and the dataset is treated as a standard Quick dataset.

Note

In this preview, Quick inherits table and column descriptions, and primary and foreign key definitions. Support for additional semantic information such as metric views and semantic views is planned for the future.

Identity propagation for data governance

In addition to the agentic experience and semantic inheritance, Quick supports identity propagation for applicable catalogs. When enabled, identity propagation enforces per-user data permissions at query time based on the user's identity in the upstream catalog.

For example, if John has access to US-Northeast region data and Mary has access to US-West region data, when each user views the same dashboard, they see only the data they are permitted to access. Permissions are enforced by the upstream catalog, not by manual Quick configuration.

Important

Identity propagation works only for DirectQuery datasets. If a dataset is switched to SPICE or has transformations applied, identity propagation does not apply.

Important

The agentic catalog experience (natural language discovery, bulk creation of datasets and topics, semantic inheritance) works with any supported authentication type. Identity propagation is not a prerequisite for the agentic experience. It is an optional, additive capability for customers who require per-user governance enforcement.

If you do not enable identity propagation, you can manage data permissions manually by using row-level security (RLS) and column-level security (CLS) rules in Quick.

The following identity propagation methods are available:

- **AWS Glue Data Catalog** – Trusted identity propagation through AWS IAM Identity Center and Lake Formation. For setup instructions, see [Setting up trusted identity propagation for AWS Glue Data Catalog](#).
- **Databricks Unity Catalog** – OAuth 3LO (three-legged OAuth) with end-user identities. For setup instructions, see [Setting up identity enforcement with Databricks 3LO](#).

When to use data catalog integration

Data catalog integration is designed for the following scenarios:

- **Large-scale catalogs that require a focused context boundary** – In enterprise environments with thousands of tables, exposing the entire catalog to end users can introduce noise and reduce answer accuracy in AI-powered Q&A. The agentic experience enables authors to define a curated subset of assets relevant to their line of business. These assets are represented as datasets and topics in Quick, providing a focused boundary for deterministic dashboards and more accurate AI-generated answers.
- **Catalog as the authoritative source of truth** – Datasets created through the agentic experience are DirectQuery projections of upstream catalog assets. The catalog remains the single source of truth for metadata and definitions. Semantic sync keeps definitions current. Quick also supports additional transformations on these assets when needed.
- **Combined enterprise context** – By building curated representations (datasets and topics) in Quick, Quick can combine catalog data with other enterprise knowledge sources. This unified context enables AI agents to deliver comprehensive insights across structured and unstructured data.

Connecting to AWS Glue Data Catalog

Note

Data catalog integration with AWS Glue Data Catalog is in Preview for Amazon Quick and is subject to change. Preview features are not typically recommended for critical or production workloads.

AWS Glue Data Catalog is available as a data source connector in Quick. It provides direct access to Glue catalog metadata including table names, descriptions, column information, and data quality scores. After you connect, data curators (authors) can use the agentic experience to discover relevant tables, create DirectQuery datasets in bulk, and inherit semantic definitions automatically.

Setting up the Data Catalog connection

Connecting to AWS Glue Data Catalog involves two steps: connecting to the catalog for metadata access and connecting to Amazon Athena for data queries.

Prerequisites

- An administrator must enable the AWS Glue Data Catalog connector. To do this, go to **AWS resources** under the **Manage Account** page in Quick and select **Glue Data Catalog**.

Important

If an author attempts to create an AWS Glue Data Catalog data source before the administrator enables it under **AWS resources** on the **Manage Account** page, the operation fails with an error. Ensure that the administrator enables AWS Glue Data Catalog for the Quick account before authors attempt to create the data source.

- The connector uses service role permissions for Glue metadata access. Attach the following IAM policy to the Quick service role:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:GetCatalog",
        "glue:GetCatalogs",
        "glue:GetDatabases",
        "glue:GetDatabase",
        "glue:GetTables",
        "glue:GetTable",
        "glue:ListDataQualityResults",
        "glue:GetDataQualityResult",
        "lakeformation:GetTemporaryGlueTableCredentials",
        "lakeformation:GetDataAccess",
        "glue:GetConnection",
        "glue:GetConnections",
        "glue:GetTags"
      ],
      "Resource": [
        "arn:aws:glue:*:account-id:catalog",
        "arn:aws:glue:*:account-id:catalog/*",
        "arn:aws:glue:*:account-id:database/*",
        "arn:aws:glue:*:account-id:table/*/*",
        "arn:aws:glue:*:account-id:dataQualityRuleset/*",
        "arn:aws:glue:*:account-id:connection/*"
      ]
    }
  ]
}
```

```
}
```

Replace *account-id* with your AWS account ID.

Note

This policy grants access to all Glue Data Catalog resources in your account. To follow the principle of least privilege, replace the wildcard (*) resource ARNs with ARNs for the specific catalogs, databases, and tables that you want to expose in Quick.

- If you are not using AWS IAM Identity Center, all data source creators have the same access to catalog metadata as the Quick service role.

Two-step connection process

Because AWS Glue Data Catalog provides metadata and Amazon Athena provides query execution, authors complete two connections:

1. **Connect to AWS Glue Data Catalog for metadata** – Navigate to **Create Data Source** and select **Glue Data Catalog**. This connection provides access to table names, table descriptions, column information, and other catalog metadata.
2. **Connect to Amazon Athena for data queries** – Select **Athena** and configure the primary workgroup. This connection enables queries against the underlying Amazon S3 and Apache Iceberg tables. The supported underlying data store is Amazon S3.

Using the agentic experience with AWS Glue Data Catalog

After you connect to AWS Glue Data Catalog, choose **Explore data** on the data source to launch the agentic experience.

The agentic experience provides the following capabilities for Data Catalog:

- **Natural language discovery** – Describe your use case and the AI agent finds relevant tables from your catalog metadata.
- **Bulk create assets** – Create multiple datasets in a single conversational flow.
- **Semantic inheritance** – Table and column descriptions are automatically inherited from Glue onto the created datasets.

Note

AWS Glue Data Catalog does not store primary and foreign key relationships. However, the agent can recommend inferred relationships to create multi-dataset topics. Review these recommendations before accepting them.

For details on the full agentic flow including discovery, creation, relationships, and semantic inheritance, see [The agentic catalog experience](#).

Setting up trusted identity propagation for AWS Glue Data Catalog

Trusted identity propagation enables AWS services to access resources based on the end user's identity context. When you configure Quick, AWS Glue Data Catalog, Amazon S3 Access Grants, and Lake Formation with AWS IAM Identity Center, the signed-in user's identity is propagated across services. Lake Formation and S3 Access Grants make authorization decisions based on permissions defined for that user or their group membership from your identity provider.

Important

Trusted identity propagation with AWS Glue Data Catalog requires AWS IAM Identity Center. It is not supported for other authentication methods.

Prerequisites**Important**

Your AWS IAM Identity Center instance, Lake Formation, AWS Glue Data Catalog, and Amazon S3 Access Grants must all be deployed in the same AWS Region.

- **Configure Quick with AWS IAM Identity Center** – Trusted identity propagation is supported only for Quick accounts integrated with AWS IAM Identity Center. To create AWS Glue Data Catalog data sources with identity propagation, you must be an AWS IAM Identity Center user (author).
- **AWS Glue Data Catalog must be managed by Lake Formation** – Lake Formation must enforce permissions on your databases and tables. If a database or table still grants Super to IAMAllowedPrincipals, Lake Formation does not enforce per-user permissions.

- **Lake Formation must be integrated with AWS IAM Identity Center** – Use the same AWS IAM Identity Center instance that Quick uses. This integration allows Lake Formation to recognize a propagated user identity.
- **Register data S3 locations with Lake Formation** – When a user queries a table, Lake Formation vends temporary, scoped S3 credentials for the data. The user's query does not need its own S3 permissions on the data bucket. Register the location for all table formats (Parquet, Apache Iceberg, S3 Tables).
- **Grant permissions to IAM Identity Center users and groups in Lake Formation** – Configure permissions and any row, column, or cell data filters to control which catalogs, databases, tables, rows, and columns each user can access.
- **Quick administrator authorizes the connection** – With trusted identity propagation, the Quick role does not need direct S3 permissions on the table data. Lake Formation vends those credentials.
- **S3 Access Grants on the Athena results bucket** – Glue queries execute through the Athena engine, which writes results to the query results bucket. That bucket is governed by S3 Access Grants (separate from Lake Formation). Each user or group may need an S3 Access Grant (READ/ WRITE) on the results bucket.

Step 1: Enable the Lake Formation – AWS IAM Identity Center integration

Lake Formation must be connected to your AWS IAM Identity Center instance so it can recognize identities propagated from Quick. This is a one-time, account-level and Region-level step. If you already use Athena trusted identity propagation, this step is already complete. You must be a Lake Formation data lake administrator.

Console: In the Lake Formation console, choose **Administration, IAM Identity Center integration**, and then **Create**. Select your AWS IAM Identity Center instance.

AWS CLI:

```
aws lakeformation create-lake-formation-identity-center-configuration \
  --catalog-id 111122223333 \
  --instance-arn arn:aws:sso:::instance/<idc-instance-id> \
  --region us-west-2
```

This command creates the Lake Formation AWS IAM Identity Center application. Note the `ApplicationArn` from the response. You use it as the authorized target when you configure identity propagation.

To retrieve the application ARN later, run:

```
aws lakeformation describe-lake-formation-identity-center-configuration \
  --catalog-id 111122223333 \
  --region us-west-2
```

The response includes an `ApplicationArn` in the following format:

```
arn:aws:sso::111122223333:application/<idc-instance-id>/<lf-application-id>
```

Step 2: Configure the IAM role with required permissions

Your Quick account must use an IAM role with the required permissions. If your account already uses a custom IAM role, modify it. Otherwise, create a new role.

Required trust policy:

The role's trust policy must allow the Quick service principal to assume it and attach the user's identity context to the session:

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Principal": { "Service": "quicksight.amazonaws.com" },
    "Action": ["sts:AssumeRole", "sts:TagSession", "sts:SetContext"]
  }]
}
```

Note

`sts:SetContext` is required so that the user's AWS IAM Identity Center identity context can be attached to the assumed-role session.

Required permissions:

The role needs permissions to read AWS Glue Data Catalog metadata and obtain Lake Formation vended data access. The role does not need direct `s3:*` permissions on the table data because Lake Formation vends scoped, temporary S3 credentials.

```
"Action": [  
    "glue:GetCatalog", "glue:GetCatalogs",  
    "glue:GetDatabase", "glue:GetDatabases",  
    "glue:GetTable", "glue:GetTables",  
    "glue:GetConnection", "glue:GetConnections",  
    "glue:GetTags", "glue:ListDataQualityResults",  
    "glue:GetDataQualityResult",  
    "lakeformation:GetTemporaryGlueTableCredentials",  
    "lakeformation:GetDataAccess"  
]
```

Step 3: Configure the Quick account to use the IAM role

This step must be completed by the Quick administrator.

1. In the Quick console, choose your profile icon and then choose **Manage Quick**.
2. Choose **Security & permissions**.
3. Under **Quick access to AWS services**, choose **Manage**.
4. Find or add the **Glue Data Catalog** resource.
5. Select the IAM role that you configured in Step 2.
6. Under **Amazon S3**, allow access to the Athena query results bucket.
7. Choose **Update**.

Step 4: Update the identity propagation configuration

Run the following AWS CLI command to enable identity propagation for Data Catalog:

```
aws quicksight update-identity-propagation-config \  
    --aws-account-id 111122223333 \  
    --service GLUE_DATA_CATALOG \  
    --authorized-targets arn:aws:sso::111122223333:application/<idc-instance-id>/<lf-  
application-id>
```

The `--authorized-targets` value is the Lake Formation AWS IAM Identity Center application ARN that you obtained in Step 1. This tells Quick which AWS IAM Identity Center application to propagate identity to.

To verify, run:

```
aws quicksight list-identity-propagation-configs \
  --aws-account-id 111122223333
```

Confirm that `GLUE_DATA_CATALOG` appears in the services list.

Step 5: Create a AWS Glue Data Catalog data source

When the author creates a AWS Glue Data Catalog data source, Quick validates accessibility by listing catalogs using the signed-in user's propagated identity. The user sees only the catalogs, databases, and tables that their Lake Formation grants allow.

Verifying the setup

Use the following checklist to verify your configuration:

- The Lake Formation–AWS IAM Identity Center integration returns an `ApplicationArn`.
- Identity propagation scope shows `GLUE_DATA_CATALOG`.
- The IAM role has correct permissions and `sts:SetContext` in the trust policy.
- Data S3 locations are registered with Lake Formation.
- Lake Formation grants are configured for IAM Identity Center users and groups.
- S3 Access Grants are configured on the Athena results bucket (if applicable).
- End-to-end test: sign in as a test user, create a data source, and query a table.

Key considerations and limits

- Permissions are evaluated against the IAM Identity Center end user and their groups.
- The query path runs through Athena. Each user needs S3 Access Grants on the Athena results bucket.
- A data filter has no effect if a full-table `SELECT` is also granted to the same user.
- Best practice: Grant permissions to groups rather than individual users for easier management.
- S3 Access Grants are eventually consistent. Newly added grants may take minutes to propagate.

- Configure fine-grained access control (row, column, and cell filters) in Lake Formation.
- Scope-down policies are evaluated against the end user's identity.

For information about Athena trusted identity propagation, see [Amazon Athena trusted identity propagation](#).

Connecting to Databricks Unity Catalog

Note

Data catalog integration with Databricks Unity Catalog is in Preview for Amazon Quick and is subject to change. Preview features are not typically recommended for critical or production workloads.

The existing Databricks connector in Quick has been enhanced with agentic catalog capabilities and identity enforcement support through OAuth 3LO. Data curators (authors) can use the agentic experience on both new and existing Databricks data sources that were created using a Personal Access Token (PAT).

Setting up the Databricks connection

The Databricks connector supports catalog integration without requiring a new connector. The following connection options are available:

- The agentic experience (**Explore Data**) is available for existing Databricks data sources that use a Personal Access Token (PAT).
- A single Databricks connection provides access to both metadata and data. This differs from AWS Glue Data Catalog, which requires two separate connections.
- Supported authentication options: Personal Access Token (PAT) or OAuth 3LO.

To create a Databricks data source, navigate to **Create Data Source** and select **Databricks**. Choose your preferred authentication method and enter the connection details.

Note

Databricks Metrics Views are not yet supported.

Using the agentic experience with Databricks Unity Catalog

After you connect to Databricks, choose **Explore data** on the data source to launch the agentic experience. The flow is the same as the broader agentic catalog experience:

- **Natural language discovery** – Describe your use case and the AI agent finds relevant tables from Unity Catalog.
- **Bulk create assets** – Create multiple datasets and topics in a single conversational flow.
- **Semantic inheritance** – Table and column descriptions, and primary and foreign key relationships, are automatically inherited from Unity Catalog onto the created datasets.

For details on the full agentic flow, see [The agentic catalog experience](#).

Setting up identity enforcement with Databricks 3LO

Quick supports three-legged OAuth (3LO) with end-user identities for Databricks. When enabled, 3LO enforces per-user data permissions based on Databricks Unity Catalog access control lists (ACLs). Each end user sees only the data that their Databricks permissions allow.

Important

Identity enforcement works only for DirectQuery datasets. If a dataset is switched to SPICE or has transformations applied, identity enforcement does not apply.

Administrator setup: Client application configuration

The Quick account administrator must configure a client application before authors can create 3LO data sources. Complete the following steps:

1. In the Quick console, choose **Manage Account**. Under **Security**, choose **Manage OAuth Client Applications**.
2. Choose **Add OAuth client application** and provide the following information:
 - Config ID
 - OAuth client application name
 - Authentication type
 - Client ID

- Client secret
 - Token endpoint URL
 - Authorization endpoint URL
 - OAuth scopes
 - VPC connection ARN (optional)
 - Data source type (select **DATABRICKS**)
3. Choose **Add** to save the client application.

Author setup: Creating a 3LO data source

After the administrator configures the client application, authors can create a Databricks data source with 3LO authentication.

1. Navigate to the **Create Data Source** page.
2. Select **Databricks**.
3. Choose **3LO** as the authentication method.
4. Enter the required connection information.
5. Enter your username (the email address associated with your Databricks account).
6. Select the option to enforce trusted identity enforcement (TIP). This ensures that permissions defined in Databricks, including table-level access and data filters, are enforced for end users.

Important

You must select this option if end-user identities must be propagated. Without it, all users share the author's Databricks permissions.

7. Choose **Create data source**.

After the data source is created, use the standard Quick workflow or the agentic experience (**Explore Data**) to create datasets, topics, and dashboards.

End-user experience: Enforcing data permissions

To enforce per-user data permissions for dashboard consumers, complete the following steps:

1. The author shares both the data source and the dashboard with the end user.

2. The end user signs in to Quick and navigates to the **Data Source** page.
3. The end user enters their own Databricks credentials (their OAuth login) and saves.
4. When the end user accesses the dashboard, they see only the data that their Databricks permissions allow.

Important considerations

- Identity enforcement works only for DirectQuery datasets.
- The agentic catalog experience (discover, create, inherit) works with both PAT and 3LO authentication. Identity enforcement through 3LO is optional and additive. It is not a prerequisite for the agentic flow.
- If you do not opt for 3LO, you can use PAT and manually manage data permissions by using row-level security (RLS) and column-level security (CLS) rules in Quick.

Data source quotas

Data sources that you use with Amazon Quick Sight must conform to the following quotas.

Topics

- [SPICE quotas for imported data](#)
- [Quotas for direct SQL queries](#)

SPICE quotas for imported data

When you create a new dataset in Amazon Quick Sight, [SPICE](#) limits the number of rows you can add to a dataset. You can ingest data into SPICE from a query or from a file. Each file can have up to 2,000 columns. Each column name can have up to 127 Unicode characters. Each field can have up to 2,047 Unicode characters. If you use the new data preparation experience to create your SPICE dataset, each field can have up to 65,534 Unicode characters.

To retrieve a subset of data from a larger set, you can deselect columns or apply filters to reduce the size of the data. If you are importing from Amazon S3, each manifest can specify up to 1,000 files.

Quotas for SPICE are as follows:

- 2,047 Unicode characters for each field. (65,534 Unicode characters with new data preparation experience)
- 127 Unicode characters for each column name
- 2,000 columns for each file
- 1,000 files for each manifest
- For Standard edition, 25 million (25,000,000) rows or 25 GB for each dataset
- For Enterprise edition, 2 billion (2,000,000,000) rows or 2 TB for each dataset

All quotas apply to SPICE datasets with row-level security, as well.

In rare cases, if you're ingesting large rows into SPICE, you might reach the quota for gigabytes per dataset before you reach the quota on rows. The size is based on the SPICE capacity the data occupies after ingestion into SPICE.

Quotas for direct SQL queries

If you aren't importing data into SPICE, different quotas apply for space and time. For operations such as connecting, sampling data for a dataset, and generating visuals, timeouts can occur. In some cases, these are timeout quotas set by the source database engine. In other cases, such as visualizing, Amazon Quick Sight generates a timeout after 2 minutes.

However, not all database drivers react to the 2-minute timeout, for example Amazon Redshift. In these cases, the query runs for as long as it takes for the response to return, which can result in long-running queries on your database. When this happens, you can cancel the query from the database server to free up database resources. Follow the instructions for your database server about how to do this. For example, for more information on how to cancel queries in Amazon Redshift, see [Canceling a query in Amazon Redshift](#), and [Implementing workload management in Amazon Redshift](#) in the *Amazon Redshift Database Developer Guide*.

Each result set from a direct query can have up to 2,000 columns. Each column name can have up to 127 Unicode characters. If you want to retrieve data from a larger table, you can use one of several methods to reduce the size of the data. You can deselect columns, or apply filters. In a SQL query, you can also use predicates, such as WHERE, HAVING. If your visuals time out during a direct query, you can simplify your query to optimize execution time or you can import the data into SPICE.

Quotas for queries are as follows:

- 127 Unicode characters for each column name.
- 2,000 columns for each dataset.
- 2-minute quota for generating a visual, or an optional dataset sample.
- Data source timeout quotas apply (varies for each database engine).

Supported data types and values

Amazon Quick Sight currently supports the following primitive data types: `Date`, `Decimal`, `Integer`, and `String`. The following data types are supported in SPICE: `Date`, `Decimal-fixed`, `Decimal-float`, `Integer`, and `String`. Quick Sight accepts Boolean values by promoting them to integers. It can also derive geospatial data types. Geospatial data types use metadata to interpret the physical data type. Latitude and longitude are numeric. All other geospatial categories are strings.

Make sure that any table or file that you use as a data source contains only fields that can be implicitly converted to these data types. Amazon Quick Sight skips any fields or columns that can't be converted. If you get an error that says "fields were skipped because they use unsupported data types", alter your query or table to remove or recast unsupported data types.

String and text data

Fields or columns that contain characters are called *strings*. A field with the data type of `STRING` can initially contain almost any type of data. Examples include names, descriptions, phone numbers, account numbers, JSON data, cities, post codes, dates, and numbers that can be used to calculate. These types are sometimes called textual data in a general sense, but not in a technical sense. Quick Sight doesn't support binary and character large objects (BLOBs) in dataset columns. In the Quick Sight documentation, the term "text" always means "string data".

The first time you query or import the data, Quick Sight tries to interpret the data that it identifies as other types, for example dates and numbers. It's a good idea to verify that the data types assigned to your fields or columns are correct.

For each string field in imported data, Quick Sight uses a field length of 8 bytes plus the UTF-8 encoded character length. Amazon Quick Sight supports UTF-8 file encoding, but not UTF-8 (with BOM).

Date and time data

Fields with a data type of Date also include time data, and are also known as Datetime fields. Quick Sight supports dates and times that use [supported date formats](#).

Quick Sight uses UTC time for querying, filtering, and displaying date data. When date data doesn't specify a time zone, Quick Sight assumes UTC values. When date data does specify a time zone, Quick Sight converts it to display in UTC time. For example, a date field with a time zone offset like **2015-11-01T03:00:00-08:00** is converted to UTC and displayed in Amazon Quick Sight as **2015-11-01T15:30:00**.

For each DATE field in imported data, Quick Sight uses a field length of 8 bytes. Quick Sight supports UTF-8 file encoding, but not UTF-8 (with BOM).

Numeric data

Numeric data includes integers and decimals. Integers with a data type of INT are negative or positive numbers that don't have a decimal place. Quick Sight doesn't distinguish between large and small integers. Integers over a value of 9007199254740991 or $2^{53} - 1$ might not display exactly or correctly in a visual.

Decimals with the data type of Decimal are negative or positive numbers that contain at least one decimal place before or after the decimal point. When you choose Direct Query mode, all non-integer decimal types are marked as Decimal and the underlying engine handles the precision of the datapoint based on the data source's supported behaviors. For more information on supported data source types, see [Supported data types and values](#).

When you store your dataset in SPICE, you can choose to store your decimal values as fixed or float decimal types. Decimal-fixed data types use the format of decimal (18, 4) that allow 18 digits total and up to 4 digits after the decimal point. Decimal-fixed data types are a good choice to conduct exact mathematical operations, but Quick Sight rounds the value to the nearest ten thousandth place when the value is ingested into SPICE.

Decimal-float data types provide approximately 16 significant digits of accuracy to a value. The significant digits can be on either side of the decimal point to support numbers with many decimal places and higher numbers at the same time. For example, the Decimal-float data type supports the number 12345.1234567890 or the number 1234567890.12345. If you work with very small numbers that are close to 0, the Decimal-float data type supports up to 15 digits to the right of the decimal point, for example 0.123451234512345. The maximum value that this

data type supports is 1.8×10^{308} to minimize the probability of an overflow error with your data set.

The Decimal-float data type is inexact and some values are stored as approximations instead of the real value. This may result in slight discrepancies when you store and return some specific values. The following considerations apply to the Decimal-float data type.

- If the dataset that you're using comes from an Amazon S3 data source, SPICE assigns the Decimal-float decimal type to all numeric decimal values.
- If the dataset that you're using comes from a database, SPICE uses the decimal type that the value is assigned in the database. For example, if the value is assigned a fixed-point numeric value in the database, the value will be a Decimal-fixed type in SPICE.

For existing SPICE datasets that contain fields that can be converted to the Decimal-float data type, a pop-up appears in the **Edit dataset** page. To convert fields of an existing dataset to the Decimal-float data type, choose **UPDATE FIELDS**. If you don't want to opt in, choose **DO NOT UPDATE FIELDS**. The **Update fields** pop up appears every time you open the **Edit dataset** page until the dataset is saved and published.

Supported data types from external data sources

The following table lists data types that are supported when using the following data sources with Amazon Quick Sight.

Database engine or source	Numeric data types	String data types	Datetime data types	Boolean data types
Amazon Athena, Presto, Starburst, Trino	• bigint • decimal • double • integer • real	• char • varchar	• date • timestamp	• boolean

Database engine or source	Numeric data types	String data types	Datetime data types	Boolean data types
	• smallint • tinyint			
Amazon Aurora, MariaDB, and MySQL	• bigint • decimal • double • int • integer • mediumint • numeric • smallint • tinyint	• char • enum • set • text • varchar	• date • datetime • timestamp • year	
Amazon OpenSearch Service	• byte • integer • long • float • double	• string (keyword string field type in OpenSearch Service) • ip	• timestamp	• boolean • binary

Database engine or source	Numeric data types	String data types	Datetime data types	Boolean data types
Oracle	• bigint • decimal • decimal • int • money • numeric • real • smallint • smallmoney • tinyint	• char • nchar • nvarchar • text • varchar	• date • datetime • datetime2 • datetimeoffset • smalldatetime	bit

Database engine or source	Numeric data types	String data types	Datetime data types	Boolean data types
PostgreSQL	• bigint • decimal • double • integer • numeric • precision • real • smallint	• char • character • text • varchar • varying character	• date • timestamp	• boolean
Apache Spark	• bigint • decimal • double • integer • real • smallint • tinyint	• varchar	• date • timestamp	• boolean

Database engine or source	Numeric data types	String data types	Datetime data types	Boolean data types
Snowflake	• bigint • byteint • decimal • double • doubleprecision • float • float4 • float8 • int • integer • number • numeric • real • smallint • tinyint	• char • character • string • text • varchar	• date • datetime • time • timestamp • timestamp_*	• boolean

Database engine or source	Numeric data types	String data types	Datetime data types	Boolean data types
Microsoft SQL Server	• bigint • bit • decimal • int • money • numeric • real • smallint • smallmoney • tinyint	• char • nchar • nvarchar • text • varchar	• date • datetime • datetime2 • smalldatetime	• bit

Supported date formats

Amazon Quick Sight supports the date and time formats described in this section. Before you add data to Amazon Quick Sight, check if your date format is compatible. If you need to use an unsupported format, see [Using unsupported or custom dates](#).

The supported formats vary depending on the data source type, as follows:

Data source	Clocks	Date formats
File uploads	Both 24-hour and	Supported date and time formats are described in the Joda API documentation.

Data source	Clocks	Date formats
Amazon S3 sources	12-hour clocks	For a complete list of Joda date formats, see Class DateTimeFormat on the Joda website.
Athena		
Salesforce		For datasets stored in memory (SPICE), Amazon Quick Sight supports dates in the following range: Jan 1, 0001 00:00:00 UTC through Dec 31, 9999, 23:59:59 UTC .

Data source	Clocks	Date formats
Relational databases sources	24-hour clock only	The following data and time formats: 1. <code>dd/MM/yyyy HH:mm:ss</code> , for example <code>31/12/2016 15:30:00</code>. 2. <code>dd/MM/yyyy</code> , for example <code>31/12/2016</code>. 3. <code>dd/MMM/yyyy HH:mm:ss</code> , for example <code>31/Dec/2016 15:30:00</code>. 4. <code>dd/MMM/yyyy</code> , for example <code>31/Dec/2016</code>. 5. <code>dd-MMM-yyyy HH:mm:ss</code> , for example <code>31-Dec-2016 15:30:00</code>. 6. <code>dd-MMM-yyyy</code> , for example <code>31-Dec-2016</code>. 7. <code>dd-MM-yyyy HH:mm:ss</code> , for example <code>31-12-2016 15:30:00</code>. 8. <code>dd-MM-yyyy</code> , for example <code>31-12-2016</code>. 9. <code>MM/dd/yyyy HH:mm:ss</code> , for example <code>12/31/2016 15:30:00</code>. 10. <code>MM/dd/yyyy</code> , for example <code>12/31/2016</code>. 11. <code>MM-dd-yyyy HH:mm:ss</code> , for example <code>12-31-2016 15:30:00</code>. 12. <code>MM-dd-yyyy</code> , for example <code>12-31-2016</code>. 13. <code>MMM/dd/yyyy HH:mm:ss</code> , for example <code>Dec/31/2016 15:30:00</code>. 14.

Data source	Clocks	Date formats
		MMM/dd/yyyy , for example Dec/31/2016. 15. MMM-dd-yyyy HH:mm:ss , for example Dec-31-2016 15:30:00. 16. MMM-dd-yyyy , for example Dec-31-2016. 17. yyyy/MM/dd HH:mm:ss , for example 2016/12/31 15:30:00. 18. yyyy/MM/dd , for example 2016/12/31. 19. yyyy/MMM/dd HH:mm:ss , for example 2016/Dec/31 15:30:00. 20. yyyy/MMM/dd , for example 2016/Dec/31. 21. yyyy-MM-dd HH:mm:ss , for example 2016-12-31 15:30:00. 22. yyyy-MM-dd , for example 2016-12-31. 23. yyyy-MMM-dd HH:mm:ss , for example 2016-Dec-31 15:30:00. 24. yyyy-MMM-dd , for example 2016-Dec-31. 25. yyyyMMdd 'T' HHmmss , for example 20161231T153000. 26. yyyy-MM-dd 'T' HH:mm:ss , for example 2016-12-31T15:30:00. 27. yyyyMMdd 'T' HHmmss .SSS , for example 20161231T153000.123.

Data source	Clocks	Date formats
		28. MM/dd/yyyy HH:mm:ss.SSS , for example 12/31/2016 15:30:00.123. 29. dd/MM/yyyy HH:mm:ss.SSS , for example 31/12/2016 15:30:00.123. 30. yyyy/MM/dd HH:mm:ss.SSS , for example 2016/12/31 15:30:00.123. 31. MMM/dd/yyyy HH:mm:ss.SSS , for example Dec/31/2016 15:30:00.123. 32. dd/MMM/yyyy HH:mm:ss.SSS , for example 31/Dec/2016 15:30:00.123. 33. yyyy/MMM/dd HH:mm:ss.SSS , for example 2016/Dec/31 15:30:00.123. 34. yyyy-MM-dd'T'HH:mm:ss.SSS , for example 2016-12-31T15:30:00.123. 35. MM-dd-yyyy HH:mm:ss.SSS , for example 12-31-2016 15:30:00.123. 36. dd-MM-yyyy HH:mm:ss.SSS , for example 31-12-2016 15:30:00.123. 37. yyyy-MM-dd HH:mm:ss.SSS , for example 2016-12-31 15:30:00.123. 38. MMM-dd-yyyy HH:mm:ss.SSS , for example Dec-31-2016 15:30:00.123. 39. dd-MMM-yyyy HH:mm:ss.SSS , for example 31-Dec-2016 15:30:00.123.

Data source	Clocks	Date formats
		40. yyyy-MMM-dd HH:mm:ss.SSS , for example 2016-Dec-31 15:30:00.123.

Unsupported values in data

If a field contains values that don't conform with the data type that Amazon Quick Sight assigns to the field, the rows containing those values are skipped. For example, take the following source data.

Sales ID	Sales Date	Sales Amount
001	10/14/2015	12.43
002	5/3/2012	25.00
003	Unknown	18.17
004	3/8/2009	86.02

Amazon Quick Sight interprets **Sales Date** as a date field and drops the row containing a nondate value, so only the following rows are imported.

Sales ID	Sales Date	Sales Amount
001	10/14/2015	12.43
002	5/3/2012	25.00
004	3/8/2009	86.02

In some cases, a database field might contain values that the JDBC driver can't interpret for the source database engine. In such cases, the uninterpretable values are replaced by null so that the rows can be imported. The only known occurrence of this issue is with MySQL date, datetime, and timestamp fields that have all-zero values, for example **0000-00-00 00:00:00**. For example, take the following source data.

Sales ID	Sales Date	Sales Amount
001	2004-10-12 09:14:27	12.43
002	2012-04-07 12:59:03	25.00

003	0000-00-00 00:00:00	18.17
004	2015-09-30 01:41:19	86.02

In this case, the following data is imported.

Sales ID	Sales Date	Sales Amount
001	2004-10-12 09:14:27	12.43
002	2012-04-07 12:59:03	25.00
003	(null)	18.17
004	2015-09-30 01:41:19	86.02

Working with datasets

Datasets are the foundation of your Quick Sight analytics, serving as the prepared and structured data sources that power your analyses and dashboards. Once you've created datasets from your data sources, you need to manage them effectively throughout their lifecycle to ensure reliable, secure, and collaborative analytics.

This section covers the complete dataset management workflow, from editing and versioning datasets to sharing them with team members and implementing security controls. You'll learn how to maintain dataset integrity while supporting collaborative analytics, track which analyses depend on your datasets, and implement both row-level and column-level security to protect sensitive information. Whether you're preparing datasets for team use, troubleshooting analysis issues, or implementing data governance policies, these topics provide the essential knowledge for effective dataset management in Quick Sight.

Topics

- [Creating datasets](#)
- [Editing datasets](#)
- [Reverting datasets back to previous published versions](#)
- [Duplicating datasets](#)
- [Sharing datasets](#)
- [Tracking dashboards and analyses that use a dataset](#)
- [Using dataset parameters in Amazon Quick](#)
- [Using row-level security in Amazon Quick](#)
- [Using column-level security to restrict access to a dataset](#)

- [Running queries as an IAM role in Amazon Quick](#)
- [Deleting datasets](#)
- [Adding a dataset to an analysis](#)

Creating datasets

You can create datasets from new or existing data sources in Amazon Quick. You can use a variety of database data sources to provide data to Amazon Quick. This includes Amazon RDS instances and Amazon Redshift clusters. It also includes MariaDB, Microsoft SQL Server, MySQL, Oracle, and PostgreSQL instances in your organization, Amazon EC2, or similar environments.

Topics

- [Creating datasets using new data sources](#)
- [Creating a dataset using an existing data source](#)
- [Creating a dataset using an existing dataset in Amazon Quick](#)

Creating datasets using new data sources

When you create a dataset based on an AWS service like Amazon RDS, Amazon Redshift, or Amazon EC2, data transfer charges might apply when consuming data from that source. Those charges might also vary depending on whether that AWS resource is in the home AWS Region that you chose for your Amazon Quick account. For details on pricing, see the pricing page for the service in question.

When creating a new database dataset, you can select one table, join several tables, or create a SQL query to retrieve the data that you want. You can also change whether the dataset uses a direct query or instead stores data in [SPICE](#).

To create a new dataset

1. To create a dataset, choose **New data set** on the **Data** page. You can then create a dataset based on an existing dataset or data source, or connect to a new data source and base the dataset on that.
2. Provide connection information to the data source:
 - For local text or Microsoft Excel files, you can simply identify the file location and upload the file.

- For Amazon S3, provide a manifest identifying the files or buckets that you want to use, and also the import settings for the target files.
- For Amazon Athena, all Athena databases for your AWS account are returned. No additional credentials are required.
- For Salesforce, provide credentials to connect with.
- For Amazon Redshift, Amazon RDS, Amazon EC2, or other database data sources, provide information about the server and database that host the data. Also provide valid credentials for that database instance.

Creating a dataset from a database

The following procedures walk you through connecting to database data sources and creating datasets. To create datasets from AWS data sources that your Amazon Quick account autodiscovered, use [Creating a dataset from an autodiscovered Amazon Redshift cluster or Amazon RDS instance](#). To create datasets from any other database data sources, use [Creating a dataset using a database that's not autodiscovered](#).

Creating a dataset from an autodiscovered Amazon Redshift cluster or Amazon RDS instance

Use the following procedure to create a connection to an autodiscovered AWS data source.

To create a connection to an autodiscovered AWS data source

1. Check [Data source quotas](#) to make sure that your target table or query doesn't exceed data source quotas.
2. Confirm that the database credentials you plan to use have appropriate permissions as described in [Required permissions](#).
3. Make sure that you have configured the cluster or instance for Amazon Quick access by following the instructions in [Network and database configuration requirements](#).
4. On the Amazon Quick start page, choose **Data**.
5. Choose **Create** then choose **New dataset**.
6. Choose either the **RDS** or the **Redshift Auto-discovered** icon, depending on the AWS service that you want to connect to.
7. Enter the connection information for the data source, as follows:
 - For **Data source name**, enter a name for the data source.

- For **Instance ID**, choose the name of the instance or cluster that you want to connect to.
 - **Database name** shows the default database for the **Instance ID** cluster or instance. To use a different database on that cluster or instance, enter its name.
 - For **UserName**, enter the user name of a user account that has permissions to do the following:
 - Access the target database.
 - Read (perform a SELECT statement on) any tables in that database that you want to use.
 - For **Password**, enter the password for the account that you entered.
8. Choose **Validate connection** to verify your connection information is correct.
 9. If the connection validates, choose **Create data source**. If not, correct the connection information and try validating again.

 Note

Amazon Quick automatically secures connections to Amazon RDS instances and Amazon Redshift clusters by using Secure Sockets Layer (SSL). You don't need to do anything to enable this.

10. Choose one of the following:

- **Custom SQL**

On the next screen, you can choose to write a query with the **Use custom SQL** option. Doing this opens a screen named **Enter custom SQL query**, where you can enter a name for your query, and then enter the SQL. For best results, compose the query in a SQL editor, and then paste it into this window. After you name and enter the query, you can choose **Edit/Preview data** or **Confirm query**. Choose **Edit/Preview data** to immediately go to data preparation. Choose **Confirm query** to validate the SQL and make sure that there are no errors.

- **Choose tables**

To connect to specific tables, for **Schema: contain sets of tables**, choose **Select** and then choose a schema. In some cases where there is only a single schema in the database, that schema is automatically chosen, and the schema selection option isn't displayed.

To prepare the data before creating an analysis, choose **Edit/Preview data** to open data preparation. Use this option if you want to join to more tables.

Otherwise, after choosing a table, choose **Select**.

11. Choose one of the following options:

- Prepare the data before creating an analysis. To do this, choose **Edit/Preview data** to open data preparation for the selected table. For more information about data preparation, see [Preparing dataset examples](#).
- Create a dataset and analysis using the table data as-is and to import the dataset data into SPICE for improved performance (recommended). To do this, check the table size and the SPICE indicator to see if you have enough capacity.

If you have enough SPICE capacity, choose **Import to SPICE for quicker analytics**, and then create an analysis by choosing **Visualize**.

 Note

If you want to use SPICE and you don't have enough space, choose **Edit/Preview data**. In data preparation, you can remove fields from the dataset to decrease its size. You can also apply a filter or write a SQL query that reduces the number of rows or columns returned. For more information about data preparation, see [Preparing dataset examples](#).

- To create a dataset and an analysis using the table data as-is, and to have the data queried directly from the database, choose the **Directly query your data** option. Then create an analysis by choosing **Visualize**.

Creating a dataset using a database that's not autodiscovered

Use the following procedure to create a connection to any database other than an autodiscovered Amazon Redshift cluster or Amazon RDS instance. Such databases include Amazon Redshift clusters and Amazon RDS instances that are in a different AWS Region or are associated with a different AWS account. They also include MariaDB, Microsoft SQL Server, MySQL, Oracle, and PostgreSQL instances that are on-premises, in Amazon EC2, or in some other accessible environment.

To create a connection to a database that isn't an autodiscovered Amazon Redshift cluster or RDS instance

1. Check [Data source quotas](#) to make sure that your target table or query doesn't exceed data source quotas.
2. Confirm that the database credentials that you plan to use have appropriate permissions as described in [Required permissions](#).
3. Make sure that you have configured the cluster or instance for Amazon Quick access by following the instructions in [Network and database configuration requirements](#).
4. On the Amazon Quick start page, choose **Manage data**.
5. Choose **Create** then choose **New data set**.
6. Choose the **Redshift Manual connect** icon if you want to connect to an Amazon Redshift cluster in another AWS Region or associated with a different AWS account. Or choose the appropriate database management system icon to connect to an instance of Amazon Aurora, MariaDB, Microsoft SQL Server, MySQL, Oracle, or PostgreSQL.
7. Enter the connection information for the data source, as follows:
 - For **Data source name**, enter a name for the data source.
 - For **Database server**, enter one of the following values:
 - For an Amazon Redshift cluster or Amazon RDS instance, enter the endpoint of the cluster or instance without the port number. For example, if the endpoint value is `clustername.1234abcd.us-west-2.redshift.amazonaws.com:1234`, then enter `clustername.1234abcd.us-west-2.redshift.amazonaws.com`. You can get the endpoint value from the **Endpoint** field on the cluster or instance detail page in the AWS console.
 - For an Amazon EC2 instance of MariaDB, Microsoft SQL Server, MySQL, Oracle, or PostgreSQL, enter the public DNS address. You can get the public DNS value from the **Public DNS** field on the instance detail pane in the Amazon EC2 console.
 - For a non-Amazon EC2 instance of MariaDB, Microsoft SQL Server, MySQL, Oracle, or PostgreSQL, enter the hostname or public IP address of the database server. If you are using Secure Sockets Layer (SSL) for a secured connection (recommended), you likely need to provide the hostname to match the information required by the SSL certificate. For a list of accepted certificates see [Amazon Quick SSL and CA certificates](#).
 - For **Port**, enter the port that the cluster or instance uses for connections.
 - For **Database name**, enter the name of the database that you want to use.

- For **UserName**, enter the user name of a user account that has permissions to do the following:
 - Access the target database.
 - Read (perform a SELECT statement on) any tables in that database that you want to use.
 - For **Password**, enter the password associated with the account you entered.
8. (Optional) If you are connecting to anything other than an Amazon Redshift cluster and you *don't* want a secured connection, make sure that **Enable SSL** is clear. *We strongly recommend leaving this checked*, because an unsecured connection can be open to tampering.

For more information on how the target instance uses SSL to secure connections, see the documentation for the target database management system. Amazon Quick doesn't accept self-signed SSL certificates as valid. For a list of accepted certificates, see [Amazon Quick SSL and CA certificates](#).

Amazon Quick automatically secures connections to Amazon Redshift clusters by using SSL. You don't need to do anything to enable this.

Some databases, such as Presto and Apache Spark, must meet additional requirements before Amazon Quick can connect. For more information, see [Creating a data source using Presto](#), or [Creating a data source using Apache Spark](#).

9. (Optional) Choose **Validate connection** to verify your connection information is correct.
10. If the connection validates, choose **Create data source**. If not, correct the connection information and try validating again.
11. Choose one of the following:
- **Custom SQL**

On the next screen, you can choose to write a query with the **Use custom SQL** option. Doing this opens a screen named **Enter custom SQL query**, where you can enter a name for your query, and then enter the SQL. For best results, compose the query in a SQL editor, and then paste it into this window. After you name and enter the query, you can choose **Edit/Preview data** or **Confirm query**. Choose **Edit/Preview data** to immediately go to data preparation. Choose **Confirm query** to validate the SQL and make sure that there are no errors.

- **Choose tables**

To connect to specific tables, for **Schema: contain sets of tables**, choose **Select** and then choose a schema. In some cases where there is only a single schema in the database, that schema is automatically chosen, and the schema selection option isn't displayed.

To prepare the data before creating an analysis, choose **Edit/Preview data** to open data preparation. Use this option if you want to join to more tables.

Otherwise, after choosing a table, choose **Select**.

12. Choose one of the following options:

- Prepare the data before creating an analysis. To do this, choose **Edit/Preview data** to open data preparation for the selected table. For more information about data preparation, see [Preparing dataset examples](#).
- Create a dataset and an analysis using the table data as-is and import the dataset data into SPICE for improved performance (recommended). To do this, check the table size and the SPICE indicator to see if you have enough space.

If you have enough SPICE capacity, choose **Import to SPICE for quicker analytics**, and then create an analysis by choosing **Visualize**.

 Note

If you want to use SPICE and you don't have enough space, choose **Edit/Preview data**. In data preparation, you can remove fields from the dataset to decrease its size. You can also apply a filter or write a SQL query that reduces the number of rows or columns returned. For more information about data preparation, see [Preparing dataset examples](#).

- Create a dataset and an analysis using the table data as-is and have the data queried directly from the database. To do this, choose the **Directly query your data** option. Then create an analysis by choosing **Visualize**.

Creating a dataset using an existing data source

After you make an initial connection to a Salesforce, AWS data store, or other database data source, Amazon Quick saves the connection information. It adds the data source to the **FROM**

EXISTING DATA SOURCES section of the **Create a Data Set** page. You can use these existing data sources to create new datasets without respecifying connection information.

Creating a dataset using an existing Amazon S3 data source

Use the following procedure to create a dataset using an existing Amazon S3 data source.

To create a dataset using an existing S3 data source

1. On the Amazon Quick start page, choose **Data**.
2. Choose **Create** then choose **New dataset**.
3. Choose the Amazon S3 data source to use.
4. To prepare the data before creating the dataset, choose **Edit/Preview data**. To create an analysis using the data as-is, choose **Visualize**.

Creating a dataset using an existing Amazon Athena data source

To create a dataset using an existing Amazon Athena data source, use the following procedure.

To create a dataset from an existing Athena connection profile

1. On the Amazon Quick start page, choose **Data**.
2. Choose **Create** then choose **New data set**.

Choose the connection profile icon for the existing data source that you want to use.

Connection profiles are labeled with the data source icon and the name provided by the person who created the connection.

3. Choose **Create data set**.

Amazon Quick creates a connection profile for this data source based only on the Athena workgroup. The database and table aren't saved.

4. On the **Choose your table** screen, do one of the following:
 - To write a SQL query, choose **Use custom SQL**.
 - To choose a database and table, first select your database from the **Database** list. Next, choose a table from the list that appears for your database.

Create a dataset using an existing Salesforce data source

Use the following procedure to create a dataset using an existing Salesforce data source.

To create a dataset using an existing Salesforce data source

1. On the Amazon Quick start page, choose **Data**.
2. Choose **Create** then choose **New data set**.
3. Choose the Salesforce data source to use.
4. Choose **Create Data Set**.
5. Choose one of the following:

- **Custom SQL**

On the next screen, you can choose to write a query with the **Use custom SQL** option. Doing this opens a screen named **Enter custom SQL query**, where you can enter a name for your query, and then enter the SQL. For best results, compose the query in a SQL editor, and then paste it into this window. After you name and enter the query, you can choose **Edit/Preview data** or **Confirm query**. Choose **Edit/Preview data** to immediately go to data preparation. Choose **Confirm query** to validate the SQL and make sure that there are no errors.

- **Choose tables**

To connect to specific tables, for **Data elements: contain your data**, choose **Select** and then choose either **REPORT** or **OBJECT**.

To prepare the data before creating an analysis, choose **Edit/Preview data** to open data preparation. Use this option if you want to join to more tables.

Otherwise, after choosing a table, choose **Select**.

6. On the next screen, choose one of the following options:
 - To create a dataset and an analysis using the data as-is, choose **Visualize**.

Note

If you don't have enough [SPICE](#) capacity, choose **Edit/Preview data**. In data preparation, you can remove fields from the dataset to decrease its size or apply a

filter that reduces the number of rows returned. For more information about data preparation, see [Preparing dataset examples](#).

- To prepare the data before creating an analysis, choose **Edit/Preview data** to open data preparation for the selected report or object. For more information about data preparation, see [Preparing dataset examples](#).

Creating a dataset using an existing database data source

Use the following procedure to create a dataset using an existing database data source.

To create a dataset using an existing database data source

1. On the Amazon Quick start page, choose **Data**.
2. Choose **Create** then choose **New data set**.
3. Choose the database data source to use, and then choose **Create Data Set**.
4. Choose one of the following:

- **Custom SQL**

On the next screen, you can choose to write a query with the **Use custom SQL** option. Doing this opens a screen named **Enter custom SQL query**, where you can enter a name for your query, and then enter the SQL. For best results, compose the query in a SQL editor, and then paste it into this window. After you name and enter the query, you can choose **Edit/Preview data** or **Confirm query**. Choose **Edit/Preview data** to immediately go to data preparation. Choose **Confirm query** to validate the SQL and make sure that there are no errors.

- **Choose tables**

To connect to specific tables, for **Schema: contain sets of tables**, choose **Select** and then choose a schema. In some cases where there is only a single schema in the database, that schema is automatically chosen, and the schema selection option isn't displayed.

To prepare the data before creating an analysis, choose **Edit/Preview data** to open data preparation. Use this option if you want to join to more tables.

Otherwise, after choosing a table, choose **Select**.

5. Choose one of the following options:

- Prepare the data before creating an analysis. To do this, choose **Edit/Preview data** to open data preparation for the selected table. For more information about data preparation, see [Preparing dataset examples](#).
- Create a dataset and an analysis using the table data as-is and import the dataset data into [SPICE](#) for improved performance (recommended). To do this, check the SPICE indicator to see if you have enough space.

If you have enough SPICE capacity, choose **Import to SPICE for quicker analytics**, and then create an analysis by choosing **Visualize**.

 Note

If you want to use SPICE and you don't have enough space, choose **Edit/Preview data**. In data preparation, you can remove fields from the dataset to decrease its size. You can also apply a filter or write a SQL query that reduces the number of rows or columns returned. For more information about data preparation, see [Preparing dataset examples](#).

- Create a dataset and an analysis using the table data as-is and have the data queried directly from the database. To do this, choose the **Directly query your data** option. Then create an analysis by choosing **Visualize**.

Creating a dataset using an existing dataset in Amazon Quick

After you create a dataset in Amazon Quick, you can create additional datasets using it as a source. When you do this, any data preparation that the parent dataset contains, such as any joins or calculated fields, is kept. You can add additional preparation to the data in the new child datasets, such as joining new data and filtering data. You can also set up your own data refresh schedule for the child dataset and track the dashboards and analyses that use it.

Child datasets that are created using a dataset with RLS rules active as a source inherit the parent dataset's RLS rules. Users who are creating a child dataset from a larger parent dataset can only see the data that they have access to in the parent dataset. Then, you can add more RLS rules to the new child dataset in addition to the inherited RLS rules to further manage who can access the data that is in the new dataset. You can only create child datasets from datasets with RLS rules active in Direct Query.

Creating datasets from existing Quick datasets has the following advantages:

- **Central management of datasets** – Data engineers can easily scale to the needs of multiple teams within their organization. To do this, they can develop and maintain a few general-purpose datasets that describe the organization's main data models.
- **Reduction of data source management** – Business analysts (BAs) often spend lots of time and effort requesting access to databases, managing database credentials, finding the right tables, and managing Quick data refresh schedules. Building new datasets from existing datasets means that BAs don't have to start from scratch with raw data from databases. They can start with curated data.
- **Predefined key metrics** – By creating datasets from existing datasets, data engineers can centrally define and maintain critical data definitions across their company's many organizations. Examples might be sales growth and net marginal return. With this feature, data engineers can also distribute changes to those definitions. This approach means that their business analysts can get started with visualizing the right data more quickly and reliably.
- **Flexibility to customize data** – By creating datasets from existing datasets, business analysts get more flexibility to customize datasets for their own business needs. They can avoid worry about disrupting data for other teams.

For example, let's say that you're part of an ecommerce central team of five data engineers. You and your team has access to sales, orders, cancellations, and returns data in a database. You have created a Quick dataset by joining 18 other dimension tables through a schema. A key metric that your team has created is the calculated field, order product sales (OPS). Its definition is: $OPS = \text{product quantity} \times \text{price}$.

Your team serves over 100 business analysts across 10 different teams in eight countries. These are the Coupons team, the Outbound Marketing team, the Mobile Platform team, and the Recommendations team. All of these teams use the OPS metric as a base to analyze their own business line.

Rather than manually creating and maintaining hundreds of unconnected datasets, your team reuses datasets to create multiple levels of datasets for teams across the organization. Doing this centralizes data management and allows each team to customize the data for their own needs. At the same time, this syncs updates to the data, such as updates to metric definitions, and maintains row-level and column-level security. For example, individual teams in your organization can use the centralized datasets. They can then combine them with the data specific to their team to create new datasets and build analyses on top of them.

Along with using the key OPS metric, other teams in your organization can reuse column metadata from the centralized datasets that you created. For example, the Data Engineering team can define metadata, such as *name*, *description*, *data type*, and *folders*, in a centralized dataset. All subsequent teams can use it.

Note

Amazon Quick supports creating up to two additional levels of datasets from a single dataset.

For example, from a parent dataset, you can create a child dataset and then a grandchild dataset for a total of three dataset levels.

Creating a dataset from an existing dataset

Use the following procedure to create a dataset from an existing dataset.

To create a dataset from an existing dataset

1. From the Quick start page, choose **Data** in the pane at left.
2. Choose **Create** then choose the dataset that you want to use to create a new dataset.
3. On the page that opens for that dataset, choose the drop-down menu for **Use in analysis**, and then choose **Use in dataset**.

The data preparation page opens and preloads everything from the parent dataset, including calculated fields, joins, and security settings.

4. On the data preparation page that opens, for **Query mode** at bottom left, choose how you want the dataset to pull in changes and updates from the original, parent dataset. You can choose the following options:
 - **Direct query** – This is the default query mode. If you choose this option, the data for this dataset automatically refreshes when you open an associated dataset, analysis, or dashboard. However, the following limitations apply:
 - If the parent dataset allows direct querying, you can use direct query mode in the child dataset.
 - If you have multiple parent datasets in a join, you can choose direct query mode for your child dataset only if all the parents are from the same underlying data source. For example, the same Amazon Redshift connection.

- Direct query is supported for a single SPICE parent dataset. It is not supported for multiple SPICE parent datasets in a join.
 - **SPICE** – If you choose this option, you can set up a schedule for your new dataset to sync with the parent dataset. For more information about creating SPICE refresh schedules for datasets, see [Refreshing SPICE data](#).
5. (Optional) Prepare your data for analysis. For more information about preparing data, see [Preparing data in Amazon Quick Sight](#).
 6. (Optional) Set up row-level or column-level security (RLS/CLS) to restrict access to the dataset. For more information about setting up RLS, see [Using row-level security with user-based rules to restrict access to a dataset](#). For more information about setting up CLS, see [Using column-level security to restrict access to a dataset](#).
-  **Note**

You can set up RLS/CLS on child datasets only. RLS/CLS on parent datasets is not supported.
7. When you're finished, choose **Save & publish** to save your changes and publish the new child dataset. Or choose **Publish & visualize** to publish the new child dataset and begin visualizing your data.

Restricting others from creating new datasets from your dataset

When you create a dataset in Amazon Quick, you can prevent others from using it as a source for other datasets. You can specify if others can use it to create any datasets at all. Or you can specify the type of datasets others can or can't create from your dataset, such as direct query datasets or SPICE datasets.

Use the following procedure to learn how to restrict others from creating new datasets from your dataset.

To restrict others from creating new datasets from your dataset

1. From the Quick start page, choose **Data** in the pane at left.
2. Choose **Create** then choose the dataset that you want to restrict creating new datasets from.
3. On the page that opens for that dataset, choose **Edit dataset**.

4. On the data preparation page that opens, choose **Manage** at upper right, and then choose **Properties**.
5. In the **Dataset properties** pane that opens, choose from the following options:
 - To restrict anyone from creating any type of new datasets from this dataset, turn off **Allow new datasets to be created from this one**.

The toggle is blue when creating new datasets is allowed. It's gray when creating new datasets isn't allowed.

- To restrict others from creating direct query datasets, clear **Allow direct query**.
- To restrict others from creating SPICE copies of your dataset, clear **Allow SPICE copies**.

For more information about SPICE datasets, see [Importing data into SPICE](#).

6. Close the pane.

Editing datasets

You can edit an existing dataset to perform data preparation. For more information about Quick Sight data preparation functionality, see [Preparing data in Amazon Quick Sight](#).

You can open a dataset for editing from the **Datasets** page, or from the analysis page. Editing a dataset from either location modifies the dataset for all analyses that use it.

Things to consider when editing datasets

In two situations, changes to a dataset might cause concern. One is if you deliberately edit the dataset. The other is if your data source has changed so much that it affects the analyses based on it.

Important

Analyses that are in production usage should be protected so they continue to function correctly.

We recommend the following when you're dealing with data changes:

- Document your data sources and datasets, and the visuals that rely upon them. Documentation should include screenshots, fields used, placement in field wells, filters, sorts, calculations, colors,

formatting, and so on. Record everything that you need to recreate the visual. You can also track which Quick Sight resources use a dataset in the dataset management options. For more information, see [Tracking dashboards and analyses that use a dataset](#).

- When you edit a dataset, try not to make changes that might break existing visuals. For example, don't remove columns that are being used in a visual. If you must remove a column, create a calculated column in its place. The replacement column should have the same name and data type as the original.
- If your data source or dataset changes in your source database, adapt your visual to accommodate the change, as described previously. Or you can try to adapt the source database. For example, you might create a view of the source table (document). Then if the table changes, you can adjust the view to include or exclude columns (attributes), change data types, fill null values, and so on. Or, in another circumstance, if your dataset is based on a slow SQL query, you might create a table to hold the results of the query.

If you can't sufficiently adapt the source of the data, recreate the visuals based on your documentation of the analysis.

- If you no longer have access to a data source, your analyses based on that source are empty. The visuals that you created still exist, but they can't display until they have some data to show. This result can happen if permissions are changed by your administrator.
- If you remove the dataset a visual is based on, you might need to recreate it from your documentation. You can edit the visual and select a new dataset to use with it. If you need to consistently use a new file to replace an older one, store your data in a location that is consistently available. For example, you might store your .csv file in Amazon S3 and create an S3 dataset to use for your visuals. For more information on access files stored in S3, see [Creating a dataset using Amazon S3 files](#).

Or you can import the data into a table, and base your visual on a query. This way, the data structures don't change, even if the data contained in them changes.

- To centralize data management, consider creating general, multiple-purpose datasets that others can use to create their own datasets from. For more information, see [Creating a dataset using an existing dataset in Amazon Quick](#).

Editing a dataset from the Datasets page

1. From the Quick start page, choose **Data** at left.

2. On the **Data** page that opens, choose the dataset that you want to edit, and then choose **Edit dataset** at upper right.

The data preparation page opens. For more information about the types of edits you can make to datasets, see [Preparing data in Amazon Quick Sight](#).

Editing a dataset in an analysis

Use the following procedure to edit a dataset from the analysis page.

To edit a dataset from the analysis page

1. In your analysis, choose the pencil icon at the top of the **Fields list** pane.
2. In **Data sets in this analysis** page that opens, choose the three dots at right of the dataset that you want to edit, and then choose **Edit**.

The dataset opens in the data preparation page. For more information about the types of edits you can make to datasets, see [Preparing data in Amazon Quick Sight](#).

Reverting datasets back to previous published versions

When you save and publish changes to a dataset in Amazon Quick Sight, a new version of the dataset is created. At any time, you can see a list of all the previous published versions of that dataset. You can also preview a specific version in that history, or even revert the dataset back to a previous version, if needed.

The following limitations apply to dataset versioning:

- Only the most recent 1,000 versions of a dataset are shown in the publishing history, and are available for versioning.
- After you exceed 1,000 published versions, the oldest versions are automatically removed from the publishing history, and the dataset can no longer be reverted back to them.

Use the following procedure to revert a dataset to a previous published version.

To revert a dataset to a previous published version

1. From the Quick start page, choose **Data**.

2. On the **Data** page, choose a dataset, and then choose **Edit dataset** at upper right.

For more information about editing datasets, see [Editing datasets](#).

3. On the dataset preparation page that opens, choose the **Manage** icon in the blue toolbar at upper right, and then choose **Publishing history**.

A list of previous published versions appears at right.

4. In the **Publishing history** pane, find the version that you want and choose **Revert**.

To preview the version before reverting, choose **Preview**.

The dataset is reverted and a confirmation message appears. The **Publishing history** pane also updates to show the active version of the dataset.

Troubleshooting reverting versions

Sometimes, the dataset can't be reverted to a specific version for one the following reasons:

- The dataset uses one or more data sources that were deleted.

If this error occurs, you can't revert the dataset to a previous version.

- Reverting would make a calculated field not valid.

If this error occurs, you can edit or remove the calculated field, and then save the dataset. Doing this creates a new version of the dataset.

- One or more columns are missing in the data source.

If this error occurs, Quick Sight shows the latest schema from the data source in the preview to reconcile differences between versions. Any calculated field, field name, field type, and filter changes shown in the schema preview are from the version that you want to revert to. You can save this reconciled schema as a new version of the dataset. Or you can return to the active (latest) version by choosing **Preview** on the top (latest) version in the publishing history.

Duplicating datasets

You can duplicate an existing dataset to save a copy of it with a new name. The new dataset is a completely separate copy.

The **Duplicate dataset** option is available if both of the following are true: you own the dataset and you have permission to the data source.

To duplicate a dataset

1. From the Quick start page, choose **Data** at left.
2. Choose the dataset that you want to duplicate.
3. On the dataset details page that opens, choose the drop-down for **Edit dataset**, and then choose **Duplicate**.
4. On the Duplicate dataset page that opens, give the duplicated dataset a name, and then choose **Duplicate**.

The duplicated dataset details page opens. From this page, you can edit the dataset, set up a refresh schedule, and more.

Sharing datasets

You can give other Quick Sight users and groups access to a dataset by sharing it with them. Then they can create analyses from it. If you make them co-owners, they can also refresh, edit, delete, or reshare the dataset.

Sharing a dataset

If you have owner permissions on a dataset, use the following procedure to share it.

To share a dataset

1. From the Quick start page, choose **Data** at left.
2. On the **Data** page, choose the dataset that you want to share.
3. On the dataset details page that opens, choose the **Permissions** tab, and then choose **Add users & groups**.
4. Enter the user or group that you want to share this dataset with, and then choose **Add**. You can only invite users who belong to the same Quick account.

Repeat this step until you have entered information for everyone you want to share the dataset with.

5. For the **Permissions** column, choose a role for each user or group to give them permissions on the dataset.

Choose **User** to allow them to create analyses and datasets from the dataset. Choose **Owner** to allow them to do that and also refresh, edit, delete, and reshare the dataset.

Users receive emails with a link to the dataset. Groups don't receive invitation emails.

Viewing and editing the permissions of users that a dataset is shared with

If you have owner permissions on a dataset, you can use the following procedure to view, edit, or change user access to it.

To view, edit, or change user access to a dataset if you have owner permissions for it

1. From the Quick start page, choose **Data** at left.
2. On the **Data** page, choose the dataset that you want to share.
3. On the dataset details page that opens, choose the **Permissions** tab.

A list of all users and groups with access to the dataset is displayed.

4. (Optional) To change permission roles for a user or group, choose the drop-down menu in the **Permissions** column for the user or group. Then choose either **User** or **Owner**.

Revoking access to a dataset

If you have owner permissions on a dataset, you can use the following procedure to revoke user access to a dataset.

To revoke user access to a dataset if you have owner permissions for it

1. From the Quick start page, choose **Data** at left.
2. On the **Data** page, choose the dataset that you want to share.
3. On the dataset details page that opens, choose the **Permissions** tab.

A list of all users and groups with access to the dataset is displayed.

4. In the **Actions** column for the user or group, choose **Revoke access**.

Tracking dashboards and analyses that use a dataset

When you create a dataset in Quick Sight, you can track which dashboards and analyses use that dataset. This approach is useful when you want to see which resources will be affected when you make changes to a dataset, or want to delete a dataset.

Use the following procedure to see which dashboards and analyses use a dataset.

To track resources that use a dataset

1. From the Quick start page, choose **Data** in the pane at left.
2. On the **Data** page, choose the dataset that you want to track resources for.
3. In the page that opens for that dataset, choose **Edit dataset**.
4. In the data preparation page that opens, choose **Manage** at upper right, and then choose **Usage**.
5. The dashboards and analyses that use the dataset are listed in the pane that opens.

Using dataset parameters in Amazon Quick

In Amazon Quick, authors can use dataset parameters in direct query to dynamically customize their datasets and apply reusable logic to their datasets. A *dataset parameter* is a parameter created at the dataset level. It's consumed by an analysis parameter through controls, calculated fields, filters, actions, URLs, titles, and descriptions. For more information on analysis parameters, see [Parameters in Amazon Quick](#). The following list describes three actions that can be performed with dataset parameters:

- **Custom SQL in direct query** – Dataset owners can insert dataset parameters into the custom SQL of a direct query dataset. When these parameters are applied to a filter control in a Quick analysis, users can filter their custom data faster and more efficiently.
- **Repeatable variables** – Static values that appear in multiple locations in the dataset page can be modified in one action using custom dataset parameters.
- **Move calculated fields to datasets** – Quick authors can copy calculated fields with parameters in an analysis and migrate them to the dataset level. This protects calculated fields at the analysis level from being accidentally modified and calculated fields be shared across multiple analyses.

In some situations, dataset parameters improve filter control performance for direct query datasets that require complex custom SQL and simplify business logic at the dataset level.

Topics

- [Dataset parameter limitations](#)
- [Creating dataset parameters in Amazon Quick](#)
- [Inserting dataset parameters into custom SQL](#)
- [Adding dataset parameters to calculated fields](#)
- [Adding dataset parameters to filters](#)
- [Using dataset parameters in Quick analyses](#)
- [Advanced use cases of dataset parameters](#)

Dataset parameter limitations

This section covers known limitations that you might encounter when working with dataset parameters in Amazon Quick.

- When dashboard readers schedule emailed reports, selected controls don't propagate to the dataset parameters that are included in the report that's attached to the email. Instead, the default values of the parameters are used.
- Dataset parameters can't be inserted into custom SQL of datasets stored in SPICE.
- Dynamic defaults can only be configured on the analysis page of the analysis that is using the dataset. You can't configure a dynamic default at the dataset level.
- The **Select all** option is not supported on multivalue controls of analysis parameters that are mapped to dataset parameters.
- Cascading controls are not supported for dataset parameters.
- Dataset parameters can only be used by dataset filters when the dataset is using direct query.
- In a custom SQL query, only 128 dataset parameters can be used.

Creating dataset parameters in Amazon Quick

Use the following procedures to get started using dataset parameters.

To create a new dataset parameter

1. From the Quick start page, choose **Data** on the left, choose the ellipsis (three dots) next to the dataset that you want to change, and then choose **Edit**.

2. On the **Dataset** page that opens, choose **Parameters** on the left, and then choose the (+) icon to create a new dataset parameter.
3. In the **Create new parameter** pop-up that appears, enter a parameter name in the **Name** box.
4. In the **Data type** dropdown, choose the parameter data type that you want. Supported data types are String, Integer, Number, and Datetime. This option can't be changed after the parameter is created.
5. For **Default value**, enter the default value that you want the parameter to have.

 Note

When you map a dataset parameter to an analysis parameter, a different default value can be chosen. When this happens, the default value configured here is overridden by the new default value.

6. For **Values**, choose the value type that you want the parameter to have. **Single value** parameters support single-select dropdowns, text field, and list controls. **Multiple values** parameters support multi-select dropdown controls. This option can't be changed after the parameter is created.
7. When you are finished configuring the new parameter, choose **Create** to create the parameter.

Inserting dataset parameters into custom SQL

You can insert dataset parameters into the custom SQL of a dataset in direct query mode by referencing it with `<<$parameter_name>>` in the SQL statement. At runtime, dashboard users can enter filter control values that are associated with a dataset parameter. Then, they can see the results in the dashboard visuals after the values propagate to the SQL query. You can use parameters to create basic filters based on customer input in where clauses. Alternatively, you could add `case when` or `if else` clauses to dynamically change the logic of the SQL query based on a parameter's input.

For example, say you want to add a `WHERE` clause to your custom SQL that filters data based on an end user's Region name. In this case, you create a single value parameter called `RegionName`:

```
SELECT *  
FROM transactions  
WHERE region = <<$RegionName>>
```

You can also let users provide multiple values to the parameter:

```
SELECT *
FROM transactions
WHERE region in (<<$RegionNames>>)
```

In the following more complex example, a dataset author refers to two dataset parameters twice based on a user's first and last names that can be selected in a dashboard filter control:

```
SELECT Region, Country, OrderDate, Sales
FROM transactions
WHERE region=
(Case
WHEN <<$UserFIRSTNAME>> In
    (select firstname from user where region='region1')
    and <<$UserLASTNAME>> In
    (select lastname from user where region='region1')
    THEN 'region1'
WHEN <<$UserFIRSTNAME>> In
    (select firstname from user where region='region2')
    and <<$UserLASTNAME>> In
    (select lastname from user where region='region2')
    THEN 'region2'
ELSE 'region3'
END)
```

You can also use parameters in SELECT clauses to create new columns in a dataset from user input:

```
SELECT Region, Country, date,
    (case
    WHEN <<$RegionName>>='EU'
    THEN sum(sales) * 0.93    --convert US dollar to euro
    WHEN <<$RegionName>>='CAN'
    THEN sum(sales) * 0.78    --convert US dollar to Canadian Dollar
    ELSE sum(sales) -- US dollar
    END
    ) as "Sales"
FROM transactions
WHERE region = <<$RegionName>>
```

To create a custom SQL query or to edit an existing query before adding a dataset parameter, see [Using SQL to customize data](#).

When you apply custom SQL with a dataset parameter, <<\$parameter_name>> is used as a placeholder value. When a user chooses one of the parameter values from a control, Quick replaces the placeholder with the values that the user selects on the dashboard.

In the following example, the user enters a new custom SQL query that filters data by state:

```
select * from all_flights
where origin_state_abr = <<$State>>
```

The default value of the parameter is applied to the SQL query and the results appear in the **Preview pane**.

Adding dataset parameters to calculated fields

You can also add dataset parameters to calculated field expressions using the format `${parameter_name}`.

When you create a calculation, you can choose from the existing parameters from the list of parameters under the **Parameters** list. You can't create a calculated field that contains a multivalued parameter.

For more information on adding calculated fields, see [Using calculated fields with parameters in Amazon Quick](#).

Adding dataset parameters to filters

For datasets in direct query mode, dataset authors can use dataset parameters in filters without custom SQL. Dataset parameters can't be added to filters if the dataset is in SPICE.

To add a dataset parameter to a filter

1. Open the dataset page of the dataset that you want to create a filter for. Choose **Filters** on the left, and then choose **Add filter**.
2. Enter the name that you want the filter to have and choose the field that you want filtered in the dropdown.
3. After you create the new filter, navigate to the filter in the **Filters** pane, choose the ellipsis (three dots) next to the filter, and then choose **Edit**.
4. For **Filter type**, choose **Custom filter**.
5. For **Filter condition**, choose the condition that you want.

6. Select the **Use parameter** box and choose the dataset parameter that you want the filter to use.
7. When you are finished making changes, choose **Apply**.

Using dataset parameters in Quick analyses

Once you create a dataset parameter, after you add the dataset to an analysis, map the dataset parameter to a new or existing analysis parameter. After you map a dataset parameter to an analysis parameter, you can use them with filters, controls, and any other analysis parameter feature.

You can manage your dataset parameters in the **Parameters** pane of the analysis that is using the dataset that the parameters belong to. In the **Dataset Parameters** section of the **Parameters** pane, you can choose to see only the unmapped dataset parameters (default). Alternatively, you can choose to see all mapped and unmapped dataset parameters by choosing **ALL** from the **Viewing** dropdown.

Mapping dataset parameters in new Quick analyses

When you create a new analysis from a dataset that contains parameters, you need to map the dataset parameters to the analysis before you can use them. This is also true when you add a dataset with parameters to an analysis. You can view all unmapped parameters in an analysis in the **Parameters** pane of the analysis. Alternatively, choose **VIEW** in the notification message that appears in the top right of the page when you create the analysis or add the dataset.

To map a dataset parameter to an analysis parameter

1. Open the [Quick console](#).
2. Choose the analysis that you want to change.
3. Choose the **Parameters** icon to open the **Parameters** pane.
4. Choose the ellipsis (three dots) next to the dataset parameter that you want to map, choose **Map Parameter**, and then choose the analysis parameter that you want to map your dataset parameter to.

If your analysis doesn't have any analysis parameters, you can choose **Map parameter** and **Create new** to create an analysis parameter that is automatically mapped to the dataset parameter upon creation.

- a. (Optional) In the **Create new parameter** pop-up that appears, for **Name**, enter a name for the new analysis parameter.
- b. (Optional) For **Static default value**, choose the static default value that you want the parameter to have.
- c. (Optional) Choose **Set a dynamic default** to set a dynamic default for the new parameter.
- d. In the **Mapped dataset parameters** table, you will see the dataset parameter that you are mapping to the new analysis parameter. You can add other dataset parameters to this analysis parameter by choosing the **ADD DATASET PARAMETER** dropdown and then choosing the parameter that you want to map. You can unmap a dataset parameter by choosing the **Remove** button next to the dataset parameter that you want to remove.

For more information on creating analysis parameters, see [Setting up parameters in Amazon Quick](#).

When you map a dataset parameter to an analysis parameter, the analysis parameter represents the dataset parameter wherever it is used in the analysis.

You can also map and unmap dataset parameters to analysis parameters in the **Edit parameter** window. To open the **Edit parameter** window, navigate to the **Parameters** pane, choose the ellipsis (three dots) next to the analysis parameter that you want to change, and then choose **Edit parameter**. You can add other dataset parameters to this analysis parameter by choosing the **ADD DATASET PARAMETER** dropdown and then choosing the parameter that you want to map. You can unmap a dataset parameter by choosing the **Remove** button next to the dataset parameter that you want to remove. You can also remove all mapped dataset parameters by choosing **REMOVE ALL**. When you are done making changes, choose **Update**.

When you delete an analysis parameter, all dataset parameters are unmapped from the analysis and appear in the **UNMAPPED** section of the **Parameters** pane. You can only map a dataset parameter to one analysis parameter at a time. To map a dataset parameter to a different analysis parameter, unmap the dataset parameter and then map it to the new analysis parameter.

Adding filter controls to mapped analysis parameters

After you map a dataset parameter to an analysis parameter in Quick, you can create filter controls for filters, actions, calculated fields, titles, descriptions, and URLs.

To add a control to a mapped parameter

1. In the **Parameters** pane of the analysis page, choose the ellipsis (three dots) next to the mapped analysis parameter that you want, and then choose **Add control**.
2. In the **Add control** window that appears, enter the **Name** that you want and choose the **Style** that you want the control to have. For single value controls, choose between Dropdown, List, and Text field. For multivalue controls, choose Dropdown.
3. Choose **Add** to create the control.

Advanced use cases of dataset parameters

This section covers more advanced options and use cases working with dataset parameters and dropdown controls. Use the following walkthroughs to create dynamic dropdown values with dataset parameters.

Using multivalue controls with dataset parameters

When you use dataset parameters that are inserted into the custom SQL of a dataset, the dataset parameters commonly filter data by values from a specific column. If you create a dropdown control and assign the parameter as the value, the dropdown only shows the value that the parameter filtered. The following procedure shows how you can create a control that is mapped to a dataset parameter and shows all unfiltered values.

To populate all assigned values in a dropdown control

1. Create a new single-column dataset in SPICE or direct query that includes all unique values from the original dataset. For example, let's say that your original dataset is using the following custom SQL:

```
select * from all_flights
      where origin_state_abr = <<$State>>
```

To create a single-column table with all unique origin states, apply the following custom SQL to the new dataset:

```
SELECT distinct origin_state_abr FROM all_flights
      order by origin_state_abr asc
```

The SQL expression returns all unique states in alphabetic order. The new dataset does not have any dataset parameters.

2. Enter a **Name** for the new dataset, and then save and publish the dataset. In our example, the new dataset is called `State Codes`.
3. Open the analysis that contains the original dataset, and add the new dataset to the analysis. For information on adding datasets to an existing analysis, see [Adding a dataset to an analysis](#).
4. Navigate to the **Controls** pane and find the dropdown control that you want to edit. Choose the ellipsis (three dots) next to the control, and then choose **Edit**.
5. In the **Format control** that appears on the left, and choose **Link to a dataset field** in the **Values** section.
6. For the **Dataset** dropdown that appears, choose the new dataset that you created. In our example, the `State Codes` dataset is chosen.
7. For the **Field** dropdown that appears, choose the appropriate field. In our example, the `origin_state_abr` field is chosen.

After you finish linking the control to the new dataset, all unique values appear in the control's dropdown. These include the values that are filtered out by the dataset parameter.

Using controls with Select all options

By default, when one or more dataset parameters are mapped to an analysis parameter and added to a control, the `Select all` option is not available. The following procedure shows a workaround that uses the same example scenario from the previous section.

Note

This walkthrough is for datasets that are small enough to load in direct query. If you have a large dataset and want to use the `Select All` option, it is recommended that you load the dataset into SPICE. However, if you want to use the `Select All` option with dataset parameters, this walkthrough describes a way to do so.

To begin, let's say you have a direct query dataset with custom SQL that contains a multivalue parameter called `States`:

```
select * from all_flights
```

```
where origin_state_abr in (<<$States>>)
```

To use the Select all option in a control that uses dataset parameters

1. In the **Parameters** pane of the analysis, find the dataset parameter that you want to use and choose **Edit** from the ellipsis (three dots) next to the parameter.
2. In the **Edit parameter** window that appears, enter a new default value in the **Static multiple default values** section. In our example, the default value is `All States`. Note that the example uses a leading space character so that the default value appears as the first item in the control.
3. Choose **Update** to update the parameter.
4. Navigate to the dataset that contains the dataset parameter that you're using in the analysis-by-analysis. Edit the custom SQL of the dataset to include a default use case for your new static multiple default values. Using the `All States` example, the SQL expression appears as follows:

```
select * from public.all_flights
where
  ' All States' in (<<$States>>) or
  origin_state_abr in (<<$States>>)
```

If the user chooses `All States` in the control, the new SQL expression returns all unique records. If the user chooses a different value from the control, the query returns values that were filtered by the dataset parameter.

Using controls with Select all and multivalue options

You can combine the previous `Select all` procedure with the multivalue control method discussed earlier to create dropdown controls that contain a `Select all` value in addition to multiple values that the user can select. This walkthrough assumes that you have followed the previous procedures, that you know how to map dataset parameters to analysis parameters, and that you can create controls in an analysis. For more information on mapping analysis parameters, see [Mapping dataset parameters in new Quick analyses](#). For more information on creating controls in an analysis that is using dataset parameters, see [Adding filter controls to mapped analysis parameters](#).

To add multiple values to a control with a Select all option and a mapped dataset parameter

1. Open the analysis that has the original dataset with a `Select all` custom SQL expression and a second dataset that includes all possible values of the filtered column that exists in the original dataset.
2. Navigate to the secondary dataset that was created earlier to return all values of a filtered column. Add a custom SQL expression that adds your previously configured `Select all` option to the query. The following example adds the `All States` record to the top of the list of returned values of the dataset:

```
(Select ' All States' as origin_state_abr)
Union All
(SELECT distinct origin_state_abr FROM all_flights
order by origin_state_abr asc)
```

3. Go back to the analysis that the datasets belong to and map the dataset parameter that you are using to the analysis parameter that you created in step 3 of the previous procedure. The analysis parameter and dataset parameter can have the same name. In our example, the analysis parameter is called `States`.
4. Create a new filter control or edit an existing filter control and choose **Hide Select All** to hide the disabled **Select All** option that appears in multivalue controls.

Once you create the control, users can use the same control to select all or multiple values of a filtered column in a dataset.

Using row-level security in Amazon Quick

Applies to: Enterprise Edition

In the Enterprise edition of Amazon Quick, you can restrict access to a dataset by configuring row-level security (RLS) on it. You can do this before or after you have shared the dataset. When you share a dataset with RLS with dataset owners, they can still see all the data. When you share it with readers, however, they can only see the data restricted by the permission dataset rules.

Also, when you embed Amazon Quick dashboards in your application for unregistered users of Quick, you can use row-level security (RLS) to filter/restrict data with tags. A tag is a user-specified string that identifies a session in your application. You can use tags to implement RLS controls for

your datasets. By configuring RLS-based restrictions in datasets, Quick filters the data based on the session tags tied to the user identity/session.

You can restrict access to a dataset using username or group-based rules, tag-based rules, or both.

Choose user-based rules if you want to secure data for users or groups provisioned (registered) in Quick. To do so, select a permissions dataset that contains rules set by columns for each user or group accessing the data. Only users or groups identified in the rules have access to data.

Choose tag-based rules only if you are using embedded dashboards and want to secure data for users not provisioned (unregistered users) in Quick. To do so, define tags on columns to secure data. Values to tags must be passed when embedding dashboards.

Topics

- [Using row-level security with user-based rules to restrict access to a dataset](#)
- [Using row-level security with tag-based rules to restrict access to a dataset when embedding dashboards for anonymous users](#)

Using row-level security with user-based rules to restrict access to a dataset

Applies to: Enterprise Edition

In the Enterprise edition of Amazon Quick, you can restrict access to a dataset by configuring row-level security (RLS) on it. You can do this before or after you have shared the dataset. When you share a dataset with RLS with dataset owners, they can still see all the data. When you share it with readers, however, they can only see the data restricted by the permission dataset rules. By adding row-level security, you can further control their access.

Note

When applying SPICE datasets to row-level security, each field in the dataset can contain up to 2,047 Unicode characters. Fields that contain more than this quota are truncated during ingestion. To learn more about SPICE data quotas, see [SPICE quotas for imported data](#).

To do this, you create a query or file with one column for user or group identification. You can use either `UserName` and `GroupName`, or alternatively `UserARN` and `GroupARN`. You can think of this as *adding a rule* for that user or group. Then you can add one column to the query or file for each field that you want to grant or restrict access to. For each user or group name that you add, you add the values for each field. You can use `NULL` (no value) to mean all values. To see examples of dataset rules, see [Creating dataset rules for row-level security](#).

To apply the dataset rules, you add the rules as a permissions dataset to your dataset. Keep in mind the following points:

- The permissions dataset can't contain duplicate values. Duplicates are ignored when evaluating how to apply the rules.
- Each user or group specified can see only the rows that *match* the field values in the dataset rules.
- If you add a rule for a user or group and leave all other columns with no value (`NULL`), you grant them access to all the data.
- If you don't add a rule for a user or group, that user or group can't see any of the data.
- The full set of rule records that are applied per user must not exceed 999. This limitation applies to the total number of rules that are directly assigned to a username, plus any rules that are assigned to the user through group names.
- If a field includes a comma (,) Amazon Quick treats each word separated from another by a comma as an individual value in the filter. For example, in ('AWS' , 'INC'), `AWS, INC` is considered as two strings: `AWS` and `INC`. To filter with `AWS, INC`, wrap the string with double quotation marks in the permissions dataset.

If the restricted dataset is a SPICE dataset, the number of filter values applied per user can't exceed 192,000 for each restricted field. This applies to the total number of filter values that are directly assigned to a username, plus any filter values that are assigned to the user through group names.

If the restricted dataset is a direct query dataset, the number of filter values applied per user varies from data sources.

Exceeding the filter value limit may cause the visual rendering to fail. We recommend adding an additional column to your restricted dataset to divide the rows into groups based on the original restricted column so that the filter list can be shortened.

Amazon Quick treats spaces as literal values. If you have a space in a field that you are restricting, the dataset rule applies to those rows. Amazon Quick treats both NULLs and blanks (empty strings "") as "no value". A NULL is an empty field value.

Depending on what data source your dataset is coming from, you can configure a direct query to access a table of permissions. Terms with spaces inside them don't need to be delimited with quotes. If you use a direct query, you can easily change the query in the original data source.

Or you can upload dataset rules from a text file or spreadsheet. If you are using a comma-separated value (CSV) file, don't include any spaces on the given line. Terms with spaces inside them need to be delimited with quotation marks. If you use dataset rules that are file-based, apply any changes by overwriting the existing rules in the dataset's permissions settings.

Datasets that are restricted are marked with the word **RESTRICTED** in the **Data** screen.

Child datasets that are created from a parent dataset that has RLS rules active retain the same RLS rules that the parent dataset has. You can add more RLS rules to the child dataset, but you can't remove the RLS rules that the dataset inherits from the parent dataset.

Child datasets that are created from a parent dataset that has RLS rules active can only be created with Direct Query. Child datasets that inherit the parent dataset's RLS rules aren't supported in SPICE.

Row-level security works only for fields containing textual data (string, char, varchar, and so on). It doesn't currently work for dates or numeric fields. Anomaly detection is not supported for datasets that use row-level security (RLS).

Creating dataset rules for row-level security

Use the following procedure to create a permissions file or query to use as dataset rules.

To create a permissions files or query to use as dataset rules

1. Create a file or a query that contains the dataset rules (permissions) for row-level security.

It doesn't matter what order the fields are in. However, all the fields are case-sensitive. Make sure that they exactly match the field names and values.

The structure should look similar to one of the following. Make sure that you have at least one field that identifies either users or groups. You can include both, but only one is required, and only one is used at a time. The field that you use for users or groups can have any name you choose.

Note

If you are specifying groups, use only Amazon Quick groups or Microsoft AD groups.

The following example shows a table with groups.

GroupName	Sales region	Segment	
EMEA-Sales	EMEA	Enterprise, SMB, Startup	
US-Sales	US	Enterprise	
US-Sales	US	SMB, Startup	
US-Sales	US	Startup	
APAC-Sales	APAC	Enterprise, SMB	
Corporate-Reporting			
APAC-Sales	APAC	Enterprise, Startup	

The following example shows a table with usernames.

UserName	Sales region	Segment	
AlejandroRosalez	EMEA	Enterprise, SMB, Startup	
MarthaRivera	US	Enterprise	
NikhilJayashankar	US	SMB, Startup	
PauloSantos	US	Startup	
SaanviSarkar	APAC	Enterprise, SMB	

UserName	Sales region	Segment	
sales-tps@example.com			
ZhangWei	APAC	Enterprise, Startup	

The following example shows a table with user and group Amazon Resource Names (ARNs).

UserARN	GroupARN	Sales region
arn:aws:quicksight:us-east-1:123456789012:user/default/Bob	arn:aws:quicksight:us-east-1:123456789012:group/default/group-1	APAC
arn:aws:quicksight:us-east-1:123456789012:user/default/Sam	arn:aws:quicksight:us-east-1:123456789012:group/default/group-2	US

Or if you use a .csv file, the structure should look similar to one of the following.

```

UserName,SalesRegion,Segment
AlejandroRosalez,EMEA,"Enterprise,SMB,Startup"
MarthaRivera,US,Enterprise
NikhilJayashankars,US,SMB
PauloSantos,US,Startup
SaanviSarkar,APAC,"SMB,Startup"
sales-tps@example.com,"",""
ZhangWei,APAC-Sales,"Enterprise,Startup"

```

```

GroupName,SalesRegion,Segment
EMEA-Sales,EMEA,"Enterprise,SMB,Startup"
US-Sales,US,Enterprise
US-Sales,US,SMB
US-Sales,US,Startup

```

```
APAC-Sales,APAC,"SMB,Startup"  
Corporate-Reporting,"",""  
APAC-Sales,APAC,"Enterprise,Startup"
```

```
UserARN,GroupARN,SalesRegion  
arn:aws:quicksight:us-east-1:123456789012:user/Bob,arn:aws:quicksight:us-  
east-1:123456789012:group/group-1,APAC  
arn:aws:quicksight:us-east-1:123456789012:user/Sam,arn:aws:quicksight:us-  
east-1:123456789012:group/group-2,US
```

Following is a SQL example.

```
/* for users*/  
select User as UserName, SalesRegion, Segment  
from tps-permissions;  
  
/* for groups*/  
select Group as GroupName, SalesRegion, Segment  
from tps-permissions;
```

2. Create a dataset for the dataset rules. To make sure that you can easily find it, give it a meaningful name, for example **Permissions-Sales-Pipeline**.

Rules Dataset flagging for row-level security

Use the following procedure to appropriately flag a dataset as a rules dataset.

Rules Dataset is a flag that distinguishes permission datasets used for row-level security from regular datasets. If a permissions dataset was applied to a regular dataset before March 31, 2025, it will have a Rules Dataset flag in the **Dataset** landing page.

If a permissions dataset was not applied to a regular dataset by March 31, 2025, it will be categorized as a regular dataset. To use it as a rules dataset, duplicate the permissions dataset and flag it as a rules dataset on the console when creating the dataset. Select EDIT DATASET and under the options, choose DUPLICATE AS RULES DATASET.

To successfully duplicate it as a rules dataset, ensure the original dataset has: 1. Required user metadata or group metadata column(s) and 2. Only string type columns.

To create a new rules dataset on the console, select NEW RULES DATASET under the NEW DATASET dropdown. When creating a rules dataset programmatically, add the following parameter: [UseAs:](#)

[RLS_RULES](#). This is an optional parameter that is only used to create a rules dataset. Once a dataset has been created, either through the console or programmatically, and flagged as either a rules dataset or a regular dataset, it cannot be changed.

Once datasets are flagged as rules datasets, Amazon Quick will apply strict SPICE ingestion rules on them. To ensure data integrity, SPICE ingestions for rules datasets will fail if there are invalid rows or cells exceeding length limits. You must fix the ingestion issues in order to re-initiate a successful ingestion. Strict ingestion rules are only applicable to rules datasets. Regular datasets will not have dataset ingestion failures when there are skipped rows or string truncations.

Applying row-level security

Use the following procedure to apply row-level security (RLS) by using a file or query as a dataset that contains the rules for permissions.

To apply row-level security by using a file or query

1. Confirm that you have added your rules as a new dataset. If you added them, but don't see them under the list of datasets, refresh the screen.
2. On the **Data** page, choose the dataset
3. On the dataset details page that opens, for **Row-level security**, choose **Set up**.
4. On the **Set up row-level security** page that opens, choose **User-based rules**.
5. From the list of datasets that appears, choose your permissions dataset.

If your permissions dataset doesn't appear on this screen, return to your datasets, and refresh the page.

6. For **Permissions policy** choose **Grant access to dataset**. Each dataset has only one active permissions dataset. If you try to add a second permissions dataset, it overwrites the existing one.

Important

Some restrictions apply to NULL and empty string values when working with row-level security:

- If your dataset has NULL values or empty strings ("") in the restricted fields, these rows are ignored when the restrictions are applied.

- Inside the permissions dataset, NULL values and empty strings are treated the same. For more information, see the following table.
- To prevent accidentally exposing sensitive information, Amazon Quick skips empty RLS rules that grant access to everyone. An *empty RLS rule* occurs when all columns of a row have no value. Quick RLS treats NULL, empty strings (""), or empty comma separated strings (for example ",",) as no value.
- After skipping empty rules, other nonempty RLS rules still apply.
- If a permission dataset has only empty rules and all of them were skipped, no one will have access to any data restricted by this permission dataset.

Rules for UserName, GroupName, SalesRegion, Segment	Granted access	
AlejandroRosalez,EMEA-Sales,EMEA,"Enterprise,SMB,Startup"	Sees all EMEA Enterprise, SMB, and Startup	
sales-tps@example.com,Corporate-Reporting,"", ""	Sees all rows	
User or group has no entry	Sees no rows	
","","",""	Skipped; sees no rows if all other rules are empty.	
NULL,"","",NULL	Skipped; sees no rows if all other rules are empty.	

Anyone whom you shared your dashboard with can see all the data in it, unless the dataset is restricted by dataset rules.

7. Choose **Apply dataset** to save your changes. Then, on the **Save data set rules?** page, choose **Apply and activate**. Changes in permissions apply immediately to existing users.
8. (Optional) To remove permissions, first remove the dataset rules from the dataset.

Make certain that the dataset rules are removed. Then, choose the permissions dataset and choose **Remove data set**.

To overwrite permissions, choose a new permissions dataset and apply it. You can reuse the same dataset name. However, make sure to apply the new permissions in the **Permissions** screen to make these permissions active. SQL queries dynamically update, so these can be managed outside of Amazon Quick. For queries, the permissions are updated when the direct query cache is automatically refreshed.

If you delete a file-based permissions dataset before you remove it from the target dataset, restricted users can't access the dataset. While the dataset is in this state, it remains marked as **RESTRICTED**. However, when you view **Permissions** for that dataset, you can see that it has no selected dataset rules.

To fix this, specify new dataset rules. Creating a dataset with the same name is not enough to fix this. You must choose the new permissions dataset on the **Permissions** screen. This restriction doesn't apply to direct SQL queries.

Using row-level security with tag-based rules to restrict access to a dataset when embedding dashboards for anonymous users

Applies to: Enterprise Edition

Intended audience: Amazon Quick Administrators and Amazon Quick developers

When you embed Amazon Quick dashboards in your application for users who are not provisioned (registered) in Quick, you can use row-level security (RLS) to filter/restrict data with tags. A tag is a user-specified string that identifies a session in your application. You can use tags to implement RLS controls for your datasets. By configuring RLS-based restrictions in datasets, Quick filters the data based on the session tags tied to the user identity/session.

For example, let's say you're a logistics company that has a customer-facing application for various retailers. Thousands of users from these retailers access your application to see metrics related to how their orders are getting shipped from your warehouse.

You don't want to manage thousands of users in Quick, so you use anonymous embedding to embed the selected dashboards in your application that your authenticated and authorized users can see. However, you want to make sure retailers see only data that is for their business and not for others. You can use RLS with tags to make sure your customers only see data that's relevant to them.

To do so, complete the following steps:

1. Add RLS tags to a dataset.
2. Assign values to those tags at runtime using the `GenerateEmbedUrlForAnonymousUser` API operation.

For more information about embedding dashboards for anonymous users using the `GenerateEmbedUrlForAnonymousUser` API operation, see [Embedding Amazon Quick Sight dashboards for anonymous \(unregistered\) users](#).

Before you can use RLS with tags, keep in mind the following points:

- Using RLS with tags is currently only supported for anonymous embedding, specifically for embedded dashboards that use the `GenerateEmbedUrlForAnonymousUser` API operation.
- Using RLS with tags isn't supported for embedded dashboards that use the `GenerateEmbedUrlForRegisteredUser` API operation or the old `GetDashboardEmbedUrl` API operation.
- RLS tags aren't supported with AWS Identity and Access Management (IAM) or the Quick identity type.
- When applying SPICE datasets to row-level security, each field in the dataset can contain up to 2,047 Unicode characters. Fields that contain more than this quota are truncated during ingestion. To learn more about SPICE data quotas, see [SPICE quotas for imported data](#).

Step 1: Add RLS tags to a dataset

You can add tag-based rules to a dataset in Amazon Quick. Alternatively, you can call the `CreateDataSet` or `UpdateDataSet` API operation and add tag-based rules that way. For more information, see [Add RLS tags to a dataset using the API](#).

Use the following procedure to add RLS tags to a dataset in Quick.

To add RLS tags to a dataset

1. From the Quick start page, choose **Data** at left.
2. Choose the dataset that you want to add RLS to.
3. On the dataset details page that opens, for **Row-level security**, choose **Set up**.
4. On the **Set up row-level security** page that opens, choose **Tag-based rules**.
5. For **Column**, choose a column that you want to add tag rules to.

For example, in the case for the logistics company, the `retailer_id` column is used.

Only columns with a string data type are listed.

6. For **Tag**, enter a tag key. You can enter any tag name that you want.

For example, in the case for the logistics company, the tag key `tag_retailer_id` is used. Doing this sets row-level security based on the retailer that's accessing the application.

7. (Optional) For **Delimiter**, choose a delimiter from the list, or enter your own.

You can use delimiters to separate text strings when assigning more than one value to a tag. The value for a delimiter can be 10 characters long, at most.

8. (Optional) For **Match all**, choose the `*`, or enter your own character or characters.

This option can be any character that you want to use when you want to filter by all the values in that column in the dataset. Instead of listing the values one by one, you can use the character. If this value is specified, it can be at least one character, or at most 256 characters long.

9. Choose **Add**.

The tag rule is added to the dataset and is listed at the bottom, but it isn't applied yet. To add another tag rule to the dataset, repeat steps 5–9. To edit a tag rule, choose the pencil icon that follows the rule. To delete a tag rule, choose the delete icon that follows the rule. You can add up to 50 tags to a dataset.

10. When you're ready to apply the tag rules to the dataset, choose **Apply rules**.
11. On the **Turn on tag-based security?** page that opens, choose **Apply and activate**.

The tag-based rules are now active. On the **Set up row-level security** page, a toggle appears for you to turn tag rules on and off for the dataset.

To turn off all tag-based rules for the dataset, switch the **Tag-Based rules** toggle off, and then enter "confirm" in the text box that appears.

On the **Data** page, a lock icon appears in the dataset row to indicate that tag rules are enabled.

You can now use tag rules to set tag values at runtime, described in [Step 2: Assign values to RLS tags at runtime](#). The rules only affect Quick readers when active.

Important

After tags are assigned and enabled on the dataset, make sure to give Quick authors permissions to see any of the data in the dataset when authoring a dashboard.

To give Quick authors permission to see data in the dataset, create a permissions file or query to use as dataset rules. For more information, see [Creating dataset rules for row-level security](#).

After you create a tag-based rule, a new **Manage rules** table appears that shows how your tag-based rules relate to each other. To make changes to the rules listed in the **Manage rules** table, choose the pencil icon that follows the rule. Then add or remove tags, and choose **Update**. To apply your updated rule to the dataset, choose **Apply**.

(Optional) Add the OR condition to RLS tags

You can also add the OR condition to your tag-based rules to further customize the way data is presented to your Quick account users. When you use the OR condition with your tag-based rules, visuals in Quick appear if at least one tag defined in the rule is valid.

To add the OR condition to your tag-based rules

1. In the **Manage rules** table, choose **Add OR condition**.
2. In the **Select tag** dropdown list that appears, choose the tag that you want to create an OR condition for. You can add up to 50 OR conditions to the **Manage rules** table. You can add multiple tags to a single column in a dataset, but at least one column tag needs to be included in a rule.
3. Choose **Update** to add the condition to your rule, then choose **Apply** to apply the updated rule to your dataset.

Add RLS tags to a dataset using the API

Alternatively, you can configure and enable tag-based row-level security on your dataset by calling the `CreateDataSet` or `UpdateDataSet` API operation. Use the following examples to learn how.

Important

When configuring session tags in the API call,

- Treat session tags as security credentials. Do not expose session tags to end users or client-side code.
- Implement server-side controls. Ensure that session tags are set exclusively by your trusted backend services, not by parameters that end users can modify.
- Protect session tags from enumeration. Ensure that users in one tenant cannot discover or guess sessionTag values belonging to other tenants.
- Review your architecture. If downstream customers or partners are allowed to call the API directly, evaluate whether those parties could specify sessionTag values for tenants they should not access.

CreateDataSet

The following is an example for creating a dataset that uses RLS with tags. It assumes the scenario of the logistics company described previously. The tags are defined in the `row-level-permission-tag-configuration` element. The tags are defined on the columns that you want to secure the data for. For more information about this optional element, see [RowLevelPermissionTagConfiguration](#) in the *Amazon Quick API Reference*.

```
create-data-set
  --aws-account-id <value>
  --data-set-id <value>
  --name <value>
  --physical-table-map <value>
  [--logical-table-map <value>]
  --import-mode <value>
  [--column-groups <value>]
  [--field-folders <value>]
  [--permissions <value>]
  [--row-level-permission-data-set <value>]
  [--column-level-permission-rules <value>]
```

```

[--tags <value>]
[--cli-input-json <value>]
[--generate-cli-skeleton <value>]
[--row-level-permission-tag-configuration
'{
  "Status": "ENABLED",
  "TagRules":
  [
    {
      "TagKey": "tag_retailer_id",
      "ColumnName": "retailer_id",
      "TagMultiValueDelimiter": ",",
      "MatchAllValue": "*"
    },
    {
      "TagKey": "tag_role",
      "ColumnName": "role"
    }
  ],
  "TagRuleConfigurations":
  [
    tag_retailer_id
  ],
  [
    tag_role
  ]
}']
]

```

The tags in this example are defined in the TagRules part of the element. In this example, two tags are defined based on two columns:

- The tag_retailer_id tag key is defined for the retailer_id column. In this case for the logistics company, this sets row-level security based on the retailer that's accessing the application.
- The tag_role tag key is defined for the role column. In this case for the logistics company, this sets an additional layer of row-level security based on the role of the user accessing your application from a specific retailer. An example is store_supervisor or manager.

For each tag, you can define TagMultiValueDelimiter and MatchAllValue. These are optional.

- **TagMultiValueDelimiter** – This option can be any string that you want to use to delimit the values when you pass them at runtime. The value can be 10 characters long, at most. In this case, a comma is used as the delimiter value.
- **MatchAllValue** – This option can be any character that you want to use when you want to filter by all the values in that column in the dataset. Instead of listing the values one by one, you can use the character. If specified, this value can be at least one character, or at most 256 characters long. In this case, an asterisk is used as the match all value.

While configuring the tags for dataset columns, turn them on or off using the mandatory property **Status**. For enabling the tag rules use the value **ENABLED** for this property. By turning on tag rules, you can use them to set tag values at runtime, described in [Step 2: Assign values to RLS tags at runtime](#).

The following is an example of the response definition.

```
{
  "Status": 201,
  "Arn": "arn:aws:quicksight:us-west-2:11112222333:dataset/RLS-Dataset",
  "DataSetId": "RLS-Dataset",
  "RequestId": "aa4f3c00-b937-4175-859a-543f250f8bb2"
}
```

UpdateDataSet

UpdateDataSet

You can use the `UpdateDataSet` API operation to add or update RLS tags for an existing dataset.

The following is an example of updating a dataset with RLS tags. It assumes the scenario of the logistics company described previously.

```
update-data-set
--aws-account-id <value>
--data-set-id <value>
--name <value>
--physical-table-map <value>
[--logical-table-map <value>]
--import-mode <value>
```

```

[--column-groups <value>
[--field-folders <value>]
[--row-level-permission-data-set <value>]
[--column-level-permission-rules <value>]
[--cli-input-json <value>]
[--generate-cli-skeleton <value>]
[--row-level-permission-tag-configuration
'{
  "Status": "ENABLED",
  "TagRules":
  [
    {
      "TagKey": "tag_retailer_id",
      "ColumnName": "retailer_id",
      "TagMultiValueDelimiter": ",",
      "MatchAllValue": "*"
    },
    {
      "TagKey": "tag_role",
      "ColumnName": "role"
    }
  ],
  "TagRuleConfigurations":
  [
    tag_retailer_id
  ],
  [
    tag_role
  ]
}']
]
```

The following is an example of the response definition.

```

{
  "Status": 201,
  "Arn": "arn:aws:quicksight:us-west-2:11112222333:dataset/RLS-Dataset",
  "DataSetId": "RLS-Dataset",
  "RequestId": "aa4f3c00-b937-4175-859a-543f250f8bb2"
}
```

⚠ Important

After tags are assigned and enabled on the dataset, make sure to give Quick authors permissions to see any of the data in the dataset when authoring a dashboard.

To give Quick authors permission to see data in the dataset, create a permissions file or query to use as dataset rules. For more information, see [Creating dataset rules for row-level security](#).

For more information about the `RowLevelPermissionTagConfiguration` element, see [RowLevelPermissionTagConfiguration](#) in the *Amazon Quick API Reference*.

Step 2: Assign values to RLS tags at runtime

You can use tags for RLS only for anonymous embedding. You can set values for tags using the `GenerateEmbedUrlForAnonymousUser` API operation.

⚠ Important

When configuring session tags in the API call,

- Treat session tags as security credentials. Do not expose session tags to end users or client-side code.
- Implement server-side controls. Ensure that session tags are set exclusively by your trusted backend services, not by parameters that end users can modify.
- Protect session tags from enumeration. Ensure that users in one tenant cannot discover or guess sessionTag values belonging to other tenants.
- Review your architecture. If downstream customers or partners are allowed to call the API directly, evaluate whether those parties could specify sessionTag values for tenants they should not access.

The following example shows how to assign values to RLS tags that were defined in the dataset in the previous step.

```
POST /accounts/AwsAccountId/embed-url/anonymous-user
HTTP/1.1
Content-type: application/json
{
```

```

"AwsAccountId": "string",
"SessionLifetimeInMinutes": integer,
"Namespace": "string", // The namespace to which the anonymous end user virtually
belongs
"SessionTags": // Optional: Can be used for row-level security
[
  {
    "Key": "tag_retailer_id",
    "Value": "West,Central,South"
  }
  {
    "Key": "tag_role",
    "Value": "shift_manager"
  }
],
"AuthorizedResourceArns":
[
  "string"
],
"ExperienceConfiguration":
{
  "Dashboard":
  {
    "InitialDashboardId": "string"
    // This is the initial dashboard ID the customer wants the user to land on. This
ID goes in the output URL.
  }
}
}

```

The following is an example of the response definition.

```

HTTP/1.1 Status
Content-type: application/json

{
  "EmbedUrl": "string",
  "RequestId": "string"
}

```

RLS support without registering users in Quick is supported only in the `GenerateEmbedUrlForAnonymousUser` API operation. In this operation, under `SessionTags`, you can define the values for the tags associated with the dataset columns.

In this case, the following assignments are defined:

- Values West, Central, and South are assigned to the `tag_retailer_id` tag at runtime. A comma is used for the delimiter, which was defined in `TagMultipleValueDelimiter` in the dataset. To use all values in the column, you can set the value to `*`, which was defined as the `MatchAllValue` when creating the tag.
- The value `shift_manager` is assigned to the `tag_role` tag.

The user using the generated URL can view only the rows having the `shift_manager` value in the `role` column. That user can view only the value West, Central, or South in the `retailer_id` column.

For more information about embedding dashboards for anonymous users using the `GenerateEmbedUrlForAnonymousUser` API operation, see [Embedding Amazon Quick Sight dashboards for anonymous \(unregistered\) users](#), or [GenerateEmbedUrlForAnonymousUser](#) in the *Amazon Quick API Reference*

Using column-level security to restrict access to a dataset

In the Enterprise edition of Quick, you can restrict access to a dataset by configuring column-level security (CLS) on it. A dataset or analysis with CLS enabled has the restricted

symbol next to it.

By default, all users and groups have access to the data. By using CLS, you can manage access to specific columns in your dataset.

If you use an analysis or dashboard that contains datasets with CLS restrictions that you don't have access to, you can't create, view, or edit visuals that use the restricted fields. For most visual types, if a visual has restricted columns that you don't have access to, you can't see the visual in your analysis or dashboard.

Tables and pivot tables behave differently. If a table or pivot table uses restricted columns in the **Rows** or **Columns** field wells, and you don't have access to these restricted columns, you can't see the visual in an analysis or dashboard. If a table or pivot table has restricted columns in the **Values** field well, you can see the table in an analysis or dashboard with only the values that you have access to. The values for restricted columns show as Not Authorized.

To enable column-level security on an analysis or dashboard, you need administrator access.

To create a new analysis with CLS

1. On the Quick start page, choose the **Analyses** tab.
2. At upper right, choose **New analysis**.
3. Choose a dataset, and choose **Column-level security**.
4. Select the columns that you want to restrict, and then choose **Next**. By default, all groups and users have access to all columns.
5. Choose who can access each column, and then choose **Apply** to save your changes.

To use an existing analysis for CLS

1. On the Quick start page, choose the **Data** tab.
2. On the Data page, open your dataset
3. On the dataset details page that opens, for **Column-level security**, choose **Set up**.
4. Select the columns that you want to restrict, and then choose **Next**. By default, all groups and users have access to all columns.
5. Choose who can access each column, and then choose **Apply** to save your changes.

To create a dashboard with CLS

1. On the Quick navigation pane, choose the **Analyses** tab.
2. Choose the analysis that you want to create a dashboard of.
3. At upper right, choose **Publish**.
4. Choose one of the following:
 - To create a new dashboard, choose **Publish new dashboard as** and enter a name for the new dashboard.
 - To replace an existing dashboard, choose **Replace an existing dashboard** and choose the dashboard from the list.

Additionally, you can choose **Advanced publish options**. For more information, see [Publishing dashboards](#).

5. Choose **Publish dashboard**.
6. (Optional) Do one of the following:

- To publish a dashboard without sharing, choose **x** at the upper right of the **Share dashboard with users** screen when it appears. You can share the dashboard later by choosing **Share** from the application bar.
- To share the dashboard, follow the procedure in [Sharing Amazon Quick Sight dashboards](#).

Running queries as an IAM role in Amazon Quick

You can enhance data security by using fine-grained access policies rather than broader permissions for data sources connected to Amazon Athena, Amazon Redshift or Amazon S3. You start by creating an AWS Identity and Access Management (IAM) role with permissions to be activated when a person or an API starts a query. Then, an Quick administrator or a developer assigns the IAM Role to an Athena or Amazon S3 data source. With the role in place, any person or API that runs the query has the exact permissions necessary to run the query.

Here are some things to consider before you commit to implementing run-as roles to enhance data security:

- Articulate how the additional security works to your advantage.
- Work with your Quick administrator to learn if adding roles to data sources helps you to better meet your security goals or requirements.
- Ask if this type of security, for the number of data sources and people and applications involved, can be feasibly documented and maintained by your team? If not, then who will undertake that part of the work?
- In a structured organization, locate stakeholders in parallel teams in Operations, Development, and IT Support. Ask for their experience, advice, and willingness to support your plan.
- Before you launch your project, consider doing a proof of concept that involves the people who need access to the data.

The following rules apply to using run-as roles with Athena, Amazon Redshift, and Amazon S3:

- Each data source can have only one associated RoleArn. Consumers of the data source, who typically access datasets and visuals, can generate many different types of queries. The role places boundaries on which queries work and which don't work.
- The ARN must correspond to an IAM role in the same AWS account as the Quick instance that uses it.

- The IAM role must have a trust relationship allowing Quick to assume the role.
- The identity that calls Quick's APIs must have permission to pass the role before they can update the `RoleArn` property. You only need to pass the role when creating or updating the role ARN. The permissions aren't re-evaluated later on. Similarly, the permission isn't required when the role ARN is omitted.
- When the role ARN is omitted, the Athena or Amazon S3 data source uses the account-wide role and scope-down policies.
- When the role ARN is present, the account-wide role and any scope-down policies are both ignored. For Athena data sources, Lake Formation permissions are not ignored.
- For Amazon S3 data sources, both the manifest file and the data specified by the manifest file must be accessible using the IAM role.
- The ARN string needs to match an existing IAM role in the AWS account and AWS Region where the data is located and queried.

When Quick connects to another service in AWS, it uses an IAM role. By default, this less granular version of the role is created by Quick for each service it uses, and the role is managed by AWS account administrators. When you add an IAM role ARN with a custom permissions policy, you override the broader role for your data sources that need extra protection. For more information about policies, see [Create a customer managed policy](#) in the IAM User Guide.

Run queries with Athena data sources

Use the API to attach the ARN to the Athena data source. To do so, add the role ARN in the [RoleArn](#) property of [AthenaParameters](#). For verification, you can see the role ARN on the **Edit Athena data source** dialog box. However, **Role ARN** is a read-only field.

To get started, you need a custom IAM role, which we demonstrate in the following example.

Keep in mind that the following code example is for learning purposes only. Use this example in a temporary development and testing environment only, and not in a production environment. The policy in this example doesn't secure any specific resource, which must be in a deployable policy. Also, even for development, you need to add your own AWS account information.

The following commands create a simple new role and attach a few policies that grant permissions to Quick.

```
aws iam create-role \  
    --role-name TestAthenaRoleForQuickSight \  
    --policy-names QuickSightAthenaPolicy,QuickSightS3Policy
```

```
--description "Test Athena Role For QuickSight" \
--assume-role-policy-document '{
  "Version": "2012-10-17"
  ,
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "quicksight.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}'
```

After you've identified or created an IAM role to use with each data source, attach the policies by using the `attach-role-policy`.

```
aws iam attach-role-policy \
  --role-name TestAthenaRoleForQuickSight \
  --policy-arn arn:aws:iam::222222222222:policy/service-role/
AWSQuickSightS3Policy1

aws iam attach-role-policy \
  --role-name TestAthenaRoleForQuickSight \
  --policy-arn arn:aws:iam::aws:policy/service-role/AWSQuicksightAthenaAccess1

aws iam attach-role-policy \
  --role-name TestAthenaRoleForQuickSight \
  --policy-arn arn:aws:iam::aws:policy/AmazonS3Access1
```

After you verify your permissions, you can use the role in Quick data sources by creating a new role or updating an existing role. When using these commands, update the AWS account ID and AWS Region to match your own.

Remember, these example code snippets are not for production environments. AWS strongly recommends that you identify and use a set of least privilege policies for your production cases.

```
aws quicksight create-data-source
  --aws-account-id 222222222222 \
  --region us-east-1 \
  --data-source-id "athena-with-custom-role" \
```

```
--cli-input-json '{
  "Name": "Athena with a custom Role",
  "Type": "ATHENA",
  "data sourceParameters": {
    "AthenaParameters": {
      "RoleArn": "arn:aws:iam::222222222222:role/
TestAthenaRoleForQuickSight"
    }
  }
}'
```

Run queries with Amazon Redshift data sources

Connect your Amazon Redshift data with the run-as role to enhance your data security with fine-grained access policies. You can create a run-as role for Amazon Redshift data sources that use a public network or a VPC connection. You specify the connection type that you want to use in the **Edit Amazon Redshift data source** dialog box. The run-as role is not supported for Amazon Redshift Serverless data sources.

To get started, you need a custom IAM role, which we demonstrate in the following example. The following commands create a sample new role and attach policies that grant permissions to Quick.

```
aws iam create-role \
--role-name TestRedshiftRoleForQuickSight \
--description "Test Redshift Role For QuickSight" \
--assume-role-policy-document '{
  "Version": "2012-10-17"
  ,
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "quicksight.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}'
```

After you identify or create an IAM role to use with each data source, attach the policies with an `attach-role-policy`. If the `redshift:GetClusterCredentialsWithIAM` permission is attached to the role that you want to use, the values for `DatabaseUser` and `DatabaseGroups` are optional.

```
aws iam attach-role-policy \
--role-name TestRedshiftRoleForQuickSight \
--policy-arn arn:aws:iam:111122223333:policy/service-role/AWSQuickSightRedshiftPolicy

aws iam create-policy --policy-name RedshiftGetClusterCredentialsPolicy1 \
--policy-document file://redshift-get-cluster-credentials-policy.json

aws iam attach-role-policy \
--role-name TestRedshiftRoleForQuickSight \
--policy-arn arn:aws:iam:111122223333:policy/RedshiftGetClusterCredentialsPolicy1
// redshift-get-cluster-credentials-policy.json
{
  "Version": "2012-10-17"      ,
  "Statement": [
    {
      "Sid": "RedshiftGetClusterCredentialsPolicy",
      "Effect": "Allow",
      "Action": [
        "redshift:GetClusterCredentials"
      ],
      "Resource": [
        "*"
      ]
    }
  ]
}
```

The example above creates a data source that uses the RoleARN, DatabaseUser, and DatabaseGroups IAM parameters. If you want to establish the connection only through the IAM RoleARN parameter, attach the `redshift:GetClusterCredentialsWithIAM` permission to your role, shown in the example below.

```
aws iam attach-role-policy \
--role-name TestRedshiftRoleForQuickSight \
--policy-arn arn:aws:iam:111122223333:policy/RedshiftGetClusterCredentialsPolicy1 //
redshift-get-cluster-credentials-policy.json {
  "Version": "2012-10-17"      ,
  "Statement": [
    {
      "Sid": "RedshiftGetClusterCredentialsPolicy",
```

```

        "Effect": "Allow",
        "Action": [ "redshift:GetClusterCredentialsWithIAM" ],
        "Resource": [ "*" ]
    }
]
}"

```

After you verify your permissions, you can use the role in Quick data sources by creating a new role or updating an existing role. When using these commands, update the AWS account ID and AWS Region to match your own.

```

aws quicksight create-data-source \
--region us-west-2 \
--endpoint https://quicksight.us-west-2.quicksight.aws.com/ \
--cli-input-json file://redshift-data-source-iam.json \
redshift-data-source-iam.json is shown as below
{
  "AwsAccountId": "AWSACCOUNTID",
  "DataSourceId": "DATSOURCEID",
  "Name": "Test redshift demo iam",
  "Type": "REDSHIFT",
  "DataSourceParameters": {
    "RedshiftParameters": {
      "Database": "integ",
      "Host": "redshiftdemocluster.us-west-2.redshift.amazonaws.com",
      "Port": 8192,
      "ClusterId": "redshiftdemocluster",
      "IAMParameters": {
        "RoleArn":
"arn:aws:iam::222222222222:role/TestRedshiftRoleForQuickSight",
        "DatabaseUser": "user",
        "DatabaseGroups": ["admin_group", "guest_group", "guest_group_1"]
      }
    }
  },
  "Permissions": [
    {
      "Principal": "arn:aws:quicksight:us-east-1:AWSACCOUNTID:user/default/demoname",
      "Actions": [
        "quicksight:DescribeDataSource",
        "quicksight:DescribeDataSourcePermissions",
        "quicksight:PassDataSource",
        "quicksight:UpdateDataSource",

```

```

        "quicksight:DeleteDataSource",
        "quicksight:UpdateDataSourcePermissions"
    ]
}
]
}

```

If your data source uses the VPC connection type, use the following VPC configuration.

```

{
  "AwsAccountId": "AWSACCOUNTID",
  "DataSourceId": "DATSOURCEID",
  "Name": "Test redshift demo iam vpc",
  "Type": "REDSHIFT",
  "DataSourceParameters": {
    "RedshiftParameters": {
      "Database": "mydb",
      "Host": "vpcdemo.us-west-2.redshift.amazonaws.com",
      "Port": 8192,
      "ClusterId": "vpcdemo",
      "IAMParameters": {
        "RoleArn":
"arn:aws:iam::222222222222:role/TestRedshiftRoleForQuickSight",
        "DatabaseUser": "user",
        "AutoCreateDatabaseUser": true
      }
    }
  },
  "VpcConnectionProperties": {
    "VpcConnectionArn": "arn:aws:quicksight:us-west-2:222222222222:vpcConnection/VPC
Name"
  },
  "Permissions": [
    {
      "Principal": "arn:aws:quicksight:us-east-1:222222222222:user/default/demoname",
      "Actions": [
        "quicksight:DescribeDataSource",
        "quicksight:DescribeDataSourcePermissions",
        "quicksight:PassDataSource",
        "quicksight:UpdateDataSource",
        "quicksight:DeleteDataSource",
        "quicksight:UpdateDataSourcePermissions"
      ]
    }
  ]
}

```

```
}  
]  
}
```

If your data source uses the `redshift:GetClusterCredentialsWithIAM` permission and doesn't use the `DatabaseUser` or `DatabaseGroups` parameters, grant the role access to some or all tables in the schema. To see if a role has been granted `SELECT` permissions to a specific table, input the following command into the Amazon Redshift Query Editor.

```
SELECT  
u.username,  
t.schemaname||'.'||t.tablename,  
has_table_privilege(u.username,t.tablename,'select') AS user_has_select_permission  
FROM  
pg_user u  
CROSS JOIN  
pg_tables t  
WHERE  
u.username = 'IAMR:RoLeName'  
AND t.tablename = tableName
```

For more information about the `SELECT` action in the Amazon Redshift Query Editor, see [SELECT](#).

To grant `SELECT` permissions to the role, input the following command in the Amazon Redshift Query Editor.

```
GRANT SELECT ON { [ TABLE ] table_name [, ...] | ALL TABLES IN SCHEMA  
schema_name [, ...] } TO "IAMR:RoLeName";
```

For more information about the `GRANT` action in the Amazon Redshift Query Editor, see [GRANT](#).

Run queries with Amazon S3 data sources

Amazon S3 data sources contain a manifest file that Quick uses to find and parse your data. You can upload a JSON manifest file through the Quick console, or you can provide a URL that points to a JSON file in an S3 bucket. If you choose to provide a URL, Quick must be granted permission to access the file in Amazon S3. Use the Quick administration console to control access to the manifest file and the data that it references.

With the **RoleArn** property, you can grant access to the manifest file and the data that it references through a custom IAM role that overrides the account-wide role. Use the API to attach the ARN to the manifest file of the Amazon S3 data source. To do so, include the role ARN in the [RoleArn](#) property of [S3Parameters](#). For verification, you can see the role ARN in the **Edit S3 data source** dialog box. However, **Role ARN** is a read-only field, as shown in the following screenshot.

To get started, create an Amazon S3 manifest file. Then, you can either upload it to Amazon Quick when you create a new Amazon S3 dataset or place the file into the Amazon S3 bucket that contains your data files. View the following example to see what a manifest file might look like:

```
{
  "fileLocations": [
    {
      "URIPrefixes": [
        "s3://quicksightUser-run-as-role/data/"
      ]
    }
  ],
  "globalUploadSettings": {
    "format": "CSV",
    "delimiter": ",",
    "textqualifier": "'",
    "containsHeader": "true"
  }
}
```

For instructions on how to create a manifest file, see [Supported formats for Amazon S3 manifest files](#).

After you have created a manifest file and added it to your Amazon S3 bucket or uploaded it to Quick, create or update an existing role in IAM that grants `s3:GetObject` access. The following example illustrates how to update an existing IAM role with the AWS API:

```
aws iam put-role-policy \
  --role-name QuickSightAccessToS3RunAsRoleBucket \
  --policy-name GrantS3RunAsRoleAccess \
  --policy-document '{
    "Version": "2012-10-17"
    ,
    "Statement": [
      {
        "Effect": "Allow",
```

```

        "Action": "s3:ListBucket",
        "Resource": "arn:aws:s3:::s3-bucket-name"
    },
    {
        "Effect": "Allow",
        "Action": "s3:GetObject",
        "Resource": "arn:aws:s3:::s3-bucket-name/manifest.json"
    },
    {
        "Effect": "Allow",
        "Action": "s3:GetObject",
        "Resource": "arn:aws:s3:::s3-bucket-name/*"
    }
]
}'

```

After your policy grants `s3:GetObject` access, you can begin creating data sources that apply the updated `put-role-policy` to the Amazon S3 data source's manifest file.

```

aws quicksight create-data-source --aws-account-id 111222333444 --region us-west-2 --
endpoint https://quicksight.us-west-2.quicksight.aws.com/ \
--data-source-id "s3-run-as-role-demo-source" \
--cli-input-json '{
    "Name": "S3 with a custom Role",
    "Type": "S3",
    "DataSourceParameters": {
        "S3Parameters": {
            "RoleArn": "arn:aws:iam::111222333444:role/
QuickSightAccessRunAsRoleBucket",
            "ManifestFileLocation": {
                "Bucket": "s3-bucket-name",
                "Key": "manifest.json"
            }
        }
    }
}'

```

After you verify your permissions, you can use the role in Quick data sources, either by creating a new role or updating an existing role. When using these commands, be sure to update the AWS account ID and AWS Region to match your own.

Deleting datasets

Important

Currently, deleting a dataset is irreversible and can cause irreversible loss of work. Deletes don't cascade to delete dependent objects. Instead, dependent objects stop working, even if you replace the deleted dataset with an identical dataset.

Before you delete a dataset, we strongly recommend that you first point each dependent analysis or dashboard to a new dataset.

Currently, when you delete a dataset while dependent visuals still exist, the analyses and dashboards that contain those visuals have no way to assimilate new metadata. They remain visible, but they can't function. They can't be repaired by adding an identical dataset.

This is because datasets include metadata that is integral to the analyses and dashboards that depend on that dataset. This metadata is uniquely generated for each dataset. Although the Quick Sight engine can read the metadata, it isn't readable by humans (for example, it doesn't contain field names). So, an exact replica of the dataset has different metadata. Each dataset's metadata is unique, even for multiple datasets that share the same name and the same fields.

To delete a dataset

1. Make sure that the dataset isn't being used by any analysis or dashboard that someone wants to keep using.

On the **Data** page, choose the dataset that you no longer need. Then choose **Delete Dataset** at upper-right.

2. If you receive a warning if this dataset is in use, track down all dependent analyses and dashboards and point them at a different dataset. If this isn't feasible, try one or more of these best practices instead of deleting it:
 - Rename the dataset, so that the dataset is clearly deprecated.
 - Filter the data, so that the dataset has no rows.
 - Remove everyone else's access to the dataset.

We recommend that you use whatever means you can to inform owners of dependent objects that this dataset is being deprecated. Also, make sure that you provide sufficient time for them to take action.

3. After you make sure that there are no dependent objects that will stop functioning after the dataset is deleted, choose the dataset and choose **Delete Data Set**. Confirm your choice, or choose **Cancel**.

Important

Currently, deleting a dataset is irreversible and can cause irreversible loss of work. Deletes don't cascade to delete dependent objects. Instead, dependent objects stop working, even if you replace the deleted dataset with an identical dataset.

Adding a dataset to an analysis

After you have created an analysis, you can add more datasets to the analysis. Then, you can use them to create more visuals.

From within the analysis, you can open any dataset for editing, for example to add or remove fields, or perform other data preparation. You can also remove or replace data sets.

The currently selected dataset displays at the top of the **Data** pane. This is the dataset that is used by the currently selected visual. Each visual can use only one dataset. Choosing a different visual changes the selected dataset to the one used by that visual.

To change the selected dataset manually, choose the dataset list at the top of the **Data** pane and then choose a different dataset. This deselects the currently selected visual if it doesn't use this dataset. Then, choose a visual that uses the selected dataset. Or choose **Add** in the **Visuals** pane to create a new visual using the selected dataset.

If you choose **Suggested** on the tool bar to see suggested visuals, you'll see visuals based on the currently selected dataset.

Only filters for the currently selected dataset are shown in the **Filter** pane, and you can only create filters on the currently selected dataset.

Topics

- [Replacing datasets](#)
- [Remove a dataset from an analysis](#)

Use the following procedure to add a dataset to an analysis or edit a dataset used by an analysis.

To add a dataset to an analysis

1. On the analysis page, navigate to the **Data** pane and expand the **Dataset** dropdown.
2. Choose **Add a new dataset** to add a dataset. Or, choose **Manage datasets** to edit a dataset. For more information about editing a dataset, see [Editing datasets](#).
3. A list of your datasets appears. Choose a dataset and then choose **Select**. To cancel, choose **Cancel**.

Replacing datasets

In an analysis, you can add, edit, replace, or remove datasets. Use this section to learn how to replace your dataset.

When you replace a dataset, the new dataset should have similar columns, if you expect the visual to work the way you designed it. Replacing the dataset also clears the undo and redo history for the analysis. This means you can't use the undo and redo buttons on the application bar to navigate your changes. So, when you decide to change the dataset, your analysis design should be somewhat stable—not in the middle of an editing phase.

To replace a dataset

1. On the analysis page, navigate to the **Data** pane and expand the **Dataset** dropdown.
2. Choose **Manage datasets**.
3. Choose the ellipsis (three dots) next to the dataset that you want to replace, and then choose **Replace**.
4. In the **Select replacement dataset** page, choose a dataset from the list, and then choose **Select**.

Note

Replacing a dataset clears the undo and redo history for this analysis.

The dataset is replaced with the new one. The field list and visuals are updated with the new dataset.

At this point, you can choose to add a new dataset, edit the new dataset, or replace it with a different one. Choose **Close** to exit.

If your new dataset doesn't match

In some cases, the selected replacement dataset doesn't contain all of the fields and hierarchies used by the visuals, filters, parameters, and calculated fields in your analysis. If so, you receive a warning from Quick Sight that shows a list of mismatched or missing columns.

If this happens, you can update the field mapping between the two datasets.

To update the field mapping

1. In the **Mismatch in replacement dataset** page, choose **Update field mapping**.
2. In the **Update field mapping** page, choose the drop-down menu for the field(s) you want to map and choose a field from the list to map it to.

If the field is missing from the new dataset, choose **Ignore this field**.

3. Choose **Confirm** to confirm your updates.
4. Choose **Close** to close the page and return to your analysis.

The dataset is replaced with the new one. The fields list and visuals are updated with the new dataset.

Any visuals that were using a field that's now missing from the new dataset update to blank. You can readd fields to the visual or remove the visual from your analysis.

If you change your mind after replacing the dataset, you can still recover. Let's say you replace the dataset and then find that it's too difficult to change your analysis to match the new dataset. You can undo any changes you made to your analysis. You can then replace the new dataset with the original one, or with a dataset that more closely matches the requirements of the analysis.

Remove a dataset from an analysis

Use the following procedure to delete a dataset from an analysis.

To delete a dataset from an analysis

1. On the analysis page, navigate to the **Data** pane and expand the **Dataset** dropdown.
2. Choose **Manage datasets**.
3. Choose the ellipsis (three dots) next to the dataset that you want to replace, and then choose **Remove**. You can't delete a dataset if it's the only one in the analysis.
4. Choose **Close** to close the dialog box.

Working with data sources in Amazon Quick Sight

Use a data source to access an external data store. Amazon S3 data sources save the manifest file information. In contrast, Salesforce and database data sources save connection information like credentials. In such cases, you can easily create multiple datasets from the data store without having to re-enter information. Connection information isn't saved for text or Microsoft Excel files.

Topics

- [Creating a data source](#)
- [Editing a data source](#)
- [Deleting a data source](#)

Creating a data source

Intended audience: Amazon Quick authors

As an analysis author in Amazon Quick, you don't need to understand anything about the infrastructure that you use to connect to your data. You set up a new data source only once.

After a data source is set up, you can access it from its tile in the Quick console. You can use it to create one or more datasets. After a dataset is set up, you can also access the dataset from its tile. By abstracting away the technical details, Amazon Quick Sight simplifies data connections.

Note

You don't need to store connection settings for files that you plan to upload manually. For more information about file uploads, see [Creating datasets](#).

Before you begin adding a new data-source connection profile to Amazon Quick, first collect the information that you need to connect to the data source. In some cases, you might plan to copy and paste settings from a file. If so, make sure that the file doesn't contain formatting characters (list bullets or numbers) or blank space characters (spaces, tabs). Also make sure that the file doesn't contain nontext "gremlin" characters such as non-ASCII, null (ASCII 0), and control characters.

The following list includes the information to collect the most commonly used settings:

- The data source to connect to.

Make sure that you know which source that you need to connect to for reporting. This source might be different than the source that stores, processes, or provides access to the data.

For example, let's say that you're a new analyst in a large company. You want to analyze data from your ordering system, which you know uses Oracle. However, you can't directly query the online transaction processing (OLTP) data. A subset of data is extracted and stored in a bucket on Amazon S3, but you don't have access to that either. Your new co-workers explain that they use AWS Glue crawlers to read the files and AWS Lake Formation to access them. With more research, you learn that you need to use an Amazon Athena query as your data source in Amazon Quick Sight. The point here is that it isn't always obvious which type of data source to choose.

- A descriptive name for the new data source tile.

Each new data source connection needs a unique and descriptive name. This name displays on the Amazon Quick Sight list of existing data sources, which is at the bottom of the **Create a Data Set** screen. Use a name that makes it easy to distinguish your data sources from other similar data sources. Your new Amazon Quick Sight data source profile displays both the database software logo and the custom name that you assign.

- The name of the server or instance to connect to.

A unique name or other identifier identifies the server connector of the data source on your network. The descriptors vary depending on which one you're connecting to, but it's usually one or more of the following:

- Hostname
- IP address
- Cluster ID
- Instance ID

- Connector
- Site-based URL
- The name of the collection of data that you want to use.

The descriptor varies depending on the data source, but it's usually one of the following:

- Database
- Warehouse
- S3 bucket
- Catalog
- Schema

In some cases, you might need to include a manifest file or a query.

- The user name that you want Amazon Quick Sight to use.

Every time Amazon Quick Sight connects using this data source profile (tile), it uses the user name from the connection settings. In some cases, this might be your personal login. But if you're going to share this with other people, ask the system administrator about creating credentials to use for Amazon Quick Sight connections.

- What type of connection to use. You can choose a public network or a VPC connection. If you have more than one VPC connection available, identify which one to use to reach your source of data.
- Additional settings, such as Secure Sockets Layer (SSL) or API tokens, are required by some data sources.

After you save the connection settings as a data source profile, you can create a dataset by selecting its tile. The connections are stored as data source connection profiles in Amazon Quick Sight.

To view your existing connection profiles, open the Quick start page, choose **Data**, choose **Create**, and then choose **New Dataset**.

For a list of supported data source connections and examples, see [Connect to your data with integrations and datasets](#).

After you create a data source in Quick Sight, you can [create a dataset](#) in Quick Sight that contains data from the connected data source. You can also [update data source connection](#) information at any time.

Editing a data source

You can edit an existing database data source to update the connection information, such as the server name or the user credentials. You can also edit an existing Amazon Athena data source to update the data source name. You can't edit Amazon S3 or Salesforce data sources.

Editing a database data source

Use the following procedure to edit a database data source.

1. From the Quick start page, choose **Data** at left. Choose **Create** and then choose **New dataset**.
2. Choose a database data source.
3. Choose **Edit Data Source**.
4. Modify the data source information:
 - If you are editing an autodiscovered database data source, you can modify any of the following settings:
 - For **Data source name**, enter a name for the data source.
 - For **Instance ID**, choose the name of the instance or cluster that you want to connect to from the list provided.
 - **Database name** shows the default database for the **Instance ID** cluster or instance. If you want to use a different database on that cluster or instance, enter its name.
 - For **UserName**, enter the user name of a user account that has permissions to do the following:
 - Access the target database.
 - Read (perform a SELECT statement on) any tables in that database that you want to use.
 - For **Password**, enter the password for the account that you entered.
 - If you are editing an external database data source, you can modify any of the following settings:
 - For **Data source name**, enter a name for the data source.
 - For **Database server**, enter one of the following values:

- For an Amazon Redshift cluster, enter the endpoint of the cluster without the port number. For example, if the endpoint value is `clustername.1234abcd.us-west-2.redshift.amazonaws.com:1234`, then enter `clustername.1234abcd.us-west-2.redshift.amazonaws.com`. You can get the endpoint value from the **Endpoint** field on the cluster detail page on the Amazon Redshift console.
 - For an Amazon EC2 instance of PostgreSQL, MySQL, or SQL Server, enter the public DNS address. You can get the public DNS value from the **Public DNS** field on the instance detail pane in the EC2 console.
 - For a non–Amazon EC2 instance of PostgreSQL, MySQL, or SQL Server, enter the hostname or public IP address of the database server.
 - For **Port**, enter the port that the cluster or instance uses for connections.
 - For **Database name**, enter the name of the database that you want to use.
 - For **UserName**, enter the user name of a user account that has permissions to do the following:
 - Access the target database.
 - Read (perform a SELECT statement on) any tables in that database that you want to use.
 - For **Password**, enter the password for the account that you entered.
5. Choose **Validate connection**.
 6. If the connection validates, choose **Update data source**. If not, correct the connection information and try validating again.
 7. If you want to create a new dataset using the updated data source, proceed with the instructions at [Creating a dataset from a database](#). Otherwise, close the **Choose your table** dialog box.

Editing an Athena data source

Use the following procedure to edit an Athena data source.

1. From the Quick start page, choose **Data** at left. Choose **Create** and then choose **New dataset**.
2. Choose an Athena data source.
3. Choose **Edit Data Source**.
4. For **Data source name**, enter a new name.

5. The **Manage data source sharing** screen appears. On the **Users** tab, locate the user that you want to remove.
6. If you want to create a new dataset using the updated data source, proceed with the instructions at [Creating a dataset using Amazon Athena data](#). Otherwise, close the **Choose your table** dialog box.

Deleting a data source

You can delete a data source if you no longer need it. Deleting a query-based database data source makes any associated datasets unusable. Deleting an Amazon S3, Salesforce, or SPICE-based database data source doesn't affect your ability to use any associated datasets. This is because the data is stored in [SPICE](#). However, you can no longer refresh those datasets.

To delete a data source

1. Choose the data source that you want to delete.
2. Choose **Delete**.

Refreshing data in Amazon Quick Sight

When refreshing data, Amazon Quick Sight handles datasets differently depending on the connection properties and the storage location of the data.

If Quick Sight connects to the data store by using a direct query, the data automatically refreshes when you open an associated dataset, analysis, or dashboard. Filter controls are refreshed automatically every 24 hours.

To refresh SPICE datasets, Quick Sight must independently authenticate using stored credentials to connect to the data. Quick Sight can't refresh manually uploaded data—even from S3 buckets, even though it's stored in SPICE—because Quick Sight doesn't store its connection and location metadata. If you want to automatically refresh data that's stored in an S3 bucket, create a dataset by using the **S3** data source card.

For files that you manually uploaded to SPICE, you refresh these manually by importing the file again. If you want to reuse the name of the original dataset for the new file, first rename or delete the original dataset. Then give the preferred name to the new dataset. Also, check that the field names are the same name and data type. Open your analysis, and replace the original dataset with the new dataset. For more information, see [Replacing datasets](#).

You can refresh your [SPICE](#) datasets at any time. Refreshing imports the data into SPICE again, so the data includes any changes since the last import.

For Amazon Quick Sight Standard Edition, you can do a full refresh of your SPICE data at any time. For Amazon Quick Sight Enterprise Edition, you can do a full refresh or an incremental refresh (SQL-based data sources only) at any time.

Note

If your dataset uses CustomSQL, refreshing incrementally might not benefit you. If the SQL query is complex, your database may not be able to optimize the filter with the look-back window. This can cause the query that pulls in the data to take longer than a full refresh. We recommend that you try reducing query execution time by refactoring the custom SQL. Note that results might vary depending on the type of optimization you make.

You can refresh SPICE data by using any of the following approaches:

- You can use the options on **Datasets** page.
- You can refresh a dataset while editing a dataset.
- You can schedule refreshes in the dataset settings.
- You can use the [CreateIngestion](#) API operation to refresh the data.

When you create or edit a SPICE dataset, you can enable email notifications about data loading status. This option notifies the owners of the dataset if the data fails to load or refresh. To turn on notifications, select the **Email owners when a refresh fails** option that appears on the **Finish dataset creation** screen. This option isn't available for datasets that you create by using **Upload a File** on the datasets page.

In the following topics, you can find an explanation of different approaches to refreshing and working with SPICE data.

Topics

- [Importing data into SPICE](#)
- [Refreshing SPICE data](#)
- [Using SPICE data in an analysis](#)
- [View SPICE ingestion history](#)

- [Troubleshooting skipped row errors](#)
- [SPICE ingestion error codes](#)
- [Updating files in a dataset](#)

Importing data into SPICE

When you import data into a dataset rather than using a direct SQL query, it becomes *SPICE data* because of how it's stored. *SPICE (Super-fast, Parallel, In-memory Calculation Engine)* is the robust in-memory engine that Amazon Quick Sight uses. It's engineered to rapidly perform advanced calculations and serve data. In Enterprise edition, data stored in SPICE is encrypted at rest.

When you create or edit a dataset, you choose to use either SPICE or a direct query, unless the dataset contains uploaded files. Importing (also called *ingesting*) your data into SPICE can save time and money:

- Your analytical queries process faster.
- You don't need to wait for a direct query to process.
- Data stored in SPICE can be reused multiple times without incurring additional costs. If you use a data source that charges per query, you're charged for querying the data when you first create the dataset and later when you refresh the dataset.

SPICE capacity is allocated separately for each AWS Region. Default SPICE capacity is automatically allocated to your home AWS Region. For each AWS account, SPICE capacity is shared by all the people using Quick Sight in a single AWS Region. The other AWS Regions have no SPICE capacity unless you choose to purchase some. Quick Sight administrators can view how much [SPICE](#) capacity you have in each AWS Region and how much of it is currently in use. A Quick Sight administrator can purchase more SPICE capacity or release unused SPICE capacity as needed. For more information, see [Configure SPICE memory capacity](#).

Topics

- [Estimating the size of SPICE datasets](#)

Estimating the size of SPICE datasets

The size of a dataset in SPICE relative to your Quick account's SPICE capacity is called *logical size*. A dataset's logical size isn't the same as the size of the dataset's source file or table. The computation

of a dataset's logical size occurs after all the data type transformations and calculated columns are defined during data preparation. These fields are materialized in SPICE in a way that enhances query performance. Any changes you make in an analysis have no effect on the logical size of the data in SPICE. Only changes that are saved in the dataset apply to SPICE capacity.

The logical size of a SPICE dataset depends on the data types of the dataset fields and the number of rows in the dataset. The three types of SPICE data are decimals, dates, and strings. You can transform a field's data type during the data preparation phase to fit your data visualization needs. For example, the file you want to import might contain all strings (text). But for these to be used in a meaningful way in an analysis, you prepare the data by changing the data types to their proper form. Fields containing prices can be changed from strings to decimals, and fields containing dates can be changed from strings to dates. You can also create calculated fields and exclude fields that you don't need from the source table. When you are finished preparing your dataset and all transformations are complete, you can estimate the logical size of the final schema.

 Note

Geospatial data types use metadata to interpret the physical data type. Latitude and longitude are numeric. All other geospatial categories are strings.

In the formula below, decimals and dates are calculated as 8 bytes per cell with 4 extra bytes for auxillary. Strings are calculated based on the text's length in UTF-8 encoding plus 24 bytes for auxillary. String data types require more space because of the extra indexing required by SPICE to provide high query performance.

```
Logical dataset size in bytes =  
(Number of Numeric cells * (12 bytes per cell))  
+ (Number of Date cells * (12 bytes per cell))  
+ SUM ((24 bytes + UTF-8 encoded length) per Text cell)
```

The formula above should only be used to estimate the size of a single dataset in SPICE. The SPICE capacity usage is the total size of all datasets in an account in a specific region. Quick Sight does not recommend that you use this formula to estimate the total SPICE capacity that your Quick Sight account is using.

Refreshing SPICE data

Refreshing a dataset

Use the following procedure to refresh a [SPICE](#) dataset based on an Amazon S3 or database data source in the **Data** tab. If there is a schema change in a database, Quick Sight will not be able to auto-detect it, resulting in an ingestion failure. Edit and save the dataset to update the schema and avoid ingestion failures.

To refresh SPICE data from the Data tab

1. Select **Data** from the left navigation menu. In the **Datasets** tab, choose the dataset to open it.
2. On the dataset details page that opens, choose the **Refresh** tab and then choose **Refresh now**.
3. Keep the refresh type as **Full refresh**.
4. If you are refreshing an Amazon S3 dataset, choose one of the following options for **S3 Manifest**:
 - To use the same manifest file you last provided to Amazon Quick Sight, choose **Existing Manifest**. If you have changed the manifest file at the file location or URL that you last provided, the data returned reflects those changes.
 - To specify a new manifest file by uploading it from your local network, choose **Upload Manifest**, and then choose **Upload manifest file**. For **Open**, choose a file, and then choose **Open**.
 - To specify a new manifest file by providing a URL, enter the URL of the manifest in **Input manifest URL**. You can find the manifest file URL in the Amazon S3 console by opening the context (right-click) menu for the manifest file, choosing **Properties**, and looking at the **Link** box.
5. Choose **Refresh**.
6. If you are refreshing an Amazon S3 dataset, choose **OK**, then **OK** again.

If you are refreshing a database dataset, choose **OK**.

Incrementally refreshing a dataset

Applies to: Enterprise Edition

For SQL-based data sources, such as Amazon Redshift, Amazon Athena, PostgreSQL, or Snowflake, you can refresh your data incrementally within a look-back window of time.

An *incremental refresh* queries only data defined by the dataset within a specified look-back window. It transfers all insertions, deletions, and modifications to the dataset, within that window's timeframe, from its source to the dataset. The data currently in SPICE that's within that window is deleted and replaced with the updates.

With incremental refreshes, less data is queried and transferred for each refresh. For example, let's say you have a dataset with 180,000 records that contains data from January 1 to June 30. On July 1, you run an incremental refresh on the data with a look-back window of seven days. Quick Sight queries the database asking for all data since June 24 (7 days ago), which is 7,000 records. Quick Sight then deletes the data currently in SPICE from June 24 and after, and appends the newly queried data. The next day (July 2), Quick Sight does the same thing, but queries from June 25 (7,000 records again), and then deletes from the existing dataset from the same date. Rather than having to ingest 180,000 records every day, it only has to ingest 7,000 records.

Use the following procedure to incrementally refresh a [SPICE](#) dataset based on a SQL data source from the **Datasets** tab.

To incrementally refresh a SQL-based SPICE dataset

1. Choose **Data** from the left navigation menu. On the **Datasets** tab, choose the dataset to open it.
2. On the dataset details page that opens, choose the **Refresh** tab and then choose **Refresh now**.
3. For **Refresh type**, choose **Incremental refresh**.
4. If this is your first incremental refresh on the dataset, choose **Configure**.
5. On the **Configure incremental refresh** page, do the following:
 - a. For **Date column**, choose a date column that you want to base the look-back window on.
 - b. For **Window size**, enter a number for **size**, and then choose an amount of time that you want to look back for changes.

You can choose to refresh changes to the data that occurred within a specified number of hours, days, or weeks from now. For example, you can choose to refresh changes to the data that occurred within two weeks of the current date.

6. Choose **Submit**.

Refreshing a dataset during data preparation

Use the following procedure to refresh a [SPICE](#) dataset based on an Amazon S3 or database data source during data preparation.

To refresh SPICE data during data preparation

1. Choose **Data** from the left navigation menu. On the **Datasets** tab, choose the dataset, and then choose **Edit Data Set**.
2. On the dataset screen, choose **Refresh now**.
3. Keep the refresh type set to **Full refresh**.
4. (Optional) If you are refreshing an Amazon S3 dataset, choose one of the following options for **S3 Manifest**:
 - To use the same manifest file that you last provided to Amazon Quick Sight, choose **Existing Manifest**. If you have changed the manifest file at the file location or URL that you last provided, the data returned reflects those changes.
 - To specify a new manifest file by uploading it from your local network, choose **Upload Manifest**, and then choose **Upload manifest file**. For **Open**, choose a file, and then choose **Open**.
 - To specify a new manifest file by providing a URL, enter the URL of the manifest in **Input manifest URL**. You can find the manifest file URL in the Amazon S3 console by opening the context (right-click) menu for the manifest file, choosing **Properties**, and looking at the **Link** box.
5. Choose **Refresh**.
6. If you are refreshing an Amazon S3 dataset, choose **OK**, then **OK** again.

If you are refreshing a database dataset, choose **OK**.

Refreshing a dataset on a schedule

Use the following procedure to schedule refreshing the data. If your dataset is based on a direct query and not stored in [SPICE](#), you can refresh your data by opening the dataset. You can also refresh your data by refreshing the page in an analysis or dashboard.

To refresh **SPICE** data on a schedule

1. Choose **Data** from the left navigation menu. On the **Datasets** tab, choose the dataset to open it.
 2. On the dataset details page that opens, choose the **Refresh** tab and then choose **Add new schedule**.
 3. On the **Create a refresh schedule** screen, choose settings for your schedule:
 - a. For **Time zone**, choose the time zone that applies to the data refresh.
 - b. For **Starting time**, choose a date and time for the refresh to start. Use HH:MM and 24-hour format, for example 13:30.
 - c. For **Frequency**, choose one of the following:
 - For Standard or Enterprise editions, you can choose **Daily**, **Weekly**, or **Monthly**.
 - **Daily**: Repeats every day.
 - **Weekly**: Repeats on the same day of each week.
 - **Monthly**: Repeats on the same day number of each month. To refresh data on the 29th, 30th or 31st day of the month, choose **Last day of month** from the list.
 - For Enterprise edition only, you can choose **Hourly**. This setting refreshes your dataset every hour, beginning at the time that you choose. So, if you select 1:05 as the starting time, the data refreshes at five minutes after the hour, every hour.
- If you decide to use an hourly refresh, you can't also use additional refresh schedules. To create an hourly schedule, remove any other existing schedules for that dataset. Also, remove any existing hourly schedule before you create a daily, weekly, or monthly schedule.
4. Choose **Save**.

Scheduled dataset ingestions take place within 10 minutes of the scheduled date and time.

Using the Quick console, you can create five schedules for each dataset. When you have created five, the **Create** button is turned off.

Incrementally refreshing a dataset on a schedule

Applies to: Enterprise Edition

For SQL-based data sources, such as Amazon Redshift, Athena, PostgreSQL, or Snowflake, you can schedule incremental refreshes. Use the following procedure to incrementally refresh a [SPICE](#) dataset based on a SQL data source in the **Datasets** tab.

To set an incremental refresh schedule for a SQL-based SPICE dataset

1. Choose **Data** from the left navigation menu. On the **Datasets** tab, choose the dataset to open it.
2. On the dataset details page that opens, choose the **Refresh** tab and then choose **Add new schedule**.
3. On the **Create a schedule** page, for **Refresh type**, choose **Incremental refresh**.
4. If this is your first incremental refresh for this dataset, choose **Configure**, and then do the following:
 - a. For **Date column**, choose a date column that you want to base the look-back window on.
 - b. For **Window size**, enter a number for **size**, and then choose an amount of time that you want to look back for changes.

You can choose to refresh changes to the data that occurred within a specified number of hours, days, or weeks from now. For example, you can choose to refresh changes to the data that occurred within two weeks of the current date.

- c. Choose **Submit**.
5. For **Time zone**, choose the time zone that applies to the data refresh.
 6. For **Repeats**, choose one of the following:
 - You can choose **Every 15 minutes**, **Every 30 minutes**, **Hourly**, **Daily**, **Weekly**, or **Monthly**.
 - **Every 15 minutes**: Repeats every 15 minutes, beginning at the time you choose. So, if you select 1:05 as the starting time, the data refreshes at 1:20, then again at 1:35, and so on.
 - **Every 30 minutes**: Repeats every 30 minutes, beginning at the time you choose. So, if you select 1:05 as the starting time, the data refreshes at 1:35, then again at 2:05, and so on.
 - **Hourly**: Repeats every hour, beginning at the time you choose. So, if you select 1:05 as the starting time, the data refreshes at five minutes after the hour, every hour.
 - **Daily**: Repeats every day.
 - **Weekly**: Repeats on the same day of each week.
 - **Monthly**: Repeats on the same day number of each month. To refresh data on the 29th, 30th or 31st day of the month, choose **Last day of month** from the list.

- If you decide to use refresh every 15 or 30 minutes, or hourly, you can't also use additional refresh schedules. To create a refresh schedule every 15 minutes, 30 minutes, or hourly, remove any other existing schedules for that dataset. Also, remove any existing minute or hourly schedule before you create a daily, weekly, or monthly schedule.
7. For **Starting**, choose a date for the refresh to start.
 8. For **At**, specify the time that the refresh should start. Use HH:MM and 24-hour format, for example 13:30.

Scheduled dataset ingestions take place within 10 minutes of the scheduled date and time.

In some cases, something might go wrong with the incremental refresh dataset that makes you want to roll back your dataset. Or you might no longer want to refresh the dataset incrementally. If so, you can delete the scheduled refresh.

To do so, choose the dataset on the **Datasets** page, choose **Schedule a refresh**, and then choose the x icon to the right of the scheduled refresh. Deleting an incremental refresh configuration starts a full refresh. As part of this full refresh, all the configurations prepared for incremental refreshes are removed.

Using SPICE data in an analysis

When you use stored data to create an analysis, a data import indicator appears next to the dataset list at the top of the **Fields list** pane. When you first open the analysis and the dataset is importing, a spinner icon appears.

After the SPICE import is complete, the indicator displays the percentage of rows that were successfully imported. A message also appears at the top of the visualization pane to provide counts of the rows imported and skipped.

If any rows were skipped, you can choose **View summary** in this message bar to see details about why those rows failed to import. To edit the dataset and resolve the issues that led to skipped rows, choose **Edit data set**. For more information about common causes for skipped rows, see [Troubleshooting skipped row errors](#).

If an import fails altogether, the data import indicator appears as an exclamation point icon, and an **Import failed** message is displayed.

View SPICE ingestion history

You can view the ingestion history for SPICE datasets to find out, for example, when the latest ingestion started and what its status is.

The SPICE ingestion history page includes the following information:

- Date and time that the ingestion started (UTC)
- Status of the ingestion
- Amount of time that the ingestion took
- The number of aggregated rows in the dataset.
- The number of rows ingested during a refresh.
- Rows skipped and rows ingested (imported) successfully
- The job type for the refresh: scheduled, full refresh, and so on

Use the following procedure to view a dataset's SPICE ingestion history.

To view a dataset's SPICE ingestion history

1. From the homepage, choose **Data** at left.
2. On the **Datasets** tab, choose the dataset that you want to examine.
3. On the dataset details page that opens, choose the **Refresh** tab.

SPICE ingestion history is shown at bottom.

4. (Optional) Choose a time frame to filter the entries from the last hour to the last 90 days.
5. (Optional) Choose a specific job status to filter the entries, for example **Running** or **Completed**. Otherwise, you can view all entries by choosing **All**.

Troubleshooting skipped row errors

When you import data, Amazon Quick Sight previews a portion of your data. If it can't interpret a row for any reason, Quick Sight skips the row. In some cases, the import will fail. When this happens, Quick Sight returns an error message that explains the failure.

Fortunately, there's a limited number of things that can go wrong. Some issues can be avoided by being aware of examples like the following:

- Make sure that there is no inconsistency between the field data type and the field data, for example occasional string data in a field with a numeric data type. Here are a few examples that can be difficult to detect when scanning the contents of a table:
 - ' ' – Using an empty string to indicate a missing value
 - 'NULL ' – Using the word "null" to indicate a missing value
 - \$1000 – Including a dollar sign in a currency value turns it into a string
 - 'O'Brien' – Using punctuation to mark a string that itself contains the same punctuation.

However, this type of error isn't always this easy to find, especially if you have a lot of data, or if your data is typed in by hand. For example, some customer service or sales applications involve entering information verbally provided by customers. The person who originally typed in the data might have put it in the wrong field. They might add, or forget to add, a character or digit. For example, they might enter a date of "0/10/12020" or enter someone's gender in a field meant for age.

- Make sure that your imported file is correctly processed with or without a header. If there is a header row, make sure that you choose the **Contains header** upload option.
- Make sure that the data doesn't exceed one or more of the [Data source quotas](#).
- Make sure that the data is compatible with the [Supported data types and values](#).
- Make sure that your calculated fields contain data that works with the calculation, rather than being incompatible with or excluded by the function in the calculated field. For example, if you have a calculated field in your dataset that uses [parseDate](#), Quick Sight skips rows where that field doesn't contain a valid date.

Quick Sight provides a detailed list of the errors that occur when the SPICE engine attempts to ingest data. When a saved dataset reports skipped rows, you can view the errors so you can take action to fix the issues.

To view errors for rows that were skipped during SPICE ingestion (data import)

1. Choose **Data** at left. In the **Datasets** tab, choose the problematic dataset to open it.
2. On the dataset details page that opens, choose the **Refresh** tab.

SPICE ingestion history is shown at bottom.

3. For the ingestion with the error, choose **View error summary**. This link is located under the **Status** column.

4. Examine the **File import log** that opens. It displays the following sections:
 - **Summary** – Provides a percentage score of how many rows were skipped out of the total number of rows in the import. For example, if there are 864 rows skipped out of a total of 1,728, the score is 50.00%.
 - **Skipped Rows** – Provides the row count, field name, and error message for each set of similar skipped rows.
 - **Troubleshooting** – Provides a link to download a file that contains error information.
5. Under **Troubleshooting**, choose **Download error rows file**.

The error file has a row for each error. The file is named `error-report_123_fe8.csv`, where `123_fe8` is replaced with a unique identifying string. The file contains the following columns:

- **ERROR_TYPE** – The type or error code for the error that occurred when importing this row. You can look up this error in the [SPICE ingestion error codes](#) section that follows this procedure.
 - **COLUMN_NAME** – The name of the column in your data that caused the error.
 - All the columns from your imported row – The remaining columns duplicate the entire row of data. If a row has more than one error, it can appear multiple times in this file.
6. Choose **Edit data set** to make changes to your dataset. You can filter the data, omit fields, change data types, adjust existing calculated fields, and add calculated fields that validate the data.
 7. After you've made changes indicated by the error codes, import the data again. If more SPICE ingestion errors appear in the log, step through this procedure again to fix all remaining errors.

Tip

If you can't solve the data issues in a reasonable amount of time by using the dataset editor, consult the administrators or developers who own the data. In the long run, it's more cost-effective to cleanse the data closer to its source, rather than adding exception processing while you're preparing the data for analysis. By fixing it at the source, you avoid a situation where multiple people fix the errors in different ways, resulting in different reporting results later on.

To practice troubleshooting skipped rows

1. Download [CSV files for troubleshooting skipped rows.zip](#).
2. Extract the files into a folder that you can use to upload the sample .csv file into Quick Sight.

The zip file contains the following two text files:

- `sample dataset - data ingestion error.csv` – A sample .csv file that contains issues that cause skipped rows. You can try to import the file yourself to see how the error process works.
 - `sample data ingestion error file` – A sample error file generated during SPICE ingestion while importing the sample .csv file into Quick Sight.
3. Import the data by following these steps:
 - a. Choose **Data, Datasets** tab, **New, Dataset**.
 - b. Choose **Upload a file**.
 - c. Find and choose the file named `sample dataset - data ingestion error.csv`.
 - d. Choose **Upload a file, Edit settings and prepare data**.
 - e. Choose **Save** to exit.
 4. Choose your dataset to view its information, then choose **View error summary**. Examine the errors and the data to help you resolve the issues.

SPICE ingestion error codes

The following list of errors codes and descriptions can help you understand and troubleshoot issues with data ingestion into SPICE.

Error codes for skipped rows

The following list of errors codes and descriptions can help you understand and troubleshoot issues with skipped rows.

ARITHMETIC_EXCEPTION – An arithmetic exception occurred while processing a value.

ENCODING_EXCEPTION – An unknown exception occurred while converting and encoding data to SPICE.

OPENSEARCH_CURSOR_NOT_ENABLED – The OpenSearch domain doesn't have SQL cursors enabled ("opendistro.sql.cursor.enabled" : "true"). For more information, see [Authorizing connections to Amazon OpenSearch Service](#).

INCORRECT_FIELD_COUNT – One or more rows have too many fields. Make sure that the number of fields in each row matches the number of fields defined in the schema.

INCORRECT_SAGEMAKER_OUTPUT_FIELD_COUNT – The SageMaker AI output has an unexpected number of fields.

INDEX_OUT_OF_BOUNDS – The system requested an index that isn't valid for the array or list being processed.

MALFORMED_DATE – A value in a field can't be transformed to a valid date. For example, if you try to convert a field that contains a value like "sale date" or "month-1", the action generates a malformed date error. To fix this error, remove nondate values from your data source. Check that you aren't importing a file with a column header mixed into the data. If your string contains a date or time that doesn't convert, see [Using unsupported or custom dates](#).

MISSING_SAGEMAKER_OUTPUT_FIELD – A field in the SageMaker AI output is unexpectedly empty.

NUMBER_BITWIDTH_TOO_LARGE – A numeric value exceeds the length supported in SPICE. For example, your numeric value has more than 19 digits, which is the length of a bigint data type. For a long numeric sequence that isn't a mathematical value, use a string data type.

NUMBER_PARSE_FAILURE – A value in a numeric field is not a number. For example, a field with a data type of int contains a string or a float.

SAGEMAKER_OUTPUT_COLUMN_TYPE_MISMATCH – The data type defined in the SageMaker AI schema doesn't match the data type received from SageMaker AI.

STRING_TRUNCATION – A string is being truncated by SPICE. Strings are truncated where the length of the string exceeds the SPICE quota. For more information about SPICE, see [Importing data into SPICE](#). For more information about quotas, see [Service Quotas](#).

UNDEFINED – An unknown error occurred while ingesting data.

UNSUPPORTED_DATE_VALUE – A date field contains a date that is in a supported format but is not in the supported range of dates, for example "12/31/1399" or "01/01/10000". For more information, see [Using unsupported or custom dates](#).

Error codes during data import

For imports and data refresh jobs that fail, Quick Sight provides an error code indicating what caused the failure. The following list of errors codes and descriptions can help you understand and troubleshoot issues with data ingestion into SPICE.

ACCOUNT_CAPACITY_LIMIT_EXCEEDED – This data exceeds your current SPICE capacity. Purchase more SPICE capacity or clean up existing SPICE data and then retry this ingestion.

CONNECTION_FAILURE – Amazon Quick Sight can't connect to your data source. Check the data source connection settings and try again.

CUSTOMER_ERROR – There was a problem parsing the data. If this persists, contact Amazon Quick Sight technical support.

DATA_SET_DELETED – The data source or dataset was deleted or became unavailable during ingestion.

DATA_SET_SIZE_LIMIT_EXCEEDED – This dataset exceeds the maximum allowable SPICE dataset size. Use filters to reduce the dataset size and try again. For information on SPICE quotas, see [Data source quotas](#).

DATA_SOURCE_AUTH_FAILED – Data source authentication failed. Check your credentials and use the **Edit data source** option to replace expired credentials.

DATA_SOURCE_CONNECTION_FAILED – Data source connection failed. Check the URL and try again. If this error persists, contact your data source administrator for assistance.

DATA_SOURCE_NOT_FOUND – No data source found. Check your Amazon Quick Sight data sources.

DATA_TOLERANCE_EXCEPTION – There are too many invalid rows. Amazon Quick Sight has reached the quota of rows that it can skip and still continue ingesting. Check your data and try again.

FAILURE_TO_ASSUME_ROLE – Amazon Quick Sight couldn't assume the correct AWS Identity and Access Management (IAM) role. Verify the policies for Amazon Quick Sight-service-role in the IAM console.

FAILURE_TO_PROCESS_JSON_FILE – Amazon Quick Sight couldn't parse a manifest file as valid JSON.

IAM_ROLE_NOT_AVAILABLE – Amazon Quick Sight doesn't have permission to access the data source. To manage Amazon Quick Sight permissions on AWS resources, go to the **Security and Permissions** page under the **Manage Amazon Quick Sight** option as an administrator.

INGESTION_CANCELED – The ingestion was canceled by the user.

INGESTION_SUPERSEDED – This ingestion has been superseded by another workflow. This happens when a new ingestion is created while another one is still in progress. Avoid manually editing the dataset multiple times in a short period, because each manual edit creates a new ingestion which will supersede and end the previous ingestion.

INTERNAL_SERVICE_ERROR – An internal service error occurred.

INVALID_DATA_SOURCE_CONFIG – Invalid values appeared in connection settings. Check your connection details and try again.

INVALID_DATAPREP_SYNTAX – Your calculated field expression contains invalid syntax. Correct the syntax and try again.

INVALID_DATE_FORMAT – An invalid date format appeared.

IOT_DATA_SET_FILE_EMPTY – No AWS IoT Analytics data was found. Check your account and try again.

IOT_FILE_NOT_FOUND – An indicated AWS IoT Analytics file wasn't found. Check your account and try again.

OAuth_TOKEN_FAILURE – Credentials to the data source have expired. Renew your credentials and retry this ingestion.

PASSWORD_AUTHENTICATION_FAILURE – Incorrect credentials appeared for a data source. Update your data source credentials and retry this ingestion.

PERMISSION_DENIED – Access to the requested resources was denied by the data source. Request permissions from your database administrator or ensure proper permission has been granted to Amazon Quick Sight before retrying.

QUERY_TIMEOUT – A query to the data source timed out waiting for a response. Check your data source logs and try again.

ROW_SIZE_LIMIT_EXCEEDED – The row size quota exceeded the maximum.

S3_FILE_INACCESSIBLE – Couldn't connect to an S3 bucket. Make sure that you grant Amazon Quick Sight and users necessary permissions before you connect to the S3 bucket.

S3_MANIFEST_ERROR – Couldn't connect to S3 data. Make sure that your S3 manifest file is valid. Also verify access to the S3 data. Both Amazon Quick Sight and the Amazon Quick Sight user need permissions to connect to the S3 data.

S3_UPLOADED_FILE_DELETED – The file or files for the ingestion were deleted (between ingestions). Check your S3 bucket and try again.

SOURCE_API_LIMIT_EXCEEDED_FAILURE – This ingestion exceeds the API quota for this data source. Contact your data source administrator for assistance.

SOURCE_RESOURCE_LIMIT_EXCEEDED – A SQL query exceeds the resource quota of the data source. Examples of resources involved can include the concurrent query quota, the connection quota, and physical server resources. Contact your data source administrator for assistance.

SPICE_TABLE_NOT_FOUND – An Amazon Quick Sight data source or dataset was deleted or became unavailable during ingestion. Check your dataset in Amazon Quick Sight and try again. For more information, see [Troubleshooting skipped row errors](#).

SQL_EXCEPTION – A general SQL error occurred. This error can be caused by query timeouts, resource constraints, unexpected data definition language (DDL) changes before or during a query, and other database errors. Check your database settings and your query, and try again.

SQL_INVALID_PARAMETER_VALUE – An invalid SQL parameter appeared. Check your SQL and try again.

SQL_NUMERIC_OVERFLOW – Amazon Quick Sight encountered an out-of-range numeric exception. Check related values and calculated columns for overflows, and try again.

SQL_SCHEMA_MISMATCH_ERROR – The data source schema doesn't match the Amazon Quick Sight dataset. Update your Amazon Quick Sight dataset definition.

SQL_TABLE_NOT_FOUND – Amazon Quick Sight can't find the table in the data source. Verify the table specified in the dataset or custom SQL and try again.

SSL_CERTIFICATE_VALIDATION_FAILURE – Amazon Quick Sight can't validate the Secure Sockets Layer (SSL) certificate on your database server. Check the SSL status on that server with your database administrator and try again.

UNRESOLVABLE_HOST – Amazon Quick Sight can't resolve the host name of the data source. Verify the host name of the data source and try again.

UNROUTABLE_HOST – Amazon Quick Sight can't reach your data source because it's inside a private network. Ensure that your private VPC connection is configured correctly in Enterprise Edition, or allow Amazon Quick Sight IP address ranges to allow connectivity for Standard Edition.

Updating files in a dataset

To get the latest version of files, you can update files in your dataset. You can update these types of files:

- Comma-delimited (CSV) and tab-delimited (TSV) text files
- Extended and common log format files (ELF and CLF)
- Flat or semistructured data files (JSON)
- Microsoft Excel (XLSX) files

Before updating a file, make sure that the new file has the same fields in the same order as the original file currently in the dataset. If there are field (column) discrepancies between the two files, an error occurs and you need to fix the discrepancies before attempting to update again. You can do this by editing the new file to match the original. Note that if you want to add new fields, you can append them after the original fields in the file. For example, in a Microsoft Excel spreadsheet, you can append new fields to the right of the original fields.

To update a file in a dataset

1. In Quick Sight, choose **Data** at left.
2. In the **Datasets** tab, choose the dataset that you want to update, and then choose **Edit dataset**.
3. On the data preparation page that opens, choose the drop-down list for the file that you want to update, and then choose **Update file**.
4. On the **Update file** page that opens, choose **Upload file**, and then navigate to a file.

Quick Sight scans the file.

5. If the file is a Microsoft Excel file, choose the sheet that you want on the **Choose your sheet** page that opens, and then choose **Select**.

6. Choose **Confirm file update** on the following page. A preview of some of the sheet columns is shown for your reference.

A message that the file updated successfully appears at top right and the table preview updates to show the new file data.

Preparing data in Amazon Quick Sight

Datasets store any data preparation you have done on that data, so that you can reuse that prepared data in multiple analyses. Data preparation provides options such as adding calculated fields, applying filters, and changing field names or data types. If you are basing the data source on a SQL database, you can also use data preparation to join tables. Or you can enter a SQL query if you want to work with data from more than a single table.

If you want to transform the data from a data source before using it in Amazon Quick Sight, you can prepare it to suit your needs. You then save this preparation as part of the dataset.

You can prepare a dataset when you create it, or by editing it later. For more information about creating a new dataset and preparing it, see [Creating datasets](#). For more information about opening an existing dataset for data preparation, see [Editing datasets](#).

Data Preparation Experience (New)

Data preparation transforms raw data into a format optimized for analysis and visualization. In business intelligence, this crucial process involves cleaning, structuring, and enriching data to enable meaningful business insights.

Amazon Quick Sight's data preparation interface revolutionizes this process with an intuitive, visual experience that enables users to create analysis-ready datasets without SQL expertise. Through its modern, streamlined approach, users can efficiently create and manage business intelligence datasets. The visual interface presents a clear, sequential view of data transformations, allowing authors to track changes from the initial state to the final output with precision.

The platform emphasizes collaboration and reusability, enabling teams to share and repurpose workflows across the organization. This collaborative design promotes consistency in data transformation practices while eliminating redundant work, ultimately fostering standardized processes across teams and enhancing overall efficiency.

Components within the data preparation experience

Amazon Quick Sight's data preparation experience has the following core components.

Workflow

A workflow in Quick Sight's data preparation experience represents a sequential series of data transformation steps that guide your dataset from its raw state to an analysis-ready form. These

workflows are designed for reusability, enabling analysts to leverage and build upon existing work while maintaining consistent data transformation standards throughout the organization.

While workflows can accommodate multiple paths through various Inputs or through Divergence (detailed in subsequent sections), they must ultimately converge into a single output table. This unified structure ensures data consistency and streamlined analysis capabilities.

Transformation

A transformation is a specific data manipulation operation that changes the structure, format, or content of your data. Quick Sight's data preparation experience offers various transformation types including Join, Filter, Aggregate, Pivot, Unpivot, Append, and Calculated Columns.

Each transformation type serves a distinct purpose in reshaping your data to meet analytical requirements. These transformations are implemented as individual steps within your workflow.

Step

A step is a collection of homogeneous transformations of the same type applied within your workflow. Each step contains one or more related operations of the same transformation category. For example, a Rename step can include multiple column renaming operations, and a Filter step can contain multiple filtering conditions—all managed as a single unit in your workflow.

Most steps can include multiple operations, with two notable exceptions: Join and Append steps are limited to two input tables per step. To join or append more than two tables, you can create additional Join or Append steps in sequence.

Steps are displayed in order, with each step building upon the results of previous steps, allowing you to track the progressive transformation of your data. To rename or delete a step, select it and choose the three-dot menu.

Connector

The connector links two steps with an arrow indicating the workflow direction. You can delete a connector by selecting it and pressing the delete key. To add a step between two existing steps, simply delete the connector, add the new step, and reconnect the steps by dragging your mouse between them.

Configure pane

The **Configuration pane** is the interactive area where you define parameters and settings for a selected step. When you select a step in your workflow, this pane displays relevant options for

that specific transformation type. For example, when configuring a Join step, you can select join type, matching columns, and other join-specific settings. The **Configuration pane**'s point-and-click interface eliminates the need for SQL knowledge.

Preview pane

The **Preview pane** displays a real-time sample of your data as it appears after applying the current transformation step. This immediate visual feedback helps you verify that each transformation produces the expected results before proceeding to the next step. The **Preview pane** updates dynamically as you modify step configurations, enabling iterative refinement of data transformations with confidence.

These components work together to create an intuitive, visual data preparation experience that makes complex data transformations accessible to business users without requiring technical expertise.

Data preparation steps

Amazon Quick Sight's data preparation experience offers eleven powerful step types that enable you to transform your data systematically. Each step serves a specific purpose in the data preparation workflow.

Steps can be configured through an intuitive interface in the **Configuration pane**, with immediate feedback visible in the **Preview pane**. Steps can be combined sequentially to create sophisticated data transformations without requiring SQL expertise.

Each step can receive input from either a physical table or the output of a previous step. Most steps accept a single input, with Append and Join steps being the exceptions—these require exactly two inputs.

Input

The Input step initiates your data preparation workflow in Quick Sight by allowing you to select and import data from multiple sources for transformation in subsequent steps.

Input options

- **Add Dataset**

Leverage existing Quick Sight datasets as input sources, building upon data that has already been prepared and optimized by your team.

- **Add Data Source**

Connect directly to databases such as Amazon Redshift, Athena, RDS, or other supported sources by selecting specific database objects and providing connection parameters.

- **Add File Upload**

Import data directly from local files in formats such as CSV, TSV, Excel, or JSON.

Configuration

The Input step requires no configuration. The **Preview** pane displays your imported data along with source information, including connection details, table name, and column metadata.

Usage notes

- Multiple Input steps can exist within a single workflow.
- You can add Input steps at any point in your workflow.

Add Calculated Columns

The Add Calculated Columns step enables you to create new columns using row-level expressions that perform calculations on existing columns. You can create new columns using scalar (row-level) functions and operators, and apply row-level calculations that reference existing columns.

Configuration

To configure the Add Calculated Columns step, in the **Configuration** pane:

1. Name your new calculated column.
2. Build expressions using the calculation editor, which supports row-level functions and operators (such as [ifelse](#) and [round](#)).
3. Save your calculation.
4. Preview the expression results.
5. Add more calculated columns as needed.

Usage notes

- Only scalar (row-level) calculations are supported in this step.

- In SPICE, calculated columns are materialized and function as standard columns in subsequent steps.

Change Data Type

Quick Sight simplifies data type management by supporting four abstract data types: `date`, `decimal`, `integer`, and `string`. These abstract types eliminate complexity by automatically mapping various source data types to their Quick Sight equivalents. For instance, `tinyint`, `smallint`, `integer`, and `bigint` are all mapped to `integer`, while `date`, `datetime`, and `timestamp` are mapped to `date`.

This abstraction means you only need to understand Quick Sight's four data types, as Quick Sight handles all underlying data type conversions and calculations automatically when interacting with different data sources.

Configuration

To configure the Change Data Type step, in the **Configuration** pane:

1. Select a column to convert.
2. Choose the target data type (`string`, `integer`, `decimal`, or `date`).
3. For date conversions, specify format settings and preview results based on input formats. See the [supported date formats](#) in Quick Sight.
4. Add additional columns to convert as needed.

Usage notes

- Convert multiple columns' data types in a single step for efficiency.
- When using SPICE, all data type changes are materialized in the imported data.

Rename Columns

The Rename Columns step enables you to modify column names to be more descriptive, user-friendly, and consistent with your organization's naming conventions.

Configuration

To configure the Rename Columns step, in the **Configuration** pane:

1. Select a column to name.
2. Enter a new name for the selected column.
3. Add more columns to rename as needed.

Usage notes

- All column names must be unique within your dataset.

Select Columns

The Select Columns step enables you to streamline your dataset by including, excluding, and reordering columns. This helps optimize your data structure by removing unnecessary columns and organizing the remaining ones in a logical sequence for analysis.

Configuration

To configure the Select Columns step, in the **Configuration** pane:

1. Choose specific columns to include in your output.
2. Select columns in your preferred order to establish sequence.
3. Use **Select All** to include remaining columns in their original order.
4. Exclude unwanted columns by leaving them unselected.

Key Features

- Output columns appear in the order of selection.
- **Select All** preserves the original column sequence.

Usage notes

- Unselected columns are removed from subsequent steps.
- Optimize dataset size by removing unnecessary columns.

Append

The Append step vertically combines two tables, similar to a SQL UNION ALL operation. Quick Sight automatically matches columns by name rather than sequence, enabling efficient data consolidation even when tables have different column orders or varying numbers of columns.

Configuration

To configure the Append step, in the **Configuration** pane:

1. Select two input tables to append.
2. Review the output column sequence.
3. Examine which columns are present in both tables versus single tables.

Key features

- Matches columns by name instead of sequence.
- Retains all rows from both tables, including duplicates.
- Supports tables with different numbers of columns.
- Follows Table 1's column sequence for matching columns, then adds unique columns from Table 2.
- Shows clear source indicators for all columns

Usage notes

- Use a Rename step first when appending columns with different names.
- Each Append step combines exactly two tables; use additional Append steps for more tables.

Join

The Join step horizontally combines data from two tables based on matching values in specified columns. Quick Sight supports Left Outer, Right Outer, Full Outer, and Inner Join types, providing flexible options for your analytical needs. The step includes intelligent column conflict resolution that automatically handles duplicate column names. While self-joins aren't available as a specific join type, you can achieve similar results using workflow divergence.

Configuration

To configure the Join step, in the **Configuration** pane:

1. Select two input tables to join.
2. Choose your join type (Left Outer, Right Outer, Full Outer, or Inner).
3. Specify join keys from each table.
4. Review auto-resolved column name conflicts.

Key features

- Supports multiple join types for different analytical needs.
- Automatically resolves duplicate column names.
- Accepts calculated columns as join keys.

Usage notes

- Join keys must have compatible data types; use the Change Data Type step if needed.
- Each Join step combines exactly two tables; use additional Join steps for more tables.
- Create a Rename step after the Join to customize auto-resolved column headers.

Aggregate

The Aggregate step enables you to summarize data by grouping columns and applying aggregation operations. This powerful transformation condenses detailed data into meaningful summaries based on your specified dimensions. Quick Sight simplifies complex SQL operations through an intuitive interface, offering comprehensive aggregation functions including advanced string operations like `ListAgg` and `ListAgg distinct`.

Configuration

To configure the Aggregate step, in the **Configuration** pane:

1. Select columns to group by.
2. Choose aggregation functions for measure columns.
3. Customize output column names.
4. For `ListAgg` and `ListAgg distinct`:

- a. Select the column to aggregate.
 - b. Choose a separator (comma, dash, semicolon, or vertical line).
5. Preview the summarized data.

Supported functions per data type

Data Type	Supported Functions
Numeric	Average, Sum Count, Count Distinct Max, Min
Date	Count, Count Distinct Max, Min ListAgg, ListAgg distinct (for date only)
String	ListAgg, ListAgg distinct Count, Count Distinct Max, Min

Key features

- Applies different aggregation functions to columns within the same step.
- **Group by** without aggregation functions acts as SQL SELECT DISTINCT.
- ListAgg concatenates all values; ListAgg distinct includes only unique values.
- ListAgg functions maintain ascending sort order by default.

Usage notes

- Aggregation significantly reduces row count in your dataset.
- ListAgg and ListAgg distinct support date values but not datetime.
- Use separators to customize string concatenation output.

Filter

The Filter step enables you to narrow down your dataset by including only rows that meet specific criteria. You can apply multiple filter conditions within a single step, all combining through AND logic to help focus your analysis on relevant data.

Configuration

To configure the Filter step, in the **Configuration** pane:

1. Select a column to filter.
2. Choose a comparison operator.
3. Specify filter values based on the column's data type.
4. Add additional filter conditions across different columns if needed.

Note

- String filters with "is in" or "is not in": Enter multiple values (one per line).
- Numeric and date filters: Enter single values (except "between" which requires two values).

Supported operators per data type

Data Type	Supported Operators
Integer and Decimal	Equals, Does not equal
	Greater than, Less than
	Is greater than or equal to, Is less than or equal to

Data Type	Supported Operators
	Is between
Date	After, Before Is between Is after or equal to, Is before or equal to
String	Equals, Does not equal Starts with, Ends with Contains, Does not contain Is in, Is not in

Usage notes

- Apply multiple filter conditions in a single step.
- Mix conditions across different data types.
- Preview filtered results in real-time.

Pivot

The Pivot step transforms row values into unique columns, converting data from a long format to a wide format for easier comparison and analysis. This transformation requires specifications for value filtering, aggregation, and grouping to manage the output columns effectively.

Configuration

To configure the Pivot step, use the following in the **Configuration** pane:

1. **Pivot column:** Select the column whose values will become column headers (e.g., Category).
2. **Pivot column row value:** Filter specific values to include (e.g., Technology, Office Supplies).
3. **Output column header:** Customize new column headers (defaults to pivot column values).

4. **Value column:** Select the column to aggregate (e.g., Sales).
5. **Aggregation function:** Choose the aggregation method (e.g., Sum).
6. **Group by:** Specify organizing columns (e.g., Segment).

Input table (full table not shown):

product_name	ship_mode	sales
Portfolio Organizer	Same Day	3054.32
USB Hub	Next Day	3465.1
Mesh Task Chair	Express	3051.43
Wall Clock	Express	3974.86
Storage Box	Next Day	321.69
Archive System	Express	644.26
Archive System	Same Day	32.14
Work Table	Same Day	1030.33
Wall Clock	Standard	568.31

Output table (full table not shown):

product_name	Standard Sales	Same Day Sales	Next Day Sales
Wireless Headset	41244.5	13722.52	21537.18
Professional Art Set	30901.940000000002	17425.24	20884.13
Ergonomic Office Chair	24058.309999999998	26860.940000000002	51962.05
View Binder	30875.64	17954.690000000002	15480.54
Drawing Markers	41170.240000000005	14449.169999999998	15397.899999999999
Wall Clock	11756.699999999999	20273.260000000002	32238.179999999997
Whiteboard	12253.109999999999	18574.629999999997	31560.699999999997
Label Printer	14349.65	18759.739999999998	12415.79

Configuration:

Pivot column

Column values become new column headers in output

Pivot column

ship_mode

Only STRING data type is supported

Pivot column row value

Standard

Same Day

Next Day

Output column header

Standard Sales

Columns identify rows of output

1 group by column

Group by columns

product_name

Supported operators per data type

Data Type	Supported Operators
Integer and Decimal	Average, Sum Count, Count Distinct Max, Min
Date	Count, Count Distinct Max, Min ListAgg, ListAgg distinct (date values only)
String	

Data Type	Supported Operators
	ListAgg, ListAgg distinct
	Count, Count Distinct
	Max, Min

Usage notes

- Each pivoted column contains aggregated values from the value column.
- Customize column headers for clarity.
- Preview transformation results in real-time.

Unpivot

The Unpivot step transforms columns into rows, converting wide data into a longer, narrower format. This transformation helps organize data spread across multiple columns into a more structured format for easier analysis and visualization.

Configuration

To configure the Unpivot step, in the **Configuration** pane:

1. Select columns to unpivot into rows.
2. Define output column row values. The default is the original column name. Some examples include Technology, Office Supplies, and Furniture.
3. Name the two new outputs columns.
 - **Unpivoted column header:** The name for former column names (e.g., Category)
 - **Unpivoted column values:** The name for the unpivoted values (e.g., Sales)

Input table (full table not shown):

product_name	Standard Sales	Same Day Sales	Next Day Sales
Wireless Headset	42444.6	15522.62	21557.18
Professional Art Set	50901.940000000002	17425.24	20984.13
Ergonomic Office Chair	24058.309999999998	26860.940000000002	51962.05
View Binder	30875.54	17954.690000000002	15480.54
Drawing Markers	41170.240000000005	16449.169999999998	15387.789999999999
Wall Clock	15756.699999999999	20275.260000000002	32238.179999999997
Whiteboard	12253.109999999999	18574.629999999997	51560.699999999997
Label Printer	14349.65	18759.739999999998	12415.79
Laser Printer	46872.649999999994	29048.97	10125.82
Executive Leather Chair	23222.37	11613.26	14295.25

Output table (full table not shown):

product_name	Ship Mode	Sales
Wireless Headset	Standard	42444.6
Professional Art Set	Standard	50901.940000000002
Ergonomic Office Chair	Standard	24058.309999999998
View Binder	Standard	30875.54
Drawing Markers	Standard	41170.240000000005
Wall Clock	Standard	15756.699999999999
Whiteboard	Standard	12253.109999999999
Label Printer	Standard	14349.65
Laser Printer	Standard	46872.649999999994

Configuration:

Unpivot columns

Select columns to unpivot

Same Day Sales

Next Day Sales

Output column row value

Standard

Same Day

Next Day

Actions

Name output columns

Columns for unpivoted column headers

Ship Mode

Columns for unpivoted column values

Sales

Key features

- Retains all non-unpivoted columns in the output.
- Creates two new columns automatically: one for former column names and one for their corresponding values.
- Transforms wide data into long format.

Usage notes

- All unpivoted columns must have compatible data types.
- Row count typically increases after unpivoting.
- Preview changes in real-time before applying them.

Advanced workflow capabilities

Amazon Quick Sight's data preparation experience offers sophisticated features that enhance your ability to create complex, reusable data transformations. This section covers two powerful capabilities that extend your workflow potential.

Divergence enables you to create multiple transformation paths from a single step, allowing parallel processing streams that can be recombined later. This capability is particularly valuable for complex scenarios like self-joins and parallel transformations.

Composite Datasets allow you to build hierarchical data structures by using existing datasets as building blocks. This feature promotes collaboration across teams and ensures consistent business logic through reusable, layered transformations.

These capabilities work together to provide flexible workflow designs, enhanced team collaboration, and reusable data transformations. They ensure clear data lineage and enable scalable data preparation solutions, empowering your organization to handle increasingly complex data scenarios with efficiency and clarity.

Divergence

Divergence enables you to create multiple parallel transformation paths from a single step in your workflow. These paths can be transformed independently and later recombined, enabling complex data preparation scenarios such as self-joins.

Creating divergent paths

To initiate a Divergence, in your workflow:

1. Select the step where you want to create divergence.
2. Choose the **+** icon that appears.
3. Configure the new branch that appears.
4. Apply your desired transformations to each path.
5. Use Join or Append steps to recombine paths into a single output.

Key features

- Creates up to five divergent paths from a single step.

- Applies different transformations to each path.
- Recombines paths using Join or Append steps.
- Previews changes in each path independently.

Best practices

- Use divergence for implementing self-joins.
- Create data copies for parallel transformations.
- Plan your recombination strategy (Join or Append).
- Maintain clear path naming for better workflow visibility.

Composite Datasets

Composite Datasets enable you to build upon existing datasets, creating hierarchical data transformation structures that can be shared and reused across your organization. Quick Sight supports up to 10 levels of composite datasets in both SPICE and Direct Query modes.

Creating a composite dataset

To create a composite dataset, in your workflow:

1. Select the Input step when creating a new dataset.
2. Choose **Dataset** as your source under **Add Data**.
3. Select an existing dataset to build upon.
4. Apply additional transformations as needed.
5. Save as a new dataset.

Key features

- Builds hierarchical data transformation structures.
- Supports for up to 10 levels of dataset nesting.
- Compatible with both SPICE and Direct Query.
- Maintains clear data lineage.
- Enables team-specific transformations.

This feature enhances collaboration across different teams. For example,

Role	Action	Output
Global Analyst	Creates dataset with global business logic	Dataset A
Americas Analyst	Uses Dataset A, adds regional logic	Dataset B
US-West Analyst	Uses Dataset B, adds local logic	Dataset C

This hierarchical approach promotes consistent business logic across your organization by assigning clear ownership of transformation layers. It creates a traceable data lineage while supporting up to 10 levels of dataset nesting, enabling controlled and systematic data transformation management.

Best practices

- Establish clear ownership for each transformation layer.
- Document dataset relationships and dependencies.
- Plan hierarchy depth based on business needs.
- Maintain consistent naming conventions.
- Review and update upstream datasets carefully.

SPICE-only features

Amazon Quick Sight's SPICE (Super-fast, Parallel, In-memory Calculation Engine) enables certain computationally intensive data preparation features. These transformations are materialized in SPICE for optimal performance, rather than being executed at query time.

SPICE-only features

Steps	Other capabilities
• Append • Aggregate	• Divergence

Steps	Other capabilities
- Pivot - Unpivot	

Features available in both SPICE and DirectQuery

Steps	Other capabilities
- Input - Add Calculated Columns - Change Data Type - Rename Columns - Select Columns - Filter - Join	Composite Datasets

Best practices

- Use SPICE for workflows requiring SPICE-only features.
- Choose SPICE to optimize performance for complex transformations and large datasets.
- Consider DirectQuery for real-time data needs when SPICE-only features are not required.

Switching between data preparation experiences

Legacy data preparation experience refers to the previous data preparation interface in Amazon Quick Sight that existed before October 2025. The new data preparation experience is the enhanced visual interface that shows step-by-step transformation sequences. Legacy datasets are those created before the new data preparation experience, while new datasets are those created after October 2025.

When creating a new dataset, Quick Sight automatically directs you to the new data preparation experience. This visual interface offers enhanced capabilities and improved usability for data transformation tasks.

Opt-out option

Before saving and publishing a dataset, you have the option to switch back to the legacy data preparation experience, if preferred. This flexibility allows teams to transition at their own pace while becoming familiar with the new interface.

Important

If a dataset is saved and published in the new experience, there will not be an option to go back to the legacy experience. This is by design, as the new experience has significant new features which are not supported in the legacy experience. Hence directly converting datasets from one experience to another is not supported. You will need to create a new dataset to switch to the legacy experience.

Transition workflow

Once a dataset is saved in either the new or legacy experience, the transformations cannot be directly converted from one experience to another. However, if a published dataset version exists, you can use version control to go to the previous version which might be in the legacy experience.

Legacy datasets will continue to be accessible for viewing and editing exclusively through the legacy interface. This maintains compatibility with previously established workflows.

Before fully transitioning, take time to familiarize yourself with the new data preparation experience. When working with legacy datasets, consider creating a new version using the new experience for future modifications. Use version control to maintain access to legacy versions of datasets if needed. Document any changes in workflow when transitioning from legacy to new experience to ensure team alignment.

Features not supported in the new data preparation experience

While the new data preparation experience offers enhanced capabilities, some features from the legacy experience are not yet supported. This section outlines these features and provides guidance for handling affected workflows.

When using unsupported data sources, Amazon Quick Sight automatically defaults to the legacy experience. For other unsupported features, select **Switch to legacy experience** in the top right corner of the data preparation page. Rules Datasets created in the legacy experience remain compatible with both legacy and new experience datasets.

 Note

The new data preparation experience now supports the following features:

- Google Sheets
- Incremental refresh
- JODA date formats
- Column folders
- Column descriptions
- Geospatial data type
- SPICE and Direct Query parent dataset selection from the legacy experience (you can now use a legacy SPICE or Direct Query dataset as a parent for a new experience dataset).

 Setting the geospatial type

You set the geospatial type on the **Output** tab, not through **Change data type** on the **Transform** tab. Geospatial types (such as latitude and longitude) are not part of the regular data types. Because Amazon Quick Sight does not apply further transformations to these columns, it places them on the **Output** tab.

To set the geospatial type of a column:

1. On the data preparation page, choose the **Output** tab at the top (next to **Transform**).
2. In the **Schema** pane on the left, choose the column you want to set (for example, **City**).
3. Open the **Geospatial type** dropdown and choose a value, such as **Country**, **State**, **County**, **City**, **Postcode**, **Latitude**, or **Longitude**. To clear the geospatial type, choose **Unspecified**.

Unsupported data sources

The following data sources are currently available only in the legacy experience.

Data Source	Details
Salesforce	Automatically defaults to legacy experience
S3 Analytics	S3 data sources are supported

Other unsupported features

The following features are currently available only in the legacy experience.

Feature Category	Unsupported features
Dataset Management	Dataset parameters
Data Types	ELF/CLF formats , Zip/GZip files in S3
Configuration Options	"Start from row" in file upload settings
Calculated Fields	UnMaterialized Calculated Columns (UMCC)
Geospatial	Geo Hierarchy

Future development

Amazon Quick Sight plans to implement these features in the new data preparation experience in the future. This approach ensures that the initial launch for the new data preparation experience prioritizes:

Enhanced capabilities

- Visual transformation workflows
- Improved process transparency
- Advanced preparation techniques through Divergence
- Powerful new features like Append, Aggregate, and Pivot

Flexible adoption

Users can choose between experiences before publishing datasets, ensuring uninterrupted workflows while teams transition at their own pace. This approach allows immediate access to new capabilities while maintaining support for specialized requirements through the legacy experience.

Data preparation limits

Amazon Quick Sight's data preparation experience is designed to handle enterprise-scale datasets while maintaining optimal performance. The following limits ensure reliable functionality.

Dataset size limits (SPICE)

- **Output size:** Up to 2TB or 2 billion rows
- **Total input size:** Combined input sources cannot exceed 2TB
- **Secondary tables size:** Combined size is limited to 20GB

Note

Primary tables are those with maximum size in a workflow; all others are secondary.

Workflow structure limits

- **Maximum steps:** Up to 256 transformation steps per workflow
- **Source tables:** Maximum 32 import steps per workflow
- **Output columns:** Up to 2048 columns at any step in the workflow and final output table with 2000 columns
- **Divergent paths:** Maximum 5 paths from a single step (SPICE only, not applicable for DirectQuery)
- **Dataset as a source:** Up to 10 levels for both SPICE and DirectQuery

These limits are designed to balance flexibility with performance, enabling complex data transformations while ensuring optimal analysis capabilities.

Ingestion behavior changes

The new data preparation experience introduces an important change in how data quality issues are handled during SPICE ingestion. This change significantly impacts data completeness and transparency in your datasets.

In the legacy experience, when encountering data type inconsistencies (such as incorrect date formats or [similar issues](#)), the entire row containing problematic cells is skipped during ingestion. This approach results in fewer rows in the final dataset, potentially obscuring data quality issues.

The new experience takes a more granular approach to data inconsistencies. When encountering problematic cells, only the inconsistent values are converted to null values while retaining the entire row. This preservation ensures that related data in other columns remains accessible for analysis.

Impact on dataset quality

Datasets created in the new experience will typically contain more rows than their legacy counterparts when the source data contains inconsistencies. This enhanced approach offers several benefits:

- Improved data completeness by retaining all rows
- Greater transparency in identifying data quality issues
- Better visibility of problematic values for remediation
- Preservation of related data in unaffected columns

This change enables analysts to identify and address data quality issues more effectively, rather than having problematic rows silently omitted from the dataset.

Frequently asked questions

1. When do users need to switch from the new to legacy experience?

Users must return to the legacy experience when working with datasets that contain currently [unsupported features](#). Quick Sight is actively working to incorporate these features into the new experience in upcoming releases.

2. Why are datasets grayed out when trying to add them in the new experience? Can datasets be combined between legacy and new experiences?

Currently, parent and child datasets must exist within the same experience environment. You cannot combine datasets across legacy and new experiences because the new experience includes additional features not available in legacy, such as Append functionalities, Pivot capabilities, and Divergence.

Using parent datasets from the legacy experience

To use parent datasets from the legacy experience, you can switch back to that environment. Simply navigate to the data preparation page and choose **Switch back to legacy experience** in the top right corner. Once there, you can create your child datasets as needed.

Future development

We are planning to implement functionality that will allow users to upgrade legacy datasets to the new experience. This upgraded pathway will enable the use of legacy parent datasets within the new experience.

3. Why is Quick Sight launching the new data preparation experience before achieving full feature parity with the legacy experience?

The new data preparation experience was developed through extensive customer collaboration to address real-world analytics challenges. The initial launch prioritizes:

Enhanced capabilities

- Visual transformation workflows
- Improved process transparency
- Advanced preparation techniques through Divergence
- Powerful new features like Append, Aggregate, and Pivot

Flexible adoption

Users can choose between experiences before publishing datasets, ensuring uninterrupted workflows while teams transition at their own pace. This approach allows immediate access to new capabilities while maintaining support for specialized requirements through the legacy experience.

4. Will features currently available only in the legacy experience be added to the new experience?

Yes. Quick Sight is actively working to incorporate legacy features into the new experience.

5. How do API changes affect existing dataset creation scripts?

Quick Sight maintains backwards compatibility while introducing new capabilities:

- Existing Scripts: Legacy API scripts will continue to function, creating datasets in the legacy experience
- API Naming: Current API names remain unchanged
- New Functionality: Additional API formats support the new experience's enhanced capabilities
- Documentation: Complete API specifications for the new experience are available in our API reference

6. Can datasets be converted between experiences after publication?

- Future Migration Path: Quick Sight will add a feature in the future to easily migrate legacy datasets to the new experience.
- One-Way Process: Converting datasets from the new experience to legacy format isn't supported due to advanced feature dependencies

Dataset Enrichment

Dataset Enrichment is a capability in Amazon Quick Sight that enables dataset authors to add rich semantic metadata to their datasets. By providing descriptions, custom instructions, and structured metadata, you ensure that both human consumers and AI-powered agents understand what a dataset represents and how to use it.

Dataset Enrichment overview

Dataset Enrichment enables authors and author pros to annotate datasets with semantic context at both the dataset level and the column level. This metadata connects raw data with business context. It serves two audiences:

- **Dataset Consumers (other Authors, Reader Pros)** – Gain better business context about what each dataset contains, its purpose, and appropriate use cases.

- **AI Agents** – Receive richer contextual information to generate more accurate queries and interpretations when answering questions through Dataset Q&A.

Dataset Enrichment components

Dataset-level enrichment

Important

Do not add sensitive information to the **Dataset Description** or **Custom Instructions** fields. This information is visible to all dataset viewers.

Dataset Description

A business-level summary of what the dataset represents, its scope, and intended use. This description is visible to all dataset consumers in the UI, helping them quickly understand the dataset's purpose. Maximum length: 5,000 characters.

Custom Instructions

Free-form text instructions specifically consumed by AI agents. These instructions guide the AI on how to interpret, query, and reason about the dataset. Maximum length: 5,000 characters.

File Upload

You can upload a single file in YAML, JSON, or TXT format containing catalog-grade semantic metadata exported from third-party tools (for example, Databricks, dbt, or Alation). This enables hundreds of column definitions, business rules, and metric calculations to be ingested in a single upload – eliminating manual column-by-column entry. Maximum length: 50,000 characters.

Column-level enrichment

Folders

Organize columns into logical groupings for easier navigation and understanding.

Column Description

A human-readable description of what each column represents, its valid values, and business meaning. Maximum length: 500 characters.

Additional Notes

Supplementary context for each column, such as data quality considerations, related tables, or common analysis patterns. Maximum length: 2,000 characters.

Benefits of Dataset Enrichment

- **More accurate AI-powered Dataset Q&A** – Richer semantic context helps AI agents generate more precise SQL queries and interpretations, leading to significantly better answers.
- **Better understanding for consumers** – Descriptions and metadata help all users across the organization understand what datasets contain and how to use them correctly.
- **Scale metadata from external catalogs** – File Upload allows authors to bring in rich metadata from third-party catalog tools in a single operation, rather than manually entering definitions column by column.

Permissions and requirements

Authors and author pros with Enterprise licenses can enrich any dataset they own or manage.

Accessing Dataset Enrichment

To access Dataset Enrichment, complete the following steps.

1. Save your dataset in the data preparation experience.
2. Choose the **Output** tab.
3. Enter the **Dataset Description** and **Custom Instructions**, or upload a semantic metadata file.

Writing effective custom instructions

Custom Instructions are the most impactful component of Dataset Enrichment. They directly guide AI agents on how to interpret and query a dataset. The following are examples of effective and ineffective custom instructions.

Good custom instructions

Example 1 – Revenue Dataset

This dataset contains net revenue after returns and discounts, calculated

on an accrual basis. Revenue is recognized at the point of sale for retail transactions and upon delivery confirmation for B2B orders. All figures are in USD. The 'revenue' column specifically excludes taxes, shipping fees, and promotional credits. For year-over-year comparisons, use the 'fiscal_year' field rather than 'calendar_year' as our fiscal year runs April-March.

Why it's effective:

- Clarifies ambiguous terms (net vs. gross revenue)
- Defines calculation methodology
- Specifies currency and exclusions
- Provides guidance on how to use specific fields correctly

Example 2 – Customer Dataset

Customer status definitions: 'Active' = purchased within last 12 months; 'Dormant' = 12-24 months since last purchase; 'Churned' = 24+ months inactive. The 'customer_segment' field uses RFM analysis (Recency, Frequency, Monetary). 'Lifetime_value' is calculated as total historical spend, not predictive LTV. When analyzing customer counts, always filter out 'is_test_account = true' to exclude internal test data.

Why it's effective:

- Defines business logic and thresholds
- Explains acronyms and methodologies
- Warns about data quality considerations
- Guides proper filtering for accurate analysis

Ineffective custom instructions

Example – Customer Dataset

Contains customer information including names, addresses, purchase history, and other details. Use this for customer analysis.

Why it's ineffective:

- Describes what is already obvious from column names
- Provides no business context or definitions
- Offers no guidance on data quality, calculations, or proper usage
- Does not help the AI distinguish between similar concepts

Key principles for writing good custom instructions

- **Clarify ambiguities** – Define terms that can have multiple interpretations.
- **Explain business logic** – Document calculations, thresholds, and categorizations.
- **Provide context** – Include units, time periods, currencies, and scope.
- **Guide usage** – Explain which fields to use for specific analyses.
- **Warn about edge cases** – Note data quality issues, test records, or special cases.
- **Be specific** – Use concrete examples and precise language.

Two approaches to semantic enrichment

Manual UI-based annotation

Dataset authors directly add dataset and column descriptions and custom instructions through the Quick Sight interface. Quick Sight displays descriptions prominently in the UI, helping all users understand dataset content, column definitions, and appropriate use cases.

File upload from external catalogs

Dataset authors can export semantic metadata from external catalogs and attach a file per dataset in YAML, JSON, or TXT format through the API or UI. While this information is used by AI models rather than displayed in the UI, it enables catalog-grade metadata at scale.

The consumption layer: Dataset Q&A

Dataset Q&A is the consumption layer that uses Dataset Enrichment metadata. It enables users to ask open-ended, natural language questions directly against the datasets they have access to – without needing pre-built dashboards or manually configured topics.

The AI agent uses enriched context in the following ways:

- **Asset discovery** – The agent uses dataset descriptions and semantic metadata to identify the right dataset for the user's question.

- **Text-to-SQL generation** – Custom instructions, column descriptions, and uploaded metadata guide the AI in generating more accurate SQL queries.
- **Governed responses** – All responses respect Row-Level Security (RLS) and Column-Level Security (CLS) rules.

Without enrichment, the AI agent only has column names and data types to work with – which are often ambiguous. With enrichment, the agent receives the full business context needed to:

- Disambiguate similar fields and concepts
- Apply correct calculations and filters
- Understand business-specific thresholds and categorizations
- Exclude test data and handle edge cases appropriately

After you add semantic context to a dataset, users can reference the dataset in Q&A and query it through chat. The AI agent consumes the added metadata to deliver more accurate responses.

Dataset Q&A for Professional subscribers

Dataset Q&A enables users to ask natural language questions directly against a dataset and receive AI-generated answers grounded in the underlying data. Previously, Dataset Q&A was available only to Author personas (Enterprise license holders) who could access datasets to build dashboards and analyses.

Starting June 1, 2026, Dataset View permissions are available for Professional subscribers (Reader Pro). Professional subscribers can now see shared datasets, view the schema (dataset name, description, column names, and column descriptions), and use Chat to ask natural language questions against the data.

Note

This change does not grant Professional subscribers any authoring capabilities. Professional subscribers cannot create analyses, edit datasets, or modify schema. Access is strictly View and Q&A for shared datasets.

Access for already shared datasets

Professional subscribers automatically gain Dataset View access if they meet either of the following criteria:

- They are a member of an Amazon Quick Sight group where a dataset has been shared.
- They are a member of a folder that contains shared datasets.

No action is required from authors or admins – existing sharing configurations automatically extend Dataset View access to Professional subscribers who are already part of these groups or folders.

To share datasets with Professional subscribers

To give Professional subscribers Dataset View access to additional datasets, use one of the following methods:

- Add the Professional subscriber to an Amazon Quick Sight group, then share the dataset with that group. The Professional subscriber automatically receives View access to the dataset.
- Place the dataset in a folder where the Professional subscriber has membership. The Professional subscriber automatically inherits View access through the folder.

In both cases, Professional subscribers receive View-only access. They can see the dataset schema and use Dataset Q&A but cannot edit or create analyses from the dataset.

What Professional subscribers can do with shared datasets

The following list summarizes the permissions that Professional subscribers have for shared datasets.

- **Can** – View the Dataset Details page (see schema including dataset name, description, column names, and column descriptions).
- **Can** – Chat against the dataset using Q&A (ask natural language questions and receive AI-generated answers).
- **Cannot** – Create analyses from the dataset.
- **Cannot** – Edit datasets (no transformations, no schema changes).

Summary

Dataset Enrichment adds semantic metadata to datasets for AI-powered analysis. By investing a few minutes in adding descriptions, custom instructions, and metadata files, dataset authors can improve the accuracy of AI-powered Q&A while making their datasets more understandable and accessible to every consumer across the organization.

Describing data

Using Amazon Quick Sight, you can add information, or *metadata*, about the columns (fields) in your datasets. By adding metadata, you make the dataset self-explanatory and easier to reuse. Doing this can help data curators and their customers know where the data came from and what it means. It's a way of communicating to the people who use your dataset or combine it with other datasets to build dashboards. Metadata is especially important for information that is shared between organizations.

After you add metadata to a dataset, field descriptions become available to anyone who is using the dataset. A column description appears when someone who is actively browsing the **Fields** list pauses on a field name. Column descriptions are visible to people who are editing a dataset or an analysis, but not to someone who is viewing a dashboard. Descriptions aren't formatted. You are able to enter line feeds and formatting marks and these are preserved by the editor. However, the description tooltip that displays is only able to show words, numbers, and symbols—but not formatting.

To edit a description to a column or field

1. From the Quick homepage, choose **Data** at left.
2. In the **Data** tab, choose the dataset that you want to work on.
3. On the dataset details page that opens, choose **Edit dataset** at upper right.
4. On the dataset page that opens, choose a column in the table preview at bottom or in the field list at left.
5. To add or change the description, do one of the following:
 - At the bottom of the screen, open the settings for the field from the pencil icon next to the field's name.
 - In the field list, open the settings for the field from the menu next to the field's name. Then choose **Edit name & description** from the context menu.

6. Add or change the description for the field.

To delete an existing description, delete all the text in the Description box.

7. (Optional) For **Name**, if you want to change the name of the field, you can enter a new one here.
8. Choose **Apply** to save your changes. Choose cancel to exit.

Choosing file upload settings

If you are using a file data source, confirm the upload settings, and correct them if necessary.

Important

If it's necessary to change upload settings, make these changes before you make any other changes to the dataset. Changing upload settings causes Amazon Quick Sight to reimport the file. This process overwrites any changes you have made so far.

Changing text file upload settings

Text file upload settings include the file header indicator, file format, text delimiter, text qualifier, and start row. If you are working with an Amazon S3 data source, the upload settings you select are applied to all files you choose to use in this dataset.

Use the following procedure to change text file upload settings.

1. On the data preparation page, open the **Upload Settings** pane by choosing the expand icon.
2. In **File format**, choose the file format type.
3. If you chose the **custom separated (CUSTOM)** format, specify the separating character in **Delimiter**.
4. If the file doesn't contain a header row, deselect the **Files include headers** check box.
5. If you want to start from a row other than the first row, specify the row number in **Start from row**. If the **Files include headers** check box is selected, the new starting row is treated as the header row. If the **Files include headers** check box is not selected, the new starting row is treated as the first data row.
6. In **Text qualifier**, choose the text qualifier, either single quotes (') or double quotes (").

Changing Microsoft Excel file upload settings

Microsoft Excel file upload settings include the range header indicator and whole worksheet selector.

Use the following procedure to change Microsoft Excel file upload settings.

1. On the data preparation page, open the **Upload Settings** pane by choosing the expand icon.
2. Leave **Upload whole sheet** selected.
3. If the file doesn't contain a header row, deselect the **Range contains headers** check box.

Data Preparation Experience (Legacy)

Topics

Adding calculations

Create calculated fields to transform your data by using one or more of the following:

- [Operators](#)
- [Functions](#)
- Fields that contain data
- Other calculated fields

You can add calculated fields to a dataset during data preparation or from the analysis page. When you add a calculated field to a dataset during data preparation, it's available to all analyses that use that dataset. When you add a calculated field to a dataset in an analysis, it's available only in that analysis. For more information about adding calculated fields, see the following topics.

Topics

- [Adding calculated fields](#)

- [Using level-aware calculations in Quick Sight](#)
- [Calculated field function and operator reference for Amazon Quick](#)

Adding calculated fields

Create calculated fields to transform your data by using one or more of the following:

- [Operators](#)
- [Functions](#)
- Aggregate functions (you can only add these to an analysis)
- Fields that contain data
- Other calculated fields

You can add calculated fields to a dataset during data preparation or from the analysis page. When you add a calculated field to a dataset during data preparation, it's available to all analyses that use that dataset. When you add a calculated field to a dataset in an analysis, it's available only in that analysis.

Analyses support both single-row operations and aggregate operations. Single-row operations are those that supply a (potentially) different result for every row. Aggregate operations supply results that are always the same for entire sets of rows. For example, if you use a simple string function with no conditions, it changes every row. If you use an aggregate function, it applies to all the rows in a group. If you ask for the total sales amount for the US, the same number applies to the entire set. If you ask for data on a particular state, the total sales amount changes to reflect your new grouping. It still provides one result for the entire set.

By creating the aggregated calculated field within the analysis, you can then drill down into the data. The value of that aggregated field is recalculated appropriately for each level. This type of aggregation isn't possible during dataset preparation.

For example, let's say that you want to figure out the percentage of profit for each country, region, and state. You can add a calculated field to your analysis, $(\text{sum}(\text{salesAmount} - \text{cost})) / \text{sum}(\text{salesAmount})$. This field is then calculated for each country, region, and state, at the time your analyst drills down into the geography.

- [Adding calculated fields to a dataset](#)
- [Handling decimal values in calculated fields](#)

Adding calculated fields to an analysis

When you add a dataset to an analysis, every calculated field that exists in the dataset is added to the analysis. You can add additional calculated fields at the analysis level to create calculated fields that are available only in that analysis.

To add a calculated field to an analysis

1. Open the [Quick console](#).
2. Open the analysis that you want to change.
3. In the **Data** pane, choose **Add** at top left, and then choose **+ CALCULATED FIELD**.
 - a. In the calculations editor that opens, do the following:
 - b. Enter a name for the calculated field.
 - c. Enter a formula using fields from your dataset, functions, and operators.
4. When finished, choose **Save**.

For more information about how to create formulas using the available functions in Quick Sight, see [Calculated field function and operator reference for Amazon Quick](#).

Adding calculated fields to a dataset

Amazon Quick Sight authors can generate calculated fields during the data preparation phase of a dataset's creation. When you create a calculated field for a dataset, the field becomes a new column in the dataset. All analyses that use the dataset inherit the dataset's calculated fields.

If the calculated field operates at the row level and the dataset is stored in SPICE, Quick Sight computes and materializes the result in SPICE. If the calculated field relies on an aggregation function, Quick Sight retains the formula and performs the calculation when the analysis is generated. This type of calculated field is called an unmaterialized calculated field.

To add or edit a calculated field for a dataset

1. Open the dataset that you want to work with. For more information, see [Editing datasets](#).
2. On the data prep page, do one of the following:
 - To create a new field, choose **Add calculated field** at left.
 - To edit an existing calculated field, choose it from **Calculated fields** at left, then choose **Edit** from the context (right-click) menu.
3. In the calculation editor, enter a descriptive name for **Add title** to name the new calculated field. This name appears in the field list in the dataset, so it should look similar to the other fields. For this example, we name the field `Total Sales This Year`.
4. (Optional) Add a comment, for example to explain what the expression does, by enclosing text in slashes and asterisks.

```
/* Calculates sales per year for this year*/
```

5. Identify the metrics, functions, and other items to use. For this example, we need to identify the following:
 - The metric to use
 - Functions: `ifelse` and `datediff`

We want to build a statement like "If the sale happened during this year, show the total sales, and otherwise show 0."

To add the `ifelse` function, open the **Functions** list. Choose **All** to close the list of all functions. Now you should see the function groups: **Aggregate**, **Conditional**, **Date**, and so on.

Choose **Conditional**, and then double-click on `ifelse` to add it to the workspace.

```
ifelse()
```

6. Place your cursor inside the parenthesis in the workspace, and add three blank lines.

```
ifelse(  
  
  

```

```
)
```

7. With your cursor on the first blank line, find the `dateDiff` function. It's listed for **Functions** under **Dates**. You can also find it by entering **date** for **Search functions**. The `dateDiff` function returns all functions that have *date* as part of their name. It doesn't return all functions listed under **Dates**; for example, the `now` function is missing from the search results.

Double-click on `dateDiff` to add it to the first blank line of the `ifelse` statement.

```
ifelse(  
  dateDiff()  
  
)
```

Add the parameters that `dateDiff` uses. Place your cursor inside the `dateDiff` parentheses to begin to add `date1`, `date2`, and `period`:

1. For `date1`: The first parameter is the field that has the date in it. Find it under **Fields**, and add it to the workspace by double-clicking it or entering its name.
2. For `date2`, add a comma, then choose `truncDate()` for **Functions**. Inside its parenthesis, add period and date, like this: `truncDate( "YYYY", now() )`
3. For `period`: Add a comma after `date2` and enter `YYYY`. This is the period for the year. To see a list of all the supported periods, find `dateDiff` in the **Functions** list, and open the documentation by choosing **Learn more**. If you're already viewing the documentation, as you are now, see [dateDiff](#).

Add a few spaces for readability, if you like. Your expression should look like the following.

```
ifelse(  
  dateDiff( {Date}, truncDate( "YYYY", now() ) , "YYYY" )  
  
)
```

8. Specify the return value. For our example, the first parameter in `ifelse` needs to return a value of `TRUE` or `FALSE`. Because we want the current year, and we're comparing it to this year, we specify that the `dateDiff` statement should return `0`. The `if` part of the `ifelse`

evaluates as true for rows where there is no difference between the year of the sale and the current year.

```
dateDiff( {Date}, truncDate( "YYYY", now() ) , "YYYY" ) = 0
```

To create a field for TotalSales for last year, you can change 0 to 1.

Another way to do the same thing is to use addDateTime instead of truncDate. Then for each previous year, you change the first parameter for addDateTime to represent each year. For this, you use -1 for last year, -2 for the year before that, and so on. If you use addDateTime, you leave the dateDiff function = 0 for each year.

```
dateDiff( {Discharge Date}, addDateTime(-1, "YYYY", now() ) , "YYYY" ) = 0 /*
Last year */
```

9. Move your cursor to the first blank line, just under dateDiff. Add a comma.

For the then part of the ifelse statement, we need to choose the measure (metric) that contains the sales amount, TotalSales.

To choose a field, open the **Fields** list and double-click a field to add it to the screen. Or you can enter the name. Add curly braces { } around names that contain spaces. It's likely that your metric has a different name. You can know which field is a metric by the number sign in front of it (#).

Your expression should look like the following now.

```
ifelse(
  dateDiff( {Date}, truncDate( "YYYY", now() ) , "YYYY" ) = 0
  ,{TotalSales}
)
```

10. Add an else clause. The ifelse function doesn't require one, but we want to add it. For reporting purposes, you usually don't want to have any null values, because sometimes rows with nulls are omitted.

We set the else part of the ifelse to 0. The result is that this field is 0 for rows that contain sales from previous years.

To do this, on the blank line add a comma and then a 0. If you added the comment at the beginning, your finished `ifelse` expression should look like the following.

```
/* Calculates sales per year for this year*/
ifelse(
  dateDiff( {Date}, truncDate( "YYYY", now() ) ,"YYYY" ) = 0
  ,{TotalSales}
  ,0
)
```

11. Save your work by choosing **Save** at upper right.

If there are errors in your expression, the editor displays an error message at the bottom. Check your expression for a red squiggly line, then hover your cursor over that line to see what the error message is. Common errors include missing punctuation, missing parameters, misspellings, and invalid data types.

To avoid making any changes, choose **Cancel**.

To add a parameter value to a calculated field

1. You can reference parameters in calculated fields. By adding the parameter to your expression, you add the current value of that parameter.
2. To add a parameter, open the **Parameters** list, and select the parameter whose value you want to include.
3. (Optional) To manually add a parameter to the expression, type the name of the parameter. Then enclosed it in curly braces {}, and prefix it with a \$, for example `${parameterName}`.

You can change the data type of any field in your dataset, including the types of calculated fields. You can only choose data types that match the data that's in the field.

To change the data type of a calculated field

- For **Calculated fields** (at left), choose the field that you want to change, then choose **Change data type** from the context (right-click) menu.

Unlike the other fields in the dataset, calculated fields can't be disabled. Instead, delete them.

To delete a calculated field

- For **Calculated fields** (at left), choose the field that you want to change, then choose **Delete** from the context (right-click) menu.

Handling decimal values in calculated fields

When your dataset uses Direct Query mode, the calculation of the decimal data type is determined by the behavior of the source engine that the dataset originates from. In some particular cases, Quick Sight applies special handlings to determine the output calculation's data type.

When your dataset uses SPICE query mode and a calculated field is materialized, the data type of the result is contingent on the specific function operators and the data type of the input. The tables below show the expected behavior for some numeric calculated fields.

Unary operators

The following table shows which data type is output based on the operator you use and the data type of the value that you input. For example, if you input an integer to an abs calculation, the output value's data type is integer.

Operator	Input type	Output type
abs	Decimal-fixed	Decimal-fixed
	Int	Int
	Decimal-float	Decimal-float
ceil	Decimal-fixed	Int
	Int	Int
	Decimal-float	Int
exp	Decimal-fixed	Decimal-float
	Int	Decimal-float
	Decimal-float	Decimal-float

Operator	Input type	Output type
floor	Decimal-fixed	Int
	Int	Int
	Decimal-float	Int
ln	Decimal-fixed	Decimal-float
	Int	Decimal-float
	Decimal-float	Decimal-float
log	Decimal-fixed	Decimal-float
	Int	Decimal-float
	Decimal-float	Decimal-float
round	Decimal-fixed	Decimal-fixed
	Int	Decimal-fixed
	Decimal-float	Decimal-fixed
sqrt	Decimal-fixed	Decimal-float
	Int	Decimal-float
	Decimal-float	Decimal-float

Binary operators

The following tables show which data type is output based on the data types of the two values that you input. For example, for an arithmetic operator, if you provide two integer data types, the result of the calculation output as an integer.

For basic operators (+, -, *):

	Integer	Decimal-fixed	Decimal-float
Integer	Integer	Decimal-fixed	Decimal-float
Decimal-fixed	Decimal-fixed	Decimal-fixed	Decimal-float
Decimal-float	Decimal-float	Decimal-float	Decimal-float

For division operators (/):

	Integer	Decimal-fixed	Decimal-float
Integer	Decimal-float	Decimal-float	Decimal-float
Decimal-fixed	Decimal-float	Decimal-fixed	Decimal-float
Decimal-float	Decimal-float	Decimal-float	Decimal-float

For exponential and mod operators (^, %):

	Integer	Decimal-fixed	Decimal-float
Integer	Decimal-float	Decimal-float	Decimal-float
Decimal-fixed	Decimal-float	Decimal-float	Decimal-float
Decimal-float	Decimal-float	Decimal-float	Decimal-float

Order of evaluation in Amazon Quick Sight

When you open or update an analysis, before displaying it Amazon Quick Sight evaluates everything that is configured in the analysis in a specific sequence. Amazon Quick Sight translates the configuration into a query that a database engine can run. The query returns the data in a similar way whether you connect to a database, a software as a service (SaaS) source, or the Amazon Quick Sight analytics engine ([SPICE](#)).

If you understand the order that the configuration is evaluated in, you know the sequence that dictates when a specific filter or calculation is applied to your data.

The following illustration shows the order of evaluation. The column on the left shows the order of evaluation when no level aware calculation window (LAC-W) nor aggregate (LAC-A) function is involved. The second column shows the order of evaluation for analyses that contain calculated fields to compute LAC-W expressions at the prefilter (PRE_FILTER) level. The third column shows the order of evaluation for analyses that contain calculated fields to compute LAC-W expressions at the preaggregate (PRE_AGG) level. The last column shows the order of evaluation for analyses that contain calculated fields to compute LAC-A expressions. Following the illustration, there is a more detailed explanation of the order of evaluation. For more information about level aware calculations, see [Using level-aware calculations in Quick Sight](#).

The following list shows the sequence in which Amazon Quick Sight applies the configuration in your analysis. Anything that's set up in your data set happens outside your analysis, for example calculations at the data set level, filters, and security settings. These all apply to the underlying data. The following list only covers what happens inside the analysis.

1. **LAC-W Prefilter level:** Evaluates the data at the original table cardinality before analysis filters
 - a. **Simple calculations:** Calculations at scalar level without any aggregations or window calculations. For example, `date_metric/60`, `parseDate(date, 'yyyy/MM/dd')`, `ifelse(metric > 0, metric, 0)`, `split(string_column, '|' 0)`.
 - b. **LAC-W function PRE_FILTER:** If any LAC-W PRE_FILTER expression is involved in the visual, Amazon Quick Sight firstly computes the window function at the original table level, before

any filters. If the LAC-W PRE_FILTER expression is used in filters, it is applied at this point. For example, `maxOver(Population, [State, County], PRE_FILTER) > 1000`.

2. **LAC-W PRE_AGG:** Evaluates the data at the original table cardinality before aggregations

- a. **Filters added during analysis:** Filters created for un-aggregated fields in the visuals are applied at this point, which are similar to WHERE clauses. For example, `year > 2020`.
- b. **LAC-W function PRE_AGG:** If any LAC-W PRE_AGG expression is involved in the visual, Amazon Quick Sight computes the window function before any aggregation applied. If the LAC-W PRE_AGG expression is used in filters, it is applied at this point. For example, `maxOver(Population, [State, County], PRE_AGG) > 1000`.
- c. **Top/bottom N filters:** Filters that are configured on dimensions to display top/bottom N items.

3. **LAC-A level:** Evaluate aggregations at customized level, before visual aggregations

- a. **Custom-level aggregations:** If any LAC-A expression is involved in the visual, it is calculated at this point. Based on the table after the filters mentioned above, Amazon QuickSight computes the aggregation, grouped by the dimensions that are specified in the calculated fields. For example, `max(Sales, [Region])`.

4. **Visual level:** Evaluates aggregations at visual level, and post-aggregation table calculations, with the remaining configurations applied in the visuals

- a. **Visual-level aggregations:** Visual aggregations should always be applied except for tabular tables (where dimension is empty). With this setting, aggregations based on the fields in the field wells are calculated, grouped by the dimensions that put into the visuals. If any filter is built on top of aggregations, it is applied at this point, similar to HAVING clauses. For example, `min(distance) > 100`.
- b. **Table calculations:** If there is any post-aggregation table calculation (it should take aggregated expression as operand) referenced in the visual, it is calculated at this point. Amazon Quick Sight performs window calculations after visual aggregations. Similarly, filters built on such calculations are applied.
- c. **Other category calculations:** This type of calculation only exists in line/bar/pie/donut charts. For more information, see [Display limits](#).
- d. **Totals and subtotals:** Totals and Subtotals are calculated in donut charts (only totals), tables (only totals) and pivot tables, if requested.

Using level-aware calculations in Quick Sight

Applies to: Enterprise Edition and Standard Edition

With *Level-aware calculations* (LAC) you can specify the level of granularity that you want to compute window functions or aggregate functions. There are two types of LAC functions: level-aware calculation - aggregate (LAC-A) functions, and level-aware calculation - window (LAC-W) functions.

Topics

- [Level-aware calculation - aggregate \(LAC-A\) functions](#)
- [Level-aware calculation - window \(LAC-W\) functions](#)

Level-aware calculation - aggregate (LAC-A) functions

With LAC-A functions, you can specify at what level to group the computation. By adding one argument into an existing aggregate function, such as `sum()` , `max()` , `count()`, you can define any group-by level that you want for the aggregation. The level added can be any dimension independent of the dimensions added to the visual. For example:

```
sum(measure,[group_field_A])
```

To use LAC-A functions, type them directly in the calculation editor by adding the intended aggregation levels as the second argument between brackets. Following is an example of an aggregate function and a LAC-A function, for comparison.

- Aggregate function: `sum({sales})`
- LAC-A function: `sum({sales}, [{Country},{Product}])`

The LAC-A results are computed with the specified level in the brackets [], can be used as operand of an aggregate function. The group-by level of the aggregate function is visual level, with **Group by** fields added to the field well of the visual.

In addition to creating a static LAC group key in the bracket [], you can make it dynamically adapted to visual group-by fields, by putting a parameter `$visualDimensions` in the

bracket. This is a system-provided parameter, in contrast to user-defined parameter. The `[$visualDimensions]` parameter represents the fields added to the **Group by** field well in current visual. The following examples show how to dynamically add group keys to the visual dimensions or remove group keys from visual dimensions

- LAC-A with dynamic-added group key : `sum({sales}, [{visualDimensions}, {Country}, {Products}])`

It calculates, before the visual level aggregation is calculated, the sum of sales, grouping by country, products, and any other fields in the **Group by** field well .

- LAC-A with dynamic-removed group key : `sum({sales}, [{visualDimensions}, !{Country}, !{Products}])`

It calculates, before visual level aggregation is calculated, the sum of sales, grouping by the fields in the visual's **Group by** field well, except country and product.

You can specify added group key or removed group key in on LAC expression, but not both.

LAC-A functions are supported for the following aggregate functions:

- [avg](#)
- [count](#)
- [distinct_count](#)
- [max](#)
- [median](#)
- [min](#)
- [percentile](#)
- [percentileCont](#)
- [percentileDisc \(percentile\)](#)
- [stdev](#)
- [stdevp](#)
- [sum](#)
- [var](#)
- [varp](#)

LAC-A examples

You can do the following with LAC-A functions:

- Run calculations that are independent of the levels in the visual. For example, if you have the following calculation, the sales numbers are aggregated only at the country level, but not across other dimensions (Region or Product) in the visual.

```
sum({Sales}, [{Country}])
```

- Run calculations for the dimensions that are not in the visual. For example, if you have the following function, you can calculate the average total country sales by region.

```
sum({Sales}, [{Country}])
```

Though Country is not included in the visual, the LAC-A function first aggregates the sales at the Country level and then the visual level calculation generates the average number for each region. If the LAC-A function isn't used to specify the level, the average sales are calculated at the lowest granular level (the base level of the dataset) for each region (showing in the sales column).

- Use LAC-A combined with other aggregate functions and LAC-W functions. There are two ways you can nest LAC-A functions with other functions.
 - You can write a nested syntax when you create a calculation. For example, the LAC-A function can be nested with a LAC-W function to calculate the total sales by country of each product's average price:

```
sum(avgOver({Sales}, [{Product}], PRE_AGG), [{Country}])
```

- When adding a LAC-A function into a visual, the calculation can be further nested with visual-level aggregate functions that you selected in the fields well. For more information about changing the aggregation of fields in the visual, see [Changing or adding aggregation to a field by using a field well](#).

LAC-A limitations

The following limitations apply to LAC-A functions:

- LAC-A functions are supported for all additive and non-additive aggregate functions, such as `sum()`, `count()`, and `percentile()`. LAC-A functions are not supported for conditional aggregate functions that end with "if", such as `sumif()` and `countif()`, nor for period aggregate functions that start with "periodToDate", such as `periodToDateSum()` and `periodToDateMax()`.
- Row-level and column-level totals are not currently supported for LAC-A functions in tables and pivot tables. When you add row-level or column-level totals to the chart, the total number will show as blank. Other non-LAC dimensions are not impacted.
- Nested LAC-A functions are not currently supported. A limited capability of LAC-A functions nested with regular aggregate functions and LAC-W functions are supported.

For example, the following functions are valid:

- `Aggregation(LAC-A())`. For example: `max(sum({sales}, [{country}]))`
- `LAC-A(LAC-W())`. For example: `sum(sumOver({Sales}, [{Product}], PRE_AGG), [{Country}])`

The following functions are not valid:

- `LAC-A(Aggregation())`. For example: `sum(max({sales}), [{country}])`
- `LAC-A(LAC-A())`. For example: `sum(max({sales}, [{country}]), [category])`
- `LAC-W(LAC-A())`. For example: `sumOver(sum({Sales}, [{Product}]), [{Country}], PRE_AGG)`

Level-aware calculation - window (LAC-W) functions

With LAC-W functions, you can specify the window or partition to compute the calculation. LAC-W functions are a group of window functions, such as `sumover()`, `(maxover)`, `denseRank`, that you can run at the prefilter or preaggregate level. For example: `sumOver(measure, [partition_field_A], pre_agg)`.

LAC-W functions used to be called level aware aggregations (LAA).

LAC-W functions help you to answer the following types of questions:

- How many of my customers made only 1 purchase order? Or 10? Or 50? We want the visual to use the count as a dimension rather than a metric in the visual.
- What are the total sales per market segment for customers whose lifetime spend is greater than \$100,000? The visual should only show the market segment and the total sales for each.

- How much is the contribution of each industry to the entire company's profit (percent of total)? We want to be able to filter the visual to show some of the industries, and how they contribute to the total sales for the displayed industries. However, we also want to see each industry's percent of total sales for the entire company (including industries that are filtered out).
- What are the total sales in each category as compared to the industry average? The industry average should include all of the categories, even after filtering.
- How are my customers grouped into cumulative spending ranges? We want to use the grouping as a dimension rather than a metric.

For more complex questions, you can inject a calculation or filter before Quick Sight gets to a specific point in its evaluation of your settings. To directly influence your results, you add a calculation level keyword to a table calculation. For more information on how Quick Sight evaluates queries, see [Order of evaluation in Amazon Quick Sight](#).

The following calculation levels are supported for LAC-W functions:

- **PRE_FILTER** – Before applying filters from the analysis, Quick Sight evaluates prefilter calculations. Then it applies any filters that are configured on these prefilter calculations.
- **PRE_AGG** – Before computing display-level aggregations, Quick Sight performs preaggregate calculations. Then it applies any filters that are configured on these preaggregate calculations. This work happens before applying top and bottom *N* filters.

You can use the PRE_FILTER or PRE_AGG keyword as a parameter in the following table calculation functions. When you specify a calculation level, you use an unaggregated measure in the function. For example, you can use `countOver({ORDER ID}, [{Customer ID}], PRE_AGG)`. By using PRE_AGG, you specify that the `countOver` executes at the preaggregate level.

- [avgOver](#)
- [countOver](#)
- [denseRank](#)
- [distinctCountOver](#)
- [minOver](#)
- [maxOver](#)
- [percentileRank](#)
- [rank](#)

- [stdevOver](#)
- [stdevpOver](#)
- [sumOver](#)
- [varOver](#)
- [varpOver](#)

By default, the first parameter for each function must be an aggregated measure. If you use either PRE_FILTER or PRE_AGG, you use a nonaggregated measure for the first parameter.

For LAC-W functions, the visual aggregation defaults to MIN to eliminate duplicates. To change the aggregation, open the field's context (right-click) menu, and then choose a different aggregation.

For examples of when and how to use LAC-W functions in real life scenarios, see the following post in the AWS Big Data Blog: [Create advanced insights using Level Aware Aggregations in Amazon QuickSight](#).

Calculated field function and operator reference for Amazon Quick

You can add calculated fields to a dataset during data preparation or from the analysis page. When you add a calculated field to a dataset during data preparation, it's available to all analyses that use that dataset. When you add a calculated field to a dataset in an analysis, it's available only in that analysis.

You can create calculated fields to transform your data by using the following functions and operators.

Topics

- [Operators](#)
- [Functions by category](#)
- [Functions](#)
- [Aggregate functions](#)
- [Table calculation functions](#)

Operators

You can use the following operators in calculated fields. Quick uses the standard order of operations: parentheses, exponents, multiplication, division, addition, subtraction (PEMDAS). Equal (=) and not equal (<>) comparisons are case-sensitive.

- Addition (+)
- Subtraction (-)
- Multiplication (*)
- Division (/)
- Modulo (%) – See also `mod( )` in the following list.
- Power (^) – See also `exp( )` in the following list.
- Equal (=)
- Not equal (<>)
- Greater than (>)
- Greater than or equal to (>=)
- Less than (<)
- Less than or equal to (<=)
- AND
- OR
- NOT

Amazon Quick supports applying the following mathematical functions to an expression.

- [Mod](#)(*number*, *divisor*) – Finds the remainder after dividing a number by a divisor.
- [Log](#)(*expression*) – Returns the base 10 logarithm of a given expression.
- [Ln](#)(*expression*) – Returns the natural logarithm of a given expression.
- [Abs](#)(*expression*) – Returns the absolute value of a given expression.
- [Sqrt](#)(*expression*) – Returns the square root of a given expression.
- [Exp](#)(*expression*) – Returns the base of natural log *e* raised to the power of a given expression.

To make lengthy calculations easier to read, you can use parenthesis to clarify groupings and precedence in calculations. In the following statement, you don't need parentheses. The multiplication statement is processed first, and then the result is added to five, returning a value of 26. However, parentheses make the statement easier to read and thus maintain.

```
5 + (7 * 3)
```

Because parenthesis are first in the order of operations, you can change the order in which other operators are applied. For example, in the following statement the addition statement is processed first, and then the result is multiplied by three, returning a value of 36.

```
(5 + 7) * 3
```

Example: Arithmetic operators

The following example uses multiple arithmetic operators to determine a sales total after discount.

```
(Quantity * Amount) - Discount
```

Example: (/) Division

The following example uses division to divide 3 by 2. A value of 1.5 is returned. Amazon Quick uses floating point divisions.

```
3/2
```

Example: (=) equal

Using = performs a case-sensitive comparison of values. Rows where the comparison is TRUE are included in the result set.

In the following example, rows where the Region field is **South** are included in the results. If the Region is **south**, these rows are excluded.

```
Region = 'South'
```

In the following example, the comparison evaluates to FALSE.

```
Region = 'south'
```

The following example shows a comparison that converts `Region` to all uppercase (**SOUTH**), and compares it to **SOUTH**. This returns rows where the region is **south**, **South**, or **SOUTH**.

```
toUpper(Region) = 'SOUTH'
```

Example: (<>)

The not equal symbol `<>` means *less than or greater than*.

So, if we say **x<>1**, then we are saying *if x is less than 1 OR if x is greater than 1*. Both `<` and `>` are evaluated together. In other words, *if x is any value except 1*. Or, *x is not equal to 1*.

Note

Use `<>`, not `!=`.

The following example compares `Status Code` to a numeric value. This returns rows where the `Status Code` is not equal to **1**.

```
statusCode <> 1
```

The following example compares multiple `statusCode` values. In this case, active records have `activeFlag = 1`. This example returns rows where one of the following applies:

- For active records, show rows where the status isn't 1 or 2
- For inactive records, show rows where the status is 99 or -1

```
( activeFlag = 1 AND (statusCode <> 1 AND statusCode <> 2) )  
OR  
( activeFlag = 0 AND (statusCode= 99 OR statusCode= -1) )
```

Example: (^)

The power symbol `^` means *to the power of*. You can use the power operator with any numeric field, with any valid exponent.

The following example is a simple expression of 2 to the power of 4 or $(2 * 2 * 2 * 2)$. This returns a value of 16.

```
2^4
```

The following example computes the square root of the revenue field.

```
revenue^0.5
```

Example: AND, OR, and NOT

The following example uses AND, OR, and NOT to compare multiple expressions. It does so using conditional operators to tag top customers NOT in Washington or Oregon with a special promotion, who made more than 10 orders. If no values are returned, the value 'n/a' is used.

```
ifelse(( NOT (State = 'WA' OR State = 'OR')) AND Orders > 10), 'Special Promotion  
XYZ', 'n/a')
```

Example: Creating comparison lists like "in" or "not in"

This example uses operators to create a comparison to find values that exist, or don't exist, in a specified list of values.

The following example compares promoCode a specified list of values. This example returns rows where the promoCode is in the list **(1, 2, 3)**.

```
promoCode    = 1  
OR promoCode = 2  
OR promoCode = 3
```

The following example compares promoCode a specified list of values. This example returns rows where the promoCode is NOT in the list **(1, 2, 3)**.

```
NOT(promoCode = 1  
OR promoCode = 2  
OR promoCode = 3  
)
```

Another way to express this is to provide a list where the promoCode is not equal to any items in the list.

```
promoCode    <> 1
```

```
AND promoCode <> 2  
AND promoCode <> 3
```

Example: Creating a "between" comparison

This example uses comparison operators to create a comparison showing values that exist between one value and another.

The following example examines `OrderDate` and returns rows where the `OrderDate` is between the first day and last day of 2016. In this case, we want the first and last day included, so we use "or equal to" on the comparison operators.

```
OrderDate >= "1/1/2016" AND OrderDate <= "12/31/2016"
```

Functions by category

In this section, you can find a list of the functions available in Amazon Quick, sorted by category.

Topics

- [Aggregate functions](#)
- [Conditional functions](#)
- [Date functions](#)
- [Numeric functions](#)
- [Mathematical functions](#)
- [String functions](#)
- [Table calculations](#)

Aggregate functions

The aggregate functions for calculated fields in Amazon Quick include the following. These are only available during analysis and visualization. Each of these functions returns values grouped by the chosen dimension or dimensions. For each aggregation, there is also a conditional aggregation. These perform the same type of aggregation, based on a condition.

- [avg](#) averages the set of numbers in the specified measure, grouped by the chosen dimension or dimensions.
- [avgIf](#) calculates the average based on a conditional statement.

- [count](#) calculates the number of values in a dimension or measure, grouped by the chosen dimension or dimensions.
- [countIf](#) calculates the count based on a conditional statement.
- [distinct_count](#) calculates the number of distinct values in a dimension or measure, grouped by the chosen dimension or dimensions.
- [distinct_countIf](#) calculates the distinct count based on a conditional statement.
- [max](#) returns the maximum value of the specified measure, grouped by the chosen dimension or dimensions.
- [maxIf](#) calculates the maximum based on a conditional statement.
- [median](#) returns the median value of the specified measure, grouped by the chosen dimension or dimensions.
- [medianIf](#) calculates the median based on a conditional statement.
- [min](#) returns the minimum value of the specified measure, grouped by the chosen dimension or dimensions.
- [minIf](#) calculates the minimum based on a conditional statement.
- [percentile](#) (alias of `percentileDisc`) computes the *n*th percentile of the specified measure, grouped by the chosen dimension or dimensions.
- [percentileCont](#) calculates the *n*th percentile based on a continuous distribution of the numbers of the specified measure, grouped by the chosen dimension or dimensions.
- [percentileDisc \(percentile\)](#) calculates the *n*th percentile based on the actual numbers of the specified measure, grouped by the chosen dimension or dimensions.
- [periodToDateAvg](#) averages the set of numbers in the specified measure for a given time granularity (for instance, a quarter) up to a point in time.
- [periodToDateCount](#) calculates the number of values in a dimension or measure for a given time granularity (for instance, Quarter) up to a point in time including duplicates.
- [periodToDateMax](#) returns the maximum value of the specified measure for a given time granularity (for instance, a quarter) up to a point in time.
- [periodToDateMedian](#) returns the median value of the specified measure for a given time granularity (for instance, a quarter) up to a point in time.
- [periodToDateMin](#) returns the minimum value of the specified measure or date for a given time granularity (for instance, a quarter) up to a point in time.
- [periodToDatePercentile](#) calculates the percentile based on the actual numbers in measure for a given time granularity (for instance, a quarter) up to a point in time.

- [periodToDatePercentileCont](#) calculates percentile based on a continuous distribution of the numbers in the measure for a given time granularity (for instance, a quarter) up to a point in time.
- [periodToDateStDev](#) calculates the standard deviation of the set of numbers in the specified measure for a given time granularity (for instance, a quarter) up to a point in time based on a sample.
- [periodToDateStDevP](#) calculates the population standard deviation of the set of numbers in the specified measure for a given time granularity (for instance, a quarter) up to a point in time based on a sample.
- [periodToDateSum](#) adds the set of numbers in the specified measure for a given time granularity (for instance, a quarter) up to a point in time.
- [periodToDateVar](#) calculates the sample variance of the set of numbers in the specified measure for a given time granularity (for instance, a quarter) up to a point in time.
- [periodToDateVarP](#) calculates the population variance of the set of numbers in the specified measure for a given time granularity (for instance, a quarter) up to a point in time.
- [stdev](#)) calculates the standard deviation of the set of numbers in the specified measure, grouped by the chosen dimension or dimensions, based on a sample.
- [stdevIf](#) calculates the sample standard deviation based on a conditional statement.
- [stdevp](#) calculates the standard deviation of the set of numbers in the specified measure, grouped by the chosen dimension or dimensions, based on a biased population.
- [stdevpIf](#) calculates the population deviation based on a conditional statement.
- [var](#)) calculates the variance of the set of numbers in the specified measure, grouped by the chosen dimension or dimensions, based on a sample.
- [varIf](#) calculates the sample variance based on a conditional statement.
- [varp](#)) calculates the variance of the set of numbers in the specified measure, grouped by the chosen dimension or dimensions, based on a biased population.
- [varpIf](#) calculates the population variance based on a conditional statement.
- [sum](#)) adds the set of numbers in the specified measure, grouped by the chosen dimension or dimensions.
- [sumIf](#)) calculates the sum based on a conditional statement.

Conditional functions

The conditional functions for calculated fields in Amazon Quick include the following:

- [Coalesce](#) returns the value of the first argument that is not null.
- [Ifelse](#) evaluates a set of *if, then* expression pairings, and returns the value of the *then* argument for the first *if* argument that evaluates to true.
- [in](#) evaluates an expression to see if it is in a given list of values.
- [isNotNull](#) evaluates an expression to see if it is not null.
- [isNull](#) evaluates an expression to see if it is null. If the expression is null, `isNull` returns true, and otherwise it returns false.
- [notIn](#) evaluates an expression to see if it is not in a given list of values.
- [nullIf](#) compares two expressions. If they are equal, the function returns null. If they are not equal, the function returns the first expression.
- [switch](#) returns an expression that matches the first label equal to the condition expression.

Date functions

The date functions for calculated fields in Amazon Quick include the following:

- [addDateTime](#) adds or subtracts a unit of time to the date or time provided.
- [addWorkDays](#) adds or subtracts the given number of work days to the date or time provided.
- [dateDiff](#) returns the difference in days between two date fields.
- [epochDate](#) converts an epoch date into a standard date.
- [Extract](#) returns a specified portion of a date value.
- [formatDate](#) formats a date using a pattern you specify.
- [isWorkDay](#) returns TRUE if a given date-time value is a work or business day.
- [netWorkDays](#) returns the number of working days between the provided two date values.
- [Now](#) returns the current date and time, using either settings for a database, or UTC for file and Salesforce.
- [truncDate](#) returns a date value that represents a specified portion of a date.

Numeric functions

The numeric functions for calculated fields in Amazon Quick include the following:

- [Ceil](#) rounds a decimal value to the next highest integer.
- [decimalToInt](#) converts a decimal value to an integer.

- [Floor](#) decrements a decimal value to the next lowest integer.
- [intToDecimal](#) converts an integer value to a decimal.
- [Round](#) rounds a decimal value to the closest integer or, if scale is specified, to the closest decimal place.

Mathematical functions

The mathematical functions for calculated fields in Amazon Quick include the following:

- [Mod](#)(*number*, *divisor*) – Finds the remainder after dividing a number by a divisor.
- [Log](#)(*expression*) – Returns the base 10 logarithm of a given expression.
- [Ln](#)(*expression*) – Returns the natural logarithm of a given expression.
- [Abs](#)(*expression*) – Returns the absolute value of a given expression.
- [Sqrt](#)(*expression*) – Returns the square root of a given expression.
- [Exp](#)(*expression*) – Returns the base of natural log e raised to the power of a given expression.

String functions

The string (text) functions for calculated fields in Amazon Quick include the following:

- [Concat](#) concatenates two or more strings.
- [contains](#) checks if an expression contains a substring.
- [endsWith](#) checks if the expression ends with the substring specified.
- [Left](#) returns the specified number of leftmost characters from a string.
- [Locate](#) locates a substring within another string, and returns the number of characters before the substring.
- [Ltrim](#) removes preceding blank space from a string.
- [parseDate](#) parses a string to determine if it contains a date value, and returns the date if found.
- [parseDecimal](#) parses a string to determine if it contains a decimal value.
- [parseInt](#) parses a string to determine if it contains an integer value.
- [parseJson](#) parses values from a native JSON or from a JSON object in a text field.
- [Replace](#) replaces part of a string with a new string.
- [Right](#) returns the specified number of rightmost characters from a string.

- [Rtrim](#) removes following blank space from a string.
- [Split](#) splits a string into an array of substrings, based on a delimiter that you choose, and returns the item specified by the position.
- [startsWith](#) checks if the expression starts with the substring specified.
- [Strlen](#) returns the number of characters in a string.
- [Substring](#) returns the specified number of characters in a string, starting at the specified location.
- [toLowerCase](#) formats a string in all lowercase.
- [toString](#) formats the input expression as a string.
- [toUpperCase](#) formats a string in all uppercase.
- [trim](#) removes both preceding and following blank space from a string.

Table calculations

Table calculations form a group of functions that provide context in an analysis. They provide support for enriched aggregated analysis. By using these calculations, you can address common business scenarios such as calculating percentage of total, running sum, difference, common baseline, and rank.

When you are analyzing data in a specific visual, you can apply table calculations to the current set of data to discover how dimensions influence measures or each other. Visualized data is your result set based on your current dataset, with all the filters, field selections, and customizations applied. To see exactly what this result set is, you can export your visual to a file. A table calculation function performs operations on the data to reveal relationships between fields.

Lookup-based functions

- [difference](#) calculates the difference between a measure based on one set of partitions and sorts, and a measure based on another.
- [lag](#) calculates the lag (previous) value for a measure.
- [lead](#) calculates the lead (following) value for a measure.
- [percentDifference](#) calculates the percentage difference between the current value and a comparison value.

Over functions

- [avgOver](#) calculates the average of a measure over one or more dimensions.
- [countOver](#) calculates the count of a field over one or more dimensions.
- [distinctCountOver](#) calculates the distinct count of the operand partitioned by the specified attributes at a specified level.
- [maxOver](#) calculates the maximum of a measure over one or more dimensions.
- [minOver](#) the minimum of a measure over one or more dimensions.
- [percentileOver](#) (alias of `percentileDiscOver`) calculates the n th percentile of a measure partitioned by a list of dimensions.
- [percentileContOver](#) calculates the n th percentile based on a continuous distribution of the numbers of a measure partitioned by a list of dimensions.
- [percentileDiscOver](#) calculates the n th percentile based on the actual numbers of a measure partitioned by a list of dimensions.
- [percentOfTotal](#) calculates the percentage that a measure contributes to the total.
- [periodOverPeriodDifference](#) calculates the difference of a measure over two different time periods as specified by period granularity and offset.
- [periodOverPeriodLastValue](#) calculates the last (previous) value of a measure from a previous time period as specified by period granularity and offset.
- [periodOverPeriodPercentDifference](#) calculates the percent difference of a measure over two different time periods as specified by period granularity and offset.
- [periodToDateAvgOverTime](#) calculates the average of a measure for a given time granularity (for instance, a quarter) up to a point in time.
- [periodToDateCountOverTime](#) calculates the count of a dimension or measure for a given time granularity (for instance, a quarter) up to a point in time.
- [periodToDateMaxOverTime](#) calculates the maximum of a measure or date for a given time granularity (for instance, a quarter) up to a point in time.
- [periodToDateMinOverTime](#) calculates the minimum of a measure or date for a given time granularity (for instance, a quarter) up to a point in time.
- [periodToDateSumOverTime](#) calculates the sum of a measure for a given time granularity (for instance, a quarter) up to a point in time.
- [sumOver](#) calculates the sum of a measure over one or more dimensions.
- [stdevOver](#) calculates the standard deviation of the specified measure, partitioned by the chosen attribute or attributes, based on a sample.

- [stdevpOver](#) calculates the standard deviation of the specified measure, partitioned by the chosen attribute or attributes, based on a biased population.
- [varOver](#) calculates the variance of the specified measure, partitioned by the chosen attribute or attributes, based on a sample.
- [varpOver](#) calculates the variance of the specified measure, partitioned by the chosen attribute or attributes, based on a biased population.

Ranking functions

- [rank](#) calculates the rank of a measure or a dimension.
- [denseRank](#) calculates the rank of a measure or a dimension, ignoring duplicates.
- [percentileRank](#) calculates the rank of a measure or a dimension, based on percentile.

Running functions

- [runningAvg](#) calculates a running average for a measure.
- [runningCount](#) calculates a running count for a measure.
- [runningMax](#) calculates a running maximum for a measure.
- [runningMin](#) calculates a running minimum for a measure.
- [runningSum](#) calculates a running sum for a measure.

Window functions

- [firstValue](#) calculates the first value of the aggregated measure or dimension partitioned and sorted by specified attributes.
- [lastValue](#) calculates the last value of the aggregated measure or dimension partitioned and sorted by specified attributes.
- [windowAvg](#) calculates the average of the aggregated measure in a custom window that is partitioned and sorted by specified attributes.
- [windowCount](#) calculates the count of the aggregated measure in a custom window that is partitioned and sorted by specified attributes.
- [windowMax](#) calculates the maximum of the aggregated measure in a custom window that is partitioned and sorted by specified attributes.

- [windowMin](#) calculates the minimum of the aggregated measure in a custom window that is partitioned and sorted by specified attributes.
- [windowSum](#) calculates the sum of the aggregated measure in a custom window that is partitioned and sorted by specified attributes.

Functions

In this section, you can find a list of functions available in Amazon Quick. To view a list of functions sorted by category, with brief definitions, see [Functions by category](#).

- [truncDate](#)

addDateTime

`addDateTime` adds or subtracts a unit of time from a datetime value. For example, `addDateTime(2, 'YYYY', parseDate('02-JUL-2018', 'dd-MMM-yyyy'))` returns 02-JUL-2020. You can use this function to perform date math on your date and time data.

Syntax

```
addDateTime(amount, period, datetime)
```

Arguments

amount

A positive or negative integer value that represents the amount of time that you want to add or subtract from the provided datetime field.

period

A positive or negative value that represents the amount of time that you want to add or subtract from the provided datetime field. Valid periods are as follows:

- YYYY: This returns the year portion of the date.
- Q: This returns the quarter that the date belongs to (1–4).
- MM: This returns the month portion of the date.
- DD: This returns the day portion of the date.
- WK: This returns the week portion of the date. The week starts on Sunday in Amazon Quick.
- HH: This returns the hour portion of the date.
- MI: This returns the minute portion of the date.
- SS: This returns the second portion of the date.
- MS: This returns the millisecond portion of the date.

datetime

The date or time that you want to perform date math on.

Return type

Datetime

Example

Let's say you have a field called `purchase_date` that has the following values.

```
2018 May 13 13:24
2017 Jan 31 23:06
2016 Dec 28 06:45
```

Using the following calculations, `addDateTime` modifies the values as shown following.

```
addDateTime(-2, 'YYYY', purchaseDate)
```

```
2016 May 13 13:24
2015 Jan 31 23:06
2014 Dec 28 06:45
```

```
addDateTime(4, 'DD', purchaseDate)
```

```
2018 May 17 13:24
2017 Feb 4 23:06
2017 Jan 1 06:45
```

```
addDateTime(20, 'MI', purchaseDate)
```

```
2018 May 13 13:44
2017 Jan 31 23:26
2016 Dec 28 07:05
```

addWorkDays

`addWorkDays` Adds or subtracts a designated number of work days to a given date value. The function returns a date for a work day, that falls a designated work days after or before a given input date value.

Syntax

```
addWorkDays(initDate, numWorkDays)
```

Arguments

initDate

A valid non-NULL date that acts as the start date for the calculation.

- **Dataset field** – Any date field from the dataset that you are adding this function to.
- **Date function** – Any date output from another date function, for example `parseDate`, `epochDate`, `addDateTime`., and so on.

Example

```
addWorkDays(epochDate(1659484800), numWorkDays)
```

- **Calculated fields** – Any Quick calculated field that returns a date value.

Example

```
calcFieldStartDate = addDateTime(10, "DD", startDate)  
addWorkDays(calcFieldStartDate, numWorkDays)
```

- **Parameters** – Any Quick datetime parameter.

Example

```
addWorkDays($paramStartDate, numWorkDays)
```

- Any combination of the above stated argument values.

numWorkDays

A non-NULL integer that acts as the end date for the calculation.

- **Literal** – An integer literal directly typed in the expression editor.

Example

- **Dataset field** – Any date field from the dataset

Example

- **Scalar function or calculation** – Any scalar Quick function that returns an integer output from another, for example `decimalToInt`, `abs`, and so on.

Example

```
addWorkDays(initDate, decimalToInt(sqrt (abs(numWorkDays))) ) )
```

- **Calculated field** – Any Quick calculated field that returns a date value.

Example

```
someOtherIntegerCalcField = (num_days * 2) + 12  
addWorkDays(initDate, someOtherIntegerCalcField)
```

- **Parameter** – Any Quick datetime parameter.

Example

```
addWorkDays(initDate, $param_numWorkDays)
```

- Any combination of the above stated argument values.

Return type

Integer

Output values

Expected output values include:

- Positive integer (when `start_date < end_date`)
- Negative integer (when `start_date > end_date`)
- NULL when one or both of the arguments get a null value from the `dataset field`.

Input errors

Disallowed argument values cause errors, as shown in the following examples.

- Using a literal NULL as an argument in the expression is disallowed.

Example

```
addWorkDays(NULL, numWorkDays)
```

Example

Error

At least one of the arguments in this function does not have correct type.
Correct the expression and choose Create again.

- Using a string literal as an argument, or any other data type other than a date, in the expression is disallowed. In the following example, the string "2022-08-10" looks like a date, but it is actually a string. To use it, you would have to use a function that converts to a date data type.

Example

```
addWorkDays("2022-08-10", 10)
```

Example

Error

Expression addWorkDays("2022-08-10", numWorkDays) for function addWorkDays has incorrect argument type addWorkDays(String, Number).
Function syntax expects Date, Integer.

Example

A positive integer as numWorkDays argument will yield a date in the future of the input date. A negative integer as numWorkDays argument will yield a resultant date in the past of the input date. A zero value for the numWorkDays argument yields the same value as input date whether or not it falls on a work day or a weekend.

The addWorkDays function operates at the granularity: DAY. Accuracy cannot be preserved at any granularity which is lower or higher than DAY level.

```
addWorkDays(startDate, endDate)
```

Let's assume there is a field named employmentStartDate with the following values:

```
2022-08-10 2022-08-06 2022-08-07
```

Using the above field and following calculations, `addWorkDays` returns the modified values as shown below:

```
addWorkDays(employmentStartDate, 7)
```

```
2022-08-19
```

```
2022-08-16
```

```
2022-08-16
```

```
addWorkDays(employmentStartDate, -5)
```

```
2022-08-02
```

```
2022-08-01
```

```
2022-08-03
```

```
addWorkDays(employmentStartDate, 0)
```

```
2022-08-10
```

```
2022-08-06
```

```
2022-08-07
```

The following example calculates the total pro-rated bonus to be paid to each employee for 2 years based on how many days each employee has actually worked.

```
last_day_of_work = addWorkDays(employment_start_date, 730)
total_days_worked = netWorkDays(employment_start_date, last_day_of_work)
total_bonus = total_days_worked * bonus_per_day
```

Field wells

Group by

- employee_id
- employment_end_date
- last_day_of_work

Value

- total_days_worked (Sum)
- bonus_per_day (Sum)
- total_bonus (Sum)

netWorkDays addWorkDays

Total pro-rated bonus expenditure

employee...	employment_end_date	last_day_of_work	total_days_worked	bonus_per_day	total_bonus
101	May 6, 2022	Oct 20, 2023	731	55	40,205
102	May 15, 2022	Oct 23, 2023	731	55	40,205
103	Aug 3, 2022	Oct 27, 2023	730	55	40,150
104	Jan 8, 2022	Oct 27, 2023	730	55	40,150
105	Jan 14, 2022	May 21, 2024	731	55	40,205
106	Sep 2, 2022	May 24, 2024	730	55	40,150
107	Aug 9, 2022	May 27, 2024	731	55	40,205
			5,114	385	281,270

Abs

abs returns the absolute value of a given expression.

Syntax

```
abs(expression)
```

Arguments

expression

The expression must be numeric. It can be a field name, a literal value, or another function.

Ceil

ceil rounds a decimal value to the next highest integer. For example, ceil(29.02) returns 30.

Syntax

```
ceil(decimal)
```

Arguments

decimal

A field that uses the decimal data type, a literal value like **17.62**, or a call to another function that outputs a decimal.

Return type

Integer

Example

The following example rounds a decimal field to the next highest integer.

```
ceil(salesAmount)
```

The following are the given field values.

```
20.13  
892.03  
57.54
```

For these field values, the following values are returned.

```
21  
893  
58
```

Coalesce

`coalesce` returns the value of the first argument that is not null. When a non-null value is found, the remaining arguments in the list are not evaluated. If all arguments are null, the result is null. 0-length strings are valid values and are not considered equivalent to null.

Syntax

```
coalesce(expression1, expression2 [, expression3, ...])
```

Arguments

coalesce takes two or more expressions as arguments. All of the expressions must have the same data type or be able to be implicitly cast to the same data type.

expression

The expression can be numeric, datetime, or string. It can be a field name, a literal value, or another function.

Return type

coalesce returns a value of the same data type as the input arguments.

Example

The following example retrieves a customer's billing address if it exists, her street address if there is no billing address, or returns "No address listed" if neither address is available.

```
coalesce(billingAddress, streetAddress, 'No address listed')
```

Concat

concat concatenates two or more strings.

Syntax

```
concat(expression1, expression2 [, expression3 ...])
```

Arguments

concat takes two or more string expressions as arguments.

expression

The expression must be a string. It can be the name of a field that uses the string data type, a literal value like '**12 Main Street**', or a call to another function that outputs a string.

Return type

String

Examples

The following example concatenates three string fields and adds appropriate spacing.

```
concat(salutation, ' ', firstName, ' ', lastName)
```

The following are the given field values.

salutation	firstName	lastName
Ms.	Li	Juan
Dr.	Ana Carolina	Silva
Mr.	Nikhil	Jayashankar

For these field values, the following values are returned.

```
Ms. Li Juan  
Dr. Ana Carolina Silva  
Mr. Nikhil Jayashankar
```

The following example concatenates two string literals.

```
concat('Hello', 'world')
```

The following value is returned.

```
Helloworld
```

contains

`contains` evaluates if the substring that you specify exists within an expression. If the expression contains the substring, `contains` returns true, and otherwise it returns false.

Syntax

```
contains(expression, substring, string-comparison-mode)
```

Arguments

expression

The expression must be a string. It can be the name of a field that uses the string data type, a literal value like **'12 Main Street'**, or a call to another function that outputs a string.

substring

The set of characters to check against the *expression*. The substring can occur one or more times in the *expression*.

string-comparison-mode

(Optional) Specifies the string comparison mode to use:

- CASE_SENSITIVE – String comparisons are case-sensitive.
- CASE_INSENSITIVE – String comparisons are case-insensitive.

This value defaults to CASE_SENSITIVE when blank.

Return type

Boolean

Examples

Default case sensitive example

The following case sensitive example evaluates if `state_nm` contains **New**.

```
contains(state_nm, "New")
```

The following are the given field values.

```
New York  
new york
```

For these field values, the following values are returned.

```
true
```

```
false
```

Case insensitive example

The following case insensitive example evaluates if `state_nm` contains **new**.

```
contains(state_nm, "new", CASE_INSENSITIVE)
```

The following are the given field values.

```
New York  
new york
```

For these field values, the following values are returned.

```
true  
true
```

Example with conditional statements

The `contains` function can be used as the conditional statement within the following If functions: [avgIf](#), [minIf](#), [distinct_countIf](#), [countIf](#), [maxIf](#), [medianIf](#), [stdevIf](#), [stdevpIf](#), [sumIf](#), [varIf](#), and [varpIf](#).

The following example sums `Sales` only if `state_nm` contains **New**.

```
sumIf(Sales, contains(state_nm, "New"))
```

Does NOT contain example

The conditional NOT operator can be used to evaluate if the expression does not contain the specified substring.

```
NOT(contains(state_nm, "New"))
```

Example using numeric values

Numeric values can be used in the expression or substring arguments by applying the `toString` function.

```
contains(state_nm, toString(5) )
```

decimalToInt

`decimalToInt` converts a decimal value to the integer data type by stripping off the decimal point and any numbers after it. `decimalToInt` does not round up. For example, `decimalToInt(29.99)` returns 29.

Syntax

```
decimalToInt(decimal)
```

Arguments

decimal

A field that uses the decimal data type, a literal value like **17.62**, or a call to another function that outputs a decimal.

Return type

Integer

Example

The following example converts a decimal field to an integer.

```
decimalToInt(salesAmount)
```

The following are the given field values.

```
20.13  
892.03  
57.54
```

For these field values, the following values are returned.

```
20  
892  
57
```

dateDiff

dateDiff returns the difference in days between two date fields. If you include a value for the period, dateDiff returns the difference in the period interval, rather than in days.

Syntax

```
dateDiff(date1, date2, [period])
```

Arguments

dateDiff takes two dates as arguments. Specifying a period is optional.

date 1

The first date in the comparison. A date field or a call to another function that outputs a date.

date 2

The second date in the comparison. A date field or a call to another function that outputs a date.

period

The period of difference that you want returned, enclosed in quotes. Valid periods are as follows:

- YYYY: This returns the year portion of the date.
- Q: This returns the date of the first day of the quarter that the date belongs to.
- MM: This returns the month portion of the date.
- DD: This returns the day portion of the date.
- WK: This returns the week portion of the date. The week starts on Sunday in Amazon Quick.
- HH: This returns the hour portion of the date.
- MI: This returns the minute portion of the date.
- SS: This returns the second portion of the date.
- MS: This returns the millisecond portion of the date.

Return type

Integer

Example

The following example returns the difference between two dates.

```
dateDiff(orderDate, shipDate, "MM")
```

The following are the given field values.

orderDate	shipdate
01/01/18	03/05/18
09/13/17	10/20/17

For these field values, the following values are returned.

```
2  
1
```

endsWith

`endsWith` evaluates if the expression ends with a substring that you specify. If the expression ends with the substring, `endsWith` returns true, and otherwise it returns false.

Syntax

```
endsWith(expression, substring, string-comparison-mode)
```

Arguments

expression

The expression must be a string. It can be the name of a field that uses the string data type, a literal value like **'12 Main Street'**, or a call to another function that outputs a string.

substring

The set of characters to check against the *expression*. The substring can occur one or more times in the *expression*.

string-comparison-mode

(Optional) Specifies the string comparison mode to use:

- **CASE_SENSITIVE** – String comparisons are case-sensitive.

- `CASE_INSENSITIVE` – String comparisons are case-insensitive.

This value defaults to `CASE_SENSITIVE` when blank.

Return type

Boolean

Examples

Default case sensitive example

The following case sensitive example evaluates if `state_nm` endsWith **"York"**.

```
endsWith(state_nm, "York")
```

The following are the given field values.

```
New York  
new york
```

For these field values, the following values are returned.

```
true  
false
```

Case insensitive example

The following case insensitive example evaluates if `state_nm` endsWith **"york"**.

```
endsWith(state_nm, "york", CASE_INSENSITIVE)
```

The following are the given field values.

```
New York  
new york
```

For these field values, the following values are returned.

```
true  
true
```

Example with conditional statements

The `endsWith` function can be used as the conditional statement within the following If functions: [avgIf](#), [minIf](#), [distinct_countIf](#), [countIf](#), [maxIf](#), [medianIf](#), [stdevIf](#), [stdevplf](#), [sumIf](#), [varIf](#), and [varplf](#).

The following example sums Sales only if `state_nm` ends with "York".

```
sumIf(Sales, endsWith(state_nm, "York"))
```

Does NOT contain example

The conditional NOT operator can be used to evaluate if the expression does not start with the specified substring.

```
NOT(endsWith(state_nm, "York"))
```

Example using numeric values

Numeric values can be used in the expression or substring arguments by applying the `toString` function.

```
endsWith(state_nm, toString(5) )
```

epochDate

`epochDate` converts an epoch date into a standard date in the format `yyyy-MM-ddTkk:mm:ss.SSSZ`, using the format pattern syntax specified in [Class DateTimeFormat](#) in the Joda project documentation. An example is `2015-10-15T19:11:51.003Z`.

`epochDate` is supported for use with analyses based on datasets stored in Quick (SPICE).

Syntax

```
epochDate(epochdate)
```

Arguments

epochdate

An epoch date, which is an integer representation of a date as the number of seconds since 00:00:00 UTC on January 1, 1970.

epochdate must be an integer. It can be the name of a field that uses the integer data type, a literal integer value, or a call to another function that outputs an integer. If the integer value is longer than 10 digits, the digits after the 10th place are discarded.

Return type

Date

Example

The following example converts an epoch date to a standard date.

```
epochDate(3100768000)
```

The following value is returned.

```
2068-04-04T12:26:40.000Z
```

Exp

exp returns the base of natural log e raised to the power of a given expression.

Syntax

```
exp(expression)
```

Arguments

expression

The expression must be numeric. It can be a field name, a literal value, or another function.

Extract

extract returns a specified portion of a date value. Requesting a time-related portion of a date that doesn't contain time information returns 0.

Syntax

```
extract(period, date)
```

Arguments

period

The period that you want extracted from the date value. Valid periods are as follows:

- YYYY: This returns the year portion of the date.
- Q: This returns the quarter that the date belongs to (1–4).
- MM: This returns the month portion of the date.
- DD: This returns the day portion of the date.
- WD: This returns the day of the week as an integer, with Sunday as 1.
- HH: This returns the hour portion of the date.
- MI: This returns the minute portion of the date.
- SS: This returns the second portion of the date.
- MS: This returns the millisecond portion of the date.

Note

Extracting milliseconds is not supported in Presto databases below version 0.216.

date

A date field or a call to another function that outputs a date.

Return type

Integer

Example

The following example extracts the day from a date value.

```
extract('DD', orderDate)
```

The following are the given field values.

```
orderDate
=====
01/01/14
```

```
09/13/16
```

For these field values, the following values are returned.

```
01  
13
```

Floor

`floor` decrements a decimal value to the next lowest integer. For example, `floor(29.08)` returns 29.

Syntax

```
floor(decimal)
```

Arguments

decimal

A field that uses the decimal data type, a literal value like **17.62**, or a call to another function that outputs a decimal.

Return type

Integer

Example

The following example decrements a decimal field to the next lowest integer.

```
floor(salesAmount)
```

The following are the given field values.

```
20.13  
892.03  
57.54
```

For these field values, the following values are returned.

```
20
892
57
```

formatDate

`formatDate` formats a date using a pattern you specify. When you are preparing data, you can use `formatDate` to reformat the date. To reformat a date in an analysis, you choose the format option from the context menu on the date field.

Syntax

```
formatDate(date, ['format'])
```

Arguments

date

A date field or a call to another function that outputs a date.

format

(Optional) A string containing the format pattern to apply. This argument accepts the format patterns specified in [Supported date formats](#).

If you don't specify a format, this string defaults to `yyyy-MM-ddTkk:mm:ss.SSS`.

Return type

String

Example

The following example formats a UTC date.

```
formatDate(orderDate, 'dd-MMM-yyyy')
```

The following are the given field values.

```
order date
=====
```

```
2012-12-14T00:00:00.000Z
2013-12-29T00:00:00.000Z
2012-11-15T00:00:00.000Z
```

For these field values, the following values are returned.

```
13 Dec 2012
28 Dec 2013
14 Nov 2012
```

Example

If the date contains single quotes or apostrophes, for example `yyyyMMdd'T'HHmmss`, you can handle this date format by using one of the following methods.

- Enclose the entire date in double quotes, as shown in the following example:

```
formatDate({myDateField}, "yyyyMMdd'T'HHmmss")
```

- Escape the single quotes or apostrophes by adding a backslash (\) to the left of them, as shown in the following example:

```
formatDate({myDateField}, 'yyyyMMdd\'T\'HHmmss')
```

Ifelse

`ifelse` evaluates a set of *if, then* expression pairings, and returns the value of the *then* argument for the first *if* argument that evaluates to true. If none of the *if* arguments evaluate to true, then the value of the *else* argument is returned.

Syntax

```
ifelse(if-expression-1, then-expression-1 [, if-expression-n, then-expression-n
...], else-expression)
```

Arguments

`ifelse` requires one or more *if, then* expression pairings, and requires exactly one expression for the *else* argument.

if-expression

The expression to be evaluated as true or not. It can be a field name like **address1**, a literal value like '**Unknown**', or another function like `toString(salesAmount)`. An example is `isNotNull(FieldName)`.

If you use multiple AND and OR operators in the `if` argument, enclose statements in parentheses to identify processing order. For example, the following `if` argument returns records with a month of 1, 2, or 5 and a year of 2000.

```
ifelse((month = 5 OR month < 3) AND year = 2000, 'yes', 'no')
```

The next `if` argument uses the same operators, but returns records with a month of 5 and any year, or with a month of 1 or 2 and a year of 2000.

```
ifelse(month = 5 OR (month < 3 AND year = 2000), 'yes', 'no')
```

then-expression

The expression to return if its *if* argument is evaluated as true. It can be a field name like **address1**, a literal value like '**Unknown**', or a call to another function. The expression must have the same data type as the other then arguments and the `else` argument.

else-expression

The expression to return if none of the *if* arguments evaluate as true. It can be a field name like **address1**, a literal value like '**Unknown**', or another function like `toString(salesAmount)`. The expression must have the same data type as all of the then arguments.

Return type

`ifelse` returns a value of the same data type as the values in *then-expression*. All data returned *then* and *else* expressions must be of the same data type or be converted to the same data type.

Examples

The following example generates a column of aliases for field `country`.

```
ifelse(country = "United States", "US", country = "China", "CN", country = "India",  
      "IN", "Others")
```

For such use cases evaluating each value in a field against a list of literals, and returns the result corresponding to the first matching value., function `switch` is recommended to simplify your work. The previous example can be rewritten to the following statement using [switch](#):

```
switch(country,"United States","US","China","CN","India","IN","Others")
```

The following example categorizes sales per customer into human-readable levels.

```
ifelse(salesPerCustomer < 1000, "VERY_LOW", salesPerCustomer < 10000, "LOW",
salesPerCustomer < 100000, "MEDIUM", "HIGH")
```

The following example uses AND, OR, and NOT to compare multiple expressions using conditional operators to tag top customers NOT in Washington or Oregon with a special promotion, who made more than 10 orders. If no values are returned, the value 'n/a' is used.

```
ifelse(( NOT (State = 'WA' OR State = 'OR')) AND Orders > 10), 'Special Promotion
XYZ', 'n/a')
```

The following examples use only OR to generate a new column that contains the name of continent that corresponds to each country.

```
ifelse(country = "United States" OR country = "Canada", "North America", country =
"China" OR country = "India" OR country = "Japan", "Asia", "Others")
```

The previous example can be simplified as shown in the next example. The following example uses `ifelse` and [in](#) to create a value in a new column for any row where the tested value is in a literal list. You could use `ifelse` with [notIn](#) as well.

```
ifelse(in(country,["United States", "Canada"]), "North America", in(country,
["China","Japan","India"]), "Asia", "Others")
```

Authors are able to save a literal list in a multivalue parameter and use it in the [in](#) or [notIn](#) functions. The following example is an equivalent of the previous example, except that the literal lists are stored in two multivalue parameters.

```
ifelse(in(country,${NorthAmericaCountryParam}), "North America", in(country,
${AsiaCountryParam}), "Asia", "Others")
```

The following example assigns a group to a sales record based on the sales total. The structure of each if-then phrase mimics the behavior of *between*, a keyword that doesn't currently work in calculated field expressions. For example, the result of the comparison `salesTotal >= 0 AND salesTotal < 500` returns the same values as the SQL comparison `salesTotal between 0 and 499`.

```
ifelse(salesTotal >= 0 AND salesTotal < 500, 'Group 1', salesTotal >= 500 AND
salesTotal < 1000, 'Group 2', 'Group 3')
```

The following example tests for a NULL value by using `coalesce` to return the first non-NULL value. Instead of needing to remember the meaning of a NULL in a date field, you can use a readable description instead. If the disconnect date is NULL, the example returns the suspend date, unless both of those are NULL. Then `coalesce(DiscoDate, SuspendDate, '12/31/2491')` returns `'12/31/2491'`. The return value must match the other data types. This date might seem like an unusual value, but a date in the 25th century reasonably simulates the "end of time," defined as the highest date in a data mart.

```
ifelse ( (coalesce(DiscoDate, SuspendDate, '12/31/2491') = '12/31/2491'), 'Active
subscriber', 'Inactive subscriber')
```

The following shows a more complex example in a more readable format, just to show that you don't need to compress your code all into one long line. This example provides for multiple comparisons of the value a survey result. It handles potential NULL values for this field and categorizes two acceptable ranges. It also labels one range that needs more testing and another that's not valid (out of range). For all remaining values, it applies the `else` condition, and labels the row as needing a retest three years after the date on that row.

```
ifelse
(
  isNull({SurveyResult}), 'Untested',
  {SurveyResult}=1, 'Range 1',
  {SurveyResult}=2, 'Range 2',
  {SurveyResult}=3, 'Need more testing',
  {SurveyResult}=99, 'Out of Range',
  concat
  (
    'Retest by ',
    toString
    (
```

```

        addDateTime(3, "YYYY", {Date}))
    )
)

```

The following example assigns a "manually" created region name to a group of states. It also uses spacing and comments, wrapped in `/* */`, to make it easier to maintain the code.

```

ifelse
(
  /* NE REGION*/
  locate('New York, New Jersey, Connecticut, Vermont, Maine, Rhode Island, New
Hampshire',{State})) > 0,
  'Northeast',

  /* SE REGION*/
  locate('Georgia, Alabama, South Carolina, Louisiana',{State})) > 0,
  'Southeast',

  'Other Region'
)

```

The logic for the region tagging breaks down as follows:

1. We list the states that we want for each region, enclosing each list in quotation marks to make each list a string, as follows:
 - 'New York, New Jersey, Connecticut, Vermont, Maine, Rhode Island, New Hampshire'
 - 'Georgia, Alabama, South Carolina, Louisiana'
 - You can add more sets, or use countries, cities, provinces, or What3Words if you want.
2. We ask if the value for State (for each row) is found in the list, by using the `locate` function to return a nonzero value if the state is found in the list, as follows.

```
locate('New York, New Jersey, Connecticut, Vermont, Maine, Rhode Island, New
Hampshire',{State})
```

and

```
locate('Georgia, Alabama, South Carolina, Louisiana',{State})
```

3. The `locate` function returns a number instead of a `TRUE` or `FALSE`, but `ifelse` requires the `TRUE/FALSE` Boolean value. To get around this, we can compare the result of `locate` to a number. If the state is in the list, the return value is greater than zero.

- a. Ask if the state is present.

```
locate('New York, New Jersey, Connecticut, Vermont, Maine, Rhode Island, New
Hampshire',{State}) > 0
```

- b. If it's present the region, label it as the specific region, in this case a Northeast region.

```
/*The if expression:*/      locate('New York, New Jersey, Connecticut, Vermont,
Maine, Rhode Island, New Hampshire',{State}) > 0,
/*The then expression:*/    'Northeast',
```

4. Because we have states that aren't in a list, and because `ifelse` requires a single `else` expression, we provide `'Other Region'` as the label for the leftover states.

```
/*The if expression:*/      locate('New York, New Jersey, Connecticut, Vermont, Maine,
Rhode Island, New Hampshire',{State}) > 0,
/*The then expression:*/    'Northeast',
/*The else expression:*/    'Other Region'
```

5. We wrap all that in the `ifelse( )` function to get the final version. The following example leaves out the Southeast region states that were in the original. You can add them back in place of the *<insert more regions here>* tag.

If you want to add more regions, you can construct more copies of those two lines and alter the list of states to suit your purpose. You can change the region name to something that suits you, and change the field name from `State` to anything that you need.

```
ifelse
(
/*The if expression:*/      locate('New York, New Jersey, Connecticut, Vermont, Maine,
Rhode Island, New Hampshire',{State}) > 0,
/*The then expression:*/    'Northeast',

/*<insert more regions here>*/

/*The else expression:*/    'Other Region'
)
```

Note

There are other ways to do the initial comparison for the if expression. For example, suppose that you pose the question "What states are not missing from this list?" rather than "Which states are on the list?" If you do, you might phrase it differently. You might compare the locate statement to zero to find values that are missing from the list, and then use the NOT operator to classify them as "not missing," as follows.

```
/*The if expression:*/      NOT (locate('New York, New Jersey, Connecticut,  
Vermont, Maine, Rhode Island, New Hampshire',{State}) = 0),
```

Both versions are correct. The version that you choose should make the most sense to you and your team, so you can maintain it easily. If all the options seem equal, choose the simplest.

in

`in` evaluates if an expression exists within a literal list. If the list contains the expression, `in` returns true, and otherwise it returns false. `in` is case sensitive for string type inputs.

`in` accepts two kinds of literal list, one is manually entered list and the other is a [multivalue parameter](#).

Syntax

Using a manually entered list:

```
in(expression, [literal-1, ...])
```

Using a multivalue parameter:

```
in(expression, $multivalue_parameter)
```

Arguments

expression

The expression to be compared with the elements in literal list. It can be a field name like address, a literal value like '**Unknown**', a single value parameter, or a call to another scalar function—provided this function is not an aggregate function or a table calculation.

literal list

(required) This can be a manually entered list or a multivalue parameter. This argument accepts up to 5,000 elements. However, in a direct query to a third party data source, for example Oracle or Teradata, the restriction can be smaller.

- **manually entered list** – One or more literal values in a list to be compared with the expression. The list should be enclosed in square brackets. All the literals to compare must have the same datatype as the expression.
- **multivalue parameter** – A pre-defined multivalue parameter passed in as a literal list. The multivalue parameter must have the same datatype as the expression.

Return type

Boolean: TRUE/FALSE

Example with a static list

The following example evaluates the `origin_state_name` field for values in a list of string. When comparing string type input, `in` only supports case sensitive comparison.

```
in(origin_state_name,["Georgia", "Ohio", "Texas"])
```

The following are the given field values.

```
"Washington"  
  "ohio"  
  "Texas"
```

For these field values the following values are returned.

```
false
```

```
false
true
```

The third return value is true because only "Texas" is one of the included values.

The following example evaluates the `fl_date` field for values in a list of string. In order to match the type, `toString` is used to cast the date type to string type.

```
in(toString(fl_date),["2015-05-14","2015-05-15","2015-05-16"])
```

Field wells

May 13, 2015	0
May 15, 2015	1

Literals and NULL values are supported in expression argument to be compared with the literals in list. Both of the following two examples will generate a new column of TRUE values.

```
in("Washington",["Washington","Ohio"])
```

```
in(NULL,[NULL,"Ohio"])
```

Example with multivalue parameter

Let's say an author creates a [multivalue parameter](#) that contains a list of all the state names. Then the author adds a control to allow the reader to select values from the list.

Next, the reader selects three values—"Georgia", "Ohio", and "Texas"—from the parameter's drop down list control. In this case, the following expression is equivalent to the first example, where those three state names are passed as the literal list to be compared with the `original_state_name` field.

```
in (origin_state_name, ${stateName MultivalueParameter})
```

Example with ifelse

`in` can be nested in other functions as a boolean value. One example is that authors can evaluate any expression in a list and return the value they want by using `in` and `ifelse`. The following example evaluates if the `dest_state_name` of a flight is in a particular list of US states and returns different categories of the states based on the comparison.

```
ifelse(in(dest_state_name, ["Washington", "Oregon", "California"]), "WestCoastUSState",  
      "Other US State")
```

intToDecimal

intToDecimal converts an integer value to the decimal data type.

Syntax

```
intToDecimal(integer)
```

Arguments

int

A field that uses the integer data type, a literal value like **14**, or a call to another function that outputs an integer.

Return type

Decimal(Fixed) in the legacy data preparation experience.

Decimal(Float) in the new data preparation experience.

Example

The following example converts an integer field to a decimal.

```
intToDecimal(price)
```

The following are the given field values.

```
20  
892  
57
```

For these field values, the following values are returned.

```
20.0  
892.0  
58.0
```

You can apply formatting inside an analysis, for example to format `price` as currency.

isNotNull

`isNotNull` evaluates an expression to see if it is not null. If the expression is not null, `isNotNull` returns true, and otherwise it returns false.

Syntax

```
isNotNull(expression)
```

Arguments

expression

The expression to be evaluated as null or not. It can be a field name like **address1** or a call to another function that outputs a string.

Return type

Boolean

Example

The following example evaluates the `sales_amount` field for null values.

```
isNotNull(salesAmount)
```

The following are the given field values.

```
20.13  
(null)  
57.54
```

For these field values, the following values are returned.

```
true  
false  
true
```

isNull

`isNull` evaluates an expression to see if it is null. If the expression is null, `isNull` returns true, and otherwise it returns false.

Syntax

```
isNull(expression)
```

Arguments

expression

The expression to be evaluated as null or not. It can be a field name like **address1** or a call to another function that outputs a string.

Return type

Boolean

Example

The following example evaluates the `sales_amount` field for null values.

```
isNull(salesAmount)
```

The following are the given field values.

```
20.13  
(null)  
57.54
```

For these field values, the following values are returned.

```
false  
true  
false
```

The following example tests for a NULL value in an `ifelse` statement, and returns a human-readable value instead.

```
ifelse( isNull({ActiveFlag}) , 'Inactive', 'Active')
```

isWorkDay

`isWorkDay` evaluates a given date-time value to determine if the value is a workday or not.

`isWorkDay` assumes a standard 5-day work week starting from Monday and ending on Friday. Saturday and Sunday are assumed to be weekends. The function always calculates its result at the DAY granularity and is exclusive of the given input date.

Syntax

```
isWorkDay(inputDate)
```

Arguments

inputDate

The date-time value that you want to evaluate. Valid values are as follows:

- **Dataset fields:** Any date field from the dataset that you are adding this function to.
- **Date Functions:** Any date output from another date function, for example, `parseDate`.
- **Calculated fields:** Any Quick calculated field that returns a date value.
- **Parameters:** Any Quick `DateTime` parameter.

Return type

Integer (0 or 1)

Example

The following example determines whether or not the `application_date` field is a work day.

Let's assume that there's a field named `application_date` with the following values:

```
2022-08-10  
2022-08-06  
2022-08-07
```

When you use these fields and add the following calculations, `isWorkDay` returns the below values:

```
isWorkDay({application_date})  
  
1  
0  
0
```

The following example filters employees whose employment ends on a work day and determines whether their employment began on work day or a weekend using conditional formatting:

```
is_start_date_work_day = isWorkDay(employment_start_date)  
is_end_date_work_day = isWorkDay(employment_end_date)
```

Left

left returns the leftmost characters from a string, including spaces. You specify the number of characters to be returned.

Syntax

```
left(expression, limit)
```

Arguments

expression

The expression must be a string. It can be the name of a field that uses the string data type, a literal value like **'12 Main Street'**, or a call to another function that outputs a string.

limit

The number of characters to be returned from *expression*, starting from the first character in the string.

Return type

String

Example

The following example returns the first 3 characters from a string.

```
left('Seattle Store #14', 3)
```

The following value is returned.

```
Sea
```

Locate

locate locates a substring that you specify within another string, and returns the number of characters until the first character in the substring. The function returns 0 if it doesn't find the substring. The function is 1-based.

Syntax

```
locate(expression, substring, start)
```

Arguments

expression

The expression must be a string. It can be the name of a field that uses the string data type, a literal value like **'12 Main Street'**, or a call to another function that outputs a string.

substring

The set of characters in *expression* that you want to locate. The substring can occur one or more times in *expression*.

start

(Optional) If *substring* occurs more than once, use *start* to identify where in the string the function should start looking for the substring. For example, suppose that you want to find the second example of a substring and you think it typically occurs after the first 10 characters. You specify a *start* value of 10. It should start from 1.

Return type

Integer

Examples

The following example returns information about where the first occurrence of the substring 'and' appears in a string.

```
locate('1 and 2 and 3 and 4', 'and')
```

The following value is returned.

```
3
```

The following example returns information about where the first occurrence of the substring 'and' appears in a string after the fourth character.

```
locate('1 and 2 and 3 and 4', 'and', 4)
```

The following value is returned.

```
9
```

Log

log returns the base 10 logarithm of a given expression.

Syntax

```
log(expression)
```

Arguments

expression

The expression must be numeric. It can be a field name, a literal value, or another function.

Ln

Ln returns the natural logarithm of a given expression.

Syntax

```
ln(expression)
```

Arguments

expression

The expression must be numeric. It can be a field name, a literal value, or another function.

Ltrim

Ltrim removes preceding blank space from a string.

Syntax

```
ltrim(expression)
```

Arguments

expression

The expression must be a string. It can be the name of a field that uses the string data type, a literal value like **'12 Main Street'**, or a call to another function that outputs a string.

Return type

String

Example

The following example removes the preceding spaces from a string.

```
ltrim('   Seattle Store #14')
```

The following value is returned.

```
Seattle Store #14
```

Mod

Use the mod function to find the remainder after dividing the number by the divisor. You can use the mod function or the modulo operator (%) interchangeably.

Syntax

```
mod(number, divisor)
```

```
number%divisor
```

Arguments

number

The number is the positive integer that you want to divide and find the remainder for.

divisor

The divisor is the positive integer that you are dividing by. If the divisor is zero, this function returns an error on dividing by 0.

Example

The following examples return the modulo of 17 when dividing by 6. The first example uses the % operator, and the second example uses the mod function.

```
17%6
```

```
mod( 17, 6 )
```

The following value is returned.

netWorkDays

netWorkDays returns the number of working days between the provided two date fields or even custom date values generated using other Quick date functions such as `parseDate` or `epochDate` as an integer.

netWorkDays assumes a standard 5-day work week starting from Monday and ending on Friday. Saturday and Sunday are assumed to be weekends. The calculation is inclusive of both `startDate` and `endDate`. The function operates on and shows results for DAY granularity.

Syntax

```
netWorkDays(startDate, endDate)
```

Arguments

startDate

A valid non-NULL date that acts as the start date for the calculation.

- Dataset fields: Any date field from the dataset that you are adding this function to.
- Date Functions: Any date output from another date function, for example, `parseDate`.
- Calculated fields: Any Quick calculated field that returns a date value.
- Parameters: Any Quick DateTime parameter.
- Any combination of the above stated argument values.

endDate

A valid non-NULL date that acts as the end date for the calculation.

- Dataset fields: Any date field from the dataset that you are adding this function to.
- Date Functions: Any date output from another date function, for example, `parseDate`.
- Calculated fields: Any Quick calculated field that returns a date value.
- Parameters: Any Quick DateTime parameter.
- Any combination of the above stated argument values.

Return type

Integer

Output values

Expected output values include:

- Positive integer (when `start_date < end_date`)
- Negative integer (when `start_date > end_date`)
- NULL when one or both of the arguments get a null value from the `dataset` field.

Example

The following example returns the number of work days falling between two dates.

Let's assume that there's a field named `application_date` with the following values:

```
netWorkDays({startDate}, {endDate})
```

The following are the given field values.

```
startDate endDate netWorkDays
9/4/2022 9/11/2022 5
9/9/2022 9/2/2022 -6
9/10/2022 9/11/2022 0
9/12/2022 9/12/2022 1
```

The following example calculates the number of days worked by each employee and the salary expended per day for each employee:

```
days_worked = netWorkDays({employment_start_date}, {employment_end_date})
salary_per_day = {salary}/{days_worked}
```

The following example filters employees whose employment ends on a work day and determines whether their employment began on work day or a weekend using conditional formatting:

```
is_start_date_work_day = netWorkDays(employment_start_date)
```

```
is_end_date_work_day = netWorkDays(employment_end_date)
```

				2,035	3,231.27

Now

For database datasets that directly query the database, now returns the current date and time using the settings and format specified by the database server. For SPICE and Salesforce data sets, now returns the UTC date and time, in the format yyyy-MM-ddTkk:mm:ss:SSSZ (for example, 2015-10-15T19:11:51:003Z).

Syntax

```
now()
```

Return type

Date

notIn

notIn evaluates if an expression exists within a literal list. If the list doesn't contain the expression, notIn returns true, and otherwise it returns false. notIn is case sensitive for string type inputs.

notIn accepts two kinds of literal list, one is manually entered list and the other is a [multivalue parameter](#).

Syntax

Using a manually entered list:

```
notIn(expression, [literal-1, ...])
```

Using a multivalue parameter:

```
notIn(expression, $multivalue_parameter)
```

Arguments

expression

The expression to be compared with the elements in literal list. It can be a field name like address, a literal value like ' **Unknown**', a single value parameter, or a call to another scalar function—provided this function is not an aggregate function or a table calculation.

literal list

(required) This can be a manually entered list or a multivalue parameter. This argument accepts up to 5,000 elements. However, in a direct query to a third party data source, for example Oracle or Teradata, the restriction can be smaller.

- **manually entered list** – One or more literal values in a list to be compared with the expression. The list should be enclosed in square brackets. All the literals to compare must have the same datatype as the expression.
- **multivalue parameter** – A pre-defined multivalue parameter passed in as a literal list. The multivalue parameter must have the same datatype as the expression.

Return type

Boolean: TRUE/FALSE

Example with a manually entered list

The following example evaluates the `origin_state_name` field for values in a list of string. When comparing string type input, `notIn` only supports case sensitive comparison.

```
notIn(origin_state_name, ["Georgia", "Ohio", "Texas"])
```

The following are the given field values.

```
"Washington"  
  "ohio"  
  "Texas"
```

For these field values the following values are returned.

```
true  
  true  
  false
```

The third return value is false because only "Texas" is one of the excluded values.

The following example evaluates the `f1_date` field for values in a list of string. In order to match the type, `toString` is used to cast the date type to string type.

```
notIn(toString(f1_date), ["2015-05-14", "2015-05-15", "2015-05-16"])
```

Field wells

Group by

fl_date

flightNotInMidMay

Value

Add measures here

Sheet 1 +

FL_date and Flightnotinmidmay

fl_date	flightNotInMidMay
May 15, 2015	0
May 12, 2015	1
May 13, 2015	1

Literals and NULL values are supported in expression argument to be compared with the literals in list. Both of the following two examples will generate a new column of FALSE values.

```
notIn("Washington",["Washington","Ohio"])
```

```
notIn(NULL,[NULL,"Ohio"])
```

Example with multivalue parameter

Let's say an author creates a [multivalue parameter](#) that contains a list of all the state names. Then the author adds a control to allow the reader to select values from the list.

Next, the reader selects three values—"Georgia", "Ohio", and "Texas"—from the parameter's drop down list control. In this case, the following expression is equivalent to the first example, where those three state names are passed as the literal list to be compared with the `original_state_name` field.

```
notIn (origin_state_name, ${stateName MultivalueParameter})
```

Example with ifelse

notIn can be nested in other functions as a boolean value. One example is that authors can evaluate any expression in a list and return the value they want by using notIn and ifelse. The following example evaluates if the dest_state_name of a flight is in a particular list of US states and returns different categories of the states based on the comparison.

```
ifelse(notIn(dest_state_name,["Washington", "Oregon", "California"]),  
      "notWestCoastUSState", "WestCoastUSState")

nullIf

nullIf compares two expressions. If they are equal, the function returns null. If they are not equal, the function returns the first expression.

Syntax

```
nullIf(expression1, expression2)
```

Arguments

nullIf takes two expressions as arguments.

expression

The expression can be numeric, datetime, or string. It can be a field name, a literal value, or another function.

Return type

String

Example

The following example returns nulls if the reason for a shipment delay is unknown.

```
nullIf(delayReason, 'unknown')
```

The following are the given field values.

```
delayReason
=====
unknown
back ordered
weather delay
```

For these field values, the following values are returned.

```
(null)
back ordered
weather delay
```

parseDate

`parseDate` parses a string to determine if it contains a date value, and returns a standard date in the format `yyyy-MM-ddTkk:mm:ss.SSSZ` (using the format pattern syntax specified in [Class DateTimeFormat](#) in the Joda project documentation), for example `2015-10-15T19:11:51.003Z`. This function returns all rows that contain a date in a valid format and skips any rows that don't, including rows that contain null values.

Quick supports dates in the range from Jan 1, 1900 00:00:00 UTC to Dec 31, 2037 23:59:59 UTC. For more information, see [Supported date formats](#).

Syntax

```
parseDate(expression, ['format'])
```

Arguments

expression

The expression must be a string. It can be the name of a field that uses the string data type, a literal value like `'1/1/2016'`, or a call to another function that outputs a string.

format

(Optional) A string containing the format pattern that *date_string* must match. For example, if you are using a field with data like `01/03/2016`, you specify the format `'MM/dd/yyyy'`. If you don't specify a format, it defaults to `yyyy-MM-dd`. Rows whose data doesn't conform to *format* are skipped.

Different date formats are supported based on the type of dataset used. Use the following table to see details of supported date formats.

Date source type	Supported date formats
File, Amazon Athena, and Salesforce datasets	All date format patterns specified in Supported date formats .
Direct query of Amazon Aurora, MariaDB, and MySQL databases	- MM/dd/yyyy

Return type

Date

Example

The following example evaluates `prodDate` to determine if it contains date values.

```
parseDate(prodDate, 'MM/dd/yyyy')
```

The following are the given field values.

```
prodDate
-----
01-01-1999
12/31/2006
1/18/1982
7/4/2010
```

For these field values, the following rows are returned.

```
12-31-2006T00:00:00.000Z
01-18-1982T00:00:00.000Z
07-04-2010T00:00:00.000Z
```

parseDecimal

`parseDecimal` parses a string to determine if it contains a decimal value. This function returns all rows that contain a decimal, integer, or null value, and skips any rows that don't. If the row contains an integer value, it is returned as a decimal with up to 4 decimal places. For example, a value of '2' is returned as '2.0'.

Syntax

```
parseDecimal(expression)
```

Arguments

expression

The expression must be a string. It can be the name of a field that uses the string data type, a literal value like **'9.62'**, or a call to another function that outputs a string.

Return type

Decimal(Fixed) in the legacy data preparation experience.

Decimal(Float) in the new data preparation experience.

Example

The following example evaluates fee to determine if it contains decimal values.

```
parseDecimal(fee)
```

The following are the given field values.

```
fee
-----
2
2a
12.13
3b
3.9
(null)
198.353398
```

For these field values, the following rows are returned.

```
2.0
12.13
3.9
```

```
(null)
198.3533
```

parseInt

`parseInt` parses a string to determine if it contains an integer value. This function returns all rows that contain a decimal, integer, or null value, and skips any rows that don't. If the row contains a decimal value, it is returned as the nearest integer, rounded down. For example, a value of '2.99' is returned as '2'.

Syntax

```
parseInt(expression)
```

Arguments

expression

The expression must be a string. It can be the name of a field that uses the string data type, a literal value like '3', or a call to another function that outputs a string.

Return type

Integer

Example

The following example evaluates `feeType` to determine if it contains integer values.

```
parseInt(feeType)
```

The following are the given field values.

```
feeType
-----
2
2.1
2a
3
```

```
3b
(null)
5
```

For these field values, the following rows are returned.

```
2
2
3
(null)
5
```

parseJson

Use `parseJson` to extract values from a JSON object.

If your dataset is stored in Quick SPICE, you can use `parseJson` when you are preparing a data set, but not in calculated fields during analysis.

For direct query, you can use `parseJson` both during data preparation and analysis. The `parseJson` function applies to either strings or to JSON native data types, depending on the dialect, as shown in the following table.

Dialect	Type
PostgreSQL	JSON
Amazon Redshift	String
Microsoft SQL Server	String
MySQL	JSON
Teradata	JSON
Oracle	String
Presto	String
Snowflake	Semistructured data type object and array

Dialect	Type
Hive	String

Syntax

```
parseJson(fieldName, path)
```

Arguments

fieldName

The field containing the JSON object that you want to parse.

path

The path to the data element you want to parse from the JSON object. Only letters, numbers, and blank spaces are supported in the path argument. Valid path syntax includes:

- `$` – Root object
- `.` – Child operator
- `[]` – Subscript operator for array

Return type

String

Example

The following example evaluates incoming JSON to retrieve a value for item quantity. By using this during data preparation, you can create a table out of the JSON.

```
parseJson({jsonField}, "$.items.qty")
```

The following shows the JSON.

```
{  
  "customer": "John Doe",
```

```
"items": {
  "product": "Beer",
  "qty": 6
},
"list1": [
  "val1",
  "val2"
],
"list2": [
  {
    "list21key1": "list1value1"
  }
]
}
```

For this example, the following value is returned.

```
6
```

Example

The following example evaluates `JSONObject1` to extract the first key value pair (KVP), labeled "State", and assign the value to the calculated field that you are creating.

```
parseJson(JSONObject1, "$.state")
```

The following are the given field values.

```
JSONObject1
-----
{"State":"New York","Product":"Produce","Date Sold":"1/16/2018","Sales Amount":"$3423.39"}
{"State":"North Carolina","Product":"Bakery Products","Date Sold":"2/1/2018","Sales Amount":"$3226.42"}
{"State":"Utah","Product":"Water","Date Sold":"4/24/2018","Sales Amount":"$7001.52"}
```

For these field values, the following rows are returned.

```
New York
North Carolina
```

```
Utah
```

Replace

`replace` replaces part of a string with another string that you specify.

Syntax

```
replace(expression, substring, replacement)
```

Arguments

expression

The expression must be a string. It can be the name of a field that uses the string data type, a literal value like **'12 Main Street'**, or a call to another function that outputs a string.

substring

The set of characters in *expression* that you want to replace. The substring can occur one or more times in *expression*.

replacement

The string you want to have substituted for *substring*.

Return type

String

Example

The following example replaces the substring 'and' with 'or'.

```
replace('1 and 2 and 3', 'and', 'or')
```

The following string is returned.

```
1 or 2 or 3
```

Right

`right` returns the rightmost characters from a string, including spaces. You specify the number of characters to be returned.

Syntax

```
right(expression, limit)
```

Arguments

expression

The expression must be a string. It can be the name of a field that uses the string data type, a literal value like **'12 Main Street'**, or a call to another function that outputs a string.

limit

The number of characters to be returned from *expression*, starting from the last character in the string.

Return type

String

Example

The following example returns the last five characters from a string.

```
right('Seattle Store#14', 12)
```

The following value is returned.

```
tle Store#14
```

Round

`round` rounds a decimal value to the closest integer if no scale is specified, or to the closest decimal place if scale is specified.

Syntax

```
round(decimal, scale)
```

Arguments

decimal

A field that uses the decimal data type, a literal value like **17.62**, or a call to another function that outputs a decimal.

scale

The number of decimal places to use for the return values.

Return type

Operand	Return type in the legacy data preparation experience	Return type in the new data preparation experience
INT	DECIMAL(FIXED)	DECIMAL(FIXED)
DECIMAL(FIXED)	DECIMAL(FIXED)	DECIMAL(FIXED)
DECIMAL(FLOAT)	DECIMAL(FIXED)	DECIMAL(FLOAT)

Example

The following example rounds a decimal field to the closest second decimal place.

```
round(salesAmount, 2)
```

The following are the given field values.

```
20.1307  
892.0388
```

```
57.5447
```

For these field values, the following values are returned.

```
20.13  
892.04  
58.54
```

Rtrim

`rtrim` removes following blank space from a string.

Syntax

```
rtrim(expression)
```

Arguments

expression

The expression must be a string. It can be the name of a field that uses the string data type, a literal value like **'12 Main Street'**, or a call to another function that outputs a string.

Return type

String

Example

The following example removes the following spaces from a string.

```
rtrim('Seattle Store #14  ')
```

For these field values, the following values are returned.

```
Seattle Store #14
```

Split

`split` splits a string into an array of substrings, based on a delimiter that you choose, and returns the item specified by the position.

You can only add `split` to a calculated field during data preparation, not to an analysis. This function is not supported in direct queries to Microsoft SQL Server.

Syntax

```
split(expression, delimiter , position)
```

Arguments

expression

The expression must be a string. It can be the name of a field that uses the string data type, a literal value like `'12 Main Street;1402 35th Ave;1818 Elm Ct;11 Janes Lane'`, or a call to another function that outputs a string.

delimiter

The character that delimits where the string is broken into substrings. For example, `split('one|two|three', '|', 2)` becomes the following.

```
one  
two  
three
```

If you choose `position = 2`, `split` returns `'two'`.

position

(Required) The position of the item to return from the array. The position of the first item in the array is 1.

Return type

String array

Example

The following example splits a string into an array, using the semicolon character (;) as the delimiter, and returns the third element of the array.

```
split('123 Test St;1402 35th Ave;1818 Elm Ct;11 Janes Lane', ';', 3)
```

The following item is returned.

```
1818 Elm Ct
```

This function skips items containing null values or empty strings.

Sqrt

`sqrt` returns the square root of a given expression.

Syntax

```
sqrt(expression)
```

Arguments

expression

The expression must be numeric. It can be a field name, a literal value, or another function.

startsWith

`startsWith` evaluates if the expression starts with a substring that you specify. If the expression starts with the substring, `startsWith` returns true, and otherwise it returns false.

Syntax

```
startsWith(expression, substring, string-comparison-mode)
```

Arguments

expression

The expression must be a string. It can be the name of a field that uses the string data type, a literal value like **'12 Main Street'**, or a call to another function that outputs a string.

substring

The set of characters to check against the *expression*. The substring can occur one or more times in the *expression*.

string-comparison-mode

(Optional) Specifies the string comparison mode to use:

- `CASE_SENSITIVE` – String comparisons are case-sensitive.
- `CASE_INSENSITIVE` – String comparisons are case-insensitive.

This value defaults to `CASE_SENSITIVE` when blank.

Return type

Boolean

Examples

Default case sensitive example

The following case sensitive example evaluates if `state_nm` startsWith **New**.

```
startsWith(state_nm, "New")
```

The following are the given field values.

```
New York  
new york
```

For these field values, the following values are returned.

```
true  
false
```

Case insensitive example

The following case insensitive example evaluates if `state_nm` startsWith **new**.

```
startsWith(state_nm, "new", CASE_INSENSITIVE)
```

The following are the given field values.

```
New York
```

```
new york
```

For these field values, the following values are returned.

```
true  
true
```

Example with conditional statements

The `startsWith` function can be used as the conditional statement within the following If functions: [avgIf](#), [minIf](#), [distinct_countIf](#), [countIf](#), [maxIf](#), [medianIf](#), [stdevIf](#), [stdevplf](#), [sumIf](#), [varIf](#), and [varplf](#).

The following example sums Sales only if `state_nm` starts with **New**.

```
sumIf(Sales, startsWith(state_nm, "New"))
```

Does NOT contain example

The conditional NOT operator can be used to evaluate if the expression does not start with the specified substring.

```
NOT(startsWith(state_nm, "New"))
```

Example using numeric values

Numeric values can be used in the expression or substring arguments by applying the `toString` function.

```
startsWith(state_nm, toString(5) )
```

Strlen

`strlen` returns the number of characters in a string, including spaces.

Syntax

```
strlen(expression)
```

Arguments

expression

An expression can be the name of a field that uses the string data type like **address1**, a literal value like **'Unknown'**, or another function like `substring(field_name,0,5)`.

Return type

Integer

Example

The following example returns the length of the specified string.

```
strlen('1421 Main Street')
```

The following value is returned.

```
16
```

Substring

`substring` returns the characters in a string, starting at the location specified by the *start* argument and proceeding for the number of characters specified by the *length* arguments.

Syntax

```
substring(expression, start, length)
```

Arguments

expression

An expression can be the name of a field that uses the string data type like **address1**, a literal value like **'Unknown'**, or another function like `substring(field_name,1,5)`.

start

The character location to start from. *start* is inclusive, so the character at the starting position is the first character in the returned value. The minimum value for *start* is 1.

length

The number of additional characters to include after *start*. *length* is inclusive of *start*, so the last character returned is (*length* - 1) after the starting character.

Return type

String

Example

The following example returns the 13th through 19th characters in a string. The beginning of the string is index 1, so you begin counting at the first character.

```
substring('Fantasy and Science Fiction',13,7)
```

The following value is returned.

```
Science
```

switch

`switch` compares a *condition-expression* with the literal labels, within a set of literal label and *return-expression* pairings. It then returns the *return-expression* corresponding to the first literal label that's equal to the *condition-expression*. If no label equals to the *condition-expression*, `switch` returns the *default-expression*. Every *return-expression* and *default-expression* must have the same datatype.

Syntax

```
switch(condition-expression, label-1, return-expression-1 [, label-n, return-expression-n ...],  
      default-expression)
```

Arguments

`switch` requires one or more *if,then* expression pairings, and requires exactly one expression for the *else* argument.

condition-expression

The expression to be compared with the label-literals. It can be a field name like `address`, a literal value like `'Unknown'`, or another scalar function like `toString(salesAmount)`.

label

The literal to be compared with the *condition-expression* argument, all of the literals must have the same data type as *condition-expression* argument. `switch` accepts up to 5000 labels.

return-expression

The expression to return if the value of its label equals to the value of the *condition-expression*. It can be a field name like `address`, a literal value like `'Unknown'`, or another scalar function like `toString(salesAmount)`. All of the *return-expression* arguments must have the same data type as the *default-expression*.

default-expression

The expression to return if no value of any label arguments equals to the value of *condition-expression*. It can be a field name like `address`, a literal value like `'Unknown'`, or another scalar function like `toString(salesAmount)`. The *default-expression* must have the same data type as all of the *return-expression* arguments.

Return type

`switch` returns a value of the same data type as the values in *return-expression*. All data returned *return-expression* and *default-expression* must be of the same data type or be converted to the same data type.

General Examples

The following example returns the AWS Region code of input region name.

```
switch(region_name,  
      "US East (N. Virginia)", "us-east-1",  
      "Europe (Ireland)", "eu-west-1",  
      "US West (N. California)", "us-west-1",  
      "other regions")
```

The following are the given field values.

```
"US East (N. Virginia)"
  "US West (N. California)"
  "Asia Pacific (Tokyo)"
```

For these field values the following values are returned.

```
"us-east-1"
  "us-west-1"
  "other regions"
```

Use switch to replace ifelse

The following `ifelse` use case is an equivalent of the previous example, for `ifelse` evaluating whether values of one field equals to different literal values, using `switch` instead is a better choice.

```
ifelse(region_name = "US East (N. Virginia)", "us-east-1",
       region_name = "Europe (Ireland)", "eu-west-1",
       region_name = "US West (N. California)", "us-west-1",
       "other regions")
```

Expression as return value

The following example uses expressions in *return-expressions*:

```
switch({origin_city_name},
      "Albany, NY", {arr_delay} + 20,
      "Alexandria, LA", {arr_delay} - 10,
      "New York, NY", {arr_delay} * 2,
      {arr_delay})
```

The preceding example changes the expected delay time for each flight from a particular city.

New York, NY	20	40

toLower

toLower formats a string in all lowercase. toLower skips rows containing null values.

Syntax

```
toLower(expression)
```

Arguments

expression

The expression must be a string. It can be the name of a field that uses the string data type, a literal value like **'12 Main Street'**, or a call to another function that outputs a string.

Return type

String

Example

The following example converts a string value into lowercase.

```
toLower('Seattle Store #14')
```

The following value is returned.

```
seattle store #14
```

toString

toString formats the input expression as a string. toString skips rows containing null values.

Syntax

```
toString(expression)
```

Arguments

expression

An expression can be a field of any data type, a literal value like **14.62**, or a call to another function that returns any data type.

Return type

String

Example

The following example returns the values from `payDate` (which uses the date data type) as strings.

```
toString(payDate)
```

The following are the given field values.

```
payDate
-----
1992-11-14T00:00:00.000Z
2012-10-12T00:00:00.000Z
1973-04-08T00:00:00.000Z
```

For these field values, the following rows are returned.

```
1992-11-14T00:00:00.000Z
2012-10-12T00:00:00.000Z
1973-04-08T00:00:00.000Z
```

toUpper

`toUpper` formats a string in all uppercase. `toUpper` skips rows containing null values.

Syntax

```
toUpper(expression)
```

Arguments

expression

The expression must be a string. It can be the name of a field that uses the string data type, a literal value like **'12 Main Street'**, or a call to another function that outputs a string.

Return type

String

Example

The following example converts a string value into uppercase.

```
toUpper('Seattle Store #14')
```

The following value is returned.

```
SEATTLE STORE #14
```

trim

`trim` removes both preceding and following blank space from a string.

Syntax

```
trim(expression)
```

Arguments

expression

The expression must be a string. It can be the name of a field that uses the string data type, a literal value like **'12 Main Street'**, or a call to another function that outputs a string.

Return type

String

Example

The following example removes the following spaces from a string.

```
trim('  Seattle Store #14  ')
```

For these field values, the following values are returned.

```
Seattle Store #14
```

truncDate

`truncDate` returns a date value that represents a specified portion of a date. For example, requesting the year portion of the value `2012-09-02T00:00:00.000Z` returns `2012-01-01T00:00:00.000Z`. Specifying a time-related period for a date that doesn't contain time information returns the initial date value unchanged.

Syntax

```
truncDate('period', date)
```

Arguments

period

The period of the date that you want returned. Valid periods are as follows:

- `YYYY`: This returns the year portion of the date.
- `Q`: This returns the date of the first day of the quarter that the date belongs to.
- `MM`: This returns the month portion of the date.
- `DD`: This returns the day portion of the date.
- `WK`: This returns the week portion of the date. The week starts on Sunday in Amazon Quick.
- `HH`: This returns the hour portion of the date.
- `MI`: This returns the minute portion of the date.
- `SS`: This returns the second portion of the date.
- `MS`: This returns the millisecond portion of the date.

date

A date field or a call to another function that outputs a date.

Return type

Date

Example

The following example returns a date representing the month of the order date.

```
truncDate('MM', orderDate)
```

The following are the given field values.

```
orderDate
=====
2012-12-14T00:00:00.000Z
2013-12-29T00:00:00.000Z
2012-11-15T00:00:00.000Z
```

For these field values, the following values are returned.

```
2012-12-01T00:00:00.000Z
2013-12-01T00:00:00.000Z
2012-11-01T00:00:00.000Z
```

Aggregate functions

Aggregate functions are only available during analysis and visualization. Each of these functions returns values grouped by the chosen dimension or dimensions. For each aggregation, there is also a conditional aggregation. These perform the same type of aggregation, based on a condition.

When a calculated field formula contains an aggregation, it becomes a custom aggregation. To make sure that your data is accurately displayed, Amazon Quick applies the following rules:

- Custom aggregations can't contain nested aggregate functions. For example, this formula doesn't work: `sum( avg(x)/avg(y) )`. However, nesting nonaggregated functions inside or outside aggregate functions does work. For example, `ceil( avg(x) )` works. So does `avg( ceil(x) )`.
- Custom aggregations can't contain both aggregated and nonaggregated fields, in any combination. For example, this formula doesn't work: `Sum(sales)+quantity`.
- Filter groups can't contain both aggregated and nonaggregated fields.
- Custom aggregations can't be converted to a dimension. They also can't be dropped into the field well as a dimension.
- In a pivot table, custom aggregations can't be added to table calculations.
- Scatter plots with custom aggregations need at least one dimension under **Group/Color** in the field wells.

For more information about supported functions and operators, see [Calculated field function and operator reference for Amazon Quick](#).

The aggregate functions for calculated fields in Quick include the following.

Topics

- [avg](#)
- [avgIf](#)

avg

The avg function averages the set of numbers in the specified measure, grouped by the chosen dimension or dimensions. For example, `avg(salesAmount)` returns the average for that measure grouped by the (optional) chosen dimension.

Syntax

```
avg(decimal, [group-by level])
```

Arguments

decimal

The argument must be a measure. Null values are omitted from the results. Literal values don't work. The argument must be a field.

group-by level

(Optional) Specifies the level to group the aggregation by. The level added can be any dimension or dimensions independent of the dimensions added to the visual.

The argument must be a dimension field. The group-by level must be enclosed in square brackets []. For more information, see [Level-aware calculation - aggregate \(LAC-A\) functions](#).

Examples

The following example calculates the average sales.

```
avg({Sales})
```

You can also specify at what level to group the computation using one or more dimensions in the view or in your dataset. This is called a LAC-A function. For more information about LAC-A functions, see [Level-aware calculation - aggregate \(LAC-A\) functions](#). The following example calculates the average sales at the Country level, but not across other dimensions (Region or Product) in the visual.

```
avg({Sales}, [{Country}])
```

Avg(sales), Sum of Avg(sales and [Country]) by Region, Country, and Product

Regi...	Country	Product	avg(sales)	avg(sales, [Country])

avgIf

Based on a conditional statement, the avgIf function averages the set of numbers in the specified measure, grouped by the chosen dimension or dimensions. For example, `avgIf(ProdRev, CalendarDay >= ${BasePeriodStartDate} AND CalendarDay <= ${BasePeriodEndDate} AND SourcingType <> 'Indirect')` returns the average for that measure grouped by the (optional) chosen dimension, if the condition evaluates to true.

Syntax

```
avgIf(dimension or measure, condition)
```

Arguments

decimal

The argument must be a measure. Null values are omitted from the results. Literal values don't work. The argument must be a field.

condition

One or more conditions in a single statement.

count

The count function calculates the number of values in a dimension or measure, grouped by the chosen dimension or dimensions. For example, `count(product type)` returns the total number of product types grouped by the (optional) chosen dimension, including any duplicates. The `count(sales)` function returns the total number of sales completed grouped by the (optional) chosen dimension, for example salesperson.

Syntax

```
count(dimension or measure, [group-by level])
```

Arguments

dimension or measure

The argument must be a measure or a dimension. Null values are omitted from the results. Literal values don't work. The argument must be a field.

group-by level

(Optional) Specifies the level to group the aggregation by. The level added can be any dimension or dimensions independent of the dimensions added to the visual.

The argument must be a dimension field. The group-by level must be enclosed in square brackets []. For more information, see [Level-aware calculation - aggregate \(LAC-A\) functions](#).

Examples

The following example calculates the count of sales by a specified dimension in the visual. In this example, the count of sales by month are shown.

```
count({Sales})
```

You can also specify at what level to group the computation using one or more dimensions in the view or in your dataset. This is called a LAC-A function. For more information about LAC-A functions, see [Level-aware calculation - aggregate \(LAC-A\) functions](#). The following example calculates the count of sales at the Country level, but not across other dimensions (Region or Product) in the visual.

```
count({Sales}, [{Country}])
```

Count(sales), Sum of Count(sales and [Country]) by Region, Country, and Product

countIf

Based on a conditional statement, the countIf function calculates the number of values in a dimension or measure, grouped by the chosen dimension or dimensions.

Syntax

```
countIf(dimension or measure, condition)
```

Arguments

dimension or measure

The argument must be a measure or a dimension. Null values are omitted from the results. Literal values don't work. The argument must be a field.

condition

One or more conditions in a single statement.

Return type

Integer

Example

The following function returns a count of the sales transactions (Revenue) that meet the conditions, including any duplicates.

```
countIf (  
    Revenue,  
    # Conditions  
        CalendarDay >= ${BasePeriodStartDate} AND  
        CalendarDay <= ${BasePeriodEndDate} AND  
        SourcingType <> 'Indirect'  
)
```

distinct_count

The `distinct_count` function calculates the number of distinct values in a dimension or measure, grouped by the chosen dimension or dimensions. For example, `distinct_count(product type)` returns the total number of unique product types grouped by the (optional) chosen dimension, without any duplicates. The `distinct_count(ship date)` function returns the total number of dates when products were shipped grouped by the (optional) chosen dimension, for example region.

Syntax

```
distinct_count(dimension or measure, [group-by level])
```

Arguments

dimension or measure

The argument must be a measure or a dimension. Null values are omitted from the results. Literal values don't work. The argument must be a field.

group-by level

(Optional) Specifies the level to group the aggregation by. The level added can be any dimension or dimensions independent of the dimensions added to the visual.

The argument must be a dimension field. The group-by level must be enclosed in square brackets []. For more information, see [Level-aware calculation - aggregate \(LAC-A\) functions](#).

Example

The following example calculates the total number of dates when products were ordered grouped by the (optional) chosen dimension in the visual, for example region.

```
distinct_count({Order Date})
```

You can also specify at what level to group the computation using one or more dimensions in the view or in your dataset. This is called a LAC-A function. For more information about LAC-A functions, see [Level-aware calculation - aggregate \(LAC-A\) functions](#). The following example calculates the average sales at the Country level, but not across other dimensions (Region) in the visual.

```
distinct_count({Order Date}, [Country])
```

Distinct_count(order Date), Sum of Distinct_count(order Date and [Country] by Region

Regi...	distinct_count(Order Date)	distinct_count(Order Date, [Country]
AMER	897	1,391
APJ	679	932
EMEA	975	1,885

distinct_countIf

Based on a conditional statement, the `distinct_countIf` function calculates the number of distinct values in a dimension or measure, grouped by the chosen dimension or dimensions. For example, `distinct_countIf(product type)` returns the total number of unique product types grouped by the (optional) chosen dimension, without any duplicates. The `distinct_countIf(ProdRev, CalendarDay >= ${BasePeriodStartDate} AND CalendarDay <= ${BasePeriodEndDate} AND SourcingType <> 'Indirect')` function returns the total number of dates when products were shipped grouped by the (optional) chosen dimension, for example region, if the condition evaluates to true.

Syntax

```
distinct_countIf(dimension or measure, condition)
```

Arguments

dimension or measure

The argument must be a measure or a dimension. Null values are omitted from the results. Literal values don't work. The argument must be a field.

condition

One or more conditions in a single statement.

max

The `max` function returns the maximum value of the specified measure or date, grouped by the chosen dimension or dimensions. For example, `max(sales goal)` returns the maximum sales goals grouped by the (optional) chosen dimension.

Syntax

```
max(measure, [group-by level])
```

Arguments

measure

The argument must be a measure or a date. Null values are omitted from the results. Literal values don't work. The argument must be a field.

Maximum dates work only in the **Value** field well of tables and pivot tables.

group-by level

(Optional) Specifies the level to group the aggregation by. The level added can be any dimension or dimensions independent of the dimensions added to the visual.

The argument must be a dimension field. The group-by level must be enclosed in square brackets []. For more information, see [Level-aware calculation - aggregate \(LAC-A\) functions](#).

Examples

The following example returns the max sales value for each region. It is compared to the total, minimum, and median sales values.

```
max({Sales})
```

Field wells

Group by

Region

APJ	17,499.95	47,417.48
EMEA	22,638.48	128,301.12

maxIf

Based on a conditional statement, the maxIf function returns the maximum value of the specified measure, grouped by the chosen dimension or dimensions. For example, `maxIf(ProdRev, CalendarDay >= ${BasePeriodStartDate} AND CalendarDay <= ${BasePeriodEndDate} AND SourcingType <> 'Indirect')` returns the maximum sales goals grouped by the (optional) chosen dimension, if the condition evaluates to true.

Syntax

```
maxIf(measure, condition)
```

Arguments

measure

The argument must be a measure. Null values are omitted from the results. Literal values don't work. The argument must be a field.

condition

One or more conditions in a single statement.

median

The median aggregation returns the median value of the specified measure, grouped by the chosen dimension or dimensions. For example, `median(revenue)` returns the median revenue grouped by the (optional) chosen dimension.

Syntax

```
median(measure, [group-by level])
```

Arguments

measure

The argument must be a measure. Null values are omitted from the results. Literal values don't work. The argument must be a field.

group-by level

(Optional) Specifies the level to group the aggregation by. The level added can be any dimension or dimensions independent of the dimensions added to the visual.

The argument must be a dimension field. The group-by level must be enclosed in square brackets []. For more information, see [Level-aware calculation - aggregate \(LAC-A\) functions](#).

Examples

The following example returns the median sales value for each region. It is compared to the total, maximum, and minimum sales.

```
median({Sales})
```

AMER	60.34	489.27
APJ	44.43	641.82
EMEA	53.42	3,656.93

medianIf

Based on a conditional statement, the medianIf aggregation returns the median value of the specified measure, grouped by the chosen dimension or dimensions. For example, `medianIf(Revenue, SaleDate >= ${BasePeriodStartDate} AND SaleDate <= ${BasePeriodEndDate})` returns the median revenue grouped by the (optional) chosen dimension, if the condition evaluates to true.

Syntax

```
medianIf(measure, condition)
```

Arguments

measure

The argument must be a measure. Null values are omitted from the results. Literal values don't work. The argument must be a field.

condition

One or more conditions in a single statement.

min

The min function returns the minimum value of the specified measure or date, grouped by the chosen dimension or dimensions. For example, `min(return_rate)` returns the minimum rate of returns grouped by the (optional) chosen dimension.

Syntax

```
min(measure, [group-by level])
```

Arguments

measure

The argument must be a measure or a date. Null values are omitted from the results. Literal values don't work. The argument must be a field.

Minimum dates work only in the **Value** field well of tables and pivot tables.

group-by level

(Optional) Specifies the level to group the aggregation by. The level added can be any dimension or dimensions independent of the dimensions added to the visual.

The argument must be a dimension field. The group-by level must be enclosed in square brackets []. For more information, see [Level-aware calculation - aggregate \(LAC-A\) functions](#).

Examples

The following example returns the minimum sales value for each region. It is compared to the total, max, and median sales.

```
min({Sales})
```

Field wells

Group by

Region

Value

Sales (Sum)

max({Sales}) (Custom)

min({Sales}) (Custom)

AMER	837,849.6	13,999.96	0.99	60.34
APJ	415,464.24	17,499.95	0.44	44.43
EMEA	1,043,887.02	22,638.48	0.85	53.42

You can also specify at what level to group the computation using one or more dimensions in the view or in your dataset. This is called a LAC-A function. For more information about LAC-A functions, see [Level-aware calculation - aggregate \(LAC-A\) functions](#). The following example calculates the minimum sales at the Country level, but not across other dimensions (Region) in the visual.

min({Sales}, [Country])

Min(sales), Sum of Min(sales and [Country]) by Region

Regi...	min(Sales)	min(Sales, [Country])
AMER	0.99	22.65
APJ	0.44	28.18
EMEA	0.85	1,716.48

minIf

Based on a conditional statement, the `minIf` function returns the minimum value of the specified measure, grouped by the chosen dimension or dimensions. For example, `minIf(ProdRev, CalendarDay >= ${BasePeriodStartDate} AND CalendarDay <= ${BasePeriodEndDate} AND SourcingType <> 'Indirect')` returns the minimum rate of returns grouped by the (optional) chosen dimension, if the condition evaluates to true.

Syntax

```
minIf(measure, condition)
```

Arguments

measure

The argument must be a measure. Null values are omitted from the results. Literal values don't work. The argument must be a field.

condition

One or more conditions in a single statement.

percentile

The `percentile` function calculates the percentile of the values in measure, grouped by the dimension that's in the field well. There are two varieties of percentile calculation available in Quick:

- [percentileCont](#) uses linear interpolation to determine result.
- [percentileDisc \(percentile\)](#) uses actual values to determine result.

The `percentile` function is an alias of `percentileDisc`.

percentileCont

The `percentileCont` function calculates percentile based on a continuous distribution of the numbers in the measure. It uses the grouping and sorting that are applied in the field wells. It answers questions like: What values are representative of this percentile? To return an exact

percentile value that might not be present in your dataset, use `percentileCont`. To return the nearest percentile value that is present in your dataset, use `percentileDisc` instead.

Syntax

```
percentileCont(expression, percentile, [group-by level])
```

Arguments

measure

Specifies a numeric value to use to compute the percentile. The argument must be a measure or metric. Nulls are ignored in the calculation.

percentile

The percentile value can be any numeric constant 0–100. A percentile value of 50 computes the median value of the measure.

group-by level

(Optional) Specifies the level to group the aggregation by. The level added can be any dimension or dimensions independent of the dimensions added to the visual.

The argument must be a dimension field. The group-by level must be enclosed in square brackets []. For more information, see [Level-aware calculation - aggregate \(LAC-A\) functions](#).

Returns

The result of the function is a number.

Usage notes

The `percentileCont` function calculates a result based on a continuous distribution of the values from a specified measure. The result is computed by linear interpolation between the values after ordering them based on settings in the visual. It's different from `percentileDisc`, which simply returns a value from the set of values that are aggregated over. The result from `percentileCont` might or might not exist in the values from the specified measure.

Examples of percentileCont

The following examples help explain how `percentileCont` works.

Example Comparing median, percentileCont, and percentileDisc

The following example shows the median for a dimension (category) by using the median, percentileCont, and percentileDisc functions. The median value is the same as the percentileCont value. percentileCont interpolates a value, which might or might not be in the data set. However, because percentileDisc always displays a value that exists in the dataset, the two results might not match. The last column in this example shows the difference between the two values. The code for each calculated field is as follows:

- `50%Cont = percentileCont( example , 50 )`
- `median = median( example )`
- `50%Disc = percentileDisc( example , 50 )`
- `Cont-Disc = percentileCont( example , 50 ) - percentileDisc( example , 50 )`
- `example = left( category, 1 )` (To make a simpler example, we used this expression to shorten the names of categories down to their first letter.)

example	median	50%Cont	50%Disc	Cont-Disc
A	22.48	22.48	22.24	0.24
B	20.96	20.96	20.95	0.01
C	24.92	24.92	24.92	0
D	24.935	24.935	24.92	0.015
E	14.48	14.48	13.99	0.49

Example 100th percentile as maximum

The following example shows a variety of percentileCont values for the example field. The calculated fields `n%Cont` are defined as `percentileCont( {example} , n )`. The interpolated values in each column represent the numbers that fall into that percentile bucket. In some cases, the actual data values match the interpolated values. For example, the column `100%Cont` shows the same value for every row because 6783.02 is the highest number.

example	50%Cont	75%Cont	99%Cont	100%Cont
A	20.97	84.307	699.99	6783.02
B	20.99	88.84	880.98	6783.02

C	20.99	90.48	842.925	6783.02
D	21.38	85.99	808.49	6783.02

You can also specify at what level to group the computation using one or more dimensions in the view or in your dataset. This is called a LAC-A function. For more information about LAC-A functions, see [Level-aware calculation - aggregate \(LAC-A\) functions](#). The following example calculates the 30th percentile based on a continuous distribution of the numbers at the Country level, but not across other dimensions (Region) in the visual.

```
percentileCont({Sales}, 30, [Country])
```

Percentilecont(sales, 30), Sum of Percentilecont(sales, 30 and [Country]) by Region

Regi...	percentileCont(Sales, 30)	percentileCont(Sales, 30, [Country])
AMER	23.84	188.74
APJ	16.77	239.59
EMEA	22.32	2,480.17

percentileDisc (percentile)

The percentileDisc function calculates the percentile based on the actual numbers in measure. It uses the grouping and sorting that are applied in the field wells. The percentile function is an alias of percentileDisc.

Use this function to answer the following question: Which actual data points are present in this percentile? To return the nearest percentile value that is present in your dataset, use percentileDisc. To return an exact percentile value that might not be present in your dataset, use percentileCont instead.

Syntax

```
percentileDisc(expression, percentile, [group-by level])
```

Arguments

measure

Specifies a numeric value to use to compute the percentile. The argument must be a measure or metric. Nulls are ignored in the calculation.

percentile

The percentile value can be any numeric constant 0–100. A percentile value of 50 computes the median value of the measure.

group-by level

(Optional) Specifies the level to group the aggregation by. The level added can be any dimension or dimensions independent of the dimensions added to the visual.

The argument must be a dimension field. The group-by level must be enclosed in square brackets []. For more information, see [Level-aware calculation - aggregate \(LAC-A\) functions](#).

Returns

The result of the function is a number.

Usage notes

`percentileDisc` is an inverse distribution function that assumes a discrete distribution model. It takes a percentile value and a sort specification and returns an element from the given set.

For a given percentile value *P*, `percentileDisc` uses the sorted values in the visual and returns the value with the smallest cumulative distribution value that is greater than or equal to *P*.

Examples of `percentileDisc`

The following examples help explain how `percentileDisc` works.

Example Comparing median, `percentileDisc`, and `percentileCont`

The following example shows the median for a dimension (category) by using the `percentileCont`, and `percentileDisc`, and `median` functions. The median value is the same as the `percentileCont` value. `percentileCont` interpolates a value, which might or might not be in the data set. However, because `percentileDisc` always displays the closest value that exists in the dataset, the two results might not match. The last column in this example shows the difference between the two values. The code for each calculated field is as follows:

- `50%Cont = percentileCont( example , 50 )`
- `median = median( example )`

- `50%Disc = percentileDisc( example , 50 )`
- `Cont-Disc = percentileCont( example , 50 ) - percentileDisc( example , 50 )`
- `example = left( category, 1 )` (To make a simpler example, we used this expression to shorten the names of categories down to their first letter.)

example	median	50%Cont	50%Disc	Cont-Disc
A	22.48	22.48	22.24	0.24
B	20.96	20.96	20.95	0.01
C	24.92	24.92	24.92	0
D	24.935	24.935	24.92	0.015
E	14.48	14.48	13.99	0.49

Example 100th percentile as maximum

The following example shows a variety of `percentileDisc` values for the `example` field. The calculated fields `n%Disc` are defined as `percentileDisc( {example} , n)`. The values in each column are actual numbers that come from the dataset.

example	50%Disc	75%Disc	99%Disc	100%Disc
A	20.97	73.98	699.99	6783.02
B	42.19	88.84	820.08	6783.02
C	30.52	90.48	733.44	6783.02
D	41.38	85.99	901.29	6783.0

You can also specify at what level to group the computation using one or more dimensions in the view or in your dataset. This is called a LAC-A function. For more information about LAC-A functions, see [Level-aware calculation - aggregate \(LAC-A\) functions](#). The following example calculates the 30th percentile based on a continuous distribution of the numbers at the Country level, but not across other dimensions (Region) in the visual.

```
percentile({Sales}, 30, [Country])
```

Percentile(sales, 30), Sum of Percentile(sales, 30 and [Country]) by Region

Regi...	percentile(Sales, 30)	percentile(Sales, 30, [Country])
AMER	23.84	187.64
APJ	16.74	237.73
EMEA	22.32	2,472.33

periodToDateAvg

The `periodToDateAvg` function averages the set of numbers in the specified measure for a given time granularity (for instance, a quarter) up to a point in time, relative to that period.

Syntax

```
periodToDateAvg(  
  measure,  
  dateTime,  
  period,  
  endDate (optional))
```

Arguments

measure

The argument must be a field. Null values are omitted from the results. Literal values don't work.

dateTime

The Date dimension over which you're computing PeriodToDate aggregations.

period

The time period across which you're computing the computation. Granularity of YEAR means YearToDate computation, Quarter means QuarterToDate, and so on. Valid granularities include YEAR, QUARTER, MONTH, WEEK, DAY, HOUR, MINUTE, and SECONDS.

endDate

(Optional) The date dimension that you're ending computing periodToDate aggregations. It defaults to `now()` if omitted.

Example

The following example calculates the week-to-date minimum fare amount per payment type, for the week of 06-30-21. For simplicity in the example, we filtered out only a single payment. 06-30-21 is Wednesday. Quick begins the week on Sundays. In our example, that is 06-27-21.

```
periodToDateAvg(fare_amount, pickupDatetime, WEEK, parseDate("06-30-2021", "MM-dd-yyyy"))
```

Field wells

Jun 27, 2021	1	A 13.85
Jun 26, 2021	1	14.81

periodToDateCount

The periodToDateCount function calculates the number of values in a dimension or measure, including duplicates, for a given time granularity (for instance, a quarter) up to a point in time, relative to that period.

Syntax

```
periodToDateCount(  
    measure,  
    dateTime,  
    period,  
    endDate (optional))
```

Arguments

measure

The argument must be a field. Null values are omitted from the results. Literal values don't work.

dateTime

The Date dimension over which you're computing PeriodToDate aggregations.

period

The time period across which you're computing the computation. Granularity of YEAR means YearToDate computation, Quarter means QuarterToDate, and so on. Valid granularities include YEAR, QUARTER, MONTH, WEEK, DAY, HOUR, MINUTE, and SECONDS.

endDate

(Optional) The date dimension that you're ending computing periodToDate aggregations. It defaults to now() if omitted.

Example

The following example calculates the week-to-date minimum fare amount per payment type, for the week of 06-30-21. For simplicity in the example, we filtered out only a single payment. 06-30-21 is Wednesday. Quick begins the week on Sundays. In our example, that is 06-27-21.

```
periodToDateCount(fare_amount, pickUpDatetime, WEEK, parseDate("06-30-2021", "MM-dd-yyyy"))
```

Jun 26, 2021	1	209,895

periodToDateMax

The `periodToDateMax` function returns the maximum value of the specified measure for a given time granularity (for instance, a quarter) up to a point in time, relative to that point.

Syntax

```
periodToDateMax(
  measure,
  dateTime,
  period,
  endDate (optional))
```

Arguments

measure

The argument must be a field. Null values are omitted from the results. Literal values don't work.

dateTime

The Date dimension over which you're computing PeriodToDate aggregations.

period

The time period across which you're computing the computation. Granularity of YEAR means YearToDate computation, Quarter means QuarterToDate, and so on. Valid granularities include YEAR, QUARTER, MONTH, WEEK, DAY, HOUR, MINUTE, and SECONDS.

endDate

(Optional) The date dimension that you're ending computing periodToDate aggregations. It defaults to now() if omitted.

Example

The following example calculates the week-to-date minimum fare amount per payment type, for the week of 06-30-21. For simplicity in the example, we filtered out only a single payment. 06-30-21 is Wednesday. Quick begins the week on Sundays. In our example, that is 06-27-21.

Jun 26, 2021	1	500

periodToDateMedian

The `periodToDateMedian` function returns the median value of the specified measure for a given time granularity (for instance, a quarter) up to a point in time, relative to that period.

Syntax

```
periodToDateMedian(
  measure,
  dateTime,
  period,
  endDate (optional))
```

Arguments

measure

The argument must be a field. Null values are omitted from the results. Literal values don't work.

dateTime

The Date dimension over which you're computing PeriodToDate aggregations.

period

The time period across which you're computing the computation. Granularity of YEAR means YearToDate computation, Quarter means QuarterToDate, and so on. Valid granularities include YEAR, QUARTER, MONTH, WEEK, DAY, HOUR, MINUTE, and SECONDS.

endDate

(Optional) The date dimension that you're ending computing periodToDate aggregations. It defaults to now() if omitted.

Example

The following example calculates the week-to-date minimum fare amount per payment type, for the week of 06-30-21. For simplicity in the example, we filtered out only a single payment. 06-30-21 is Wednesday. Quick begins the week on Sundays. In our example, that is 06-27-21.

Jun 26, 2021	1	10.50

periodToDateMin

The `periodToDateMin` function returns the minimum value of the specified measure or date, or a given time granularity (for instance, a quarter) up to a point in time, relative to that period.

Syntax

```
periodToDateMin(
  measure,
  dateTime,
  period,
  endDate (optional))
```

Arguments

measure

The argument must be a field. Null values are omitted from the results. Literal values don't work.

dateTime

The Date dimension over which you're computing PeriodToDate aggregations.

period

The time period across which you're computing the computation. Granularity of YEAR means YearToDate computation, Quarter means QuarterToDate, and so on. Valid granularities include YEAR, QUARTER, MONTH, WEEK, DAY, HOUR, MINUTE, and SECONDS.

endDate

(Optional) The date dimension that you're ending computing periodToDate aggregations. It defaults to now() if omitted.

Example

The following example calculates the week-to-date minimum fare amount per payment type, for the week of 06-30-21. For simplicity in the example, we filtered out only a single payment. 06-30-21 is Wednesday. Quick begins the week on Sundays. In our example, that is 06-27-21.

periodToDatePercentile

The `periodToDatePercentile` function calculates the percentile based on the actual numbers in measure for a given time granularity (for instance, a quarter) up to a point in time, relative to that period. It uses the grouping and sorting that are applied in the field wells.

To return the nearest percentile value that is present in your dataset, use `periodToDatePercentile`. To return an exact percentile value that might not be present in your dataset, use `periodToDatePercentileCont` instead.

Syntax

```
periodToDatePercentile(
  measure,
```

```
percentile,  
dateTime,  
period,  
endDate (optional))
```

Arguments

measure

The argument must be a field. Null values are omitted from the results. Literal values don't work.

percentile

The percentile value can be any numeric constant 0-100. A percentile of 50 computes the median value of the measure.

dateTime

The Date dimension over which you're computing PeriodToDate aggregations.

period

The time period across which you're computing the computation. Granularity of YEAR means YearToDate computation, Quarter means QuarterToDate, and so on. Valid granularities include YEAR, QUARTER, MONTH, WEEK, DAY, HOUR, MINUTE, and SECONDS.

endDate

(Optional) The date dimension that you're ending computing periodToDate aggregations. It defaults to now() if omitted.

Example

The following example calculates the week-to-date, 90th percentile of fare amount per payment type for the week of 06-30-21. For simplicity in the example, we filtered out only a single payment. 06-30-21 is Wednesday. Quick begins the week on Sundays. In our example. that is 06-27-21.

```
periodToDatePercentile(fare_amount, 90, pickupDatetime, WEEK, parseDate("06-30-2021",  
"MM-dd-yyyy"))

Jun 27, 2021	1	28.50
Jun 26, 2021	1	30.00

periodToDatePercentileCont

The `periodToDatePercentileCont` function calculates percentile based on a continuous distribution of the numbers in the measure for a given time granularity (for instance, a quarter) up to a point in time in that period. It uses the grouping and sorting that are applied in the field wells.

To return an exact percentile value that might not be present in your dataset, use `periodToDatePercentileCont`. To return the nearest percentile value that is present in your dataset, use `periodToDatePercentile` instead.

Syntax

```
periodToDatePercentileCont(
  measure,
```

```
percentile,  
dateTime,  
period,  
endDate (optional))
```

Arguments

measure

The argument must be a field. Null values are omitted from the results. Literal values don't work.

percentile

The percentile value can be any numeric constant 0-100. A percentile of 50 computes the median value of the measure.

dateTime

The Date dimension over which you're computing PeriodToDate aggregations.

period

The time period across which you're computing the computation. Granularity of YEAR means YearToDate computation, Quarter means QuarterToDate, and so on. Valid granularities include YEAR, QUARTER, MONTH, WEEK, DAY, HOUR, MINUTE, and SECONDS.

endDate

(Optional) The date dimension that you're ending computing periodToDate aggregations. It defaults to now() if omitted.

Example

The following example calculates the week-to-date, 90th percentile of fare amount per payment type for the week of 06-30-21. For simplicity in the example, we filtered out only a single payment. 06-30-21 is Wednesday. Quick begins the week on Sundays. In our example, that is 06-27-21.

Jun 27, 2021	1	28.50
Jun 26, 2021	1	30.00

periodToDateStDev

The `periodToDateStDev` function calculates the standard deviation of the set of numbers in the specified measure for a given time granularity (for instance, a quarter) up to a point in time, based on a sample and relative to that period.

Syntax

```
periodToDateStDev(
  measure,
  dateTime,
  period,
  endDate (optional))
```

Arguments

measure

The argument must be a field. Null values are omitted from the results. Literal values don't work.

dateTime

The Date dimension over which you're computing PeriodToDate aggregations.

period

(Optional) The time period across which you're computing the computation. Granularity of YEAR means YearToDate computation, Quarter means QuarterToDate, and so on. Valid granularities include YEAR, QUARTER, MONTH, WEEK, DAY, HOUR, MINUTE, and SECONDS.

endDate

(Optional) The date dimension that you're ending computing periodToDate aggregations. It defaults to now() if omitted.

Example

The following example calculates the week-to-date minimum fare amount per payment type, for the week of 06-30-21. For simplicity in the example, we filtered out only a single payment. 06-30-21 is Wednesday. Quick begins the week on Sundays. In our example, that is 06-27-21.

Jun 27, 2021	1	12.21
Jun 26, 2021	1	12.87

periodToDateStDevP

The `periodToDateStDevP` function calculates the population standard deviation of the set of numbers in the specified measure, for a given time granularity (for instance, a quarter) up to a point in time, based on a sample in that period.

Syntax

```
periodToDateStDevP(
  measure,
  dateTime,
  period,
  endDate (optional))
```

Arguments

measure

The argument must be a field. Null values are omitted from the results. Literal values don't work.

dateTime

The Date dimension over which you're computing PeriodToDate aggregations.

period

The time period across which you're computing the computation. Granularity of YEAR means YearToDate computation, Quarter means QuarterToDate, and so on. Valid granularities include YEAR, QUARTER, MONTH, WEEK, DAY, HOUR, MINUTE, and SECONDS.

Jun 26, 2021	1	12.87

periodToDateSum

The `periodToDateSum` function adds the specified measure for a given time granularity (for instance, a quarter) up to a point in time, relative to that period.

Syntax

```
periodToDateSum(
  measure,
  dateTime,
  period,
  endDate)
```

Arguments

measure

The argument must be a field. Null values are omitted from the results. Literal values don't work.

dateTime

The Date dimension over which you're computing PeriodToDate aggregations.

period

The time period across which you're computing the computation. Granularity of YEAR means YearToDate computation, Quarter means QuarterToDate, and so on. Valid granularities include YEAR, QUARTER, MONTH, WEEK, DAY, HOUR, MINUTE, and SECONDS.

endDate

(Optional) The date dimension that you're ending computing periodToDate aggregations. It defaults to now() if omitted.

Example

The following function calculates the week to date sum of fare amount per payment, for the week of 06-30-21. For simplicity in the example, we filtered out only a single payment. 06-30-21 is Wednesday. Quick begins the week on Sundays. In our example, that is 06-27-21.

```
periodToDateSum(fare_amount, pickUpDateTime, WEEK, parseDate("06-30-2021", "MM-dd-yyyy"))

periodToDateVar

The `periodToDateVar` function calculates the sample variance of the set of numbers in the specified measure for a given time granularity (for instance, a quarter) up to a point in time in that period.

Syntax

```
periodToDateVar(
  measure,
  dateTime,
  period,
  endDate (optional))
```

Arguments

measure

The argument must be a field. Null values are omitted from the results. Literal values don't work.

dateTime

The Date dimension over which you're computing PeriodToDate aggregations.

period

The time period across which you're computing the computation. Granularity of YEAR means YearToDate computation, Quarter means QuarterToDate, and so on. Valid granularities include YEAR, QUARTER, MONTH, WEEK, DAY, HOUR, MINUTE, and SECONDS.

Jun 26, 2021	1	165.76

periodToDateVarP

The `periodToDateVarP` function calculates the population variance of the set of numbers in the specified measure for a given time granularity (for instance, a quarter) up to a point in time, relevant to that period.

Syntax

```
periodToDateVarP(
  measure,
  dateTime,
  period,
  endDate (optional))
```

Arguments

measure

The argument must be a field. Null values are omitted from the results. Literal values don't work.

dateTime

The Date dimension over which you're computing PeriodToDate aggregations.

period

The time period across which you're computing the computation. Granularity of YEAR means YearToDate computation, Quarter means QuarterToDate, and so on. Valid granularities include YEAR, QUARTER, MONTH, WEEK, DAY, HOUR, MINUTE, and SECONDS.

stdev

The `stdev` function calculates the standard deviation of the set of numbers in the specified measure, grouped by the chosen dimension or dimensions, based on a sample.

Syntax

```
stdev(measure, [group-by level])
```

Arguments

measure

The argument must be a measure. Null values are omitted from the results. Literal values don't work. The argument must be a field.

group-by level

(Optional) Specifies the level to group the aggregation by. The level added can be any dimension or dimensions independent of the dimensions added to the visual.

The argument must be a dimension field. The group-by level must be enclosed in square brackets []. For more information, see [Level-aware calculation - aggregate \(LAC-A\) functions](#).

Examples

The following example returns the standard deviation of test scores for a class, using a sample of the test scores recorded.

```
stdev({Score})
```

You can also specify at what level to group the computation using one or more dimensions in the view or in your dataset. This is called a LAC-A function. For more information about LAC-A functions, see [Level-aware calculation - aggregate \(LAC-A\) functions](#). The following example calculates the standard deviation of test scores at the subject level, but not across other dimensions (Class) in the visual.

```
stdev({Score}, [Subject])
```

stdevp

The `stdevp` function calculates the population standard deviation of the set of numbers in the specified measure, grouped by the chosen dimension or dimensions.

Syntax

```
stdevp(measure, [group-by level])
```

Arguments

measure

The argument must be a measure. Null values are omitted from the results. Literal values don't work. The argument must be a field.

group-by level

(Optional) Specifies the level to group the aggregation by. The level added can be any dimension or dimensions independent of the dimensions added to the visual.

The argument must be a dimension field. The group-by level must be enclosed in square brackets []. For more information, see [Level-aware calculation - aggregate \(LAC-A\) functions](#).

Examples

The following example returns the standard deviation of test scores for a class using all the scores recorded.

```
stdevp({Score})
```

You can also specify at what level to group the computation using one or more dimensions in the view or in your dataset. This is called a LAC-A function. For more information about LAC-A functions, see [Level-aware calculation - aggregate \(LAC-A\) functions](#). The following example calculates the standard deviation of test scores at the subject level, but not across other dimensions (Class) in the visual using all the scores recorded.

```
stdevp({Score}, [Subject])
```

stdevIf

Based on a conditional statement, the `stdevIf` function calculates the standard deviation of the set of numbers in the specified measure, grouped by the chosen dimension or dimensions, based on a sample.

Syntax

```
stdevIf(measure, conditions)
```

Arguments

measure

The argument must be a measure. Null values are omitted from the results. Literal values don't work. The argument must be a field.

condition

One or more conditions in a single statement.

stdevpIf

Based on a conditional statement, the `stdevpIf` function calculates the standard deviation of the set of numbers in the specified measure, grouped by the chosen dimension or dimensions, based on a biased population.

Syntax

```
stdevpIf(measure, conditions)
```

Arguments

measure

The argument must be a measure. Null values are omitted from the results. Literal values don't work. The argument must be a field.

condition

One or more conditions in a single statement.

sum

The `sum` function adds the set of numbers in the specified measure, grouped by the chosen dimension or dimensions. For example, `sum(profit amount)` returns the total profit amount grouped by the (optional) chosen dimension.

Syntax

```
sum(measure, [group-by level])
```

Arguments

measure

The argument must be a measure. Null values are omitted from the results. Literal values don't work. The argument must be a field.

group-by level

(Optional) Specifies the level to group the aggregation by. The level added can be any dimension or dimensions independent of the dimensions added to the visual.

The argument must be a dimension field. The group-by level must be enclosed in square brackets []. For more information, see [Level-aware calculation - aggregate \(LAC-A\) functions](#).

Examples

The following example returns the sum of sales.

```
sum({Sales})
```

You can also specify at what level to group the computation using one or more dimensions in the view or in your dataset. This is called a LAC-A function. For more information about LAC-A functions, see [Level-aware calculation - aggregate \(LAC-A\) functions](#). The following example calculates the sum of sales at the Country level, but not across other dimensions (Region and Product) in the visual.

```
sum(Sales, [Country])
```

Sum(sales), Sum of Sum(sales and [Country]) by Region, Product, and Country

sumIf

Based on a conditional statement, the sumIf function adds the set of numbers in the specified measure, grouped by the chosen dimension or dimensions. For example, `sumIf(ProdRev, CalendarDay >= ${BasePeriodStartDate} AND CalendarDay <= ${BasePeriodEndDate} AND SourcingType <> 'Indirect')` returns the total profit amount grouped by the (optional) chosen dimension, if the condition evaluates to true.

Syntax

```
sumIf(measure, conditions)
```

Arguments*measure*

The argument must be a measure. Null values are omitted from the results. Literal values don't work. The argument must be a field.

condition

One or more conditions in a single statement.

Examples

The following example uses a calculated field with `sumIf` to display the sales amount if Segment is equal to SMB.

```
sumIf(Sales, Segment='SMB')
```

Field wells

Strategic	706,146	

The following example uses a calculated field with `sumIf` to display the sales amount if Segment is equal to SMB and Order Date greater than year 2022.

```
sumIf(Sales, Segment='SMB' AND {Order Date} >='2022-01-01')
```

var

The `var` function calculates the sample variance of the set of numbers in the specified measure, grouped by the chosen dimension or dimensions.

Syntax

```
var(measure, [group-by level])
```

Arguments

measure

The argument must be a measure. Null values are omitted from the results. Literal values don't work. The argument must be a field.

group-by level

(Optional) Specifies the level to group the aggregation by. The level added can be any dimension or dimensions independent of the dimensions added to the visual.

The argument must be a dimension field. The group-by level must be enclosed in square brackets []. For more information, see [Level-aware calculation - aggregate \(LAC-A\) functions](#).

Examples

The following example returns the variance of a sample of test scores.

```
var({Scores})
```

You can also specify at what level to group the computation using one or more dimensions in the view or in your dataset. This is called a LAC-A function. For more information about LAC-A functions, see [Level-aware calculation - aggregate \(LAC-A\) functions](#). The following example returns the variance of a sample of test scores at the subject level, but not across other dimensions (Class) in the visual.

```
var({Scores}, [Subject])
```

varIf

Based on a conditional statement, the `varIf` function calculates the variance of the set of numbers in the specified measure, grouped by the chosen dimension or dimensions, based on a sample.

Syntax

```
varIf(measure, conditions)
```

Arguments

measure

The argument must be a measure. Null values are omitted from the results. Literal values don't work. The argument must be a field.

condition

One or more conditions in a single statement.

varp

The `varp` function calculates the population variance of the set of numbers in the specified measure, grouped by the chosen dimension or dimensions.

Syntax

```
varp(measure, [group-by level])
```

Arguments

measure

The argument must be a measure. Null values are omitted from the results. Literal values don't work. The argument must be a field.

group-by level

(Optional) Specifies the level to group the aggregation by. The level added can be any dimension or dimensions independent of the dimensions added to the visual.

The argument must be a dimension field. The group-by level must be enclosed in square brackets []. For more information, see [Level-aware calculation - aggregate \(LAC-A\) functions](#).

Examples

The following example returns the variance of a population of test scores.

```
varp({Scores})
```

You can also specify at what level to group the computation using one or more dimensions in the view or in your dataset. This is called a LAC-A function. For more information about LAC-A functions, see [Level-aware calculation - aggregate \(LAC-A\) functions](#). The following example returns the variance of a population test scores at the subject level, but not across other dimensions (Class) in the visual.

```
varp({Scores}, [Subject])
```

varpIf

Based on a conditional statement, the `varpIf` function calculates the variance of the set of numbers in the specified measure, grouped by the chosen dimension or dimensions, based on a biased population.

Syntax

```
varpIf(measure, conditions)
```

Arguments

measure

The argument must be a measure. Null values are omitted from the results. Literal values don't work. The argument must be a field.

condition

One or more conditions in a single statement.

Table calculation functions

When you are analyzing data in a specific visual, you can apply table calculations to the current set of data to discover how dimensions influence measures or each other. *Visualized data* is your result set based on your current dataset, with all the filters, field selections, and customizations applied. To see exactly what this result set is, you can export your visual to a file. A *table calculation function* performs operations on the data to reveal relationships between fields.

In this section, you can find a list of the functions available in table calculations that you can perform on visualized data in Amazon Quick.

To view a list of functions sorted by category, with brief definitions, see [Functions by category](#).

difference

The difference function calculates the difference between a measure based on one set of partitions and sorts, and a measure based on another.

The difference function is supported for use with analyses based on SPICE and direct query data sets.

Syntax

The brackets are required. To see which arguments are optional, see the following descriptions.

```
difference
(
    measure
    , [ sortorder_field ASC_or_DESC, ... ]
    , lookup_index,
    , [ partition field, ... ]
)
```

Arguments

measure

An aggregated measure that you want to see the difference for.

sort order field

One or more measures and dimensions that you want to sort the data by, separated by commas. You can specify either ascending (**ASC**) or descending (**DESC**) sort order.

Each field in the list is enclosed in {} (curly braces), if it is more than one word. The entire list is enclosed in [] (square brackets).

lookup index

The lookup index can be positive or negative, indicating a following row in the sort (positive) or a previous row in the sort (negative). The lookup index can be 1–2,147,483,647. For the engines MySQL, MariaDB and Aurora MySQL-Compatible Edition, the lookup index is limited to just 1.

partition field

(Optional) One or more dimensions that you want to partition by, separated by commas.

Each field in the list is enclosed in {} (curly braces), if it is more than one word. The entire list is enclosed in [] (square brackets).

Example

The following example calculates the difference between of `sum({Billed Amount})`, sorted by `Customer Region` ascending, compared to the next row, and partitioned by `Service Line`.

```
difference(  
    sum( {Billed Amount} ),  
    [{Customer Region} ASC],  
    1,  
    [{Service Line}]  
)
```

The following example calculates the difference between `Billed Amount` compared to the next line, partitioned by (`[{Customer Region}]`). The fields in the table calculation are in the field wells of the visual.

```
difference(
  sum( {Billed Amount} ),
  [{Customer Region} ASC],
  1
)
```

The red highlights show how each amount is added ($a + b = c$) to show the difference between amounts a and c.

Field wells

Group by

Customer Region

Value

difference (Custom)

Billed Amount (Sum)

Sum of Billed Amount and Difference by Customer Region

Customer Region	difference	Billed Amount
APAC		a 8,390,654
EMEA	+b 2,647,510	=c 11,038,164
US	12,509,001	23,547,165

distinctCountOver

The `distinctCountOver` function calculates the distinct count of the operand partitioned by the specified attributes at a specified level. Supported levels are `PRE_FILTER` and `PRE_AGG`. The operand must be unaggregated.

Syntax

The brackets are required. To see which arguments are optional, see the following descriptions.

```
distinctCountOver
(
  measure or dimension field
```

```
,[ partition_field, ... ]  
,calculation_level  
)
```

Arguments

measure or dimension field

The measure or dimension that you want to do the calculation for, for example {Sales Amt}. Valid values are PRE_FILTER and PRE_AGG.

partition field

(Optional) One or more dimensions that you want to partition by, separated by commas.

Each field in the list is enclosed in {} (curly braces), if it is more than one word. The entire list is enclosed in [] (square brackets).

calculation level

(Optional) Specifies the calculation level to use:

- **PRE_FILTER** – Prefilter calculations are computed before the dataset filters.
- **PRE_AGG** – Preaggregate calculations are computed before applying aggregations and top and bottom *N* filters to the visuals.

This value defaults to POST_AGG_FILTER when blank. POST_AGG_FILTER is not a valid level for this operation and will result in an error message. For more information, see [Using level-aware calculations in Amazon Quick](#).

Example

The following example gets the distinct count of Sales partitioned over City and State at the PRE_AGG level.

```
distinctCountOver  
(  
  Sales,  
  [City, State], PRE_AGG  
)
```

lag

The `lag` function calculates the lag (previous) value for a measure based on specified partitions and sorts.

`lag` is supported for use with analyses based on SPICE and direct query data sets.

Syntax

The brackets are required. To see which arguments are optional, see the following descriptions.

```
lag
(  
  lag  
  (  
    measure  
    , [ sortorder_field ASC_or_DESC, ... ]  
    , lookup_index  
    , [ partition_field, ... ]  
  )  
)
```

Arguments

measure

The measure that you want to get the lag for. This can include an aggregate, for example `sum({Sales Amt})`.

sort order field

One or more measures and dimensions that you want to sort the data by, separated by commas. You can specify either ascending (**ASC**) or descending (**DESC**) sort order.

Each field in the list is enclosed in `{ }` (curly braces), if it is more than one word. The entire list is enclosed in `[ ]` (square brackets).

lookup index

The lookup index can be positive or negative, indicating a following row in the sort (positive) or a previous row in the sort (negative). The lookup index can be 1–2,147,483,647. For the engines MySQL, MariaDB, and Amazon Aurora MySQL-Compatible Edition, the lookup index is limited to just 1.

partition field

(Optional) One or more dimensions that you want to partition by, separated by commas.

Each field in the list is enclosed in {} (curly braces), if it is more than one word. The entire list is enclosed in [] (square brackets).

Example

The following example calculates the previous `sum(sales)`, partitioned by the state of origin, in the ascending sort order on `cancellation_code`.

```
lag
(
    sum(Sales),
    [cancellation_code ASC],
    1,
    [origin_state_nm]
)
```

The following example uses a calculated field with `lag` to display sales amount for the previous row next to the amount for the current row, sorted by `Order Date`. The fields in the table calculation are in the field wells of the visual.

```
lag(
    sum({Sales}),
    [{Order Date} ASC],
    1
)
```

The following screenshot shows the results of the example.

Field wells

Group by
Order Date

Value
Sales (Sum)
lag1 (Custom)

Sheet 1 +

Sum of Sales and Lag1 by Order Date

Order Date	Sales	lag1
Jan 4, 2020	16	
Jan 5, 2020	288	16
Jan 6, 2020	20	288

Jan 7, 2020	Enterprise	4,375	288
Jan 7, 2020	SMB	19	20
Jan 7, 2020	Strategic	13	

lead

The `lead` function calculates the lead (following) value for a measure based on specified partitions and sorts.

Syntax

The brackets are required. To see which arguments are optional, see the following descriptions.

```
lead
(
    measure
    , [ sortorder_field ASC_or_DESC, ... ]
    , lookup_index
    , [ partition_field, ... ]
)
```

Arguments

measure

The measure that you want to get the lead for. This can include an aggregate, for example `sum({Sales Amt})`.

sort order field

One or more measures and dimensions that you want to sort the data by, separated by commas. You can specify either ascending (**ASC**) or descending (**DESC**) sort order.

Each field in the list is enclosed in `{ }` (curly braces), if it is more than one word. The entire list is enclosed in `[ ]` (square brackets).

lookup index

The lookup index can be positive or negative, indicating a following row in the sort (positive) or a previous row in the sort (negative). The lookup index can be 1–2,147,483,647. For the engines MySQL, MariaDB, and Amazon Aurora MySQL-Compatible Edition, the lookup index is limited to just 1.

partition field

(Optional) One or more dimensions that you want to partition by, separated by commas.

Each field in the list is enclosed in `{ }` (curly braces), if it is more than one word. The entire list is enclosed in `[ ]` (square brackets).

Example

The following example calculates the next `sum(sales)`, partitioned by the state of origin, in the ascending sort order on `cancellation_code`.

```
lead
(
    sum(sales),
    [cancellation_code ASC],
    1,
    [origin_state_nm]
)
```

The following example uses a calculated field with lead to display the amount for the next row beside the amount for the current row, sorted by Customer Segment. The fields in the table calculation are in the field wells of the visual.

```
lead(
  sum({Billed Amount}),
  [{Customer Segment} ASC],
  1
)
```

The following screenshot shows the results of the example.

Field wells

percentDifference

The percentDifference function calculates the percentage difference between the current value and a comparison value, based on partitions, sorts, and lookup index.

Syntax

The brackets are required. To see which arguments are optional, see the following descriptions.

```
percentDifference
(
  measure
```

```
,[ sortorder_field ASC_or_DESC, ... ]  
,lookup index  
,[ partition_field, ... ]  
)
```

Arguments

measure

An aggregated measure that you want to see the percent difference for.

sort order field

One or more measures and dimensions that you want to sort the data by, separated by commas. You can specify either ascending (**ASC**) or descending (**DESC**) sort order.

Each field in the list is enclosed in {} (curly braces), if it is more than one word. The entire list is enclosed in [] (square brackets).

lookup index

The lookup index can be positive or negative, indicating a following row in the sort (positive) or a previous row in the sort (negative). The lookup index can be 1–2,147,483,647. For the engines MySQL, MariaDB and Aurora MySQL-Compatible Edition, the lookup index is limited to just 1.

partition field

(Optional) One or more dimensions that you want to partition by, separated by commas.

Each field in the list is enclosed in {} (curly braces), if it is more than one word. The entire list is enclosed in [] (square brackets).

Example

The following example calculates the percentage of difference between the sum(Sales) for the current and the previous State, sorted by Sales.

```
percentDifference  
(  
  sum(amount),  
  [sum(amount) ASC],  
  -1,  
  [State]
```

)

The following example calculates the percent that a specific Billed Amount is of another Billed Amount, sorted by ([{Customer Region} ASC]). The fields in the table calculation are in the field wells of the visual.

```
percentDifference
(
  sum( {Billed Amount} ),
  [{Customer Region} ASC],
  1
)
```

The following screenshot shows the results of the example. The red letters show that the total Billed Amount for the Customer Region **APAC** is 24 percent less than the amount for the **EMEA** region.

Field wells

Group by

Customer Region

Value

Billed Amount (Sum)

percentDifference (Custom)

Percentdifference and Sum of Billed Amount by Customer Region		
Customer Region	Billed Amount	percentDifference
APAC	a 8,390,654	c -24.0%
EMEA	b 11,038,164	-53.1%
US	23,547,165	(b-a) / b = c

avgOver

The avgOver function calculates the average of a measure partitioned by a list of dimensions.

Syntax

The brackets are required. To see which arguments are optional, see the following descriptions.

```
avgOver
(
    measure
    ,[ partition_field, ... ]
    ,calculation level
)
```

The following example shows the average Billed Amount over Customer Region. The fields in the table calculation are in the field wells of the visual.

```
avgOver
(
    sum({Billed Amount}),
    [{Customer Region}]
)
```

The following screenshot shows the results of the example. With the addition of Service Line, the total amount billed for each is displayed, and the average of these three values displays in the calculated field.

Field wells

Group by

Customer Region

Service Line

Value

Billed Amount (Sum)

avgOver (Custom)

Sum of Billed Amount and Avgover by Customer Region and Service Line

Customer Region	Service Line	Billed Amount	avgOver
APAC	Billing	3,569,780	2,796,885
APAC	HR	3,441,106	2,796,885
APAC	Marketing	1,379,768	2,796,885
EMEA	Billing	4,446,586	3,679,388
EMEA	HR	4,316,700	3,679,388
EMEA	Marketing	2,274,878	3,679,388

Arguments

measure

The measure that you want to do the calculation for, for example `sum( {Sales Amt} )`. Use an aggregation if the calculation level is set to `NULL` or `POST_AGG_FILTER`. Don't use an aggregation if the calculation level is set to `PRE_FILTER` or `PRE_AGG`.

partition field

(Optional) One or more dimensions that you want to partition by, separated by commas.

Each field in the list is enclosed in `{ }` (curly braces), if it is more than one word. The entire list is enclosed in `[ ]` (square brackets).

calculation level

(Optional) Specifies the calculation level to use:

- **PRE_FILTER** – Prefilter calculations are computed before the dataset filters.
- **PRE_AGG** – Preaggregate calculations are computed before applying aggregations and top and bottom *N* filters to the visuals.
- **POST_AGG_FILTER** – (Default) Table calculations are computed when the visuals display.

This value defaults to `POST_AGG_FILTER` when blank. For more information, see [Using level-aware calculations in Quick](#).

Example

The following example gets the average `sum(Sales)` partitioned over `City` and `State`.

```
avgOver
(
    sum(Sales),
    [City, State]
)
```

countOver

The `countOver` function calculates the count of a dimension or measure partitioned by a list of dimensions.

Syntax

The brackets are required. To see which arguments are optional, see the following descriptions.

```
countOver  
(  
  measure or dimension field  
  , [ partition_field, ... ]  
  , calculation level  
)
```

Arguments

measure or dimension field

The measure or dimension that you want to do the calculation for, for example `sum( {Sales Amt} )`. Use an aggregation if the calculation level is set to `NULL` or `POST_AGG_FILTER`. Don't use an aggregation if the calculation level is set to `PRE_FILTER` or `PRE_AGG`.

partition field

(Optional) One or more dimensions that you want to partition by, separated by commas.

Each field in the list is enclosed in `{ }` (curly braces), if it is more than one word. The entire list is enclosed in `[ ]` (square brackets).

calculation level

(Optional) Specifies the calculation level to use:

- **PRE_FILTER** – Prefilter calculations are computed before the dataset filters.
- **PRE_AGG** – Preaggregate calculations are computed before applying aggregations and top and bottom *N* filters to the visuals.
- **POST_AGG_FILTER** – (Default) Table calculations are computed when the visuals display.

This value defaults to `POST_AGG_FILTER` when blank. For more information, see [Using level-aware calculations in Quick](#).

Example

The following example gets the count of Sales partitioned over City and State.

```
countOver
(
  Sales,
  [City, State]
)
```

The following example gets the count of {County} partitioned over City and State.

```
countOver
(
  {County},
  [City, State]
)
```

The following example shows the count of Billed Amount over Customer Region. The fields in the table calculation are in the field wells of the visual.

```
countOver
(
  sum({Billed Amount}),
  [{Customer Region}]
)
```

The following screenshot shows the results of the example. Because there are no other fields involved, the count is one for each region.

Field wells

If you add additional fields, the count changes. In the following screenshot, we add Customer Segment and Service Line. Each of those fields contains three unique values. With 3 segments, 3 service lines, and 3 regions, the calculated field shows 9.

Field wells

The screenshot shows two panels. The 'Group by' panel on the left has a light gray header and three blue buttons with white text and downward arrows: 'Customer Segment', 'Service Line', and 'Customer Region'. The 'Value' panel on the right has a light gray header and a single green button with white text and a downward arrow: 'countOver (Custom)'.

Countover by Customer Segment, Service Line, and Customer Region			
Customer Segment	Service Line	Customer Region	countOver
Enterprise	Billing	APAC	9
Enterprise	Billing	EMEA	9
Enterprise	Billing	US	9
Enterprise	HR	APAC	9

If you add the two additional fields to the partitioning fields in the calculated field, `countOver( sum({Billed Amount}), [{Customer Region}, {Customer Segment}, {Service Line}])`, then the count is again 1 for each row.

Field wells

Group by

Customer Segment

Service Line

Customer Region

Value

countOver (Custom)

Countover by Customer Region, Service Line, and Customer Segment

Customer Segment	Service Line	Customer Region	countOver
Enterprise	Billing	APAC	1
Enterprise	Billing	EMEA	1
Enterprise	Billing	US	1
Enterprise	HR	APAC	1
Enterprise	HR	EMEA	1
Enterprise	HR	US	1

maxOver

The `maxOver` function calculates the maximum of a measure or date partitioned by a list of dimensions.

Syntax

The brackets are required. To see which arguments are optional, see the following descriptions.

```
maxOver
(
    measure
    , [ partition_field, ... ]
    , calculation level
)
```

Arguments

measure

The measure that you want to do the calculation for, for example `sum( {Sales Amt} )`. Use an aggregation if the calculation level is set to `NULL` or `POST_AGG_FILTER`. Don't use an aggregation if the calculation level is set to `PRE_FILTER` or `PRE_AGG`.

partition field

(Optional) One or more dimensions that you want to partition by, separated by commas.

Each field in the list is enclosed in `{ }` (curly braces), if it is more than one word. The entire list is enclosed in `[ ]` (square brackets).

calculation level

(Optional) Specifies the calculation level to use:

- **PRE_FILTER** – Prefilter calculations are computed before the dataset filters.
- **PRE_AGG** – Preaggregate calculations are computed before applying aggregations and top and bottom *N* filters to the visuals.
- **POST_AGG_FILTER** – (Default) Table calculations are computed when the visuals display.

This value defaults to `POST_AGG_FILTER` when blank. For more information, see [Using level-aware calculations in Quick](#).

Example

The following example calculates the maximum `sum(Sales)`, partitioned by `City` and `State`.

```
maxOver
(  
    sum(Sales),  
    [City, State]  
)
```

The following example shows the maximum `Billed Amount` over `Customer Region`. The fields in the table calculation are in the field wells of the visual.

```
maxOver
```

```
(
    sum({Billed Amount}),
    [{Customer Region}]
)
```

The following screenshot shows the results of the example. With the addition of Service Line, the total amount billed for each is displayed, and the maximum of these three values displays in the calculated field.

Field wells

Group by

Customer Region

Service Line

Value

Billed Amount (Sum)

maxOver (Custom)

Sum of Billed Amount and Maxover by Customer Region and Service Line

Customer Region	Service Line	Billed Amount	maxOver
APAC	Billing	3,569,780	3,569,780
APAC	HR	3,441,106	= 3,569,780
APAC	Marketing	1,379,768	3,569,780
EMEA	Billing	4,446,586	4,446,586
EMEA	HR	4,316,700	4,446,586
EMEA	Marketing	2,274,878	4,446,586

minOver

The minOver function calculates the minimum of a measure or date partitioned by a list of dimensions.

Syntax

The brackets are required. To see which arguments are optional, see the following descriptions.

```
minOver
(
    measure
)
```

```
,[ partition_field, ... ]  
,calculation level  
)
```

Arguments

measure

The measure that you want to do the calculation for, for example `sum({Sales Amt})`. Use an aggregation if the calculation level is set to `NULL` or `POST_AGG_FILTER`. Don't use an aggregation if the calculation level is set to `PRE_FILTER` or `PRE_AGG`.

partition field

(Optional) One or more dimensions that you want to partition by, separated by commas.

Each field in the list is enclosed in `{ }` (curly braces), if it is more than one word. The entire list is enclosed in `[ ]` (square brackets).

calculation level

(Optional) Specifies the calculation level to use:

- **PRE_FILTER** – Prefilter calculations are computed before the dataset filters.
- **PRE_AGG** – Preaggregate calculations are computed before applying aggregations and top and bottom *N* filters to the visuals.
- **POST_AGG_FILTER** – (Default) Table calculations are computed when the visuals display.

This value defaults to `POST_AGG_FILTER` when blank. For more information, see [Using level-aware calculations in Quick](#).

Example

The following example calculates the min `sum(Sales)`, partitioned by `City` and `State`.

```
minOver  
(  
    sum(Sales),  
    [City, State]  
)
```

The following example shows the minimum Billed Amount over Customer Region. The fields in the table calculation are in the field wells of the visual.

```
minOver
(
    sum({Billed Amount}),
    [{Customer Region}]
)
```

The following screenshot shows the results of the example. With the addition of Service Line, the total amount billed for each is displayed, and the minimum of these three values displays in the calculated field.

Field wells

Group by

Customer Region

Service Line

Value

Billed Amount (Sum)

minOver (Custom)

Customer Region	Service Line	Billed Amount	minOver
APAC	Billing	3,569,780	1,379,768
APAC	HR	3,441,106	= 1,379,768
APAC	Marketing	1,379,768	1,379,768
EMEA	Billing	4,446,586	2,274,878
EMEA	HR	4,316,700	2,274,878
EMEA	Marketing	2,274,878	2,274,878

percentileOver

The `percentileOver` function calculates the n th percentile of a measure partitioned by a list of dimensions. There are two varieties of the `percentileOver` calculation available in Quick:

- [percentileContOver](#) uses linear interpolation to determine result.
- [percentileDiscOver](#) uses actual values to determine result.

The `percentileOver` function is an alias of `percentileDiscOver`.

percentileContOver

The `percentileContOver` function calculates the percentile based on the actual numbers in measure. It uses the grouping and sorting that are applied in the field wells. The result is partitioned by the specified dimension at the specified calculation level.

Use this function to answer the following question: Which actual data points are present in this percentile? To return the nearest percentile value that is present in your dataset, use `percentileDiscOver`. To return an exact percentile value that might not be present in your dataset, use `percentileContOver` instead.

Syntax

```
percentileContOver (  
    measure  
    , percentile-n  
    , [partition-by, ...]  
    , calculation-level  
)
```

Arguments

measure

Specifies a numeric value to use to compute the percentile. The argument must be a measure or metric. Nulls are ignored in the calculation.

percentile-n

The percentile value can be any numeric constant 0–100. A percentile value of 50 computes the median value of the measure.

partition-by

(Optional) One or more dimensions that you want to partition by, separated by commas. Each field in the list is enclosed in { } (curly braces), if it is more than one word. The entire list is enclosed in [] (square brackets).

calculation-level

Specifies where to perform the calculation in relation to the order of evaluation. There are three supported calculation levels:

- PRE_FILTER
- PRE_AGG
- POST_AGG_FILTER (default) – To use this calculation level, specify an aggregation on measure, for example `sum(measure)`.

PRE_FILTER and PRE_AGG are applied before the aggregation occurs in a visualization. For these two calculation levels, you can't specify an aggregation on measure in the calculated field expression. To learn more about calculation levels and when they apply, see [Order of evaluation in Amazon Quick](#) and [Using level-aware calculations in Quick](#).

Returns

The result of the function is a number.

Example of percentileContOver

The following example helps explain how percentileContOver works.

Example Comparing calculation levels for the median

The following example shows the median for a dimension (category) by using different calculation levels with the percentileContOver function. The percentile is 50. The dataset is filtered by a region field. The code for each calculated field is as follows:

- `example = left( category, 1 )` (A simplified example.)
- `pre_agg = percentileContOver ( {Revenue} , 50 , [ example ] , PRE_AGG)`
- `pre_filter = percentileContOver ( {Revenue} , 50 , [ example ] , PRE_FILTER)`
- `post_agg_filter = percentileContOver ( sum ( {Revenue} ) , 50 , [ example ] , POST_AGG_FILTER )`

example	pre_filter	pre_agg	post_agg_filter
0	106,728	119,667	4,117,579
1	102,898	95,946	2,307,547
2	97,807	93,963	554,570
3	101,043	112,585	2,709,057
4	96,533	99,214	3,598,358

5	106,293	97,296	1,875,648
6	97,118	69,159	1,320,672
7	100,201	90,557	969,807

percentileDiscOver

The `percentileDiscOver` function calculates the percentile based on the actual numbers in measure. It uses the grouping and sorting that are applied in the field wells. The result is partitioned by the specified dimension at the specified calculation level. The `percentileOver` function is an alias of `percentileDiscOver`.

Use this function to answer the following question: Which actual data points are present in this percentile? To return the nearest percentile value that is present in your dataset, use `percentileDiscOver`. To return an exact percentile value that might not be present in your dataset, use `percentileContOver` instead.

Syntax

```
percentileDiscOver (  
    measure  
    , percentile-n  
    , [partition-by, ...]  
    , calculation-level  
)
```

Arguments

measure

Specifies a numeric value to use to compute the percentile. The argument must be a measure or metric. Nulls are ignored in the calculation.

percentile-n

The percentile value can be any numeric constant 0–100. A percentile value of 50 computes the median value of the measure.

partition-by

(Optional) One or more dimensions that you want to partition by, separated by commas. Each field in the list is enclosed in { } (curly braces), if it is more than one word. The entire list is enclosed in [] (square brackets).

calculation-level

Specifies where to perform the calculation in relation to the order of evaluation. There are three supported calculation levels:

- PRE_FILTER
- PRE_AGG
- POST_AGG_FILTER (default) – To use this calculation level, you need to specify an aggregation on measure, for example `sum(measure)`.

PRE_FILTER and PRE_AGG are applied before the aggregation occurs in a visualization. For these two calculation levels, you can't specify an aggregation on measure in the calculated field expression. To learn more about calculation levels and when they apply, see [Order of evaluation in Amazon Quick](#) and [Using level-aware calculations in Quick](#).

Returns

The result of the function is a number.

Example of percentileDiscOver

The following example helps explain how percentileDiscOver works.

Example Comparing calculation levels for the median

The following example shows the median for a dimension (category) by using different calculation levels with the percentileDiscOver function. The percentile is 50. The dataset is filtered by a region field. The code for each calculated field is as follows:

- `example = left( category, 1 )` (A simplified example.)
- `pre_agg = percentileDiscOver ( {Revenue} , 50 , [ example ] , PRE_AGG)`
- `pre_filter = percentileDiscOver ( {Revenue} , 50 , [ example ] , PRE_FILTER)`
- `post_agg_filter = percentileDiscOver ( sum ( {Revenue} ) , 50 , [ example ] , POST_AGG_FILTER )`

example	pre_filter	pre_agg	post_agg_filter

0	106,728	119,667	4,117,579
1	102,898	95,946	2,307,547
2	97,629	92,046	554,570
3	100,867	112,585	2,709,057
4	96,416	96,649	3,598,358
5	106,293	97,296	1,875,648
6	97,118	64,395	1,320,672
7	99,915	90,557	969,807

Example The median

The following example calculates the median (the 50th percentile) of Sales partitioned by City and State.

```
percentileDiscOver
(
  Sales,
  50,
  [City, State]
)
```

The following example calculates the 98th percentile of `sum({Billed Amount})` partitioned by Customer Region. The fields in the table calculation are in the field wells of the visual.

```
percentileDiscOver
(
  sum({Billed Amount}),
  98,
  [{Customer Region}]
)
```

The following screenshot shows the how these two examples look on a chart.

Sum of Billed Amount, PercOver50, and PercOver98 by Customer Region			
Customer Region	Billed Amount	percOver50	percOver98
APAC	\$598,114	\$850,406	\$1,648,034
EMEA	\$850,406	\$850,406	\$1,648,034
US	\$1,648,034	\$850,406	\$1,648,034

percentOfTotal

The `percentOfTotal` function calculates the percentage a measure contributes to the total, based on the dimensions specified.

Syntax

The brackets are required. To see which arguments are optional, see the following descriptions.

```
percentOfTotal  
(  
    measure  
    , [ partition_field, ... ]  
)
```

Arguments

measure

An aggregated measure that you want to see the percent of total for. Currently, the `distinct count` aggregation is not supported for `percentOfTotal`.

partition field

(Optional) One or more dimensions that you want to partition by, separated by commas.

Each field in the list is enclosed in `{ }` (curly braces), if it is more than one word. The entire list is enclosed in `[ ]` (square brackets).

Example

The following example creates a calculation for the percent of total `Sales` contributed by each `State`.

```
percentOfTotal  
(  
    sum(Sales),  
    [State]  
)
```

The following example calculates the percent that a specific Billed Amount is when compared to the total Billed Amount, partitioned by ([Service Line] ASC). The fields in the table calculation are in the field wells of the visual.

```
percentOfTotal
(
    sum( {Billed Amount} ),
    [{Service Line}]
)
```

The following screenshot shows the results of the example. The red highlights show that the partition field with the value "Billing" has three entries, one for each region. The total billed amount for this service line is divided into three percentages, which total 100 percent. Percentages are rounded and might not always add up to exactly 100 percent.

Billing	US	53.8%	9,330,832.51
HR	APAC	20.0%	3,441,106.16
HR	EMEA	25.1%	4,316,700.48
HR	US	55.0%	9,464,168.33

periodOverPeriodDifference

The periodOverPeriodDifference function calculates the difference of a measure over two different time periods as specified by period granularity and offset. Unlike a difference calculation,

this function uses a date-based offset instead of a fixed sized offset. This ensures that only the correct dates are compared, even if data points are missing in the dataset.

Syntax

```
periodOverPeriodDifference(  
  measure,  
  date,  
  period,  
  offset)
```

Arguments

measure

An aggregated measure that you want to perform the periodOverPeriod calculation on.

dateTime

The Date dimension over which we are computing Period-Over-Period calculations.

period

(Optional) The time period across which you're computing the computation. Granularity of YEAR means YearToDate computation, Quarter means QuarterToDate, and so on. Valid granularities include YEAR, QUARTER, MONTH, WEEK, DAY, HOUR, MINUTE, and SECONDS.

The defaults value is the visual date dimension granularity.

offset

(Optional) The offset can be a positive or negative integer representing the prior time period (specified by period) that you want to compare against. For instance, period of a quarter with offset 1 means comparing against the previous quarter.

The default value is 1.

Example

The following example uses a calculated field PeriodOverPeriod to display the sales amount difference of yesterday

```
periodOverPeriodDifference(sum(Sales), {Order Date})
```

The screenshot shows the Amazon QuickSight interface. In the 'Group by' section, 'Order Date' is selected. In the 'Value' section, 'Sales (Sum)' and 'PeriodOverPeriod (Custom)' are listed. Below the fields, the calculated field 'PeriodOverPeriodDifference' is shown. The resulting table displays the sum of sales and the period-over-period difference for each order date.

Order Date	Sales	PeriodOverPeriod
Jan 4, 2020	16	
Jan 5, 2020	288	272
Jan 6, 2020	20	-269
Jan 7, 2020	4,407	4,388
Jan 8, 2020	87	-4,320

The following example uses a calculated field `PeriodOverPeriod` to display the sales amount difference of previous 2 months. Below example is comparing sales of Mar2020 with Jan2020.

```
periodOverPeriodDifference(sum(Sales), {Order Date}, MONTH, 1)
```

The screenshot shows the Amazon QuickSight interface. In the 'Group by' section, 'Order Date (MONTH)' is selected. In the 'Value' section, 'Sales (Sum)' and 'PeriodOverPeriod2 (Custom)' are listed. Below the fields, the calculated field 'PeriodOverPeriodDifference' is shown. The resulting table displays the sum of sales and the period-over-period difference for each month, comparing March 2020 with January 2020.

Order ...	Sales	PeriodOverPeriod2
Jan 2020	13,946	
Feb 2020	4,811	
Mar 2020	55,691	41,745
Apr 2020	28,295	23,485
May 2020	23,648	-32,043

periodOverPeriodLastValue

The `periodOverPeriodLastValue` function calculates the last (previous) value of a measure from the previous time period as specified by the period granularity and offset. This function uses a

date-based offset instead of a fixed sized offset. This ensures only the correct dates are compared, even if data points are missing in the dataset.

Syntax

```
periodOverPeriodLastValue(  
    measure,  
    date,  
    period,  
    offset)
```

Arguments

measure

An aggregated measure that you want to see the difference for.

date

The date dimension over which you're computing periodOverPeriod calculations.

period

(Optional) The time period across which you're computing the computation. Granularity of YEAR means YearToDate computation, Quarter means QuarterToDate, and so on. Valid granularities include YEAR, QUARTER, MONTH, WEEK, DAY, HOUR, MINUTE, and SECONDS.

This argument defaults to the granularity of the visual aggregation

offset

(Optional) The offset can a positive or negative integer representing the prior time period (specified by period) that you want to compare against. For instance, period of a quarter with offset 1 means comparing against the previous quarter.

This argument default value is 1.

Example

The following example calculates the month over month value in sales with the visual dimension granularity and default offset of 1.

```
periodOverPeriodLastValue(sum(Sales), {Order Date})
```

The following example calculates the month over month value in sales with a fixed granularity of MONTH and fixed offset of 1.

```
periodOverPeriodLastValue(sum(Sales), {Order Date},MONTH, 1)
```

periodOverPeriodPercentDifference

The `periodOverPeriodPercentDifference` function calculates the percent difference of a measure over two different time periods as specified by the period granularity and offset. Unlike `percentDifference`, this function uses a date-based offset instead of a fixed sized offset. This ensures only the correct dates are compared, even if data points are missing in the dataset.

Syntax

```
periodOverPeriodPercentDifference(
```

```
measure,  
date,  
period,  
offset)
```

Arguments

measure

An aggregated measure that you want to see the difference for.

date

The date dimension over which you're computing periodOverPeriod calculations.

period

(Optional) The time period across which you're computing the computation. Granularity of YEAR means YearToDate computation, Quarter means QuarterToDate, and so on. Valid granularities include YEAR, QUARTER, MONTH, WEEK, DAY, HOUR, MINUTE, and SECONDS.

This argument defaults to the granularity of the visual aggregation

offset

(Optional) The offset can a positive or negative integer representing the prior time period (specified by period) that you want to compare against. For instance, period of a quarter with offset 1 means comparing against the previous quarter.

This argument default value is 1.

Example

The following example calculates the month over month percent difference in sales with the visual dimension granularity and default offset of 1.

```
periodOverPeriodPercentDifference(sum(Sales), {Order Date})
```

The following example calculates the month over month percent difference in sales with a fixed granularity of MONTH and fixed offset of 1.

```
periodOverPeriodPercentDifference(sum(Sales), {Order Date}, MONTH, 1)
```

periodToDateAvgOverTime

The `periodToDateAvgOverTime` function calculates the average of a measure for a given time granularity (for instance, a quarter) up to a point in time.

Syntax

```
periodToDateAvgOverTime(
  measure,
  dateTime,
  period)
```

Arguments

measure

An aggregated measure that you want to do the calculation

dateTime

The date dimension over which you're computing PeriodOverTime calculations.

period

(Optional) The time period across which you're computing the computation. Granularity of YEAR means YearToDate computation, Quarter means QuarterToDate, and so on. Valid granularities include YEAR, QUARTER, MONTH, WEEK, DAY, HOUR, MINUTE, and SECONDS.

The default value is the visual's date dimension granularity.

Example

The following function calculates the average fare amount month over month.

```
periodToDateAvgOverTime(sum({fare_amount}), pickupDatetime, MONTH)
```

periodToDateCountOverTime

The `periodToDateCountOverTime` function calculates the count of a dimension or measure for a given time granularity (for instance, a quarter) up to a point in time.

Syntax

```
periodToDateCountOverTime(
  measure,
  dateTime,
  period)
```

Arguments

measure

An aggregated measure that you want to do the calculation

dateTime

The date dimension over which you're computing PeriodOverTime calculations.

period

(Optional) The time period across which you're computing the computation. Granularity of YEAR means YearToDate computation, Quarter means QuarterToDate, and so on. Valid granularities include YEAR, QUARTER, MONTH, WEEK, DAY, HOUR, MINUTE, and SECONDS.

The default value is the visual's date dimension granularity.

Example

The following example calculates the count of vendors month over month.

stdevOver

The stdevOver function calculates the standard deviation of the specified measure, partitioned by the chosen attribute or attributes, based on a sample.

Syntax

The brackets are required. To see which arguments are optional, see the following descriptions.

```
stdevOver
(
    measure
    , [ partition_field, ... ]
    , calculation level
)
```

Arguments

measure

The measure that you want to do the calculation for, for example `sum({Sales Amt})`. Use an aggregation if the calculation level is set to `NULL` or `POST_AGG_FILTER`. Don't use an aggregation if the calculation level is set to `PRE_FILTER` or `PRE_AGG`.

partition field

(Optional) One or more dimensions that you want to partition by, separated by commas.

Each field in the list is enclosed in `{ }` (curly braces), if it is more than one word. The entire list is enclosed in `[ ]` (square brackets).

calculation level

(Optional) Specifies the calculation level to use:

- **PRE_FILTER** – Prefilter calculations are computed before the dataset filters.
- **PRE_AGG** – Preaggregate calculations are computed before applying aggregations and top and bottom *N* filters to the visuals.
- **POST_AGG_FILTER** – (default) table calculations are computed when the visuals display.

This value defaults to `POST_AGG_FILTER` when blank. For more information, see [Using level-aware calculations in Quick](#).

Example

The following example calculates the standard deviation of `sum(Sales)`, partitioned by `City` and `State`, based on a sample..

```
stdevOver
(  
    sum(Sales),  
    [City, State]  
)
```

The following example calculates the standard deviation of `Billed Amount` over `Customer Region`, based on a sample. The fields in the table calculation are in the field wells of the visual.

```
stdevOver
```

```
(  
    sum({Billed Amount}),  
    [{Customer Region}]  
)
```

stdevpOver

The `stdevpOver` function calculates the standard deviation of the specified measure, partitioned by the chosen attribute or attributes, based on a biased population.

Syntax

The brackets are required. To see which arguments are optional, see the following descriptions.

```
stdevpOver  
(  
    measure  
    , [ partition_field, ... ]  
    , calculation level  
)
```

Arguments

measure

The measure that you want to do the calculation for, for example `sum({Sales Amt})`. Use an aggregation if the calculation level is set to `NULL` or `POST_AGG_FILTER`. Don't use an aggregation if the calculation level is set to `PRE_FILTER` or `PRE_AGG`.

partition field

(Optional) One or more dimensions that you want to partition by, separated by commas.

Each field in the list is enclosed in `{ }` (curly braces), if it is more than one word. The entire list is enclosed in `[ ]` (square brackets).

calculation level

(Optional) Specifies the calculation level to use:

- **PRE_FILTER** – Prefilter calculations are computed before the dataset filters.
- **PRE_AGG** – Preaggregate calculations are computed before applying aggregations and top and bottom *N* filters to the visuals.

- **POST_AGG_FILTER** – (default) table calculations are computed when the visuals display.

This value defaults to `POST_AGG_FILTER` when blank. For more information, see [Using level-aware calculations in Quick](#).

Example

The following example calculates the standard deviation of `sum(Sales)`, partitioned by `City` and `State`, based on a biased population.

```
stdevpOver
(  
    sum(Sales),  
    [City, State]  
)
```

The following example calculates the standard deviation of `Billed Amount` over `Customer Region`, based on a biased population. The fields in the table calculation are in the field wells of the visual.

```
stdevpOver
(  
    sum({Billed Amount}),  
    [{Customer Region}]  
)
```

varOver

The `varOver` function calculates the variance of the specified measure, partitioned by the chosen attribute or attributes, based on a sample.

Syntax

The brackets are required. To see which arguments are optional, see the following descriptions.

```
varOver
(  
    measure  
    , [ partition_field, ... ]  
    , calculation level
```

```
)
```

Arguments

measure

The measure that you want to do the calculation for, for example `sum({Sales Amt})`. Use an aggregation if the calculation level is set to `NULL` or `POST_AGG_FILTER`. Don't use an aggregation if the calculation level is set to `PRE_FILTER` or `PRE_AGG`.

partition field

(Optional) One or more dimensions that you want to partition by, separated by commas.

Each field in the list is enclosed in `{ }` (curly braces), if it is more than one word. The entire list is enclosed in `[ ]` (square brackets).

calculation level

(Optional) Specifies the calculation level to use:

- **PRE_FILTER** – Prefilter calculations are computed before the dataset filters.
- **PRE_AGG** – Preaggregate calculations are computed before applying aggregations and top and bottom *N* filters to the visuals.
- **POST_AGG_FILTER** – (Default) Table calculations are computed when the visuals display.

This value defaults to `POST_AGG_FILTER` when blank. For more information, see [Using level-aware calculations in Quick](#).

Example

The following example calculates the variance of `sum(Sales)`, partitioned by `City` and `State`, based on a sample.

```
varOver
(  
    sum(Sales),  
    [City, State]  
)
```

The following example calculates the variance of `Billed Amount` over `Customer Region`, based on a sample. The fields in the table calculation are in the field wells of the visual.

```
varOver
(
    sum({Billed Amount}),
    [{Customer Region}]
)
```

varpOver

The `varpOver` function calculates the variance of the specified measure, partitioned by the chosen attribute or attributes, based on a biased population.

Syntax

The brackets are required. To see which arguments are optional, see the following descriptions.

```
varpOver
(
    measure
    , [ partition_field, ... ]
    , calculation level
)
```

Arguments

measure

The measure that you want to do the calculation for, for example `sum({Sales Amt})`. Use an aggregation if the calculation level is set to `NULL` or `POST_AGG_FILTER`. Don't use an aggregation if the calculation level is set to `PRE_FILTER` or `PRE_AGG`.

partition field

(Optional) One or more dimensions that you want to partition by, separated by commas.

Each field in the list is enclosed in `{ }` (curly braces), if it is more than one word. The entire list is enclosed in `[ ]` (square brackets).

calculation level

(Optional) Specifies the calculation level to use:

- **PRE_FILTER** – Prefilter calculations are computed before the dataset filters.

- **PRE_AGG** – Preaggregate calculations are computed before applying aggregations and top and bottom *N* filters to the visuals.
- **POST_AGG_FILTER** – (Default) Table calculations are computed when the visuals display.

This value defaults to POST_AGG_FILTER when blank. For more information, see [Using level-aware calculations in Quick](#).

Example

The following example calculates the variance of `sum(Sales)`, partitioned by `City` and `State`, based on a biased population.

```
varpOver  
(  
    sum(Sales),  
    [City, State]  
)
```

The following example calculates the variance of `Billed Amount` over `Customer Region`, based on a biased population. The fields in the table calculation are in the field wells of the visual.

```
varpOver  
(  
    sum({Billed Amount}),  
    [{Customer Region}]  
)
```

sumOver

The `sumOver` function calculates the sum of a measure partitioned by a list of dimensions.

Syntax

The brackets are required. To see which arguments are optional, see the following descriptions.

```
sumOver  
(  
    measure  
    , [ partition_field, ... ]  
    , calculation level  
)
```

Arguments

measure

The measure that you want to do the calculation for, for example `sum( {Sales Amt} )`. Use an aggregation if the calculation level is set to `NULL` or `POST_AGG_FILTER`. Don't use an aggregation if the calculation level is set to `PRE_FILTER` or `PRE_AGG`.

partition field

(Optional) One or more dimensions that you want to partition by, separated by commas.

Each field in the list is enclosed in `{ }` (curly braces), if it is more than one word. The entire list is enclosed in `[ ]` (square brackets).

calculation level

(Optional) Specifies the calculation level to use:

- **PRE_FILTER** – Prefilter calculations are computed before the dataset filters.
- **PRE_AGG** – Preaggregate calculations are computed before applying aggregations and top and bottom *N* filters to the visuals.
- **POST_AGG_FILTER** – (default) table calculations are computed when the visuals display.

This value defaults to `POST_AGG_FILTER` when blank. For more information, see [Using level-aware calculations in Quick](#).

Example

The following example calculates the sum of `sum(Sales)`, partitioned by `City` and `State`.

```
sumOver
(  
    sum(Sales),  
    [City, State]  
)
```

The following example sums `Billed Amount` over `Customer Region`. The fields in the table calculation are in the field wells of the visual.

```
sumOver
```

```
(  
    sum({Billed Amount}),  
    [{Customer Region}]  
)
```

The following screenshot shows the results of the example. With the addition of Customer Segment, the total amount billed for each is summed for the Customer Region, and displays in the calculated field.

Field wells

Group by

Customer Region

Customer Segment

Value

Billed Amount (Sum)

sumOver (Custom)

Sum of Billed Amount and Sumover by Customer Region and Customer Segment

Customer Region	Customer Segment	Billed Amount	sumOver
APAC	Enterprise	2,035,949	8,390,654
APAC	SMB	660,097	= 8,390,654
APAC	Startup	5,694,609	8,390,654
EMEA	Enterprise	5,678,783	11,038,164
EMEA	SMB	1,341,834	11,038,164
EMEA	Startup	4,017,547	11,038,164

denseRank

The denseRank function calculates the rank of a measure or a dimension in comparison to the specified partitions. It counts each item only once, ignoring duplicates, and assigns a rank "without holes" so that duplicate values share the same rank.

Syntax

The brackets are required. To see which arguments are optional, see the following descriptions.

```
denseRank  
(  
    [ sort_order_field ASC_or_DESC, ... ]
```

```
, [ partition_field, ... ]  
)
```

Arguments

sort order field

One or more aggregated fields, either measures or dimensions or both, that you want to sort the data by, separated by commas. You can either specify ascending (**ASC**) or descending (**DESC**) sort order.

Each field in the list is enclosed in {} (curly braces), if it is more than one word. The entire list is enclosed in [] (square brackets).

partition field

(Optional) One or more dimensions that you want to partition by, separated by commas.

Each field in the list is enclosed in {} (curly braces), if it is more than one word. The entire list is enclosed in [] (square brackets).

calculation level

(Optional) Specifies the calculation level to use:

- **PRE_FILTER** – Prefilter calculations are computed before the dataset filters.
- **PRE_AGG** – Preaggregate calculations are computed before applying aggregations and top and bottom *N* filters to the visuals.
- **POST_AGG_FILTER** – (Default) Table calculations are computed when the visuals display.

This value defaults to POST_AGG_FILTER when blank. For more information, see [Using level-aware calculations in Quick](#).

Example

The following example densely ranks max(Sales), based on a descending sort order, by State and City. Any cities with the same max(Sales) are assigned the same rank, and the next city is ranked consecutively after them. For example, if three cities share the same ranking, the fourth city is ranked as second.

```
denseRank
```

```
(  
  [max(Sales) DESC],  
  [State, City]  
)
```

The following example densely ranks `max(Sales)`, based on a descending sort order, by `State`. Any states with the same `max(Sales)` are assigned the same rank, and the next is ranked consecutively after them. For example, if three states share the same ranking, the fourth state is ranked as second.

```
denseRank  
(  
  [max(Sales) DESC],  
  [State]  
)
```

rank

The `rank` function calculates the rank of a measure or a dimension in comparison to the specified partitions. It counts each item, even duplicates, once and assigns a rank "with holes" to make up for duplicate values.

Syntax

The brackets are required. To see which arguments are optional, see the following descriptions.

```
rank  
(  
  [ sort_order_field ASC_or_DESC, ... ]  
  , [ partition_field, ... ]  
)
```

Arguments

sort_order_field

One or more aggregated measures and dimensions that you want to sort the data by, separated by commas. You can specify either ascending (**ASC**) or descending (**DESC**) sort order.

Each field in the list is enclosed in `{ }` (curly braces), if it is more than one word. The entire list is enclosed in `[ ]` (square brackets).

partition field

(Optional) One or more dimensions that you want to partition by, separated by commas.

Each field in the list is enclosed in {} (curly braces), if it is more than one word. The entire list is enclosed in [] (square brackets).

calculation level

(Optional) Specifies the calculation level to use:

- **PRE_FILTER** – Prefilter calculations are computed before the dataset filters.
- **PRE_AGG** – Preaggregate calculations are computed before applying aggregations and top and bottom *N* filters to the visuals.
- **POST_AGG_FILTER** – (Default) Table calculations are computed when the visuals display.

This value defaults to POST_AGG_FILTER when blank. For more information, see [Using level-aware calculations in Quick](#).

Example

The following example ranks `max(Sales)`, based on a descending sort order, by State and City, within the State of **WA**. Any cities with the same `max(Sales)` are assigned the same rank, but the next rank includes the count of all previously existing ranks. For example, if three cities share the same ranking, the fourth city is ranked as fourth.

```
rank
(  
  [max(Sales) DESC],  
  [State, City]  
)
```

The following example ranks `max(Sales)`, based on an ascending sort order, by State. Any states with the same `max(Sales)` are assigned the same rank, but the next rank includes the count of all previously existing ranks. For example, if three states share the same ranking, the fourth state is ranked as fourth.

```
rank
(  
  [max(Sales) ASC],  
  [State]
```

```
)
```

The following example ranks Customer Region by total Billed Amount. The fields in the table calculation are in the field wells of the visual.

```
rank(  
  [sum({Billed Amount}) DESC]  
)
```

The following screenshot shows the results of the example, along with the total Billed Amount so you can see how each region ranks.

Field wells

Group by

Customer Region

Value

rank (Custom)

Billed Amount (Sum)

Rank and Sum of Billed Amount by Customer Region

Customer Region	rank	Billed Amount
APAC	3	8,390,654
EMEA	2	11,038,164
US	1	23,547,165

percentileRank

The percentileRank function calculates the percentile rank of a measure or a dimension in comparison to the specified partitions. The percentile rank value(*x*) indicates that the current item is above *x*% of values in the specified partition. The percentile rank value ranges from 0 (inclusive) to 100 (exclusive).

Syntax

The brackets are required. To see which arguments are optional, see the following descriptions.

```
percentileRank
```

```
(  
    [ sort_order_field ASC_or_DESC, ... ]  
    , [ {partition_field}, ... ]  
)
```

Arguments

sort order field

One or more aggregated measures and dimensions that you want to sort the data by, separated by commas. You can specify either ascending (**ASC**) or descending (**DESC**) sort order.

Each field in the list is enclosed in {} (curly braces), if it is more than one word. The entire list is enclosed in [] (square brackets).

partition field

(Optional) One or more dimensions that you want to partition by, separated by commas.

Each field in the list is enclosed in {} (curly braces), if it is more than one word. The entire list is enclosed in [] (square brackets).

calculation level

(Optional) Specifies the calculation level to use:

- **PRE_FILTER** – Prefilter calculations are computed before the dataset filters.
- **PRE_AGG** – Preaggregate calculations are computed before applying aggregations and top and bottom *N* filters to the visuals.
- **POST_AGG_FILTER** – (Default) Table calculations are computed when the visuals display.

This value defaults to POST_AGG_FILTER when blank. For more information, see [Using level-aware calculations in Quick](#).

Example

The following example does a percentile ranking of max(Sales) in descending order, by State.

```
percentileRank  
(  
    [max(Sales) DESC],  
    [State]  
)
```

The following example does a percentile ranking of Customer Region by total Billed Amount. The fields in the table calculation are in the field wells of the visual.

```
percentileRank(
  [sum({Billed Amount}) DESC],
  [{Customer Region}]
)
```

The following screenshot shows the results of the example, along with the total Billed Amount so you can see how each region compares.

runningAvg

The `runningAvg` function calculates a running average for a measure based on the specified dimensions and sort orders.

Syntax

The brackets are required. To see which arguments are optional, see the following descriptions.

```
runningAvg
(
  measure
  , [ sortorder_field ASC_or_DESC, ... ]
  , [ partition_field, ... ]
```

)

Arguments

measure

An aggregated measure that you want to see the running average for.

sort order field

One or more measures and dimensions that you want to sort the data by, separated by commas. You can specify either ascending (**ASC**) or descending (**DESC**) sort order.

Each field in the list is enclosed in {} (curly braces), if it is more than one word. The entire list is enclosed in [] (square brackets).

partition field

(Optional) One or more dimensions that you want to partition by, separated by commas.

Each field in the list is enclosed in {} (curly braces), if it is more than one word. The entire list is enclosed in [] (square brackets).

Example

The following example calculates a running average of `sum(Sales)`, sorted by Sales, partitioned by City and State.

```
runningAvg
(
  sum(Sales),
  [Sales ASC],
  [City, State]
)
```

The following example calculates a running average of `Billed Amount`, sorted by month (`[truncDate("MM",Date) ASC]`). The fields in the table calculation are in the field wells of the visual.

```
runningAvg
(
  sum({Billed Amount}),
  [truncDate("MM",Date) ASC]
```

```
)
```

runningCount

The `runningCount` function calculates a running count for a measure or dimension, based on the specified dimensions and sort orders.

Syntax

The brackets are required. To see which arguments are optional, see the following descriptions.

```
runningCount
(  
  measure_or_dimension  
  , [ sortorder_field ASC_or_DESC, ... ]  
  , [ partition_field, ... ]  
)
```

Arguments

measure or dimension

An aggregated measure or dimension that you want to see the running count for.

sort order field

One or more measures and dimensions that you want to sort the data by, separated by commas. You can specify either ascending (**ASC**) or descending (**DESC**) sort order.

Each field in the list is enclosed in {} (curly braces), if it is more than one word. The entire list is enclosed in [] (square brackets).

partition field

(Optional) One or more dimensions that you want to partition by, separated by commas.

Each field in the list is enclosed in {} (curly braces), if it is more than one word. The entire list is enclosed in [] (square brackets).

Example

The following example calculates a running count of `sum(Sales)`, sorted by `Sales`, partitioned by `City` and `State`.

```
runningCount
(  
    sum(Sales),  
    [Sales ASC],  
    [City, State]  
)
```

The following example calculates a running count of Billed Amount, sorted by month ([truncDate("MM",Date) ASC]). The fields in the table calculation are in the field wells of the visual.

```
runningCount
(  
    sum({Billed Amount}),  
    [truncDate("MM",Date) ASC]  
)
```

runningMax

The runningMax function calculates a running maximum for a measure based on the specified dimensions and sort orders.

Syntax

The brackets are required. To see which arguments are optional, see the following descriptions.

```
runningMax
(  
    measure  
    ,[ sortorder_field ASC_or_DESC, ... ]  
    ,[ partition_field, ... ]  
)
```

Arguments

measure

An aggregated measure that you want to see the running maximum for.

sort order field

One or more measures and dimensions that you want to sort the data by, separated by commas. You can specify either ascending (**ASC**) or descending (**DESC**) sort order.

Each field in the list is enclosed in {} (curly braces), if it is more than one word. The entire list is enclosed in [] (square brackets).

partition field

(Optional) One or more dimensions that you want to partition by, separated by commas.

Each field in the list is enclosed in {} (curly braces), if it is more than one word. The entire list is enclosed in [] (square brackets).

Example

The following example calculates a running maximum of `sum(Sales)`, sorted by `Sales`, partitioned by `City` and `State`.

```
runningMax
(  
  sum(Sales),  
  [Sales ASC],  
  [City, State]  
)
```

The following example calculates a running maximum of `Billed Amount`, sorted by month (`[truncDate("MM",Date) ASC]`). The fields in the table calculation are in the field wells of the visual.

```
runningMax
(  
  sum({Billed Amount}),  
  [truncDate("MM",Date) ASC]  
)
```

runningMin

The `runningMin` function calculates a running minimum for a measure based on the specified dimensions and sort orders.

Syntax

The brackets are required. To see which arguments are optional, see the following descriptions.

```
runningMin
(  
  measure  
  , [ sortorder_field ASC_or_DESC, ... ]  
  , [ partition_field, ... ]  
)
```

Arguments

measure

An aggregated measure that you want to see the running minimum for.

sort order field

One or more measures and dimensions that you want to sort the data by, separated by commas. You can specify either ascending (**ASC**) or descending (**DESC**) sort order.

Each field in the list is enclosed in {} (curly braces), if it is more than one word. The entire list is enclosed in [] (square brackets).

partition field

(Optional) One or more dimensions that you want to partition by, separated by commas.

Each field in the list is enclosed in {} (curly braces), if it is more than one word. The entire list is enclosed in [] (square brackets).

Example

The following example calculates a running minimum of `sum(Sales)`, sorted by `Sales`, partitioned by `City` and `State`.

```
runningMin
(  
  sum(Sales),  
  [Sales ASC],  
  [City, State]
```

```
)
```

The following example calculates a running minimum of Billed Amount, sorted by month ([truncDate("MM",Date) ASC]). The fields in the table calculation are in the field wells of the visual.

```
runningMin
(  
  sum({Billed Amount}),  
  [truncDate("MM",Date) ASC]  
)
```

runningSum

The runningSum function calculates a running sum for a measure based on the specified dimensions and sort orders.

Syntax

The brackets are required. To see which arguments are optional, see the following descriptions.

```
runningSum
(  
  measure  
  ,[ sortorder_field ASC_or_DESC, ... ]  
  ,[ partition_field, ... ]  
)
```

Arguments

measure

An aggregated measure that you want to see the running sum for.

sort order field

One or more measures and dimensions that you want to sort the data by, separated by commas. You can specify either ascending (**ASC**) or descending (**DESC**) sort order.

Each field in the list is enclosed in {} (curly braces), if it is more than one word. The entire list is enclosed in [] (square brackets).

partition field

(Optional) One or more dimensions that you want to partition by, separated by commas.

Each field in the list is enclosed in {} (curly braces), if it is more than one word. The entire list is enclosed in [] (square brackets).

Example

The following example calculates a running sum of `sum(Sales)`, sorted by Sales, partitioned by City and State.

```
runningSum
(  
  sum(Sales),  
  [Sales ASC],  
  [City, State]  
)
```

The following example calculates a running sum of Billed Amount, sorted by month ([`truncDate("MM",Date) ASC`]). The fields in the table calculation are in the field wells of the visual.

```
runningSum
(  
  sum({Billed Amount}),  
  [truncDate("MM",Date) ASC]  
)
```

The following screenshot shows the results of the example. The red labels show how each amount is added ($a + b = c$) to the next amount, resulting in a new total.

Field wells Rows Date Columns Values Billed Amount (Sum) runningSum (Custom)

Sum of Billed Amount and Runningsum by Date			
Date		Billed Amount	runningSum
Jan 2012		54,675.45	a 54,675.45
Feb 2012	+b	57,127.93	=c 111,803.38
Mar 2012		66,303.97	178,107.35
Apr 2012		66,694.23	244,801.58
May 2012		75,906.62	a 320,708.2
Jun 2012	+b	83,531.67	=c 404,239.87

firstValue

The `firstValue` function calculates the first value of the aggregated measure or dimension partitioned and sorted by specified attributes.

Syntax

The brackets are required. To see which arguments are optional, see the following descriptions.

```
firstValue
(
    aggregated measure or dimension,
    [ sort_attribute ASC_or_DESC, ... ],
    [ partition_by_attribute, ... ]
)
```

Arguments

aggregated measure or dimension

An aggregated measure or dimension that you want to see the first value for.

sort attribute

One or more aggregated fields, either measures or dimensions or both, that you want to sort the data by, separated by commas. You can either specify ascending (**ASC**) or descending (**DESC**) sort order.

Each field in the list is enclosed in {} (curly braces), if it's more than one word. The entire list is enclosed in [] (square brackets).

partition by attribute

(Optional) One or more measure or dimensions that you want to partition by, separated by commas.

Each field in the list is enclosed in {} (curly braces), if it is more than one word. The entire list is enclosed in [] (square brackets).

Example

The following example calculates the first Destination Airport, sorted by Flight Date, partitioned by Flight Date ascending and Origin Airport.

```
firstValue(  
  {Destination Airport}  
  [{Flight Date} ASC],  
  [  
    {Origin Airport},  
    {Flight Date}  
  ]  
)
```

lastValue

The lastValue function calculates the last value of the aggregated measure or dimension partitioned and sorted by specified attributes.

Syntax

The brackets are required. To see which arguments are optional, see the following descriptions.

```
lastValue  
(  
  aggregated measure or dimension,  
  [ sort_attribute ASC_or_DESC, ... ],  
  [ partition_by_attribute, ... ]  
)
```

Arguments

aggregated measure or dimension

An aggregated measure or dimension that you want to see the last value for.

sort attribute

One or more aggregated fields, either measures or dimensions or both, that you want to sort the data by, separated by commas. You can either specify ascending (ASC) or descending (DESC) sort order.

Each field in the list is enclosed in {} (curly braces), if it's more than one word. The entire list is enclosed in [] (square brackets).

partition by attribute

(Optional) One or more measures or dimensions that you want to partition by, separated by commas.

Each field in the list is enclosed in {} (curly braces), if it is more than one word. The entire list is enclosed in [] (square brackets).

Example

The following example calculates the last value for `Destination Airport`. This calculation is sorted by the `Flight Date` value and partitioned by the `Flight Date` value sorted in ascending order and the `Origin Airport` value.

```
lastValue(  
  [{Destination Airport}],  
  [{Flight Date} ASC],  
  [  
    {Origin Airport},  
    truncDate('DAY', {Flight Date})  
  ]  
)
```

windowAvg

The `windowAvg` function calculates the average of the aggregated measure in a custom window that is partitioned and sorted by specified attributes. Usually, you use custom window functions

on a time series, where your visual shows a metric and a date field. For example, you can use `windowAvg` to calculate a moving average, which is often used to smooth out the noise in a line chart.

Window functions aren't supported for MySQL versions earlier than 8 and MariaDB versions earlier than 10.2.

Syntax

The brackets are required. To see which arguments are optional, see the following descriptions.

```
windowAvg
(
    measure
    , [sort_order_field ASC/DESC, ...]
    , start_index
    , end_index
    , [partition_field, ... ]
)
```

Arguments

measure

The aggregated metric that you want to get the average for, for example `sum( {Revenue} )`.

sort attribute

One or more aggregated fields, either measures or dimensions or both, that you want to sort the data by, separated by commas. You can either specify ascending (**ASC**) or descending (**DESC**) sort order.

Each field in the list is enclosed in `{ }` (curly braces), if it's more than one word. The entire list is enclosed in `[ ]` (square brackets).

start index

The start index is a positive integer, indicating *n* rows above the current row. The start index counts the available data points above the current row, rather than counting actual time periods. If your data is sparse (missing months or years, for example), adjust the indexes accordingly.

end index

The end index is a positive integer, indicating n rows below the current row. The end index counts the available data points below the current row, rather than counting actual time periods. If your data is sparse (missing months or years, for example), adjust the indexes accordingly.

partition field

(Optional) One or more dimensions that you want to partition by, separated by commas.

Each field in the list is enclosed in {} (curly braces), if it's more than one word. The entire list is enclosed in [] (square brackets).

Example

The following example calculates the moving average of `sum(Revenue)`, partitioned by `SaleDate`. The calculation includes three rows above and two row below of the current row.

```
windowAvg
(
    sum(Revenue),
    [SaleDate ASC],
    3,
    2
)
```

The following screenshot shows the results of this moving average example. The `sum(Revenue)` field is added to the chart to show the difference between the revenue and the moving average of revenue.

windowCount

The `windowCount` function calculates the count of the aggregated measure or dimension in a custom window that is partitioned and sorted by specified attributes. Usually, you use custom window functions on a time series, where your visual shows a metric and a date field.

Window functions aren't supported for MySQL versions earlier than 8 and MariaDB versions earlier than 10.2.

Syntax

The brackets are required. To see which arguments are optional, see the following descriptions.

```

windowCount
(
    measure_or_dimension
    , [ sort_order_field ASC/DESC, ... ]
    , start_index
    , end_index
    , [ partition_field, ... ]
  
```

```
)
```

Arguments

measure or dimension

The aggregated metric that you want to get the average for, for example `sum( {Revenue} )`.

sort attribute

One or more aggregated fields, either measures or dimensions or both, that you want to sort the data by, separated by commas. You can either specify ascending (**ASC**) or descending (**DESC**) sort order.

Each field in the list is enclosed in `{ }` (curly braces), if it's more than one word. The entire list is enclosed in `[ ]` (square brackets).

start index

The start index is a positive integer, indicating n rows above the current row. The start index counts the available data points above the current row, rather than counting actual time periods. If your data is sparse (missing months or years, for example), adjust the indexes accordingly.

end index

The end index is a positive integer, indicating n rows below the current row. The end index counts the available data points below the current row, rather than counting actual time periods. If your data is sparse (missing months or years, for example), adjust the indexes accordingly.

partition field

(Optional) One or more dimensions that you want to partition by, separated by commas.

Each field in the list is enclosed in `{ }` (curly braces), if it's more than one word. The entire list is enclosed in `[ ]` (square brackets).

Example

The following example calculates the moving count of `sum(Revenue)`, partitioned by `SaleDate`. The calculation includes three rows above and two row below of the current row.

```
windowCount
(
    sum(Revenue),
    [SaleDate ASC],
    3,
    2
)
```

windowMax

The windowMax function calculates the maximum of the aggregated measure in a custom window that is partitioned and sorted by specified attributes. Usually, you use custom window functions on a time series, where your visual shows a metric and a date field. You can use windowMax to help you identify the maximum of the metric over a period time.

Window functions aren't supported for MySQL versions earlier than 8 and MariaDB versions earlier than 10.2.

Syntax

The brackets are required. To see which arguments are optional, see the following descriptions.

```
windowMax
(
    measure
    , [sort_order_field ASC/DESC, ...]
    , start_index
    , end_index
    , [ partition_field, ... ]
)
```

Arguments

measure

The aggregated metric that you want to get the average for, for example sum({Revenue}).

sort attribute

One or more aggregated fields, either measures or dimensions or both, that you want to sort the data by, separated by commas. You can either specify ascending (**ASC**) or descending (**DESC**) sort order.

Each field in the list is enclosed in {} (curly braces), if it's more than one word. The entire list is enclosed in [] (square brackets).

start index

The start index is a positive integer, indicating n rows above the current row. The start index counts the available data points above the current row, rather than counting actual time periods. If your data is sparse (missing months or years, for example), adjust the indexes accordingly.

end index

The end index is a positive integer, indicating n rows below the current row. The end index counts the available data points below the current row, rather than counting actual time periods. If your data is sparse (missing months or years, for example), adjust the indexes accordingly.

partition field

(Optional) One or more dimensions that you want to partition by, separated by commas.

Each field in the list is enclosed in {} (curly braces), if it is more than one word. The entire list is enclosed in [] (square brackets).

Example

The following example calculates the trailing 12-month maximum of `sum(Revenue)`, partitioned by `SaleDate`. The calculation includes 12 rows above and 0 row below of the current row.

```
windowMax
(
    sum(Revenue),
    [SaleDate ASC],
    12,
    0
)
```

The following screenshot shows the results of this trailing 12-month example. The `sum(Revenue)` field is added to the chart to show the difference between the revenue and the trailing 12-month maximum revenue.

windowMin

The `windowMin` function calculates the minimum of the aggregated measure in a custom window that is partitioned and sorted by specified attributes. Usually, you use custom window functions on a time series, where your visual shows a metric and a date field. You can use `windowMin` to help you identify the minimum of the metric over a period time.

Window functions aren't supported for MySQL versions earlier than 8 and MariaDB versions earlier than 10.2.

Syntax

The brackets are required. To see which arguments are optional, see the following descriptions.

```

windowMin
(
    measure
    , [sort_order_field ASC/DESC, ...]
    , start_index
    , end_index
    , [ partition_field, ... ]

```

```
)
```

Arguments

measure

The aggregated metric that you want to get the average for, for example `sum( {Revenue} )`.

sort attribute

One or more aggregated fields, either measures or dimensions or both, that you want to sort the data by, separated by commas. You can either specify ascending (**ASC**) or descending (**DESC**) sort order.

Each field in the list is enclosed in `{ }` (curly braces), if it's more than one word. The entire list is enclosed in `[ ]` (square brackets).

start index

The start index is a positive integer, indicating n rows above the current row. The start index counts the available data points above the current row, rather than counting actual time periods. If your data is sparse (missing months or years, for example), adjust the indexes accordingly.

end index

The end index is a positive integer, indicating n rows below the current row. The end index counts the available data points below the current row, rather than counting actual time periods. If your data is sparse (missing months or years, for example), adjust the indexes accordingly.

partition field

(Optional) One or more dimensions that you want to partition by, separated by commas.

Each field in the list is enclosed in `{ }` (curly braces), if it's more than one word. The entire list is enclosed in `[ ]` (square brackets).

Example

The following example calculates the trailing 12-month minimum of `sum(Revenue)`, partitioned by `SaleDate`. The calculation includes 12 rows above and 0 row below of the current row.

```

windowMin
(
    sum(Revenue),
    [SaleDate ASC],
    12,
    0
)

```

The following screenshot shows the results of this trailing 12-month example. The `sum(Revenue)` field is added to the chart to show the difference between the revenue and the trailing 12-month minimum revenue.

windowSum

The `windowSum` function calculates the sum of the aggregated measure in a custom window that is partitioned and sorted by specified attributes. Usually, you use custom window functions on a time series, where your visual shows a metric and a date field.

Window functions aren't supported for MySQL versions earlier than 8 and MariaDB versions earlier than 10.2.

Syntax

The brackets are required. To see which arguments are optional, see the following descriptions.

```
windowSum
(
    measure
    , [ sort_order_field ASC/DESC, ... ]
    , start_index
    , end_index
    , [ partition_field, ... ]
)
```

Arguments

measure

The aggregated metric that you want to get the sum for, for example `sum( {Revenue} )`.

For the engines MySQL, MariaDB, and Amazon Aurora with MySQL compatibility, the lookup index is limited to just 1. Window functions aren't supported for MySQL versions below 8 and MariaDB versions earlier than 10.2.

sort attribute

One or more aggregated fields, either measures or dimensions or both, that you want to sort the data by, separated by commas. You can either specify ascending (**ASC**) or descending (**DESC**) sort order.

Each field in the list is enclosed in {} (curly braces), if it's more than one word. The entire list is enclosed in [] (square brackets).

start index

The start index is a positive integer, indicating n rows above the current row. The start index counts the available data points above the current row, rather than counting actual time periods. If your data is sparse (missing months or years, for example), adjust the indexes accordingly.

end index

The end index is a positive integer, indicating n rows below the current row. The end index counts the available data points below the current row, rather than counting actual time

periods. If your data is sparse (missing months or years, for example), adjust the indexes accordingly.

partition field

(Optional) One or more dimensions that you want to partition by, separated by commas.

Each field in the list is enclosed in {} (curly braces), if it's more than one word. The entire list is enclosed in [] (square brackets).

Example

The following example calculates the moving sum of `sum(Revenue)`, sorted by `SaleDate`. The calculation includes two rows above and one row ahead of the current row.

```
windowSum
(
    sum(Revenue),
    [SaleDate ASC],
    2,
    1
)
```

The following example show a trailing 12-month sum.

```
windowSum(sum(Revenue), [SaleDate ASC], 12, 0)
```

The following screenshot shows the results of this trailing 12-month sum example. The `sum(Revenue)` field is added to the chart to show the difference between the revenue and the trailing 12-month sum of revenue.

Joining data

You can use the join interface in Amazon Quick Sight to join objects from one or more data sources. By using Amazon Quick Sight to join the data, you can merge disparate data without duplicating the data from different sources.

Types of joined datasets

A join is performed between two Quick Sight *logical tables*, where each logical table contains information about how to fetch data. When editing a dataset in Quick Sight, the join diagram at the top half of the page shows each logical table as a rectangular block.

There are two different types of joined datasets in Quick Sight: same-source and cross-source. A dataset is considered same-source when it doesn't have any joins, or when all of the following conditions are met:

- If any of the logical tables refer to a Quick Sight data source:
 - All of the logical tables in this dataset must refer to the same Quick Sight data source. This doesn't apply if two separate Quick Sight data sources refer to the same underlying database.

It must be the exact same Quick Sight data source. For more information about using a single data source, see [Creating a dataset using an existing data source](#).

- If any of the logical tables refer to a Quick Sight dataset that is a parent dataset:
 - The parent dataset must use direct query.
 - The parent dataset must refer to the same Quick Sight data source.

If the above conditions aren't met, the dataset is considered a cross-source join.

Facts about joining datasets

Both same-source and cross-source dataset joins have the following limitations.

What's the maximum number of tables a joined dataset can contain?

All joined datasets can contain up to 32 tables.

How large can joined data be?

The maximum allowed size of a join is determined by the query mode and query engine that is used. The list below provides information about the different size limits for the tables to be joined. The size limit applies to all secondary tables combined. There are no join size limits for the primary table.

- **Same-source tables** – When tables originate from a single query data source, Quick Sight imposes no restrictions on the join size. This does not override join size limitations that the source query engine may have in place.
- **Cross-source datasets** – This type of join contains tables from different data sources that aren't stored in SPICE. For these types of joins, Quick Sight automatically identifies the largest table in the dataset. The combined size of all other secondary tables must be less than 1 GB.
- **Datasets stored in SPICE** – This type of join contains tables that are all ingested into SPICE. The combined size of all secondary tables in this join cannot exceed 20 GB.

For more information about SPICE dataset size calculations, see [Estimating the size of SPICE datasets](#).

Can a joined dataset use direct query?

Same-source datasets support direct query, assuming there are no other restrictions on using direct query. For example, S3 data sources don't support direct query, so a same-source S3 dataset must still use SPICE.

Cross-source datasets must use SPICE.

Can calculated fields be used in a join?

All joined datasets can use calculated fields, but calculated fields can't be used in any on-clauses.

Can geographical data be used in a join?

Same-source datasets support geographical data types, but geographical fields can't be used in any on-clauses.

Cross-source datasets don't support geographical data in any form.

For some examples of joining tables across data sources, see the [Joining across data sources on Amazon Quick Sight](#) post on the AWS Big Data Blog.

Creating a join

Use the following procedure to join tables to use in a dataset. Before you begin, import or connect to your data. You can create a join between any of the data sources supported by Amazon Quick Sight, except Internet of Things (IoT) data. For example, you can add comma-separated value (.csv) files, tables, views, SQL queries, or JSON objects in an Amazon S3 bucket.

To add one or more joins

1. Open the dataset that you want to work with.
2. (Optional) Before you get started, decide if you want to disable the autogenerated preview based on of a sample of your data. To turn that off, choose **Auto-preview** at top right. It's turned on by default.
3. If you haven't already chosen a query mode, choose **Query mode**.

Choose **SPICE** to store your dataset in [SPICE](#), or choose **Direct query** to pull live data every time. If your dataset contains one ore more manually uploaded file, your dataset is automatically stored in SPICE.

If you choose **SPICE**, the data is ingested into Quick Sight. Visuals that use the dataset run queries in SPICE, instead of on the database.

If you choose **Direct query**, the data isn't ingested into SPICE. Visuals that use the dataset run queries on the database, instead of in SPICE.

If you choose **Query mode**, make sure to set unique keys in the join, if applicable, to improve performance when loading visuals.

4. On the data preparation page, choose **Add data**.
5. In the **Add data page** that opens, choose one of the following options and complete the steps following:
 - Add data from a dataset:
 1. Choose **Dataset**.
 2. Select a dataset from the list.
 3. Choose **Select**.
 - Add data from a data source:
 1. Choose **Data source**.
 2. Select a data source from the list.
 3. Choose **Select**.
 4. Select a table from the list.
 5. Choose **Select**.
 - Create self-joins by adding a table multiple times. A counter appears after the name. An example is **Product**, **Product (2)**, and **Product (3)**. Field names in the **Fields** or **Filters** sections include the same counter so you can know which instance of the table a field came from.
 - Add a new file by choosing **Upload a file**, and then choose the file that you want to join.
6. (Optional) Choose **Use custom SQL** to open the query editor and write a query for a SQL data source.
7. (Optional) After you add data, interact with each table by choosing its menu icon. Rearrange the tables by dragging and dropping them.

An icon with red dots appears to indicate that you need to configure this join. Two red dots appear for joins that aren't yet configured. To create joins, choose the first join configuration icon.

8. (Optional) To change an existing join, reopen **Join configuration** by choosing the join icon between two tables.

The **Join Configuration** pane opens. On the join interface, specify the join type and the fields to use to join the tables.

9. At the bottom of the screen, you can see options to set a field in one table equal to a field in another table.

- In the **Join clauses** section, choose the join column for each table.

(Optional) If the tables that you selected join on multiple columns, choose **Add a new join clause**. Doing this adds another row to the join clauses, so you can specify the next set of columns to join. Repeat this process until you have identified all of the join columns for the two data objects.

10. In the **Join configuration** pane, choose the kind of join to apply. If the join fields are a unique key for one or both tables, enable the unique key setting. Unique keys only apply to direct queries, not to SPICE data.

For more information about joins, see [Join types](#).

11. Choose **Apply** to confirm your choices.

To cancel without making changes, choose **Cancel**.

12. The join icon in the workspace changes to show the new relationship.

13. (Optional) In the **Fields** section, you can use each field's menu to do one or more of the following:

- **Add a hierarchy** to a geospatial field.
- **Include** or **Exclude** the field.
- **Edit name & description** of the field.
- **Change data type**.
- **Add a calculation** (a calculated field).
- **Restrict access to only me**, so only you can see it. This can be helpful when you are adding fields to a dataset that's already in use.

14. (Optional) In the **Filters** section, you can add or edit filters. For more information, see [Filtering data in Amazon Quick Sight](#).

Join types

Amazon Quick Sight supports the following join types:

- Inner joins
- Left and right outer joins
- Full outer joins

Let's take a closer look at what these join types do with your data. For our example data, we're using the following tables named `widget` and `safety_rating`.

```
SELECT * FROM safety-rating
```

```
rating_id safety_rating
```

```
1      A+
2      A
3      A-
4      B+
5      B
```

```
SELECT * FROM WIDGET
```

```
widget_id    widget safety_rating_id
```

```
1      WidgetA  3
2      WidgetB  1
3      WidgetC  1
4      WidgetD  2
5      WidgetE
6      WidgetF  5
7      WidgetG
```

Inner joins

Use an inner join when you want to see only the data where there is a match between two tables. For example, suppose that you perform an inner join on the **safety-rating** and **widget** tables.

In the following result set, widgets without safety ratings are removed, and safety ratings without associated widgets are removed. Only the rows that match perfectly are included.

```
SELECT * FROM safety-rating
INNER JOIN widget
ON safety_rating.rating_id = widget.safety_rating_id
```

rating_id	safety_rating	widget_id	widget	safety_rating_id
3	A-	1	WidgetA	3
1	A+	2	WidgetB	1
1	A+	3	WidgetC	1
2	A	4	WidgetD	2
5	B	6	WidgetF	5

Left and right outer joins

These are also known as left or right outer joins. Use a left or right outer join when you want to see all the data from one table, and only the matching rows from the other table.

In a graphical interface, you can see which table is on the right or the left. In a SQL statement, the first table is considered to be on the left. Therefore, choosing a left outer join as opposed to a right outer join depends only on how the tables are laid out in your query tool.

For example, suppose that you perform a left outer join on `safety-rating` (the left table) and `widgets` (the right table). In this case, all `safety-rating` rows are returned, and only matching widget rows are returned. You can see blanks in the result set where there is no matching data.

```
SELECT * FROM safety-rating
LEFT OUTER JOIN widget
ON safety_rating.rating_id = widget.safety_rating_id
```

rating_id	safety_rating	widget_id	widget	safety_rating_id
1	A+	2	WidgetB	1
1	A+	3	WidgetC	1
2	A	4	WidgetD	2
3	A-	1	WidgetA	3
4	B+			
5	B	6	WidgetF	5

If you instead use a right outer join, call the tables in the same order so `safety-rating` is on the left and `widgets` is on the right. In this case, only matching `safety-rating` rows are returned,

and all widget rows are returned. You can see blanks in the result set where there is no matching data.

```
SELECT * FROM safety-rating
RIGHT OUTER JOIN widget
ON safety_rating.rating_id = widget.safety_rating_id
```

rating_id	safety_rating	widget_id	widget	safety_rating_id
3	A-	1	WidgetA	3
1	A+	2	WidgetB	1
1	A+	3	WidgetC	1
2	A	4	WidgetD	2
		5	WidgetE	
5	B	6	WidgetF	5
		7	WidgetG	

Full outer joins

These are sometimes called just outer joins, but this term can refer to either a left outer, right outer, or full outer join. To define the meaning, we use the complete name: full outer join.

Use a full outer join to see data that matches, plus data from both tables that doesn't match. This type of join includes all rows from both tables. For example, if you perform a full outer join on the safety-rating and widget tables, all rows are returned. The rows are aligned where they matched, and all extra data is included on separate rows. You can see blanks in the result set where there is no matching data.

```
SELECT * FROM safety-rating
FULL OUTER JOIN widget
ON safety_rating.rating_id = widget.safety_rating_id
```

rating_id	safety_rating	widget_id	widget	safety_rating_id
1	A+	2	WidgetB	1
1	A+	3	WidgetC	1
2	A	4	WidgetD	2
3	A-	1	WidgetA	3
4	B+			
5	B	6	WidgetF	5
		5	WidgetE	
		7	WidgetG	

Preparing data fields for analysis in Amazon Quick Sight

Before you start analyzing and visualizing your data, you can prepare the fields (columns) in your dataset for analysis. You can edit field names and descriptions, change the data type for fields, set up drill-down hierarchies for fields, and more.

Use the following topics to prepare fields in your dataset.

Topics

- [Editing field names and descriptions](#)
- [Setting fields as a dimensions or measures](#)
- [Changing a field data type](#)
- [Adding drill-downs to visual data in Quick Sight](#)
- [Selecting fields](#)
- [Organizing fields into folders in Amazon QuickSight](#)
- [Mapping and joining fields](#)

Editing field names and descriptions

You can change any field name and description from what is provided by the data source. If you change the name of a field used in a calculated field, make sure also to change it in the calculated field function. Otherwise, the function fails.

To change a field name or description

1. In the **Fields** pane of the data prep page, choose the three-dot icon on the field that you want to change. Then choose **Edit name & description**.
2. Enter the new name or description that you want to change, and choose **Apply**.

You can also change the name and description of a field on the data prep page. To do this, select the column header of the field that you want to change in the **Dataset** table in that page's lower half. Then make any changes there.

Setting fields as a dimensions or measures

In the **Field list** pane, dimension fields have blue icons and measure fields have green icons. *Dimensions* are text or date fields that can be items, like products, or attributes that are related to

measures. You can use dimensions to partition these items or attributes, like sales date for sales figures. *Measures* are numeric values that you use for measurement, comparison, and aggregation.

In some cases, Quick Sight interprets a field as a measure that you want to use it as a dimension (or the other way around). If so, you can change the setting for that field.

Changing a field's measure or dimension setting changes it for all visuals in the analysis that use that dataset. However, it doesn't change it in the dataset itself.

Changing a field's dimension or measure setting

Use the following procedure to change a field's dimension or measure setting

To change a field's dimension or measure setting

1. In the **Field list** pane, hover over the field that you want to change.
2. Choose the selector icon to the right of the field name, and then choose **Convert to dimension** or **Convert to measure** as appropriate.

Changing a field data type

When Quick Sight retrieves data, it assigns each field a data type based on the data in the field. The possible data types are as follows:

- **Date** – The date data type is used for date data in a supported format. For information about the date formats Quick Sight supports, see [Data source quotas](#).
- **Decimal** – The decimal data type is used for numeric data that requires one or more decimal places of precision, for example 18.23. The decimal data type supports values with up to four decimal places to the right of the decimal point. Values that have a higher scale than this are truncated to the fourth decimal place in two cases. One is when these values are displayed in data preparation or analyses, and one is when these values are imported into Quick Sight. For example, 13.00049 is truncated to 13.0004.
- **Geospatial** – The geospatial data type is used for geospatial data, for example longitude and latitude, or cities and countries.
- **Integer** – The int data type is used for numeric data that only contains integers, for example 39.
- **String** – The string data type is used for nondatetime alphanumeric data.

Quick Sight reads a small sample of rows in the column to determine the data type. The data type that occurs most in the small sample size is the suggested type. In some cases, there might be blank values (treated as strings by Quick Sight) in a column that contains mostly numbers. In these cases, it might be that the String data type is the most frequent type in the sample set of rows. You can manually modify the data type of the column to make it integer. Use the following procedures to learn how.

Changing a field data type during data prep

During data preparation, you can change the data type of any field from the data source. On the **Change data type** menu, you can change calculated fields that don't include aggregations to geospatial types. You can make other changes to the data type of a calculated field by modifying its expression directly. Quick Sight converts the field data according to the data type that you choose. Rows that contain data that is incompatible with that data type are skipped. For example, suppose that you convert the following field from String to Integer.

```
10020
36803
14267a
98457
78216b
```

All records containing alphabetic characters in that field are skipped, as shown following.

```
10020
36803
98457
```

If you have a database dataset with fields whose data types aren't supported by Quick Sight, use a SQL query during data preparation. Then use CAST or CONVERT commands (depending on what is supported by the source database) to change the field data types. For more information about adding a SQL query during data preparation, see [Using SQL to customize data](#). For more information about how different source data types are interpreted by Quick Sight, see [Supported data types from external data sources](#).

You might have numeric fields that act as dimensions rather than metrics, for example ZIP codes and most ID numbers. In these cases, it's helpful to give them a string data type during data preparation. Doing this lets Quick Sight understand that they are not useful for performing mathematical calculations and can only be aggregated with the Count function. For more

information about how Quick Sight uses dimensions and measures, see [Setting fields as a dimensions or measures](#).

In [SPICE](#), numbers converted from numeric into an integer are truncated by default. If you want to round your numbers instead, you can create a calculated field using the [round](#) function. To see whether numbers are rounded or truncated before they are ingested into SPICE, check your database engine.

To change a field data type during data prep

1. From the Quick Sight homepage, choose **Data** at left. In the **Data** tab, choose the dataset that you want, and then choose **Edit dataset**.
2. In the data preview pane, choose the data type icon under the field you want to change.
3. Choose the target data type. Only data types other than the one currently in use are listed.

Changing a field data type in an analysis

You can use the **Field list** pane, visual field wells, or on-visual editors to change numeric field data types within the context of an analysis. Numeric fields default to displaying as numbers, but you can choose to have them display as currency or as a percentage instead. You can't change the data types for string or date fields.

Changing a field's data type in an analysis changes it for all visuals in the analysis that use that dataset. However, it doesn't change it in the dataset itself.

Note

If you are working in a pivot table visual, applying a table calculation changes the data type of the cell values in some cases. This type of change occurs if the data type doesn't make sense with the applied calculation.

For example, suppose that you apply the Rank function to a numeric field that you modified to use a currency data type. In this case, the cell values display as numbers rather than currency. Similarly, if you apply the Percent difference function instead, the cell values display as percentages rather than currency.

To change a field's data type

1. Choose one of the following options:

- In the **Field list** pane, hover over the numeric field that you want to change. Then choose the selector icon to the right of the field name.
 - On any visual that contains an on-visual editor associated with the numeric field that you want to change, choose that on-visual editor.
 - Expand the **Field wells** pane, and then choose the field well associated with the numeric field that you want to change.
2. Choose **Show as**, and then choose **Number**, **Currency**, or **Percent**.

Adding drill-downs to visual data in Quick Sight

All visual types except pivot tables offer the ability to create a hierarchy of fields for a visual element. The hierarchy lets you drill down to see data at different levels of the hierarchy. For example, you can associate the country, state, and city fields with the x-axis on a bar chart. Then, you can drill down or up to see data at each of those levels. As you drill down each level, the data displayed is refined by the value in the field you drill down on. For example, if you drill down on the state of California, you see data on all of the cities in California.

The field wells you can use to create drill-downs varies by visual type. Refer to the topic on each visual type to learn more about its drill-down support.

Drill-down functionality is added automatically for dates when you associate a date field with the drill-down field well of a visual. In this case, you can always drill up and down through the levels of date granularity. Drill-down functionality is also added automatically for geospatial groupings, after you define these in the dataset.

Use the following table to identify the field wells/on-visual editors that support drill-down for each visual type.

Visual type	Field well or on-visual editor
Bar charts (all horizontal)	Y axis and Group/Color
Bar charts (all vertical)	X axis and Group/Color
Combo charts (all)	X axis and Group/Color
Geospatial charts	Geospatial and Color

Visual type	Field well or on-visual editor
Heat map	Rows and Columns
KPIs	Trend Group
Line charts (all)	X axis and Color
Pie chart	Group/Color
Scatter plot	Group/Color
Tree map	Group by

Important

Drill-downs are not supported for tables or pivot tables.

Adding a drill-down

Use the following procedure to add drill-down levels to a visual.

To add drill-down levels to a visual

1. On the analysis page, choose the visual that you want to add drill-downs to.
2. Drag a field item into a **Field well**.
3. If your dataset has a defined hierarchy, you can drag the entire hierarchy into the field well as one. An example is geospatial or coordinate data. In this case, you don't need to follow the remaining steps.

If you don't have a predefined hierarchy, you can create one in your analysis, as described in the remaining steps.

4. Drag a field that you want to use in the drill-down hierarchy to an appropriate field well, depending on the visual type. Make sure that the label for the dragged field says **Add drill-down layer**. Position the dragged field above or below the existing field based on where you want it to be in the hierarchy you're creating.

5. Continue until you have added all of the levels of hierarchy that you want. To remove a field from the hierarchy, choose the field, and then choose **Remove**.
6. To drill down or up to see data at a different level of the hierarchy, choose an element on the visual (like a line or bar), and then choose **Drill down to <lower level>** or **Drill up to <higher level>**. In this example, from the `car-make` level you can drill down to `car-model` to see data at that level. If you drill down to `car-model` from the **Ford** `car-make`, you see only `car-models` in that `car-make`.

After you drill down to the `car-model` level, you can then drill down further to see `make-year` data, or go back up to `car-make`. If you drill down to `make-year` from the bar representing **Ranger**, you see only years for that model of car.

Selecting fields

When you prepare data, you can select one or more fields to perform an action on them, such as excluding them or adding them to a folder.

To select one or more fields in the data preparation pane, click or tap the field or fields in the **Fields** pane at left. You can then choose the field menu (the three dots) to the right of the field name and choose an action to take. The action is performed on all selected fields.

You can select or deselect all fields at once by choosing either **All** or **None** at the top of the **Fields** pane.

If you edit a dataset and exclude a field that is used in a visual, that visual breaks. You can fix it the next time you open that analysis.

Searching for fields

If you have a long field list in the **Fields** pane, you can search to locate a specific field by entering a search term for **Search fields**. Any field whose name contains the search term is shown.

Search is case-insensitive and wildcards are not supported. Choose the cancel icon (X) to the right of the search box to return to viewing all fields.

Organizing fields into folders in Amazon QuickSight

When prepping your data in Quick Sight, you can use folders to organize your fields for multiple authors across your enterprise. Arranging fields into folders and subfolders can make it easier for authors to find and understand fields in your dataset.

You can create folders while preparing your dataset, or when editing a dataset. For more information about creating a new dataset and preparing it, see [Creating datasets](#). For more information about opening an existing dataset for data preparation, see [Editing datasets](#).

While performing an analysis, authors can expand and collapse folders, search for specific fields within folders, and see your descriptions of folders on the folder menu. Folders appear at the top of the **Fields** pane in alphabetical order.

Creating a folder

Use the following procedure to create a new folder in the **Fields** pane.

To create a new folder

1. On the data preparation page, in the **Fields** pane, select the three-dot icon, and choose **Add to folder**.

To select more than one field at a time, press the Ctrl key while you select (Command key on Mac).

2. On the **Add to folder** page that appears, choose **Create a new folder** and enter a name for the new folder.
3. Choose **Apply**.

The folder appears at the top of the **Fields** pane with the fields that you chose inside it. Fields inside folders are arranged in alphabetical order.

Creating a subfolder

To further organize your data fields in the **Fields** pane, you can create subfolders within parent folders.

To create a subfolder

1. On the data preparation page, in the **Fields** pane, select the field menu for a field already in a folder and choose **Move to folder**.
2. On the **Move to folder** page that appears, choose **Create a new folder** and enter a name for the new folder.
3. Choose **Apply**.

The subfolder appears within the parent folder at the top of the list of fields. Subfolders are arranged in alphabetical order.

Adding fields to an existing Folder

Use the following procedure to add fields to an existing folder in the **Fields** pane.

To add one or more fields to a folder

1. On the data preparation page, in the **Fields** pane, select the fields that you want to add to a folder.

To select more than one field at a time, press the Ctrl key while you select (Command key on Mac).

2. On the field menu, choose **Add to folder**.
3. On the **Add to folder** page that appears, choose a folder for **Existing folder**.
4. Choose **Apply**.

The field or fields are added to the folder.

Moving fields between folders

Use the following procedure to move fields between folders in the **Fields** pane.

To move fields between folders

1. On the data preparation page, in the **Fields** pane, select the fields that you want to move to another folder.

To select more than one field at a time, press the Ctrl key while you select (Command key on Mac).

2. On the field menu, choose **Move to folder**.
3. On the **Move to folder** page that appears, choose a folder for **Existing folder**.
4. Choose **Apply**.

Removing fields from a folder

Use the following procedure to remove fields from a folder in the **Fields** pane. Removing a field from a folder doesn't delete the field.

To remove fields from a folder

1. On the data preparation page, in the **Fields** pane, select the fields that you want to remove.
2. On the field menu, choose **Remove from folder**.

The fields that you selected are removed from the folder and placed back in the list of fields in alphabetical order.

Editing a folder name and adding a folder description

You can edit the name or add a description of a folder to provide context about the data fields inside it. The folder name appears in the **Fields** pane. While performing an analysis, authors can read your folder's description when they select the folder menu in the **Fields** pane.

To edit a folder name or edit or add a description for a folder

1. On the data preparation page, in the **Fields** pane, select the folder menu for the folder that you want to edit and choose **Edit name & description**.
2. On the **Edit folder** page that appears, do the following:
 - For **Name**, enter a name for the folder.
 - For **Description**, enter a description of the folder.
3. Choose **Apply**.

Moving folders

You can move folders and subfolders to new or existing folders in the **Fields** pane.

To move a folder

1. On the data preparation page, in the **Fields** pane, choose **Move folder** on the folder menu.
2. On the **Move folder** page that appears, do one of the following:
 - Choose **Create a new folder** and enter a name for the folder.
 - For **Existing folder**, choose a folder.
3. Choose **Apply**.

The folder appears within the folder that you chose in the **Fields** pane.

Removing folders from the fields pane

Use the following procedure to remove a folder from the **Fields** pane.

To remove a folder

1. On the data preparation page, in the **Fields** pane, choose **Remove folder** on the folder menu.
2. On the **Remove folder?** page that appears, choose **Remove**.

The folder is removed from the **Fields** pane. Any fields that were in the folder are placed back in the list of fields in alphabetical order. Removing folders doesn't exclude fields from view or delete fields from the dataset.

Mapping and joining fields

When you are using different datasets together in Quick Sight, you can simplify the process of mapping fields or joining tables during the data preparation stage. You should already be verifying that your fields have the correct data type and an appropriate field name. However, if you already know which datasets are going to be used together, you can take a couple of extra steps to make your work easier later on.

Mapping fields

Quick Sight can automatically map fields between datasets in the same analysis. The following tips can help make it easier for Quick Sight to automatically map fields between datasets, for example if you are creating a filter action across datasets:

- Matching field names – Field names must match exactly, with no differences in case, spacing, or punctuation. You can rename fields that describe the same data, so an automatic mapping is accurate.
- Matching data types – Fields must have the same data type for automatic mapping. You can change the data types while you are preparing the data. This step also gives you the opportunity to discover whether you need to filter out any data that isn't the correct data type.
- Using calculated fields – You can use calculated fields to create a matching field, and give it the correct name and data type for automatic mapping.

Note

After an automatic mapping exists, you can rename a field without breaking the field mapping. However, if you change the data type, the mapping is broken.

For more information on field mapping for filter actions across datasets, see [Creating and editing custom actions in Amazon Quick Sight](#).

Joining fields

You can create joins between data from different data sources, including files or databases. The following tips can help make it easier for you to join data from different files or data sources:

- **Similar field names** – It is simpler to join fields when you can see what should match; for example, **Order ID** and **order-id** seem as if they should be the same. But if one is a work order, and the other is a purchase order, then the fields are probably different data. If possible, make sure that the files and tables that you want to join have field names making it clear what data they contain.
- **Matching data types** – Fields must have the same data type before you can join on them. Make sure that the files and tables that you want to join having matching data types in join fields. You can't use a calculated field for a join. Also, you can't join two existing datasets. You create the joined dataset by directly accessing the source data.

For more information on joining data across data sources, see [Joining data](#).

Filtering data in Amazon Quick Sight

You can use filters to refine the data in a dataset or an analysis. For example, you can create a filter on a region field that excludes data from a particular region in a dataset. You can also add a filter to an analysis, such as a filter on the range of dates that you want to include in any visuals in your analysis.

When you create a filter in a dataset, that filter applies to the entire dataset. Any analyses and subsequent dashboards created from that dataset contains the filter. If someone creates a dataset from your dataset, the filter also is in the new dataset.

When you create a filter in an analysis, that filter only applies to that analysis and any dashboards you publish from it. If someone duplicates your analysis, the filter persists in the new analysis. In

analyses, you can scope filters to a single visual, some visuals, all visuals that use this dataset, or all applicable visuals.

Also, when you create filters in an analysis, you can add a filter control to your dashboard. For more information about filter controls, see [Adding filter controls to analysis sheets](#).

Each filter you create applies only to a single field. You can apply filters to both regular and calculated fields.

There are several types of filters you can add to datasets and analyses. For more information about the types of filters you can add, and some of their options, see [Filter types in Amazon Quick](#).

If you create multiple filters, all top-level filters apply together using AND. If you group filters by adding them inside a top-level filter, the filters in the group apply using OR.

Amazon Quick Sight applies all of the enabled filters to the field. For example, suppose that there is one filter of `state = WA` and another filter of `sales >= 500`. Then the dataset or analysis only contains records that meet both of those criteria. If you disable one of these, only one filter applies.

Take care that multiple filters applied to the same field aren't mutually exclusive.

Use the following sections to learn how to view, add, edit, and delete filters.

Topics

- [Viewing existing filters](#)
- [Adding filters](#)
- [Cross-sheet filters and controls](#)
- [Filter types in Amazon Quick](#)
- [Adding filter controls to analysis sheets](#)
- [Editing filters](#)
- [Enabling or disabling filters](#)
- [Deleting filters](#)

Viewing existing filters

When you edit a dataset or open an analysis, you can view any existing filters that were created. Use the following procedures to learn how.

Viewing filters in datasets

1. Open the [Quick console](#).
2. From the Quick homepage, choose **Data** at left.
3. In the **Datasets** tab, choose the dataset that you want, and then choose **Edit dataset**.
4. On the data preparation page that opens, choose **Filters** at lower left to expand the **Filters** section.

Any filters that are applied to the dataset appear here. If a single field has multiple filters, they are grouped together. They display in order of create date, with the oldest filter on top.

Viewing filters in analyses

Use the following procedure to view filters in analyses.

To view a filter in an analysis

1. From the Quick homepage, choose **Analyses**.
2. On the **Analyses** page, choose the analysis that you want to work with.
3. In the analysis, choose the **Filter** icon to open the **Filters** pane.

Any filters applied to the analysis appear here.

The way that a filter is scoped is listed at the bottom of each filter. For more information about scoping filters, see [Adding filters](#).

Adding filters

You can add filters to a dataset or an analysis. Use the following procedures to learn how.

Adding filters to datasets

Use the following procedure to add filters to datasets.

To add a filter to a dataset

1. Open the [Quick console](#).
2. From the Quick homepage, choose **Data** at left.

3. In the **Datasets** tab, choose the dataset that you want, and then choose **Edit dataset**.
4. On the data preparation page that opens, choose **Add filter** at lower left, and then choose a field that you want to filter.

The filter is added to the **Filters** pane.

5. Choose the new filter in the pane to configure the filter. Or you can choose the three dots to the right of the new filter and choose **Edit**.

Depending on the data type of the field, your options for configuring the filter vary. For more information about the types of filters that you can create and their configurations, see [Filter types in Amazon Quick](#).

6. When finished, choose **Apply**.

Note

The data preview shows you the results of your combined filters only as they apply to the first 1,000 rows. If all of the first 1,000 rows are filtered out, then no rows show in the preview. This effect occurs even when rows after the first 1,000 aren't filtered out.

Adding filters in analyses

Use the following procedure to add filters to analyses.

To add a filter to an analysis

1. Open the [Quick console](#).
2. From the Quick homepage, choose **Analyses**.
3. On the **Analyses** page, choose the analysis that you want to work with.
4. In the analysis, choose the **Filter** icon to open the **Filters** pane, and then choose **ADD**.
5. Choose the new filter in the pane to configure it. Or you can choose the three dots to the right of the new filter and choose **Edit**.
6. In the **Edit filter** pane that opens, for **Applied to**, choose one of the following options.
 - **Single visual** – The filter applies to the selected item only.
 - **Single sheet** – The filter applies to a single sheet.
 - **Cross sheet** – The filter applies to multiple sheets in the dataset.

Depending on the data type of the field, your remaining options for configuring the filter vary. For more information about the types of filters you can create and their configurations, see [Filter types in Amazon Quick](#).

Cross-sheet filters and controls

Cross-sheet filters and controls are filters that are scoped to either your entire analysis or dashboard or multiple sheets within your analysis and dashboard.

Filters

Creating a Cross-Sheet Filter

1. Once you have [Added a filter](#), you update the scope of the filter to cross-sheet. By default, this applies to all of the the sheets in your analysis.
2. If the **Apply cross-datasets** box is checked, then the filter will be applied to all visuals from up to 100 different datasets that are applicable to all sheets in the filter scope.
3. If you want to customize the sheets that it is applied to, then choose the Cross-sheet icon. You can then view the sheets the filter is currently applied to or toggle on the custom select sheets.
4. When you enable **Custom select sheets**, you can select which sheets to apply the filter to.
5. Follow the steps at [Editing filters in analyses](#). Your changes will be applied to all of the filters for all of the sheets you have selected. This includes newly added sheets if the filter is scoped to your entire analysis.

Removing a Cross-Sheet Filter

Deleting

If you have no controls created from these filters, see [Deleting filters in analyses](#).

If you have controls created then:

1. Follow the instructions at [Deleting filters in analyses](#).
2. If you choose **Delete Filter and Controls**, the controls will be deleted from all pages. This may impact the layout of your analysis. Alternatively, you can remove these controls individually.

Downscoping

If you want to remove a cross-sheet filter, you can also do this by changing the filter scope:

1. Follow the instructions at [Editing filters in analyses](#) to get to the filter.
2. One of the edits you can make is changing the scope. You can switch to **Single sheet** or **Single visual**. You can also remove a sheet from the Cross-sheet selection.

Or the custom sheet selection:

3. If there are controls, you will see a modal to warn you that you will be bulk-removing controls from any of the sheets where the filter no longer applies and this can impact your layout. You can also remove the controls individually. For more information, see [Removing a Cross-Sheet Control](#).

4. If you add controls to the **Top of all sheets in filter scope** then new sheets will by default be added with this new control if the filter is scoped to your entire analysis.

Controls

Creating a Cross-Sheet Control

New filter control

1. Create a cross-sheet filter. For more information, see [Filters](#).
2. From the three-dot menu, you can see an option that says **Add control**. Hovering over this, you will see three options:
 - **Top of all sheets in filter scope**
 - **Top of this sheet**
 - **Inside this sheet**

If you want to add to multiple-sheets within the sheets themselves, you can do that sheet-by-sheet. Or you can add to the top and then use the option on each control to **Move to sheet**. For more information, see [Editing a Cross-Sheet Control](#).

Increasing Scope of Existing Control

1. Navigate to the existing filter in the analysis
2. Change the scope of what sheets this filter is **Applied to to Cross-sheet**.
3. If there is already a control created from the filter, you will see a modal, which if you check the box will bulk-add controls to the top of all the sheets in the filter scope. This will not impact the position of the already created control if it is on the sheet.

Editing a Cross-Sheet Control

1. Go to the cross-sheet control and select the three-dot menu if the control is pinned to the top or the edit pencil icon if the control is on the sheet. You will be presented with the following options:
 - **Go to filter** (which directs you to the cross-sheet filter for you to edit or review)
 - **Move to sheet** (which moves the control into the analysis pane)

- **Reset**
 - **Refresh**
 - **Edit**
 - **Remove**
2. Choose **Edit**. This brings up the **Format Control** pane on the right side of your analysis.
 3. You can then edit your control. The top section labeled **Cross-sheet settings** will apply to all controls, whereas any settings outside of this section are not applicable to all controls and only to the specific control you're editing. For instance, **Relevant value** is not a cross-sheet control setting.
 4. You can also see the sheets that this control is on as well as the location (Top or Sheet) that the control is on for each sheet. You can do this by choosing **Sheets(8)**.

Removing a Cross-Sheet Control

You can remove controls in two places. First, from the control:

1. Go to the cross-sheet control and select the three-dot menu if the control is pinned to the top or the edit pencil icon if the control is on the sheet. You will be presented with the following options:
 - **Go to filter** (which directs you to the cross-sheet filter for you to edit or review)
 - **Move to sheet** (which moves the control into the analysis pane)
 - **Reset**
 - **Refresh**
 - **Edit**
 - **Remove**
2. Choose **Remove**

Second, you can remove controls from the filter:

1. Choose the three-dot menu on the cross-sheet filter that the cross-sheet controls are created from. You will see that instead of an option to **Add control** there is now an option to **Manage control**.
2. Hover over **Manage control**. You will be presented with the following options:

- **Move inside this sheet**
- **Top of this sheet**

These options are applicable to just the control on the sheet, depending on where the current control is. If you don't have controls on all of the sheets within the filter scope, you will get the option to **Add to top of all sheets in filter scope**. This will not move sheet controls to the top of the sheet if you have already added them to the sheet in the analysis. You will also get the option to **Remove from this sheet** or **Remove from all sheets**.

Filter types in Amazon Quick

You can create several different types of filters in Quick. The type of filter you create mostly depends on the data type of the field that you want to filter.

In datasets, you can create the following types of filters:

- Text filters
- Numeric filters
- Date filters

In analyses, you can create the same types of filters as you can in datasets. You can also create:

- Group filters with and/or operators
- Cascading filters
- Nested filters

Use the following sections to learn more about each type of filter you can create and some of their options.

Topics

- [Adding text filters](#)
- [Adding nested filters](#)
- [Adding numeric filters](#)
- [Adding date filters](#)

- [Adding filter conditions \(group filters\) with AND and OR operators](#)
- [Creating cascading filters](#)

Adding text filters

When you add a filter using a text field, you can create the following types of text filters:

- **Filter list (Analyses only)** – This option creates a filter that you can use to select one or more field values to include or exclude from all the available values in the field. For more information about creating this type of text filter, see [Filtering text field values by a list \(analyses only\)](#).
- **Custom filter list** – With this option, you can enter one or more field values to filter on, and whether you want to include or exclude records that contain those values. The values that you enter must match the actual field values exactly for the filter to be applied to a given record. For more information about creating this type of text filter, see [Filtering text field values by a custom list](#).
- **Custom filter** – With this option, you enter a single value that the field value must match in some way. You can specify that the field value must equal, not equal, starts with, ends with, contains, or does not contain the value you specify. If you choose an equal comparison, the specified value and actual field value must match exactly in order for the filter to be applied to a given record. For more information about creating this type of text filter, see [Filtering a single text field value](#).
- **Top and bottom filter (Analyses only)** – You can use this option to show the top or bottom *n* value of one field ranked by the values in another field. For example, you might show the top five salespeople based on revenue. You can also use a parameter to allow dashboard users to dynamically choose how many top or bottom ranking values to show. For more information about creating top and bottom filters, see [Filtering a text field by a top or bottom value \(analyses only\)](#).

Filtering text field values by a list (analyses only)

In analyses, you can filter a text field by selecting values to include or exclude from a list of all value in the field.

To filter a text field by including and excluding values

1. Create a new filter using a text field. For more information about creating filters, see [Adding filters](#).

2. In the **Filters** pane, choose the new filter to expand it.
3. For **Filter type**, choose **Filter list**.
4. For **Filter condition**, choose **Include** or **Exclude**.
5. Choose the field values that you want to filter on. To do this, select the check box in front of each value.

If there are too many values to choose from, enter a search term into the box above the checklist and choose **Search**. Search terms are case-insensitive and wildcards aren't supported. Any field value that contains the search term is returned. For example, searching on L returns al, AL, la, and LA.

The values display alphabetically in the control, unless there are more than 1,000 distinct values. Then the control displays a search box instead. Each time that you search for the value that you want to use, it starts a new query. If the results contain more than 1,000 values, you can scroll through the values with pagination.

6. When finished, choose **Apply**.

Filtering text field values by a custom list

You can specify one or more field values to filter on, and whether you want to include or exclude records that contain those values. The specified value and actual field value must match exactly for the filter to be applied to a given record.

To filter text field values by a custom list

1. Create a new filter using a text field. For more information about creating filters, see [Adding filters](#).
2. In the **Filters** pane, choose the new filter to expand it.
3. For **Filter type**, choose **Custom filter list**.
4. For **Filter condition**, choose **Include** or **Exclude**.
5. For **List**, enter a value in the text box. The value must match an existing field value exactly.
6. (Optional) To add additional values, enter them in the text box, one per line.
7. For **Null options** choose **Exclude nulls**, **Include nulls**, or **Nulls only**.
8. When finished, choose **Apply**.

Filtering a single text field value

With the **Custom filter** filter type, you specify a single value that the field value must equal or not equal, or must match partially. If you choose an equal comparison, the specified value and actual field value must match exactly for the filter to be applied to a given record.

To filter a text field by a single value

1. Create a new filter using a text field. For more information about creating filters, see [Adding filters](#).
2. In the **Filters** pane, choose the new filter to expand it.
3. For **Filter type**, choose **Custom filter**.
4. For **Filter condition**, choose one of the following:
 - **Equals** – When you choose this option, the values included or excluded in the field must match the value that you enter exactly.
 - **Does not equal** – When you choose this option, the values included or excluded in the field must match the value that you enter exactly.
 - **Starts with** – When you choose this option, the values included or excluded in the field must start with the value that you enter.
 - **Ends with** – When you choose this option, the values included or excluded in the field must start with the value that you enter.
 - **Contains** – When you choose this option, the values included or excluded in the field must contain the whole value that you enter.
 - **Does not contain** – When you choose this option, the values included or excluded in the field must not contain any part of the value that you enter.

Note

Comparison types are case-sensitive.

5. Do one of the following:
 - For **Value**, enter a literal value.
 - Select **Use parameters** to use an existing parameter, and then choose a parameter from the list.

For parameters to appear in this list, create your parameters first. Usually, you create a parameter, add a control for it, and then add a filter for it. For more information, see [Parameters in Amazon Quick](#).

The values display alphabetically in the control, unless there are more than 1,000 distinct values. Then the control displays a search box instead. Each time that you search for the value that you want to use, it starts a new query. If the results contain more than 1,000 values, you can scroll through the values with pagination.

6. For **Null options** choose **Exclude nulls**, **Include nulls**, or **Nulls only**.
7. When finished, choose **Apply**.

Filtering a text field by a top or bottom value (analyses only)

You can use a **Top and bottom filter** to show the top or bottom n value of one field ranked by the values in another field. For example, you might show the top five salespeople based on revenue. You can also use a parameter to allow dashboard users to dynamically choose how many top or bottom ranking values to show.

To create a top and bottom text filter

1. Create a new filter using a text field. For more information about creating filters, see [Adding filters](#).
2. In the **Filters** pane, choose the new filter to expand it.
3. For **Filter type**, choose **Top and bottom filter**.
4. Choose **Top** or **Bottom**.
5. For **Show top** integer (or **Show bottom** integer), do one of the following:
 - Enter the number of top or bottom items to show.
 - To use a parameter for the number of top or bottom items to show, select **Use parameters**. Then choose an existing integer parameter.

For example, let's say that you want to show the top three salespersons by default. However, you want the dashboard viewer to be able to choose whether to show 1–10 top salespersons. In this case, take the following actions:

- Create an integer parameter with a default value.

- To link the number of displayed items to a parameter control, create a control for the integer parameter. Then you make the control a slider with a step size of 1, a minimum value of 1, and a maximum value of 10.
 - To make the control work, link it to a filter by creating a top and bottom filter on Salesperson by Weighted Revenue, enable **Use parameters**, and choose your integer parameter.
6. For **By**, choose a field to base the ranking on. If you want to show the top five salespeople per revenue, choose the revenue field. You can also set the aggregate that you want to perform on the field.
 7. (Optional) Choose **Tie breaker** and then choose another field to add one or more aggregations as tie breakers. This is useful, in the case of this example, when there are more than five results returned for the top five salespeople per revenue. This situation can happen if multiple salespeople have the same revenue amount.

To remove a tie breaker, use the delete icon.

8. When finished, choose **Apply**.

Adding nested filters

Nested filters are advanced filters that can be added to a Quick analysis. A Nested filter filters a field using a subset of data defined by another field in that same dataset. This allows authors to show additional contextual data without the need to filter data out if the data point doesn't meet an initial condition.

Nested filters function similarly to a correlated subquery in SQL or a market basket analysis. For example, say you want to perform a market basket analysis on your sales data. You can use nested filters to find the sales quantity by product for customers who have or have not purchased a specific product. You can also use nested filters to identify groups of customers that did not purchase a selected product or who only purchased a specific list of products.

Nested filters can only be added at the analysis level. You can't add a nested filter to a dataset.

Use the procedure below to add a nested filter to a Quick analysis.

1. Open the [Quick console](#).
2. Choose **Analyses**, and then choose the analysis that you want to add a nested filter to.

3. Create a new filter on the text field that you want to filter on. For more information about creating a filter, see [Adding filters in analyses](#).
4. After you create the new filter, locate the new filter in the **Filters** pane. Choose the ellipsis (three dots) next to the new filter, and then choose **Edit filter**. Alternatively, choose the filter entity in the **Filters** pane to open the **Edit filter** pane.
5. The **Edit filter** pane opens. Open the **Filter type** dropdown menu, navigate to the **Advanced filter** section, and then choose **Nested filter**.
6. For **Qualifying condition**, choose **Include** or **Exclude**. The *qualifying condition* allows you to run a not in the set query on the data in your analysis. In our sales example above, the qualifying condition determines if the filter returns a list of customers who did buy the specific product or a list of customers who did not buy the product.
7. For **Nested field**, choose the text field that you want to filter data with. The nested field cannot be the same as the primary field selected in step 3. Category fields are the only supported field type for the inner filter.
8. For **Nested filter type**, choose the filter type that you want. The filter type that you choose determines the final configuration steps for the nested filter. Available filter types and information about their configuration can be found in the list below.
 - [Filter list](#)
 - [Custom filter list](#)
 - [Custom filter](#)

Adding numeric filters

Fields with decimal or int data types are considered numeric fields. You create filters on numeric fields by specifying a comparison type, for example **Greater than** or **Between**, and a comparison value or values as appropriate to the comparison type. Comparison values must be positive integers and can't contain commas.

You can use the following comparison types in numeric filters:

- Equals
- Does not equal
- Greater than
- Greater than or equal to

- Less than
- Less than or equal to
- Between

Note

To use a top and bottom filter for numeric data (analyses only), first change the field from a measure to a dimension. Doing this converts the data to text. Then you can use a text filter. For more information, see [Adding text filters](#).

In analyses, for datasets based on database queries, you can also optionally apply an aggregate function to the comparison value or values, for example **Sum** or **Average**.

You can use the following aggregate functions in numeric filters:

- Average
- Count
- Count distinct
- Max
- Median
- Min
- Percentile
- Standard deviation
- Standard deviation - population
- Sum
- Variance
- Variance - population

Creating numeric filters

Use the following procedure to create a numeric field filter.

To create a numeric field filter

1. Create a new filter using a text field. For more information about creating filters, see [Adding filters](#).
2. In the **Filters** pane, choose the new filter to expand it.
3. (Optional) For **Aggregation**, choose an aggregation. No aggregation is applied by default. This option is available only when creating numeric filters in an analysis.
4. For **Filter condition**, choose a comparison type.
5. Do one of the following:

- If you chose a comparison type other than **Between**, enter a comparison value.

If you chose a comparison type of **Between**, enter the beginning of the value range in **Minimum value** and the end of the value range in **Maximum value**.

- (Analyses only) To use an existing parameter, enable **Use parameters**, then choose your parameter from the list.

For parameters to appear in this list, create your parameters first. Usually, you create a parameter, add a control for it, and then add a filter for it. For more information, see [Parameters in Amazon Quick](#). The values display alphabetically in the control, unless there are more than 1,000 distinct values. Then the control displays a search box instead. Each time you search for the value that you want to use, it initiates a new query. If the results contain more than 1,000 values, you can scroll through the values with pagination.

6. (Analyses only) For **Null options** choose **Exclude nulls**, **Include nulls**, or **Nulls only**.
7. When finished, choose **Apply**.

Adding date filters

You create filters on date fields by selecting the filter conditions and date values that you want to use. There are three filter types for dates:

- **Range** – A series of dates based on a time range and comparison type. You can filter records based on whether the date field value is before or after a specified date, or within a date range. You enter date values in the format MM/DD/YYYY. You can use the following comparison types:
 - **Between** – Between a start date and an end date
 - **After** – After a specified date

- **Before** – Before a specified date
- **Equals** – On a specified date

For each comparison type, you can alternatively choose a rolling date relative to a period or dataset value.

- **Relative** (analyses only) – A series of date and time elements based on the current date. You can filter records based on the current date and your selected unit of measure (UOM). Date filter units include years, quarters, months, weeks, days, hours, and minutes. You can exclude current period, add support for Next N filters similar to Last N with an added capability to allow for Anchor date. You can use the following comparison types:
 - **Previous** – The previous UOM—for example, the previous year.
 - **This** – This UOM, which includes all dates and times that fall within the select UOM, even if they occur in the future.
 - **To date or up to now** – UOM to date, or UOM up to now. The displayed phrase adapts to the UOM that you choose. However, in all cases this option filters out data that is not between the beginning of the current UOM and the current moment.
 - **Last n** – The last specified number of the given UOM, which includes all of this UOM and all of the last $n - 1$ UOM. For example, let's say today is May 10, 2017. You choose to use *years* as your UOM, and set Last n years to 3. The filtered data includes data for all of 2017, plus all of 2016, and all of 2015. If you have any data for the future dates of the current year (2017 in this example), these records are included in your dataset.
- **Top and bottom** (analyses only) – A number of date entries ranked by another field. You can show the top or bottom n for the type of date or time UOM you choose, based on values in another field. For example, you can choose to show the top 5 sales days based on revenue.

Comparisons are applied inclusive to the date specified. For example, if you apply the filter **Before 1/1/16**, the records returned include all rows with date values through 1/1/16 23:59:59. If you don't want to include the date specified, you can clear the option to **Include this date**. If you want to omit a time range, you can use the **Exclude the last N periods** option to specify the number and type of time periods (minutes, days, and so on) to filter out.

You can also choose to include or exclude nulls, or exclusively show rows that contain nulls in this field. If you pass in a null date parameter (one without a default value), it doesn't filter the data until you provide a value.

Note

If a column or attribute has no time zone information, then the client query engine sets the default interpretation of that date-time data. For example, suppose that a column contains a timestamp, rather than a timestamptz, and you are in a different time zone than the data's origin. In this case, the engine can render the timestamp differently than you expect. Amazon Quick and [SPICE](#) both use Universal Coordinated Time (UTC) times.

Use the following sections to learn how to create date filters in datasets and analyses.

Creating date filters in datasets

Use the following procedure to create a range filter for a date field in a dataset.

To create a range filter for a date field in a dataset

1. Create a new filter using a text field. For more information about creating filters, see [Adding filters](#).
2. In the **Filters** pane, choose the new filter to expand it.
3. For **Condition**, choose a comparison type: **Between**, **After**, or **Before**.

To use **Between** as a comparison, choose **Start date** and **End date** and choose dates from the date picker controls that appear.

You can choose if you want to include either or both the start and end dates in the range by selecting **Include start date** or **Include end date**.

To use **Before** or **After** comparisons, enter a date or choose the date field to bring up the date picker control and choose a date instead. You can include this date (the one you chose), to exclude the last N time periods, and specify how to handle nulls.

4. For **Time granularity**, choose **Day**, **Hour**, **Minute**, or **Second**.
5. When finished, choose **Apply**.

Creating date filters in analyses

You can create date filters in analyses as described following.

Creating range date filters in analyses

Use the following procedure to create a range filter for a date field in an analysis.

To create a range filter for a date field in an analysis

1. Create a new filter using a text field. For more information about creating filters, see [Adding filters](#).
2. In the **Filters** pane, choose the new filter to expand it.
3. For **Filter type**, choose **Date & time range**.
4. For **Condition**, choose a comparison type: **Between**, **After**, **Before**, or **Equals**.

To use **Between** as a comparison, choose **Start date** and **End date** and choose dates from the date picker controls that appear.

You can choose to include either or both the start and end dates in the range by selecting **Include start date** or **Include end date**.

To use a **Before**, **After**, or **Equals** comparison, enter a date or choose the date field to bring up the date picker control and choose a date instead. You can include this date (the one you chose), to exclude the last N time periods, and specify how to handle nulls.

To **Set a rolling date** for your comparison, choose **Set a rolling date**.

In the **Set a rolling date** pane that opens, choose **Relative date** and then select if you want to set the date to **Today**, **Yesterday**, or you can specify the **Filter condition** (start of or end of), **Range** (this, previous, or next), and **Period** (year, quarter, month, week, or day).

5. For **Time granularity**, choose **Day**, **Hour**, **Minute**, or **Second**.
6. (Optional) If you are filtering by using an existing parameter, instead of specific dates, choose **Use parameters**, then choose your parameter or parameters from the list. To use **Before**, **After**, or **Equals** comparisons, choose one date parameter. You can include this date in the range.

To use **Between**, enter both the start date and end date parameters separately. You can include the start date, the end date, or both in the range.

To use parameters in a filter, create them first. Usually, you create a parameter, add a control for it, and then add a filter for it. For more information, see [Parameters in Amazon Quick](#).

7. For **Null options** choose **Exclude nulls**, **Include nulls**, or **Nulls only**.

8. When finished, choose **Apply**.

Creating relative date filters in analyses

Use the following procedure to create a relative filter for a date field in an analysis.

To create a relative filter for a date field in an analysis

1. Create a new filter using a text field. For more information about creating filters, see [Adding filters](#).
2. In the **Filters** pane, choose the new filter to expand it.
3. For **Filter type**, choose **Relative dates**.
4. For **Time granularity**, choose a granularity of time that you want to filter by (days, hours, minutes).
5. For **Period**, choose a unit of time (years, quarters, quarters, months, weeks, days).
6. For **Range**, choose how you want the filter to relate to the time frame. For example, if you choose to report on months, your options are previous month, this month, month to date, last N months, and next N months.

If you choose Last N or Next N years, quarters, months, weeks, or days, enter a number for **Number of**. For example, last 3 years, next 5 quarters, last 5 days.

7. For **Null options** choose **Exclude nulls**, **Include nulls**, or **Nulls only**.
8. For **Set dates relative to**, choose one of the following options:
 - **Current date time** – If you choose this option, you can set it to **Exclude last**, and then specify the number and type of time periods.
 - **Date and time from a parameter** – If you choose this option, you can select an existing datetime parameter.
9. (Optional) If you are filtering by using an existing parameter, instead of specific dates, enable **Use parameters**, then choose your parameter or parameters from the list.

To use parameters in a filter, create them first. Usually, you create a parameter, add a control for it, and then add a filter for it. For more information, see [Parameters in Amazon Quick](#).

10. When finished, choose **Apply**.

Creating top and bottom date filters in analyses

Use the following procedure to create a top and bottom filter for a date field in an analysis.

To create a top and bottom filter for a date field in an analysis

1. Create a new filter using a text field. For more information about creating filters, see [Adding filters](#).
2. In the **Filters** pane, choose the new filter to expand it.
3. For **Filter type**, choose **Top and bottom**.
4. Select **Top** or **Bottom**.
5. For **Show**, enter the number of top or bottom items you want to show and choose a unit of time (years, quarters, months, weeks days, hours, minutes).
6. For **By**, choose a field to base the ranking on.
7. (Optional) Add another field as a tie breaker, if the field for **By** has duplicates. Choose **Tie breaker**, and then choose another field. To remove a tie breaker, use the delete icon.
8. (Optional) If you are filtering by using an existing parameter, instead of specific dates, select **Use parameters**, then choose your parameter or parameters from the list.

To use a parameter for **Top and bottom**, choose an integer parameter for the number of top or bottom items to show.

To use parameters in a filter, create them first. Usually, you create a parameter, add a control for it, and then add a filter for it. For more information, see [Parameters in Amazon Quick](#).

9. When finished, choose **Apply**.

Adding filter conditions (group filters) with AND and OR operators

In analyses, when you add multiple filters to a visual, Quick uses the AND operator to combine them. You can also add filter conditions to a single filter with the OR operator. This is called a compound filter, or filter group.

To add multiple filters using the OR operator, create a filter group. Filter grouping is available for all types of filters in analyses.

When you filter on multiple measures (green fields marked with #), you can apply the filter conditions to an aggregate of that field. Filters in a group can contain either aggregated or nonaggregated fields, but not both.

To create a filter group

1. Create a new filter in an analysis. For more information about creating filters, see [Adding filters](#).
2. In the **Filters** pane, choose the new filter to expand it.
3. In the expanded filter, choose **Add filter condition** at bottom, and then choose a field to filter on.
4. Choose the conditions to filter on.

The data type of the field that you selected determines the options available here. For example, if you chose a numeric field, you can specify the aggregation, filter condition, and values. If you chose a text field, you can choose the filter type, filter condition, and values. And if you chose a date field, you can specify the filter type, condition, and time granularity. For more information about these options, see [Filter types in Amazon Quick](#).

5. (Optional) You can add additional filter conditions to the filter group by choosing **Add filter condition** again at bottom.
6. (Optional) To remove a filter from the filter group, choose the trash-can icon near the field name.
7. When finished, choose **Apply**.

The filters appear as a group in the **Filters** pane.

Creating cascading filters

The idea behind cascading any action, such as a filter, is that choices in the higher levels of a hierarchy affect the lower levels of a hierarchy. The term *cascading* comes from the way that a cascade waterfall flows from one tier to the next.

To set up cascading filters, you need a trigger point where the filter is activated, and target points where the filter is applied. In Quick, the trigger and target points are included in visuals.

To create a cascading filter, you set up an action, not a filter. This approach is because you need to define how the cascading filter is activated, which fields are involved, and which visuals are filtered when someone activates it. For more information, including step-by-step instructions, see [Using custom actions for filtering and navigating](#).

There are two other ways to activate a filter across multiple visuals:

- **For a filter that is activated from a widget on a dashboard** – The widget is called a *sheet control*, which is a custom menu that you can add to the top of your analysis or dashboard. The most common sheet control is a drop-down list, which displays a list of options to choose from when you open it. To add one of these to your analysis, create a parameter, add a control to the parameter, and then add a filter that uses the parameter. For more information, see [Setting up parameters in Amazon Quick](#), [Using a control with a parameter in Amazon Quick](#), and [Adding filter controls to analysis sheets](#).
- **For a filter that always applies to multiple visuals** – This is a regular filter, except that you set its scope to apply to multiple (or all) visuals. This type of filter doesn't really cascade, because there is no trigger point. It always filters all the visuals that it's configured to filter. To add this type of filter to your analysis, create or edit a filter and then choose its scope: **Single visual**, **Single sheet**, or **Cross sheets**. Note the option to **Apply cross-datasets**. If this box is checked, then the filter will be applied to all visuals from different datasets that are applicable on all sheets in the filter scope. For more information, see [Filters](#).

Adding filter controls to analysis sheets

When you're designing an analysis, you can add a filter to the analysis sheet near the visuals that you want to filter. It appears in the sheet as a control that dashboard viewers can use when you publish the analysis as a dashboard. The control uses the analysis theme settings so it looks like it's part of the sheet.

Filter controls share some settings with their filters. They apply to one, some, or all of the objects on the same sheet.

Use the following sections add and customize filter controls to an analysis. To learn how to add cross-sheet controls, see [Controls](#).

Topics

- [Adding filter controls](#)
- [Pinning filter controls to the top of a sheet](#)
- [Customizing filter controls](#)
- [Sorting filter control values](#)
- [Cascading filter controls](#)

Adding filter controls

Use the following procedure to add a filter control.

To add a filter control

1. Open the [Quick console](#).
2. From the Quick homepage, choose **Analyses**, and then choose the analysis that you want to work with.
3. In the analysis, choose **Filter**.
4. If you don't already have some filters available, create one. For more information about creating filters, see [Adding filters](#).
5. In the **Filters** pane, choose the three dots to the right of the filter that you want to add a control for, and choose **Add to sheet**.

The filter control is added to the sheet, usually at the bottom. You can resize it or drag it to different positions on the sheet. You can also customize how it appears and how dashboard viewers can interact with it. For more information about customizing filter controls, see the following sections.

Pinning filter controls to the top of a sheet

Use the following procedure to pin filter controls to the top of a sheet.

To pin a control to the top of a sheet

1. On the filter control that you want to move, choose the three dots next to the pencil icon and choose **Pin to top**.

The filter is pinned to the top of the sheet and is collapsed. You can click it to expand it.

2. (Optional) To unpin the control, expand it and hover over it at the top of the sheet until three dots appear. Choose the three dots, and then choose **Move to sheet**.

Customizing filter controls

Depending on the data type of the field and the type of filter, filter controls have different settings available. You can customize how they appear in the sheet and how dashboard viewers can interact with them.

To customize a filter control

1. Choose the filter control in the sheet.
2. On the filter control, choose the pencil icon.

If the filter control is pinned to the top of the sheet, expand it and hover your cursor over it until the three dots appear. Choose the three dots, and then choose **Edit**.

3. In the **Format control** pane that opens, do the following:
 - a. For **Display name**, enter a name for the filter control.
 - b. (Optional) To hide the display name from the filter control, clear the check box for **Show title**.
 - c. For **Title font size**, choose the title font size that you want to use. The options range from extra small to extra large. The default setting is medium.

The remaining steps depend on the type of field the control is referencing. For options by filter type, see the following sections.

Date filters

If your filter control is from a date filter, use the following procedure to customize the remaining options.

To customize further options for a date filter

1. In the **Format control** pane, for **Style**, choose one of the following options:
 - **Date picker – range** – Displays a set of two fields to define a time range. You can enter a date or time, or you can choose a date from the calendar control. You can also customize how you want the dates to appear in the control by entering a date token for **Date format**. For more information, see [Customizing date formats in Quick](#).
 - **Date picker – relative** – Displays settings like the time period, its relation to the current date and time, and the option to exclude time periods. You can also customize how you want the dates to appear in the control by entering a date token for **Date format**. For more information, see [Customizing date formats in Quick](#).
 - **Text field** – Displays a box where you can enter the top or bottom *N* date.

Helper text is included in the text field control by default, but you can choose to remove it by clearing the **Show helper text in control** option.

By default, Quick visuals are reloaded whenever a change is made to a control. For Calendar and Relative date picker controls, authors can add an **Apply** button to a control that delays visual reload until the user chooses **Apply**. This allows users to make multiple changes at a time without additional queries. This setting can be configured with the **Show an apply button** checkbox in the **Control options** section of the **Format control** pane.

2. When finished, choose **Apply**.

Text filters

If your filter control is from a text filter, for example dimensions, categories, or labels, use the following procedure to customize the remaining options.

To customize further options for a text filter

1. In the **Format control** pane, for **Style**, choose one of the following options:
 - **Dropdown** – Displays a dropdown list with buttons that you can use to select a single value.

When you select this option, you can choose the following options for **Values**:

- **Filter** – Displays all the values that are available in the filter.
- **Specific values** – Enables you to enter the values to display, one entry per line.

You can also choose to **Hide Select all option from the control values**. This removes the option to select or clear the selection of all values in the filter control.

- **Dropdown - multiselect** – Displays a dropdown list with boxes that you can use to select multiple values.

When you select this option, you can choose the following options for **Values**:

- **Filter** – Displays all the values that are available in the filter.
- **Specific values** – Enables you to enter the values to display, one entry per line.

By default, Quick visuals are reloaded whenever a change is made to a control. For Multiselect dropdown controls, authors can add an **Apply** button to a control that delays visual reload until the user chooses **Apply**. This allows users to make multiple changes at

a time without additional queries. This setting can be configured with the **Show an apply button** checkbox in the **Control options** section of the **Format control** pane.

- **List** – Displays a list with buttons that you can use to select a single value.

When you select this option, you can choose the following options for **Values**:

- **Filter** – Displays all the values that are available in the filter.
- **Specific values** – Enables you to enter the values to display, one entry per line.

You can also choose the following:

- **Hide search bar when control is on sheet** – Hides the search bar in the filter control, so users can't search for specific values.
- **Hide Select all option from the control values** – Removes the option to select or clear the selection of all values in the filter control.
- **List - multiselect** – Displays a list with boxes that you can use to select multiple values.

When you select this option, you can choose the following options for **Values**:

- **Filter** – Displays all the values that are available in the filter.
- **Specific values** – Enables you to enter the values to display, one entry per line.

You can also choose the following:

- **Hide search bar when control is on sheet** – Hides the search bar in the filter control, so users can't search for specific values.
- **Hide Select all option from the control values** – Removes the option to select or clear the selection of all values in the filter control.
- **Text field** – Displays a text box where you can enter a single entry. Text fields support up to 79950 characters.

When you select this option, you can choose the following:

- **Show helper text in control** – Removes the helper text in text fields.
- **Text field - multiline** – Displays a text box where you can enter multiple entries. Multiline text fields support up to 79950 characters across all entries.

When you select this option, you can choose the following:

- For **Separate values by**, choose how you want to separate values you enter into the filter control. You can choose to separate values by a line break, comma, pipe (|), or semicolon.

- **Show helper text in control** – Removes the helper text in text fields.

2. When finished, choose **Apply**.

Numeric filters

If your filter control is from a numeric filter, use the following procedure to customize the remaining options.

To customize further options for a numeric filter

1. In the **Format control** pane, for **Style**, choose one of the following options:

- **Dropdown** – Displays a list where you can select a single value.

When you select this option, you can choose the following options for **Values**:

- **Filter** – Displays all the values that are available in the filter.
- **Specific values** – Enables you to enter the values to display, one entry per line.

You can also choose to **Hide Select all option from the control values**. This removes the option to select or clear the selection of all values in the filter control.

- **Filter** – Displays all the values that are available in the filter.
- **Specific values** – Enables you to enter the values to display, one entry per line.
- **Hide Select all option from the control values** – Removes the option to select or clear the selection of all values in the filter control.
- **List** – Displays a list with buttons that enable selecting a single value.

When you select this option, you can choose the following options for **Values**:

- **Filter** – Displays all the values that are available in the filter.
- **Specific values** – Enables you to enter the values to display, one entry per line.

You can also choose the following:

- **Hide search bar when control is on sheet** – Hides the search bar in the filter control, so users can't search for specific values.
- **Hide Select all option from the control values** – Removes the option to select or clear the selection of all values in the filter control.

- **Slider** – Displays a horizontal bar with a toggle that you can slide to change the value. If you have a ranged filter for values between a minimum and a maximum, the slider provides a toggle for each number. For sliders, you can specify the following options:
 - **Minimum value** – Displays the smaller value at the left of the slider.
 - **Maximum value** – Displays the larger value at the right of the slider.
 - **Step size** – Enables you to set the number of increments that the bar is divided into.
- **Text box** – Displays a box where you can enter the value. When you select this option, you can choose the following:
 - **Show helper text in control** – Removes the helper text in text fields.

2. When finished, choose **Apply**.

Sorting filter control values

Custom sort gives authors control over how values appear in dropdown and list filter controls. By default, control values are sorted alphabetically in ascending order. With custom sort, you can display values in a specific business order (such as fiscal quarters or priority levels) or sort by related metrics (such as sorting regions by total sales).

Custom sort is available for **Dropdown** (single select and multiselect) and **List** (single select and multiselect) control styles. The available sort options depend on whether the control uses specific values or values from a dataset column.

Note

Custom sort is not available for date type columns at this time. To sort date values in a logical order, use the sort by another field option with a date-related field.

When to use custom sort

Use custom sort when you need to do the following:

- **Display values in business logic order** – For example, priority levels (Critical, High, Medium, Low), fiscal quarters (Q1, Q2, Q3, Q4), or custom status workflows (New, In Progress, Review, Complete).
- **Sort by related metrics** – For example, products sorted by total sales, regions sorted by customer count, categories sorted by average revenue, or departments sorted by headcount.

Configuring custom sort

The sort configuration options depend on whether the control uses specific values or values from a dataset column.

Controls with specific values

When a control uses specific values that you entered manually, the following sort options are available in the **Sort** section of the **Format control** pane.

To configure sort for a specific values control

1. Choose the filter control in the sheet.
2. Choose the pencil icon to open the **Format control** pane.
3. In the **Format control** pane, locate the **Sort** section.
4. Choose one of the following options:
 - **Ascending (A–Z, 0–9)** – Sorts values in ascending order. This is the default.
 - **Descending (Z–A, 9–0)** – Sorts values in descending order.
 - **User-defined order** – Displays the values in the exact order you entered them. This preserves your custom ordering without any automatic sorting.

Note

When a control has values from both specific values and a source entity (such as a filter or parameter), the combined list is sorted together. For user-defined order, values are appended in the order they were entered. If a value from the source cannot be sorted based on the current configuration, it is appended at the end of the list.

Controls with values from a dataset column

When a control displays values from a dataset column, you can sort by that field or another field in the dataset using an aggregation function. This is useful when you want to order control values by a related metric, such as sorting a list of products by total sales.

To configure sort for a column-based control

1. Choose the filter control in the sheet.

2. Choose the pencil icon to open the **Format control** pane.
3. In the **Format control** pane, locate the **Sort** section.
4. Configure the following options:
 - **Sort by control column** – Sorts the control values based on the column that the control is tied to.
 - For **Sort direction**, choose **Ascending** or **Descending**.
 - For **Aggregation**, choose an aggregation function or choose **No aggregation** to sort by the raw column values.
 - **Sort by another field** – Sorts the control values based on a different column in the dataset.
 - For **Sort by field**, choose a column from the dataset. For calculated fields, only scalar (non-aggregated) calculated columns are available.
 - For **Aggregation**, choose an aggregation function to apply to the sort field. The available functions depend on the data type of the selected column. For numeric fields, you can use Sum, Average, Count, Distinct count, Min, Max, Median, Percentile, Var, Stdev, and other statistical functions. For non-numeric fields, you can use Count and Distinct count.
 - For **Sort direction**, choose **Ascending** or **Descending**.

Cross-sheet filter controls

You can configure sort order for cross-sheet filter controls through the cross-sheet settings. The sort configuration applies to all instances of the control across sheets.

To configure sort for a cross-sheet filter control

1. Open the cross-sheet settings for the filter.
2. In the default control configuration section, locate the **Sort** settings.
3. Configure the sort options as described in the preceding sections.
4. Choose **Apply**.

Note

Dashboard controls inherit the sort configuration from the analysis. Sort configuration changes are not available to dashboard readers.

Cascading filter controls

You can limit the values displayed in the control, so they only show values that are valid for what is selected in other controls. This is called a cascading control.

When creating cascading controls, the following limitations apply:

1. Cascading controls must be tied to dataset columns from the same dataset.
2. The child control must be a dropdown or list control.
3. For parameter controls, the child control must be linked to a dataset column.
4. For filter controls, the child control must be linked to a filter (instead of showing only specific values).
5. The parent control must be one of the following:
 - a. A string, integer, or numeric parameter control. DateTime parameter control is not supported.
 - b. A string filter control (excluding top-bottom filters).
 - c. A non-aggregated numeric filter control.
 - d. A date filter control (excluding top-bottom filters).

To create a cascading control

1. Choose **Show relevant values only**. Note that this option might not be available for all filter control types.
2. In the **Show relevant values only** pane that opens, choose one or more controls from the available list.
3. Choose a field to match the value to.
4. Choose **Update**.

Editing filters

You can edit filters at any time in a dataset or analysis.

You can't change the field a filter applies to. To apply a filter to a different field, create a new filter instead.

Use the following procedures to learn how to edit filters.

Editing filters in datasets

Use the following procedure to edit filters in datasets.

To edit a filter in a dataset

1. Open the [Quick console](#).
2. From the Quick homepage, choose **Data** at left.
3. Under the **Datasets** tab, choose the dataset that you want, and then choose **Edit dataset**.
4. On the data preparation page that opens, choose **Filters** at lower left.
5. Choose the filter that you want to edit.
6. When finished editing, choose **Apply**.

Editing filters in analyses

Use the following procedure to edit filters in analyses.

To edit a filter in an analysis

1. Open the [Quick console](#).
2. From the Quick homepage, choose **Analyses** at left.
3. On the **Analyses** page, choose the analysis that you want to work with.
4. In the analysis, choose the **Filter** icon shown to open the **Filters** pane.
5. Choose the filter that you want to edit.
6. When finished editing, choose **Apply**.

Enabling or disabling filters

You can use the filter menu to enable or disable a filter in a dataset or an analysis. When you create a filter, it's enabled by default. Disabling a filter removes the filter from the field, but it doesn't delete the filter from the dataset or analysis. Disabled filters are grayed out in the filters pane. If you want to re-apply the filter to the field, you can simply enable it.

Use the following procedures to learn how to enable or disable filters.

Disabling filters in datasets

Use the following procedure to disable filters in datasets.

To disable a filter in a dataset

1. From the Quick homepage, choose **Data** at left.
2. Under the **Datasets** tab, choose the dataset that you want, and then choose **Edit dataset**.
3. On the data preparation page that opens, choose **Filters** at lower left.
4. In the **Filters** pane at left, choose the three dots to the right of the filter that you want to disable, and then choose **Disable**. To enable a filter that was disabled, choose **Enable**.

Disabling filters in analyses

Use the following procedure to disable filters in analyses.

To disable a filter in an analysis

1. Open the [Quick console](#).
2. From the Quick homepage, choose **Analyses**.
3. On the **Analyses** page, choose the analysis that you want to work with.
4. In the analysis, choose the **Filter** icon to open the **Filters** pane.
5. In the **Filters** pane that opens, choose the three dots to the right of the filter that you want to disable, and then choose **Disable**. To enable a filter that was disabled, choose **Enable**.

Deleting filters

You can delete filters at any time in a dataset or analysis. Use the following procedures to learn how.

Deleting filters in datasets

Use the following procedure to delete filters in datasets.

To delete a filter in a dataset

1. Open the [Quick console](#).
2. From the Quick homepage, choose **Data**.
3. Under the **Datasets** tab, choose the dataset that you want, and then choose **Edit dataset**.
4. On the data preparation page that opens, choose **Filters** at lower left.
5. Choose the filter that you want to delete, and then choose **Delete filter**.

Deleting filters in analyses

Use the following procedure to delete filters in analyses.

To delete a filter in an analysis

1. Open the [Quick console](#).
2. From the Quick homepage, choose **Analyses**.
3. On the **Analyses** page, choose the analysis that you want to work with.
4. In the analysis, choose the **Filter** icon to open the **Filters** pane.
5. Choose the filter that you want to delete, and then choose **Delete filter**.

Previewing tables in a dataset

You can preview each individual data table within a dataset. When you choose a data table to preview, a read-only preview of the table appears in a new tab in the data preview section. You can have multiple table preview tabs open at once.

You can only preview tables that you have access to in a dataset. If a table doesn't appear in the top half of the data preparation space, you can't preview the table.

The **Dataset** tab contains all transformations, like new columns or filters. Table preview tabs don't show any of your transforms.

To preview a data table

1. On the Quick homepage, choose **Data** at left.
2. In the **Data** tab, choose the dataset that you want, and choose **Edit dataset**.
3. Choose the data table that you want to preview, choose the down arrow to open the menu, and choose **Show table preview**.

Using SQL to customize data

When you create a dataset or prepare your data for use in an analysis, you can customize the data in the query editor.

The query editor is made up of multiple components, as follows:

- **Query mode** – At the top left, you can choose between direct query or SPICE query modes:

- **Direct query** – To run the SELECT statement directly against the database
- **SPICE** – To run the SELECT statement against data that was previously stored in memory
- **Fields** – Use this section to disable fields you want to remove from the final dataset. You can add calculated fields in this section, and augment your data with SageMaker AI
- **Query archive** – Use this section to find previous version of your SQL queries.
- **Filters** – Use this section to add, edit, or remove filters.
- **Schema explorer** – This section only appears while you are editing SQL. You can use it to explore your schemas, tables, fields, and data types.
- **SQL editor** – Use this to edit your SQL. The SQL editor, which offers syntax highlighting, basic autocomplete, autoindent, and line numbering. You can specify a SQL query only for datasets that come from data sources compatible with SQL. Your SQL must conform to the target database requirements regarding syntax, capitalization, command termination, and so on. If you prefer, you can instead paste SQL from another editor.
- **Data workspace** – When the SQL editor is closed, the data workspace displays at top right with a grid background. Here you can see a graphical representation of your data objects, including queries, tables, files, and joins created in the join editor.

To view details about each table, use the data source options menu and choose **Table details** or **Edit SQL Query**. Details display for table name and alias, schema, data source name, and data source type. For upload settings on a file, choose **Configure upload settings** from the data source options menu to view or change the following settings:

- **Format** – the file format, CSV, CUSTOM, CLF, and so on
- **The starting row** – the row to start with
- **The text qualifier** – double quote or single quote
- **Header** – indicates if the file includes a header row
- **Preview rows** – A preview of the sampled rows appear at bottom right when the join configuration editor isn't in use.
- **Join configuration editor** – The join editor opens when you have more than one data object in the data workspace. To edit a join, you select the join icon between two tables (or files). Choose a join type and the fields to join on, by using the join configuration panel at the bottom of the screen. Then choose **Apply** to create the join. You must complete all joins before you can save your work.

To add more queries, tables, or files, use the **Add data** option above the workspace.

Creating a basic SQL query

Use the following procedure to connect to a data source by using a custom SQL query.

To create a basic SQL query

1. Create a new data source and validate the connection.
2. Fill in the options necessary to connection, however you don't need to select a schema or a table.
3. Choose **Use custom SQL**.
4. (Optional) You can enter your query in the SQL editor, or continue on to the next step to use the full-screen version. To enter it now, create a name for the query. Then type or paste a SQL query into the editor. The SQL editor offers syntax highlighting, basic autocomplete, autoindent, and line numbering.

(Optional) Choose **Confirm query** to validate it and view settings for direct query, SPICE memory, and SageMaker AI settings.

5. Choose **Edit/Preview data**. The full query editor appears with the SQL editor displayed. The query is processed and a sample of the query results displays in the data preview pane. You can make changes to the SQL and confirm them by choosing **Apply**. When you are done with the SQL, choose **Close** to continue.
6. At the top, enter a name for the dataset. Then choose **Save & visualize**.

Modifying existing queries

To update a SQL query

1. Open the dataset that you want to work with.
2. In the workspace with the grid, locate the box-shaped object that represents the existing query.
3. Open the options menu on the query object and choose **Edit SQL query**. If this option doesn't appear in the list, the query object isn't based on SQL.

To view previous versions of queries, open the **Query archive** at left.

Adding geospatial data

You can flag geographic fields in your data, so that Amazon Quick Sight can display them on a map. Amazon Quick Sight can chart latitude and longitude coordinates. It also recognizes geographic components such as country, state or region, county or district, city, and ZIP code or postal code. You can also create geographic hierarchies that can disambiguate similar entities, for example the same city name in two states.

Note

Geospatial charts in Amazon Quick Sight aren't currently supported in some AWS Regions, including in China. We are working on adding support for more Regions.

Use the following procedures to add geospatial data types and hierarchies to your dataset.

To add geospatial data types and hierarchies to your dataset

1. On the data preparation page, label the geographic components with the correct data type.

There are several ways to do this. One is to choose the field under **Fields** and use the ellipses icon (...) to open the context menu.

Then choose the correct geospatial data type.

You can also change the data type in the work area with the data sample. To do this, choose the data type listed under the field name. Then choose the data type you want to assign.

2. Verify that all geospatial fields necessary for mapping are labeled as geospatial data types. You can check this by looking for the place marker icon. This icon appears under the field names across the top of the page, and also in the **Fields** pane on the left.

Also check the name of the data type, for example latitude or country.

3. (Optional) You can set up a hierarchy or grouping for geographical components (state, city), or for latitude and longitude coordinates. For coordinates, you must add both latitude and longitude to the geospatial field wells.

To create a hierarchy or grouping, first choose one of these fields in the **Fields** pane. Each field can only belong to one hierarchy. It doesn't matter which one you choose first, or what order you add the fields in.

Choose the ellipsis icon (...) next to the field name. Then choose **Add to a hierarchy**.

4. On the **Add field to hierarchy** screen, choose one of the following:
 - Choose **Create a new geospatial hierarchy** to create a new grouping.
 - Choose **Add to existing geospatial hierarchy** to add a field to a grouping that already exists. The existing hierarchies displayed include only those of matching geospatial types.

Choose **Add** to confirm your choice.

5. On the **Create hierarchy** screen, name your hierarchy.

If you are creating a latitude and longitude grouping, the **Create hierarchy** screen appears. Depending on whether you chose latitude or longitude in the previous steps, either latitude or longitude displays on this screen. Make sure that your latitude field shows under **Field to use for latitude**. Also make sure that your longitude shows under **Field to use for longitude**.

For geographical components, the **Create hierarchy** screen has two choices:

- Choose **This hierarchy is for a single country** if your data only contains one country. Choose the specific country from the list. Your data doesn't need to contain every level of the hierarchy. You can add fields to the hierarchy in any order.
- Choose **This hierarchy is for multiple countries** if your data contains more than one country. Choose the field that contains the country names.

For either hierarchy type, choose **Update** to continue.

6. Continue by adding as many fields to the hierarchy as you need to.

Your geospatial groupings appear in the **Fields** pane.

Changing a geospatial grouping

You can change a geospatial hierarchy or grouping that exists in a dataset.

Use the following procedure to edit or disband a geospatial hierarchy.

To edit or disband a geospatial hierarchy

1. Open the dataset. In the **Fields** pane, choose the hierarchy name.

2. Choose the ellipsis icon (...), then choose one of the following options.

Choose **Disband hierarchy** to remove the hierarchy from the dataset. You can't undo this operation. However, you can recreate your hierarchy or grouping by starting again at step 1. Disbanding the hierarchy doesn't remove any fields from the dataset.

Choose **Edit hierarchy** to make changes to the hierarchy. Doing this reopens the creation screens, so you can make different choices in rebuilding your hierarchy.

Geospatial troubleshooting

Use this section to discover the Amazon Quick Sight requirements for correctly processing geospatial data. If Amazon Quick Sight doesn't recognize your geospatial data as geospatial, use this section to help troubleshoot the issue. Make sure that your data follows the guidelines listed, so that it works in geospatial visuals.

Note

Geospatial charts in Amazon Quick Sight currently aren't supported in some AWS Regions, including in China. We are working on adding support for more Regions. If your geography follows all the guidelines listed here, and still generates errors, contact the Amazon Quick Sight team from within the Amazon Quick Sight console.

Topics

- [Geocoding issues](#)
- [Issues with latitude and longitude](#)
- [Supported administrative areas and postal codes by country](#)

Geocoding issues

Amazon Quick Sight geocodes place names into latitude and longitude coordinates. It uses these coordinates to display place names on the map. Amazon Quick Sight skips any places that it can't geocode.

For this process to work properly, your data must include at least the country. Also, there can't be duplicate place names inside of a parent place name.

A few issues prevent place names from showing up on a map chart. These issues include unsupported, ambiguous, or invalid locations, as described following.

Topics

- [Issues with unsupported areas](#)
- [Issues with ambiguous locations](#)
- [Issues with invalid geospatial data](#)
- [Issues with the default country in geocoding](#)

Issues with unsupported areas

To map unsupported locations, include latitude and longitude coordinates in your data. Use these coordinates in the geospatial field well to make locations show on a map chart.

Issues with ambiguous locations

Geospatial data can't contain ambiguous locations. For example, suppose that the data contains a city named **Springfield**, but the next level in the hierarchy is country. Because multiple states have a city named **Springfield**, it isn't possible to geocode the location to a specific point on a map.

To avoid this problem, you can add enough geographical data to indicate what location should show on a map chart. For example, you can add a state level into your data and its hierarchy. Or, you might add latitude and longitude.

Issues with invalid geospatial data

Invalid geospatial data occurs when a place name (a city, for example) is listed under an incorrect parent (a state, for example). This issue might be a simple misspelling, or data entry error.

Note

Amazon Quick Sight doesn't support regions (for example, West Coast or South) as geospatial data. However, you can use a region as a filter in a visual.

Issues with the default country in geocoding

Make sure that you are using the correct default country.

The default for each hierarchy is based on the country or country field that you choose when you create the hierarchy.

To change this default, you can return to the **Create hierarchy** screen. Then edit or create a hierarchy, and choose a different country.

If you don't create a hierarchy, your default country is based on your AWS Region. For details, see the following table.

Region	Default country
US West (Oregon) Region	US
US East (Ohio) Region	
US East (N. Virginia) Region	
Asia Pacific (Singapore)	Singapore
Asia Pacific (Sydney)	Australia
Europe (Ireland) Region	Ireland

Issues with latitude and longitude

Amazon Quick Sight uses latitude and longitude coordinates in the background to find place names on a map. However, you can also use coordinates to create a map without using place names. This approach also works with unsupported place names.

Latitude and longitude values must be numeric. For example, the map point indicated by **28.5383355 -81.3792365** is compatible with Amazon Quick Sight. But **28° 32' 18.0096' ' N 81° 22' 45.2424' ' W** is not.

Topics

- [Valid ranges for latitude and longitude coordinates](#)
- [Using coordinates in degrees, minutes, and seconds \(DMS\) format](#)

Valid ranges for latitude and longitude coordinates

Amazon Quick Sight supports latitude and longitude coordinates within specific ranges.

Coordinate	Valid range
Latitude	Between -90 and 90
Longitude	Between -180 to 180

Amazon Quick Sight skips any data outside these ranges. Out-of-range points can't be mapped on a map chart.

Using coordinates in degrees, minutes, and seconds (DMS) format

You can use a calculated field with a formula to create a numeric latitude and longitude out of character strings. Use this section to find different ways that you can create calculated fields in Amazon Quick Sight, to parse GPS latitude and longitude into numeric latitude and longitude.

The following sample converts latitude and longitude to numeric format from separate fields. For example, suppose that you parse **51° 30' 26.4636' ' N 0° 7' 39.9288' ' W** using space as a delimiter. In this case, you can use something like the following sample to convert the resulting fields to numeric latitude and longitude.

In this example, the seconds are followed by two single quotation marks. If your data has a double quotation mark instead, then you can use `strlen(LatSec)-1` instead of `strlen(LatSec)-2`.

```
/*Latitude*/
  ifelse(
    LatDir = "N",
    parseInt(split(LatDeg, "°", 1)) +
      (parseFloat(split(LatMin, "'", 1) ) /60) +
      (parseFloat(substring(LatSec, 1, strlen(LatSec)-2) ) ) /3600),
    (parseInt(split(LatDeg, "°", 1)) +
      (parseFloat(split(LatMin, "'", 1) ) /60) +
      (parseFloat(substring(LatSec, 1, strlen(LatSec)-2) ) ) /3600)) * -1
  )

/*Longitude*/
  ifelse(
```

```

LongDir = "E",
parseInt(split(LongDeg, "°", 1)) +
    (parseFloat(split(LongMin, "'", 1) ) /60) +
    (parseFloat((substring(LongSec, 1, strlen(LongSec)-2) ) ) /3600),
(parseInt(split(LongDeg, "°", 1)) +
    (parseFloat(split(LongMin, "'", 1) ) /60) +
    (parseFloat((substring(LongSec, 1, strlen(LongSec)-2) ) ) /3600)) * -1
)

```

If your data doesn't include the symbols for degree, minute and second, the formula looks like the following.

```

/*Latitude*/
ifelse(
    LatDir = "N",
    (LatDeg + (LatMin / 60) + (LatSec / 3600)),
    (LatDeg + (LatMin / 60) + (LatSec / 3600)) * -1
)

/*Longitude*/
ifelse(
    LongDir = "E",
    (LongDeg + (LongMin / 60) + (LongSec / 3600)),
    (LongDeg + (LongMin / 60) + (LongSec / 3600)) * -1
)

```

The following sample converts **53°21'N 06°15'W** to numeric format. However, without the seconds, this location doesn't map as accurately.

```

/*Latitude*/
ifelse(
    right(Latitude, 1) = "N",
    (parseInt(split(Latitude, '°', 1)) +
        parseFloat(substring(Latitude, (locate(Latitude, '°',3)+1), 2) ) / 60) ,
    (parseInt(split(Latitude, '°', 1)) +
        parseFloat(substring(Latitude, (locate(Latitude, '°',3)+1), 2) ) / 60) * -1
)

/*Longitude*/
ifelse(
    right(Longitude, 1) = "E",

```

```
(parseInt(split(Longitude, '°', 1)) +
  parseDecimal(substring(Longitude, (locate(Longitude, '°',3)+1), 2) ) / 60) ,
(parseInt(split(Longitude, '°', 1)) +
  parseDecimal(substring(Longitude, (locate(Longitude, '°',3)+1), 2) ) / 60) *
-1
)
```

The formats of GPS latitude and longitude can vary, so customize your formulas to match your data. For more information, see the following:

- [Degrees Minutes Seconds to Decimal Degrees](#) on LatLong.net
- [Converting Degrees/Minutes/Seconds to Decimals using SQL](#) on Stack Overflow
- [Geographic Coordinate Conversion](#) on Wikipedia

Supported administrative areas and postal codes by country

The following is a list of supported administrative areas by country.

Supported administrative areas

Country name	Country code	Country	State	County	City
Aruba	ABW	Country	Regions	Zones	
Afghanistan	AFG	Country	Wilayat	Wuleswali	Localities/Urban Areas
Angola	AGO	Country	Provinces /Províncias	Municipios	Localities/Urban Areas

The following is a list of the supported postal code formats by country, including the number of digits and an example postal code.

Note

PO BOX zipcodes are not supported postal code formats. Union territory zip codes that are used in India are also not supported.

Supported postal codes

Country	Postal format	Example
Afghanistan	4 digit	1001
Albania	4 digit	1001
Algeria	5 digit	01000
American Samoa	5 digit	96799
Andorra	5 digit	AD100
Anguilla	6 digit	AI-2640
Argentina	5 digit	A4126
Armenia	2 digit	00
Australia	4 digit	0800
Austria	4 digit	1010
Azerbaijan	2 digit	01
Brunei Darussalam	6 digit	BA1111
Bahrain	4 digit	0101
Bangladesh	2 digit	10

Country	Postal format	Example
Belarus	6 digit	202115
Belgium	4 digit	1000
Bermuda	4 digit	CR 01
Bhutan	2 digit	11
Bosnia and Herzegovina	5 digit	70101
Brazil	5 digit	01001
British Indian Ocean Territory	Alphanumeric - 5 digit	BBND 1
British Virgin Islands	4 digit	1110
Bulgaria	4 digit	1000
Cabo Verde	4 digit	1101
Cambodia	2 digit	01
Canada	3 digit	A0A
Cayman Islands	Alphanumeric - 7 digit	KY1-1000
Chile	3 digit	100
China	4 digit	0100

Country	Postal format	Example
Colombia	4 digit	0500
Costa Rica	5 digit	10101
Croatia	5 digit	10000
Cuba	1 digit	1
Cyprus	4 digit	1010
Czechia	5 digit	100 00
Democratic Republic of the Congo	4 digit	1001
Denmark	4 digit	1050
Dominican Republic	5 digit	10101
Ecuador	6 digit	010101
Egypt	2 digit	11
El Salvador	4 digit	1101
Estonia	5 digit	10001
Falkland Islands	Alphanumeric - 5 digit	FIQQ 1

Country	Postal format	Example
Faroe Islands	3 digit	100
Finland	5 digit	00100
France	5 digit	01000
French Guiana	5 digit	97300
French Polynesia	5 digit	98701
Georgia	2 digit	01
Germany	5 digit	01067
Ghana	2 digit	A2
Gibraltar	Alphanumeric - 5 digit	GX11 1
Greece	5 digit	104 31
Greenland	4 digit	3900
Guadeloupe	5 digit	97100
Guam	5 digit	96910
Guatemala	5 digit	01001

Country	Postal format	Example
Guernsey	Alphanumeric - 4 digit, 5 digit	GY1 1, GY10 1
Guinea-Bissau	4 digit	1000
Haiti	4 digit	1110
Holy See	5 digit	00120
Honduras	2 digit	11
Hungary	4 digit	1007
Iceland	3 digit	101
India	6 digit	110001
Indonesia	5 digit	10110
Iran	2 digit	11
Iraq	2 digit	10
Ireland	3 digit	A41
Isle of Man	Alphanumeric - 4 digit	IM1 1
Israel	5 digit	10292

Country	Postal format	Example
Italy	5 digit	00010
Japan	7 digit	001-0010
Jersey	Alphanumeric - 4 digit	JE2 3
Jordan	5 digit	11100
Kazakhstan	4 digit	0100
Kenya	1 digit	0
Kiribati	6 digit	KI0101
Kosovo	5 digit	10000
Kuwait	2 digit	00
Kyrgyzstan	4 digit	7200
Laos	2 digit	01
Latvia	4 digit	1001
Lesotho	1 digit	1
Liberia	2 digit	10

Country	Postal format	Example
Liechtenstein	4 digit	9485
Lithuania	5 digit	00100
Luxembourg	4 digit	1110
Macedonia	4 digit	1000
Madagascar	3 digit	101
Malawi	3 digit	101
Malaysia	5 digit	01000
Maldives	2 digit	00
Malta	3 digit	ATD
Marshall Islands	3 digit	969
Martinique	5 digit	97200
Mauritius	3 digit	111
Mayotte	5 digit	97600
Mexico	5 digit	01000

Country	Postal format	Example
Micronesia	5 digit	96941
Moldova	4 digit	2001
Monaco	5 digit	98000
Mongolia	4 digit	1200
Montenegro	5 digit	81000
Montserrat	4 digit	1120
Morocco	5 digit	10000
Mozambique	4 digit	1100
Myanmar	2 digit	01
Namibia	3 digit	100
Nepal	3 digit	101
Netherlands	4 digit	1011
New Caledonia	5 digit	98800
New Zealand	4 digit	0110

Country	Postal format	Example
Nicaragua	3 digit	110
Niger	4 digit	1000
Nigeria	4 digit	1002
Niue	4 digit	9974
Norfolk Island	4 digit	2899
Northern Mariana Islands	5 digit	96950
Norway	4 digit	0010
Oman	1 digit	1
Pakistan	2 digit	10
Palau	5 digit	96939
Palestine	4 digit	P104
Papua New Guinea	3 digit	111
Paraguay	6 digit	001001
Peru	5 digit	01000

Country	Postal format	Example
Philippines	4 digit	1000
Pitcairn	Alphanumeric - 5 digit	PCRN 1
Poland	5 digit	00-002
Portugal	4 digit	1000
Puerto Rico	5 digit	00601
Romania	6 digit	010011
Russia	6 digit	101000
Réunion	5 digit	97400
Saint Barthélemy	5 digit	97133
Saint Helena, Ascension and Tristan da Cunha	Alphanumeric - 5 digit	ASCN 1
Saint Lucia	7 digit	LC01 101
Saint Martin	5 digit	97150
Saint Pierre and Miquelon	5 digit	97500
Saint Vincent and the Grenadines	4 digit	VC01

Country	Postal format	Example
Samoa	2 digit	11
San Marino	5 digit	47890
Saudi Arabia	2 digit	12
Senegal	5 digit	10000
Serbia	5 digit	11000
Singapore	6 digit	018906
Slovakia	5 digit	010 01
Slovenia	4 digit	1000
South Africa	4 digit	0001
South Georgia and the South Sandwich Islands	Alphanumeric - 5 digit	SIQQ 1
South Korea	5 digit	01000
Spain	5 digit	01001
Sri Lanka	2 digit	00
Sudan	2 digit	11

Country	Postal format	Example
Svalbard and Jan Mayen	4 digit	8099
Swaziland	1 digit	H
Sweden	5 digit	111 15
Switzerland	4 digit	1000
Taiwan	3 digit	100
Tajikistan	4 digit	7340
Tanzania, United Republic of	3 digit	111
Thailand	5 digit	10100
Timor-Leste	4 digit	TL10
Trinidad and Tobago	2 digit	10
Tunisia	4 digit	1000
Turkey	5 digit	01010
Turkmenistan	3 digit	744
Turks and Caicos Islands	Alphanumeric - 5 digit	TKCA 1

Country	Postal format	Example
U.S. Virgin Islands	5 digit	00802
Ukraine	3 digit, 5 digit	070, 01001
United Kingdom	Alphanumeric - 2 to 5 digits	B1, AL1, AB10, AB10 1
United States	5 digit	00001
Uruguay	5 digit	11000
Uzbekistan	4 digit	1000
Venezuela	4 digit	0000
Vietnam	5 digit	01106
Wallis and Futuna	5 digit	98600
Zambia	5 digit	10100

Using unsupported or custom dates

Amazon Quick Sight natively supports a limited number of date formats. However, you can't always control the format of the data provided to you. When your data contains a date in an unsupported format, you can tell Amazon Quick Sight how to interpret it.

You can do this by editing the dataset, and changing the format of the column from text or numeric to date. A screen appears after you make this change, so you can enter the format. For example, if you are using a relational data source, you can specify MM-dd-yyyy for a text field

containing '09-19-2017', so it is interpreted as 2017-09-19T00:00:00.000Z. If you are using a nonrelational data source, you can do the same thing starting with a numeric field or a text field.

Amazon Quick Sight only supports text to date for relational (SQL) sources.

For more information on supported date formats, see [Supported date formats](#).

Use this procedure to help Amazon Quick Sight understand dates in different formats.

1. For a dataset containing unsupported date formats, edit the data as follows. For the column containing your datetime data, change the data type from text to date. Do this by choosing the colorful data type icon beneath the column name in the data preview.

 Note

Integer dates that aren't Unix epoch datetimes don't work as is. For example, these formats are not supported as integers: MMddyy, MMddyyyy, ddMMyy, ddMMyyyy, and yyMMdd. The workaround is to first change them to text format. Make sure all your rows contain six digits (not five). Then change the text data type to datetime. For more information on Unix epoch datetimes, see [epochDate](#).

When you change the data type to date, the **Edit date format** screen appears.

2. Enter your date format, indicating which parts are month, date, year, or time. Formats are case-sensitive.
3. Choose **Validate** to make sure Amazon Quick Sight can now interpret your datetime data with the format you specified. Rows that don't validate are skipped and omitted from the dataset.
4. When you are satisfied with the results, choose **Update**. Otherwise, choose **Close**.

Adding a unique key to an Amazon Quick Sight dataset

Quick authors can configure a unique key column to a Quick Sight dataset during data preparation. This unique key acts as a global sorting key for the dataset and optimizes query generation for table visuals. When a user creates a table visual in Quick Sight and adds the unique key column to the value field well, data is sorted from left to right up to the unique key column. All columns to the right of the unique key column are ignored in the sort order. Tables that don't contain a unique key are sorted based on the order that the columns appear in the dataset.

The following limitations apply to unique keys:

- Unique keys are only supported for unaggregated tables.
- If a dataset column is used for column level security (CLS), the column can't also be used as the unique key.

Use the following procedure to designate a unique key for a dataset in Amazon Quick Sight.

To set up a unique key

1. Open the [Quick console](#).
2. Choose **Data**.
3. Perform one of the following actions:
 - a. Navigate to the dataset that you want to add a unique key to, choose the ellipsis (three dots) next to the dataset, and then choose **Edit**.
 - b. Choose **New** then **Dataset**. Choose the dataset that you want to add and then choose **Edit data source**. For more information about creating new datasets in Amazon Quick Sight, see [Creating datasets](#).
4. The data preparation page for the dataset opens. Navigate to the **Fields** pane and locate the field that you want to set as the unique key.
5. Choose the ellipsis (three dots) next to the field name, and then choose **Set as unique key**.

After you create a unique key, a key icon appears next to the field to show that the field is now the unique key for the dataset. When you save and publish the dataset, the unique key configuration is applied to the dataset and to all dashboards and analyses that are created with that dataset. To remove a unique key from a dataset, navigate to the data preparation page for the dataset, choose the ellipsis next to the unique key field, and then choose **Remove as unique key**. After you remove a unique key from a dataset, you can designate a different field as the unique key.

Integrating Amazon SageMaker AI models with Amazon Quick Sight

Note

You don't need any technical experience in machine learning (ML) to author analyses and dashboards that use the ML-powered features in Amazon Quick Sight.

You can augment your Amazon Quick Enterprise edition data with Amazon SageMaker AI machine learning models. You can run inferences on data stored in SPICE imported from any data source supported by Quick. For a full list of supported data sources, see [Supported data sources](#).

Using Quick with SageMaker AI models can save the time that you might otherwise spend managing data movement and writing code. The results are useful both for evaluating the model and—when you're satisfied with the results—for sharing with decision-makers. You can begin immediately after the model is built. Doing this surfaces your data scientists' prebuilt models, and enables you to apply the data science to your datasets. Then you can share these insights in your predictive dashboards. With the Quick serverless approach, the process scales seamlessly, so you don't need to worry about inference or query capacity.

Amazon Quick supports SageMaker AI models that use regression and classification algorithms. You can apply this feature to get predictions for just about any business use case. Some examples include predicting the likelihood of customer churn, employee attrition, scoring sales leads, and assessing credit risks. To use Quick to provide predictions, the SageMaker AI model data for both input and output must be in tabular format. In multiclass or multilabel classification use cases, each output column has to contain a single value. Quick doesn't support multiple values inside a single column.

Topics

- [How SageMaker AI integration works](#)
- [Costs incurred \(no additional costs with integration itself\)](#)
- [Usage guidelines](#)
- [Defining the schema file](#)
- [Adding a SageMaker AI model to your Quick Sight dataset](#)
- [Build predictive models with SageMaker AI Canvas](#)

How SageMaker AI integration works

In general, the process works like this:

1. An Amazon Quick administrator adds permissions for Quick to access SageMaker AI. To do this, open **Security & Permissions** settings from the **Manage Quick** page. Go to **Quick access to AWS services**, and add SageMaker AI.

When you add these permissions, Quick is added to an AWS Identity and Access Management (IAM) role that provides access to list all the SageMaker AI models in your AWS account. It also provides permissions to run SageMaker AI jobs that have names that are prefixed with `quicksight-auto-generated-`.

2. We recommend that you connect to an SageMaker AI model that has an inference pipeline, because it automatically performs data preprocessing. For more information, see [Deploy an Inference Pipeline](#) in the *SageMaker AI Developer Guide*.
3. After you identify the data and the pretrained model that you want to use together, the owner of the model creates and provides a schema file. This JSON file is a contract with SageMaker AI. It provides metadata about the fields, data types, column order, output, and settings that the model expects. The optional settings component provides the instance size and count of the compute instances to use for the job.

If you're the data scientist who built the model, create this schema file using the format documented following. If you're a consumer of the model, get the schema file from the owner of the model.

4. In Quick, you begin by creating a new dataset with the data that you want to make predictions on. If you're uploading a file, you can add the SageMaker AI model on the upload settings screen. Otherwise, add the model on the data preparation page.

Before you proceed, verify the mappings between the dataset and the model.

5. After the data is imported into the dataset, the output fields contain the data returned from SageMaker AI. You use these fields just as you use other fields, within the guidelines described in [Usage guidelines](#).

When you run SageMaker AI integration, Quick passes a request to SageMaker AI to run batch transform jobs with inference pipelines. Quick starts provisions and deployment of the instances needed in your AWS account. When processing is complete, these instances are shut down and terminated. The compute capacity incurs costs only when it's processing models.

To make it easier for you to identify them, Quick names all its SageMaker AI jobs with the prefix `quicksight-auto-generated-`.

6. The output of the inference is stored in SPICE and appended to the dataset. As soon as the inference is complete, you can use the dataset to create visualizations and dashboards using the prediction data.

7. The data refresh starts every time you save the dataset. You can start the data refresh process manually by refreshing the SPICE dataset, or you can schedule it to run at a regular interval. During each data refresh, the system automatically calls SageMaker AI batch transform to update the output fields with new data.

You can use the Amazon Quick Sight SPICE ingestion API operations to control the data refresh process. For more information about using these API operations, see the [Amazon Quick Sight API Reference](#).

Costs incurred (no additional costs with integration itself)

Using this feature doesn't require an additional fee in itself. Your costs include the following:

- The cost of model deployment through SageMaker AI, which is incurred only when the model is running. Saving a dataset—after either creating or editing it—or refreshing its data starts the data ingestion process. This process includes calling SageMaker AI if the dataset has inferred fields. Costs are incurred in the same AWS account where your Quick subscription is.
- Your Quick subscription costs are as follows:
 - The cost of storing your data in the in-memory calculation engine in Quick (SPICE). If you are adding new data to SPICE, you might need to purchase enough SPICE capacity to accommodate it.
 - Quick subscriptions for the authors or admins who build the datasets.
 - Pay-per-session charges for viewers (readers) to access interactive dashboards.

Usage guidelines

In Amazon Quick, the following usage guidelines apply to this Enterprise edition feature:

- The processing of the model occurs in SPICE. Therefore, it can only apply to datasets that are stored in SPICE. The process currently supports up to 500 million rows per dataset.
- Only Quick admins or authors can augment datasets with ML models. Readers can only view the results when they are part of a dashboard.
- Each dataset can work with one and only one ML model.
- Output fields can't be used to calculate new fields.
- Datasets can't be filtered by fields that are integrated with the model. In other words, if your dataset field is currently mapped to the ML model, you can't filter on that field.

In SageMaker AI, the following usage guidelines apply to a pretrained model that you use with Amazon Quick Sight:

- When you create the model, associate it with the Amazon Resource Name (ARN) for the appropriate IAM role. The IAM role for the SageMaker AI model needs to have access to the Amazon S3 bucket that Amazon Quick Sight uses.
- Make sure that your model supports .csv files for both input and output. Make sure that your data is in a tabular format.
- Provide a schema file that contains metadata about the model, including the list of input and output fields. Currently, you must create this schema file manually.
- Consider the amount of time that it takes to complete your inference, which depends on a number of factors. These include the complexity of the model, the amount of data, and the compute capacity defined. Completing the inference can take several minutes to several hours. Amazon Quick Sight caps all data ingestion and inferencing jobs to a maximum of 10 hours. To reduce the time it takes to perform an inference, consider increasing the instance size or the number of instances.
- Currently, you can use only batch transforms for integration with SageMaker AI, not real-time data. You can't use an SageMaker AI endpoint.

Defining the schema file

Before you use an SageMaker AI model with Quick Sight data, create the JSON schema file that contains the metadata that Amazon Quick Sight needs to process the model. The Amazon Quick author or admin uploads the schema file when configuring the dataset.

The schema fields are defined as follows. All fields are required unless specified in the following description. Attributes are case-sensitive.

inputContentType

The content type that this SageMaker AI model expects for the input data. The only supported value for this is "text/csv". Quick Sight doesn't include any of the header names that you add to the input file.

outputContentType

The content type of the output that is produced by the SageMaker AI model that you want to use. The only supported value for this is "text/csv".

input

A list of features that the model expects in the input data. Quick Sight produces the input data in exactly the same order. This list contains the following attributes:

- *name* – The name of the column. If possible, make this the same as the name of the corresponding column in the QuickSight dataset. This attribute is limited to 100 characters.
- *type* – The data type of this column. This attribute takes the values "INTEGER", "STRING", and "DECIMAL".
- *nullable* – (Optional) The nullability of the field. The default value is `true`. If you set `nullable` to `false`, Quick Sight drops rows that don't contain this value before calling SageMaker AI. Doing this helps avoid causing SageMaker AI to fail on missing required data.

output

A list of output columns that the SageMaker AI model produces. Quick Sight expects these fields in exactly the same order. This list contains the following attributes:

- *name* – This name becomes the default name for the corresponding new column that's created in Quick Sight. You can override the name specified here in Quick Sight. This attribute is limited to 100 characters.
- *type* – The data type of this column. This attribute takes the values "INTEGER", "STRING", and "DECIMAL".

instanceTypes

A list of the ML instance types that SageMaker AI can provision to run the transform job. The list is provided to the Amazon Quick user to choose from. This list is limited to the types supported by SageMaker AI. For more information on supported types, see [TransformResources](#) in the *SageMaker AI Developer Guide*.

defaultInstanceType

(Optional) The instance type that is presented as the default option in the SageMaker AI wizard in Quick Sight. Include this instance type in `instanceTypes`.

instanceCount

(Optional) The instance count defines how many of the selected instances for SageMaker AI to provision to run the transform job. This value must be a positive integer.

description

This field provides a place for the person who owns the SageMaker AI model to communicate with the person who is using this model in Quick Sight. Use this field to provide hints about successfully using this model. For example, this field can contain information about selecting an effective instance type to choose from the list in `instanceTypes`, based on the size of dataset. This field is limited to 1,000 characters.

version

The version of the schema, for example "1.0".

The following example shows the structure of the JSON in the schema file.

```
{
  "inputContentType": "CSV",
  "outputContentType": "CSV",
  "input": [
    {
      "name": "buying",
      "type": "STRING"
    },
    {
      "name": "maint",
      "type": "STRING"
    },
    {
      "name": "doors",
      "type": "INTEGER"
    },
    {
      "name": "persons",
      "type": "INTEGER"
    },
    {
      "name": "lug_boot",
      "type": "STRING"
    },
    {
      "name": "safety",
      "type": "STRING"
    }
  ],
}
```

```
    "output": [
      {
        "name": "Acceptability",
        "type": "STRING"
      }
    ],
    "description": "Use ml.m4.xlarge instance for small datasets, and ml.m4.4xlarge
for datasets over 10 GB",
    "version": "1.0",
    "instanceCount": 1,
    "instanceTypes": [
      "ml.m4.xlarge",
      "ml.m4.4xlarge"
    ],
    "defaultInstanceType": "ml.m4.xlarge"
  }
}
```

The structure of the schema file is related to the kind of model that is used in examples provided by SageMaker AI.

Adding a SageMaker AI model to your Quick Sight dataset

Using the following procedure, you can add a pretrained SageMaker AI model to your dataset, so that you can use predictive data in analyses and dashboards.

Before you begin, have the following items available:

- The data that you want to use to build the dataset.
- The name of the SageMaker AI model that you want to use to augment the dataset.
- The schema of the model. This schema includes field name mappings and data types. It's helpful if it also contains recommended settings for instance type and number of instances to use.

To augment your Amazon Quick Sight dataset with SageMaker AI

1. Create a new dataset from the start page by choosing **Datasets**, and then choose **New dataset**.

You can also edit an existing dataset.

2. Choose **Augment with SageMaker** on the data preparation screen.
3. For **Select your model**, choose the following settings:

- **Model** – Choose the SageMaker AI model to use to infer fields.

- **Name** – Provide a descriptive name for the model.
- **Schema** – Upload the JSON schema file provided for the model.
- **Advanced settings** – QuickSight recommends the selected defaults based on your dataset. You can use specific runtime settings to balance the speed and cost of your job. To do this, enter the SageMaker AI ML instance types for **Instance type** and number of instances for **Count**.

Choose **Next** to continue.

4. For **Review inputs**, review the fields that are mapped to your dataset. Quick Sight attempts to automatically map the fields in your schema to the fields in your dataset. You can make changes here if the mapping needs adjustment.

Choose **Next** to continue.

5. For **Review outputs**, view the fields that are added to your dataset.

Choose **Save and prepare data** to confirm your choices.

6. To refresh the data, choose the dataset to view details. Then either choose **Refresh Now** to manually refresh the data, or choose **Schedule refresh** to set up a regular refresh interval. During each data refresh, the system automatically runs the SageMaker AI batch transform job to update the output fields with new data.

Build predictive models with SageMaker AI Canvas

Amazon Quick authors can export data into SageMaker AI Canvas to build ML models that can be sent back to Quick. Authors can use these ML models to augment their datasets with predictive analytics that can be used to build analyses and dashboards.

Prerequisites

- A Quick account that's integrated with IAM Identity Center. If your Quick account isn't integrated with IAM Identity Center, create a new Quick account and choose **Use IAM Identity Center enabled application** as the identity provider.
 - For more information on IAM Identity Center, see [Getting started](#).
 - To learn more about integrating your Quick with IAM Identity Center, see [Configure your Amazon Quick account with IAM Identity Center](#).

- To import assets from an existing Quick account to a new Quick account that's integrated with IAM Identity Center, see [Asset bundle operations](#).
- A new SageMaker AI domain that is integrated with IAM Identity Center. For more information about onboarding to SageMaker AI Domain with IAM Identity Center, see [Onboard to SageMaker AI Domain using IAM Identity Center](#).

Topics

- [Build a predictive model in SageMaker AI Canvas from Amazon Quick Sight](#)
- [Create a dataset with a SageMaker AI Canvas model](#)
- [Considerations](#)

Build a predictive model in SageMaker AI Canvas from Amazon Quick Sight

To build a predictive model in SageMaker AI Canvas

1. Log in to Amazon Quick and navigate to the tabular table or pivot table that you want to create a predictive model for.
2. Open the on-visual menu and choose **Build a predictive model**.
3. In the **Build a predictive model in SageMaker AI Canvas** pop up that appears, review the information presented and then choose **EXPORT DATA TO SAGEMAKER CANVAS**.
4. In the **Exports** pane that appears, choose **GO TO SAGEMAKER CANVAS** when the export is completed to go to the SageMaker AI Canvas console.
5. In SageMaker AI Canvas, create a predictive model with the data that you exported from Quick Sight. You can choose to follow a guided tour that helps you create the predictive model, or you can skip the tour and work at your own pace. For more information about creating a predictive model in SageMaker AI Canvas, see [Build a model](#).
6. Send the predictive model back to Quick Sight. For more information about sending a model from SageMaker AI Canvas to Amazon Quick Sight, see [Send your model to Amazon Quick Sight](#).

Create a dataset with a SageMaker AI Canvas model

After you create a predictive model in SageMaker AI Canvas and send it back to Quick Sight, use the new model to create a new dataset or apply it to an existing dataset.

To add a predictive field to a dataset

1. Open the Quick console, choose **Data** at left, and choose the **Datasets** tab.
2. Upload a new dataset or choose an existing dataset.
3. Choose **Edit**.
4. On the dataset's data prep page, choose **ADD**, and then choose **Add predictive field** to open the **Augment with SageMaker AI** modal.
5. For **Model**, choose the model that you sent to Quick Sight from SageMaker AI Canvas. The schema file automatically populates in the **Advanced settings** pane. Review the inputs, and then choose **Next**.
6. On the **Review outputs** pane, enter a field name and description for a column to be targeted by the model that you created in SageMaker AI Canvas.
7. When you are finished, choose **Prepare data**.
8. After you choose **Prepare data**, you are redirected to the dataset page. To publish the new dataset, choose, **Publish & Visualize**.

When you publish a new dataset that uses a model from SageMaker AI Canvas, the data is imported into SPICE and a batch inference job begins in SageMaker AI. It can take up to 10 minutes for these processes to complete.

Considerations

The following limitations apply to the creation of SageMaker AI Canvas models with Quick Sight data.

- The **Build a predictive model** option that is used to send data to SageMaker AI Canvas is only available on table and tabular pivot table visuals. The table or pivot table visual must have between 2 and 1,000 fields and at least 500 rows.
- Datasets that contain integer or geographic data types will experience schema mapping errors when you add a predictive field to the dataset. To resolve this issue, remove the integer or geographic data types from the dataset or convert them to a new data type.

Preparing dataset examples

You can prepare data in any dataset to make it more suitable for analysis, for example changing a field name or adding a calculated field. For database datasets, you can also determine the data used by specifying a SQL query or joining two or more tables.

Use the following topics to learn how to prepare datasets.

Topics

- [Preparing a dataset based on file data](#)
- [Preparing a dataset based on Salesforce data](#)
- [Preparing a dataset based on database data](#)

Preparing a dataset based on file data

Use the following procedure to prepare a dataset based on text or Microsoft Excel files from either your local network or Amazon S3.

To prepare a dataset based on text or Microsoft Excel files from a local network or S3

1. Open a file dataset for data preparation by choosing one of the following options:
 - Create a new local file dataset, and then choose **Edit/Preview data**. For more information about creating a new dataset from a local text file, see [Creating a dataset using a local text file](#). For more information about creating a new dataset from a Microsoft Excel file, see [Creating a dataset using a Microsoft Excel file](#).
 - Create a new Amazon S3 dataset, and then choose **Edit/Preview data**. For more information about creating a new Amazon S3 dataset using a new Amazon S3 data source, see [Creating a dataset using Amazon S3 files](#). For more information about creating a new Amazon S3 dataset using an existing Amazon S3 data source, see [Creating a dataset using an existing Amazon S3 data source](#).
 - Open an existing Amazon S3, text file, or Microsoft Excel dataset for editing, from either the analysis page or the **Your Datasets** page. For more information about opening an existing dataset for data preparation, see [Editing datasets](#).
2. (Optional) On the data preparation page, enter a new name into the dataset name box on the application bar.

This name defaults to the file name for local files. For example, it defaults to **Group 1** for Amazon S3 files.

3. Review the file upload settings and correct them if necessary. For more information about file upload settings, see [Choosing file upload settings](#).

 Important

If you want to change upload settings, make this change before you make any other changes to the dataset. New upload settings cause Amazon Quick Sight to reimport the file. This process overwrites all of your other changes.

4. Prepare the data by doing one or more of the following:
 - [Selecting fields](#)
 - [Editing field names and descriptions](#)
 - [Changing a field data type](#)
 - [Adding calculated fields](#)
 - [Filtering data in Amazon Quick Sight](#)
5. Check the [SPICE](#) indicator to see if you have enough capacity to import the dataset. File datasets automatically load into SPICE. The import happens when you choose either **Save & visualize** or **Save**.

If you don't have access to enough SPICE capacity, you can make the dataset smaller by using one of the following options:

- Apply a filter to limit the number of rows.
- Select fields to remove from the dataset.

 Note

The SPICE indicator doesn't update to how much space you save by removing fields or filtering the data. It continues to reflect the SPICE usage from the last import.

6. Choose **Save** to save your work, or **Cancel** to cancel it.

You might also see **Save & visualize**. This option appears based on the screen that you started from. If this option isn't there, you can create a new visualization by starting from the dataset screen.

Preparing a dataset based on a Microsoft Excel file

Use the following procedure to prepare a Microsoft Excel dataset.

To prepare a Microsoft Excel dataset

1. Open a text file dataset for preparation by choosing one of the following options:
 - Create a new Microsoft Excel dataset, and then choose **Edit/Preview data**. For more information about creating a new Excel dataset, see [Creating a dataset using a Microsoft Excel file](#).
 - Open an existing Excel dataset for editing. You can do this from the analysis page or the **Your Datasets** page. For more information about opening an existing dataset for data preparation, see [Editing datasets](#).
2. (Optional) On the data preparation page, enter a name into the dataset name box in the application bar. If you don't rename the dataset, its name defaults to the Excel file name.
3. Review the file upload settings and correct them if necessary. For more information about file upload settings, see [Choosing file upload settings](#).

Important

If it's necessary to change upload settings, make this change before you make any other changes to the dataset. Changing upload settings causes Amazon Quick Sight to reimport the file. This process overwrites any changes you have made so far.

4. (Optional) Change the worksheet selection.
5. (Optional) Change the range selection. To do this, open **Upload Settings** from the on-dataset menu beneath the login name at upper right.
6. Prepare the data by doing one or more of the following:
 - [Selecting fields](#)
 - [Editing field names and descriptions](#)

- [Changing a field data type](#)
 - [Adding calculated fields](#)
 - [Filtering data in Quick Sight](#)
7. Check the [SPICE](#) indicator to see if you have enough space to import the dataset. Amazon Quick Sight must import Excel datasets into SPICE. This import happens when you choose either **Save & visualize** or **Save**.

If you don't have enough SPICE capacity, you can choose to make the dataset smaller using one of the following methods:

- Apply a filter to limit the number of rows.
- Select fields to remove from the dataset.
- Define a smaller range of data to import.

 Note

The SPICE indicator doesn't update to reflect your changes until after you load them. It shows the SPICE usage from the last import.

8. Choose **Save** to save your work, or **Cancel** to cancel it.

You might also see **Save & visualize**. This option appears based on the screen that you started from. If this option isn't there, you can create a new visualization by starting from the dataset screen.

Preparing a dataset based on Salesforce data

Use the following procedure to prepare a Salesforce dataset.

To prepare a Salesforce dataset

1. Open a Salesforce dataset for preparation by choosing one of the following options:
 - Create a new Salesforce dataset and choose **Edit/Preview data**. For more information about creating a new Salesforce dataset using a new Salesforce data source, see [Creating a dataset from Salesforce](#). For more information about creating a new Salesforce dataset using an existing Salesforce data source, see [Create a dataset using an existing Salesforce data source](#).

- Open an existing Salesforce dataset for editing from either the analysis page or the **Your Datasets** page. For more information about opening an existing dataset for data preparation, see [Editing datasets](#).
2. (Optional) On the data preparation page, enter a name into the dataset name box in the application bar if you want to change the dataset name. This name defaults to the report or object name.
 3. (Optional) Change the data element selection to see either reports or objects.
 4. (Optional) Change the data selection to choose a different report or object.

If you have a long list in the **Data** pane, you can search to locate a specific item by entering a search term into the **Search tables** box. Any item whose name contains the search term is shown. Search is case-insensitive and wildcards are not supported. Choose the cancel icon (X) to the right of the search box to return to viewing all items.

5. Prepare the data by doing one or more of the following:
 - [Selecting fields](#)
 - [Editing field names and descriptions](#)
 - [Changing a field data type](#)
 - [Adding calculated fields](#)
 - [Filtering data in Quick Sight](#)
6. Check the [SPICE](#) indicator to see if you have enough space to import the dataset. Importing data into SPICE is required for Salesforce datasets. Importing occurs when you choose either **Save & visualize** or **Save**.

If you don't have enough SPICE capacity, you can remove fields from the dataset or apply a filter to decrease its size. For more information about adding and removing fields from a dataset, see [Selecting fields](#).

 Note

The SPICE indicator doesn't update to reflect the potential savings of removing fields or filtering the data. It continues to reflect the size of the dataset as retrieved from the data source.

7. Choose **Save** to save your work, or **Cancel** to cancel it.

You might also see **Save & visualize**. This option appears based on the screen you started from. If this option isn't there, you can create a new visualization by starting from the dataset screen.

Preparing a dataset based on database data

Use the following procedure to prepare a dataset based on a query to a database. The data for this dataset can be from an AWS database data source like Amazon Athena, Amazon RDS, or Amazon Redshift, or from an external database instance. You can choose whether to import a copy of your data into [SPICE](#), or to query the data directly.

To prepare a dataset based on a query to a database

1. Open a database dataset for preparation by choosing one of the following options:
 - Create a new database dataset and choose **Edit/Preview data**. For more information about creating a new dataset using a new database data source, see [Creating a dataset from a database](#). For more information about creating a new dataset using an existing database data source, see [Creating a dataset using an existing database data source](#).
 - Open an existing database dataset for editing from either the analysis page or the **Your Datasets** page. For more information about opening an existing dataset for data preparation, see [Editing datasets](#).
2. (Optional) On the data preparation page, enter a name into the dataset name box on the application bar.

This name defaults to the table name if you selected one before data preparation. Otherwise, it's **Untitled data source**.

3. Decide how your data is selected by choosing one of the following:
 - To use a single table to provide data, choose a table or change the table selection.

If you have a long table list in the **Tables** pane, you can search for a specific table by typing a search term for **Search tables**.

Any table whose name contains the search term is shown. Search is case-insensitive and wildcards are not supported. Choose the cancel icon (X) to the right of the search box to return to viewing all tables.

- To use two or more joined tables to provide data, choose two tables and join them using the join pane. You must import data into Quick Sight if you choose to use joined tables. For more information about joining data using the Amazon Quick Sight interface, see [Joining data](#).
- To use a custom SQL query to provide data in a new dataset, choose **Switch to Custom SQL** tool on the **Tables** pane. For more information, see [Using SQL to customize data](#).

To change the SQL query in an existing dataset, choose **Edit SQL** on the **Fields** pane to open the SQL pane and edit the query.

4. Prepare the data by doing one or more of the following:

- [Selecting fields](#)
- [Editing field names and descriptions](#)
- [Changing a field data type](#)
- [Adding calculated fields](#)
- [Filtering data in Quick Sight](#)

5. If you aren't joining tables, choose whether to query the database directly or to import the data into SPICE by selecting either the **Query** or **SPICE** radio button. We recommend using SPICE for enhanced performance.

If you want to use SPICE, check the SPICE indicator to see if you have enough space to import the dataset. Importing occurs when you choose either **Save & visualize** or **Save**.

If you don't have enough space, you can remove fields from the dataset or apply a filter to decrease its size.

 Note

The SPICE indicator doesn't update to reflect the potential savings of removing fields or filtering the data. It continues to reflect the size of the dataset as retrieved from the data source.

6. Choose **Save** to save your work, or **Cancel** to cancel it.

You might also see an option to **Save & visualize**. This option appears based on the screen you started from. If this option isn't there, you can create a new visualization by starting from the dataset screen.

Analyses and reports: Visualizing data in Amazon Quick Sight

Following, you can find descriptions of how to create and customize Amazon Quick Sight charts, arrange charts in a dashboard, and more.

Topics

- [Working with an analysis in Amazon Quick Sight](#)
- [Adding and managing sheets](#)
- [Working with interactive sheets in Amazon Quick Sight](#)
- [Working with pixel perfect reports in Amazon Quick Sight](#)
- [Working with items on sheets in Amazon Quick Sight analyses](#)
- [Using themes in Amazon Quick Sight](#)
- [Accessing Amazon Quick Sight using keyboard shortcuts](#)

Working with an analysis in Amazon Quick Sight

In Quick Sight, an analysis is the same thing as a dashboard, except that it can only be accessed by the authors you choose. You can keep it private, and make it as robust and detailed as you like. When and if you decide to publish it, the shared version of it is called a dashboard.

Use the following sections to learn how to interact with a Quick Sight analysis.

Topics

- [Starting an analysis in Quick Sight](#)
- [Generating an analysis with natural language prompts](#)
- [Adding a title and description to an analysis](#)
- [Sharing Quick Sight analyses](#)
- [Renaming an analysis](#)
- [Duplicating analyses](#)
- [Customize date and time values of an analysis](#)
- [The analysis menu](#)
- [Configure analysis settings](#)
- [Item limits for Amazon Quick Sight analyses in the Quick Sight APIs](#)
- [Saving changes to analyses](#)

- [Exporting data from Quick Sight analyses](#)
- [Deleting an analysis](#)

Starting an analysis in Quick Sight

In Quick Sight, you analyze and visualize your data in analyses. When you're finished, you can publish your analysis as a dashboard to share with others in your organization.

Use the following procedure to create a new analysis.

To create a new analysis

1. On the Amazon Quick start page, choose **Analyses**, and then choose **New analysis**.
2. Choose the dataset that you want to include in your new analysis, and then choose **USE IN ANALYSIS** in the top right.
3. In the **New sheet** pop-up that appears, choose the sheet type that you want. You can choose between an **Interactive sheet** and a **Pixel perfect report**. To create a pixel perfect report, you need the pixel perfect reports add-on for your account. For more information about pixel perfect reports, see [Working with pixel perfect reports in Amazon Quick Sight](#). For more information on sheets, see [Adding and managing sheets](#).
4. (Optional) If you choose **Interactive sheet**, follow these steps:
 - (Optional): Choose the type layout that you want for your interactive sheet. You can choose one of the following options:
 - Free-form
 - Tiled

The default option is **Free-form**.

For more information about interactive sheet layouts, see [Types of layout](#).

- Choose the canvas size that you want your sheet optimized for. You can choose one of the following options:
 - 1024px
 - 1280px
 - 1366px
 - 1600px

- 1920px

For more information on formatting interactive sheets, see [Working with interactive sheets in Amazon Quick Sight](#).

5. (Optional) If you choose **Pixel perfect report**, follow these steps:

- (Optional) Choose the paper size that you want for your paginated report. You can choose from the following options:
 - US letter (8.5 x 11 in.)
 - US legal (8.5 x 14 in.)
 - A0 (841 x 1189 mm)
 - A1 (594 x 841 mm)
 - A2 (420 x 594 mm)
 - A3 (297 x 420 mm)
 - A4 (210 x 297 mm)
 - A5 (148 x 210 mm)
 - Japan B4 (257 x 364 mm)
 - Japan B5 (182 x 257 mm)

The default paper size is US letter (8.5 x 11 in.)

- (Optional) Choose the orientation of the sheet. You can choose between **Portrait** or **Landscape**. The default option is portrait.

Before you can create Amazon Quick Sight pixel perfect reports, first get the pixel perfect reporting add-on for your Quick account. For more information on getting the pixel perfect reporting add-on, see [Get the Quick pixel perfect reports add-on](#).

For more information on formatting pixel perfect reports, see [Working with pixel perfect reports in Amazon Quick Sight](#).

6. Choose **Add**.

7. Create a visual. For more information about creating visuals, see [Adding visuals to Quick Sight analyses](#).

After you are done creating the analysis, you can iterate on it by modifying the visual, adding more visuals, adding scenes to the default story, or adding more stories.

You can also generate a complete multi-sheet analysis from a natural language prompt. For more information, see [Generating an analysis with natural language prompts](#).

Generating an analysis with natural language prompts

With Quick Sight, you can use artificial intelligence (AI) to author analyses in three ways within the analysis authoring experience. You can generate a full, multi-sheet analysis from a natural language prompt (Generate Analysis). You can generate a single sheet within an open analysis (Generate Sheet). You can also generate an analysis from an image. This topic describes the full-analysis flow. The following sections describe the two additional flows.

To generate a full analysis, describe the analysis or dashboard that you want, and select up to three datasets. Before generation begins, you can review and modify an interactive plan that outlines the proposed structure. When you generate, Quick Sight creates multiple organized sheets with visuals, filter controls, and calculated fields such as year-over-year growth and month-over-month comparisons.

The generated output is a native Quick Sight analysis. It works with existing publishing workflows, embedding patterns, CI/CD pipelines, and point-and-click editing in the analysis surface. After generation, you can refine each visual.

Prerequisites

To generate an analysis from a natural language prompt, you need the following:

- An AWS account
- Amazon Quick Enterprise Edition with at least one Author Pro user
- At least one dataset in your Quick Sight account

Generating an analysis

Use the following procedure to generate an analysis from a natural language prompt.

To generate an analysis from a natural language prompt

1. Do one of the following:
 - Open a dataset and choose **Generate analysis**.
 - From the **Analyses** page, choose **Generate analysis**.

2. Choose **Add data** to select one to three datasets for the analysis. If your data spans multiple tables (for example, orders in one dataset and products in another), you can select them together.

3. Enter a natural language prompt that describes the analysis that you want to create. You can describe the business questions that you want answered, the metrics that you care about, and how you want the information organized across sheets.

Example prompt:

"Create an operations dashboard showing order volume trends, revenue KPIs, delivery performance comparing estimated vs actual delivery dates, and product category breakdown by revenue and order count. Include calculated fields for total revenue, average order value, and month-over-month order growth."

4. Do one of the following:
 - Choose **Generate analysis** to begin generation immediately.
 - Choose **Preview analysis outline** to review an outline first.
5. Wait while Quick Sight analyzes your dataset structure and column statistics. Real-time progress updates display the current status.

Note

If you navigate away from the progress screen, you can check the generation status on the **Analyses** page by choosing the **Generations** tab. Choose the generation name to return to the progress screen.

6. Quick Sight presents a two-pane view:

- The left pane shows your initial prompt and a summary of the selected datasets.
- The right pane shows the proposed filter controls, sheets, and visuals planned for each sheet.

You can edit sheet names, add or remove visuals, adjust the plan, and refine the prompt before generating.

7. Choose **Generate**. Real-time progress updates display the current status. Generation takes 2 to 5 minutes depending on the number of sheets and visuals.

Publishing a generated analysis

After you are satisfied with the generated analysis, choose **Publish** to create a dashboard.

You can share the dashboard with other users, embed it in applications, or schedule email deliveries. For more information about publishing and sharing, see [Publishing dashboards](#) and [Sharing Quick Sight analyses](#).

Generating a single sheet

Within an open analysis, you can generate a single sheet with AI instead of generating a full analysis. Use the following procedure to generate a single sheet.

To generate a single sheet

1. In an open analysis, choose the + (plus) next to the sheet tabs.
2. In the **New sheet** dialog, select **Interactive sheet**, then choose **Generate**. Choosing **Add** creates a blank sheet to build by hand, and **Generate** starts the AI flow. **Generate** is available for interactive sheets only.
3. On the **Generate sheet** screen, select one or more datasets that are already part of the analysis, write a prompt that describes the sheet, and choose **Generate**.
4. Quick Sight adds the sheet with visuals selected for the data, filter controls, and calculated fields such as year-over-year growth and month-over-month comparisons.

Adding an image to your prompt

You can generate an analysis from an image of a dashboard, including dashboards from other business intelligence (BI) tools. Use the following procedure to add an image to your prompt.

To add an image to your prompt

1. From the **Visualize your data with AI** prompt, choose **Add image** (located next to **+ Add data**) to attach an image of a dashboard.
2. Quick Sight reads the image and builds the sheets and visuals that Quick Sight supports.

Adding a title and description to an analysis

In addition to the analysis name, you can add a title and description to an analysis. A useful title and description provides context about the information in the analysis.

Add a title and description

Use the following procedure to add a title and description to an analysis. Titles and descriptions can contain up to 1,024 characters. Titles and descriptions are not supported for pixel perfect reports.

To add a title and description to an analysis

1. On the analysis page, choose **Sheets** in the application bar and then choose **Add title**.
2. For **Sheet title**, enter a title and press **Enter**. To remove a title, choose **Sheets** in the application bar and then choose **Delete title**. Or, to remove the title, you can select the title and then choose the x-shaped delete icon.

To create a dynamic sheet title, you can add existing parameters to the sheet title. For more information, see [Using parameters in titles and descriptions in Amazon Quick](#).

3. Choose **Sheets** in the application bar, and then choose **Add description**.
4. In the description space that appears on the sheet, enter the description that you want and press **Enter**. To remove a description, choose **Sheets** in the application bar and then choose **Delete description**. Or, to remove the description, you can select the description and then choose the x-shaped delete icon.

Sharing Quick Sight analyses

You can share an analysis with one or more other users by emailing them a link, making it easy to collaborate and disseminate findings. You can only share an analysis with other users in your Quick account.

After you share an analysis, you can review the other users who have access to it, and also revoke access from any user.

Topics

- [Sharing an analysis](#)
- [Viewing the users that an analysis is shared with](#)
- [Revoking access to an analysis](#)

Sharing an analysis

Use the following procedure to share an analysis.

To share an analysis

1. Open the [Quick console](#).
2. Open the analysis that you want to change.
3. On the analysis page, choose **File** on the application bar, and then choose **Share**.

You can only share analyses with users or groups who are in your Quick account.

4. Add a user or group to share with. To do this, for **Type a user name or email**, enter the first user or group that you want to share this analysis with. Then choose **Share**. Repeat this step until you have entered information for everyone you want to share the analysis with.

To edit sharing permissions for this analysis, choose **Manage analysis permissions**.

The **Manage analysis permissions** screen appears. On this screen, choose **Invite user** to edit permissions and add more users or groups.

5. For **Permission**, choose the role to assign to each user or group. The role determines the permission level to grant to that user or group.
6. Choose **Share**.

The users that you have shared the analysis with get emails with a link to the analysis. Groups don't receive invitation emails.

Viewing the users that an analysis is shared with

If you have shared an analysis, you can use the following procedure to see which users or groups have access to it.

To view which users or groups have access to an analysis

1. Open the [Quick console](#).
2. Open the analysis that you want to change.
3. On the analysis page, choose **File** on the application bar, and then choose **Share**.
4. Choose **Manage analysis permissions**.
5. Review who this analysis has been shared with. You can search to locate a specific account by typing a search term. The search returns any user, group, or email address that contains the search term. Searching is case-sensitive, and wildcards are not supported. Delete the search term to view all users and groups.

Revoking access to an analysis

Use the following procedure to revoke access to an analysis.

To revoke access to an analysis

1. Open the [Quick console](#).
2. Open the analysis that you want to change.
3. On the analysis page, choose **File** on the application bar, and then choose **Share**.
4. Choose **Manage analysis permissions**.
5. Locate the user or group whose access you want to revoke, and then choose the trash-can icon next to the user or group.
6. Choose **Confirm**.

Renaming an analysis

Use the following procedure to rename an analysis.

To rename an analysis

1. Open the analysis that you want to rename.
2. In the **Analysis name** box in the application bar, select the current name and then enter a new name.

Duplicating analyses

You can duplicate analyses in Quick Sight. Use the following procedure to learn how.

To duplicate an analysis

1. From the Quick homepage, choose **Analyses**, and then open the analysis that you want to duplicate.
2. In the analysis, choose **Save as** in the application bar at upper right.
3. In the **Save a copy** page that opens, enter a name for the analysis, and then choose **Save**.

The new analysis opens. You can find the original analysis by returning to the Quick start page and selecting **Analyses**.

Customize date and time values of an analysis

In Amazon Quick, authors can set custom time zones and week start days of an analysis. When you set a custom week start or time zone, all visuals in the analysis that use datetime data are formatted to reflect the time zone or week start that the analysis uses.

Setting custom time zones in an analysis

Quick authors can use *custom time zones* to help manage data across multiple geographic regions. When you set a custom time zone, all visible dimensions, measures, calculated fields, and filters are converted to the chosen time zone at query run time. Daylight Savings Time (DST) adjustments are applied automatically to eliminate the need for time consuming workarounds that don't accurately handle historical dates.

Custom time zones refer to the use of IANA time zone abbreviations that represent specific geographic regions around the world. Each time zone is defined as an offset from Coordinated Universal Time (UTC). Time zones are different from simple offsets because they incorporate DST.

The default time zone for all analyses is UTC.

The following rules apply to time zones.

- **Datetime displays with a granularity that is lower than hour are converted to the selected time zone.** For example, if you set the timezone of an analysis to `America/New_York` (UTC-04:00), the datetime value `Dec.1, 2020 12:00am` in UTC+00:00 is converted and displayed as `Nov.30, 2020 7:00pm`. Daylight Savings Time (DST) is incorporated into the datetime conversion.
- **Datetime literals that are added to calculations or selected in filters honor the selected time zone of the analysis.** For example, if you manually enter a literal into a calculated field such as `01-01-2022 7:00pm`, or select a fixed filter time, Quick Sight applies the chosen timezone to the literal value.
- **Measures that are aggregated above the hour/minute granularity are aggregated based on the timezone that the analysis is set to.** When Quick Sight processes a dataset, all timestamps are initially converted at the lowest granularity level. Values are then aggregated based on the boundary of the selected time zone for the analysis. For example, a sum of hourly revenues at the day level with a UTC+00:00 time zone aggregate all hourly revenues from 12am-11pm for the UTC time zone. When you convert UTC+00:00 to `New_York` (UTC-04:00), all revenue datapoints are aggregated from 8:00pm-7:00pm(+1day) in UTC to correspond with the start and end of the day in `New_York` (UTC-04:00).
- **The `now()` function, rolling date filter, and parameters are converted to the chosen time zone.** Relative date filters, rolling date filters, and relative date parameters that use the `now()` function also honor the chosen time zone when they are applied to the visual. For example, when you select a relative filter such as `last week` or a rolling date filter such as `start of the month`, the chosen timezone is automatically applied to the filter to display the values `last week of New_York time zone` and `start of the month of New_York time zone`, respectively.

To set the custom time zone of an analysis

1. From the analysis that you want to change, navigate to the top menu and choose **Edit**.
2. Choose **Analysis settings**, and then choose **Date and time**.
3. Toggle **Convert time zone** ON, and choose the **Time zone** that you want.
4. Choose **Apply**.

When an analysis is assigned a time zone, an icon appears at the top of the analysis that indicates which time zone the analysis uses. This icon also appears on any dashboard that is published from the analysis.

Considerations

The following considerations apply to custom time zones.

- To use custom time zones, all datetime columns in a dataset must be normalized to UTC. If your datetime columns aren't normalized in your data source, you need to convert the columns in your data source before you can use this feature.
- For analyses that are not assigned a custom time zone, author and reader experiences are unaffected.
- Once a time zone is added to an analysis, the time zone is applied to all visuals and sheets in the analysis.
- Quick authors can choose only one time zone for an analysis. All dashboards that are published from the analysis use the time zone that the analysis uses. To create a dashboard that uses a different time zone than the one that the analysis uses, change the time zone of the analysis and republish the dashboard.
- Quick readers can't change the time zone of a dashboard.
- If you set the time zone of an analysis that uses a dataset that is stored in Direct Query and experience slow load times, consider storing the dataset in SPICE. SPICE is engineered to handle time zone conversions in a performant way.
- Custom time zones do not support the following database engines:
 - Timestream
 - OpenSearch Service
 - Teradata
 - SqlServer

Setting custom week start days in an analysis

Quick authors can define the week start day of an analysis to align their data with the schedule that their company or industry follows. When you set a custom week start day, all dimensions, calculated fields, and filters that are aggregated at the week level are calculated to align with the new week start day. The default week start day is Sunday.

To set the custom week start day of an analysis

1. From the analysis that you want to change, navigate to the top menu and choose **Edit**.
2. Choose **Analysis settings**, and then choose **Date and time**.
3. For **Custom start day**, choose the start day that you want.
4. Choose **Apply**.

Considerations

The following considerations apply to custom week start days.

- Datetime fields are converted at run time. When you work with calculated fields that use datetime values, define the fields at the analysis level instead of the dataset level.
- Once you choose a new week start day, the change is applied to all visuals and sheets in the analysis.
- Quick authors can choose only one week start day for an analysis. All dashboards that are published from the analysis use the week start day that the analysis uses. To create a dashboard that uses a different week start day than the one that the analysis uses, change the week start day of the analysis and republish the dashboard.
- Quick readers can't change the week start day of a dashboard.

The analysis menu

While working on an analysis, Amazon Quick provides several menu options. You use these menu options to efficiently perform tasks without needing to manually navigate through your analysis to find the assets that you want to change.

You can use these options to perform the following tasks.

- *File* – Perform analysis management tasks, including creating, sharing, and publishing. Authors can use this option to make changes across all sheets or visuals in an analysis.
- *Edit* – Navigate between changes that you make to the analysis. You can undo or redo changes that you make.
- *Data* – Manage datasets, data fields, and parameters. Changes that you make by using this option are applied to all sheets in the analysis.

- *Insert* – Use an ingress point where you can add visuals, text boxes, insights, reporting objects, filters, and parameters to an analysis. The content that you insert can be data or objects.
- *Sheets* – Manage the sheet settings of the analysis, including layout settings, actions to add or remove assets from a sheet, and sheet properties.
- *Objects* – Manage objects and their features, including style, canvas placement, sizing, card background, and borders. You can also manage these objects by using the **Properties** pane when working on a visual object.
- *Search* – Access the *Quick search* bar. Quick search is a search bar that will begin showing results for the asset you are searching for as you type. The suggested results continue to modify as you type until you see the result that you're looking for.

To use quick search, open the **Search** menu, and in the **Search analysis actions** box, begin typing a name or phrase associated with the asset you are trying to find.

Configure analysis settings

Amazon Quick authors can use the Analysis settings menu to configure the refresh and date time settings of an analysis. To access the Analysis Settings menu, choose **Edit**, and then choose **Analysis Settings**. The following settings can be configured in the Analysis settings menu:

Refresh settings

- **Reload visuals every time I switch sheets** – Use this setting to reload every visual in a Quick Sight analysis whenever the user switches to a different sheet in the analysis.
- **Update visuals manually** – Use this setting to only update applicable visuals in an analysis when the user applies their changes. When this setting is toggled on, the analysis loads the visuals blank by default because the queries won't be fired until the user selects the **UPDATE VISUALS** button located in the toolbar or on the impacted visuals. The **UPDATE VISUALS** button confirms that the user is finished with the filter and control choices that they want to apply to the affected visuals. The image below shows the **UPDATE VISUALS** button.

When **Update visuals manually** is toggled on, authors can still add visuals, edit visuals, and edit control selections, but the affected visuals won't update until the author applies the new changes. This allows authors to build analyses without increasing their database load and gives better control over which values are loaded in an analysis.

Date and time settings

- **Convert time zone** – Use this setting to convert all date field related visualizations, filters, and parameters to reflect the chosen time zone. All daylight savings adjustments are made automatically. For more information about time zone configuration, see [Customize date and time values of an analysis](#).
- **Start of the week** – Use this setting to choose the week start day for an analysis.

Interactivity

- Use this setting to highlight specific data points across visuals in a sheet. When you select or hover over a data point on a visual, related data across other visuals will stand out, while unrelated data is dimmed. Highlighting allows you to understand correlations, spot patterns, trends, and outliers, and facilitate stronger, more informed analyses. Select either **On selection** or **On hover** to turn highlighting on, or **No highlight** to turn it off.
- To customize highlighting on a per-sheet level see [Adding and managing sheets](#).

No data message customization

- Use this setting to control the message displayed when a visual in the analysis returns no data. Customizing this can give readers of the dashboards reasons why no data is shown and potential fixes. Parameters are supported for all text input.
- **Title and subtitle** – Use these settings to customize the text shown on the message title or subtitle and to toggle visibility of either option.
- **Hyperlink** – Use this setting to control the hyperlink displayed at the bottom of the message. The link label field controls the displayed text of the hyperlink, while the link URL field controls where the user is redirected when clicking the hyperlink text. Only http://, https://, and mailto: URL schemas are supported.
- **Pixel-perfect reporting** – In pixel-perfect (paginated) report output, hyperlinks are rendered as clickable links, not as static display text. To show the full URL in a printed report, enter the full URL as the link label so it remains visible in the static output.
- **Dataset or data refresh errors** – The no data message customization applies only to visuals that return zero rows of data. Dataset or data refresh errors are a separate error type and are not customizable as part of this feature.

Item limits for Amazon Quick Sight analyses in the Quick Sight APIs

Use the following table to review the current limits or quotas for different analysis items in Amazon Quick Sight that are created and managed with the Amazon Quick Sight APIs. If your analysis contains more than the supported number of analysis items, remove items to optimize the performance of the analysis. New analysis items cannot be added to an analysis that contains more than the supported number of analysis items.

Analysis item	Limit
Sheets	20 sheets per analysis
Visuals	50 visuals per sheet
Calculated fields	500 per analysis and 200 per dataset*
Bookmarks	200 per dashboard
Custom actions	10 per visual
Filter groups	2000 per analysis
Filters	20 filters per filter group
Parameters	400 per analysis
Controls	200 per sheet
Text boxes	100 per sheet
Image components	10 per sheet
Layer map visuals	5 per sheet

* The per dataset limit applies to calculations that were created in the analysis. Dataset level calculations are not included in this limit. For more information about dataset level calculations, see [Adding calculated fields](#).

Saving changes to analyses

When working on an analysis, you can set Autosave either on (the default) or off. When Autosave is on, your changes are automatically saved every minute or so. When Autosave is off, your changes aren't automatically saved, which means that you can make changes and pursue different lines of inquiry without permanently altering the analysis. If you decide that you want to save your results after all, re-enable Autosave. Your changes up to that point are then saved.

In either Autosave mode, you can undo or redo up to 200 changes that you make by choosing **Undo** or **Redo** on the application bar.

Changing the Autosave mode

Changed to To change the Autosave mode for an analysis, choose **File** and then choose **Autosave On** or **Autosave OFF**.

When Autosave can't save changes

Suppose that one of the following things occurs:

- Autosave is on and another user makes a conflicting change to the analysis.
- Autosave is on and there is a service failure, such that your most recent changes can't be saved.
- Autosave is off, you turn it on, and one of the backlogged changes now being saved to the server conflicts with another user's changes.

In this case, Amazon Quick Sight gives you the option to do one of two things. You can either let Amazon Quick Sight turn Autosave off and continue working in unsaved mode, or reload the analysis from the server and then redo your most recent changes.

If your client authentication expires while you are editing an analysis, you are directed to sign in again. On successful sign-in, you are directed back to the analysis where you can continue working normally.

If your permissions on the analysis are revoked while you are editing it, you can't make any further changes.

Exporting data from Quick Sight analyses

Note

Export files can directly return information from the dataset import. This makes the files vulnerable to CSV injection if the imported data contains formulas or commands. For this reason, export files can prompt security warnings. To avoid malicious activity, turn off links and macros when reading exported files.

You can export data from an analysis to a CSV or PDF file. To export data from an analysis or dashboard to a CSV file, follow the procedure in [Exporting data from visuals](#).

Use the procedure below to export an analysis as a PDF.

1. From the analysis that you want to export, choose **File > Export to PDF**. Quick Sight begins to prepare the analysis for download.
2. Choose **VIEW EXPORTS** in the blue pop-up to open the **Exports** pane on the right.
3. Choose **DOWNLOAD** in the green pop-up.
4. To see all analyses or reports that are ready to download, choose **File** then **Exports**. The Exports panel will open on the right side of the screen. Select **Click to download** next to the file that you want to save to your preferred location.

The process for exporting to a PDF works the same way for both dashboards and analyses.

You can also attach a PDF to dashboard email reports. For more information, see [Scheduling and sending Quick Sight reports by email](#).

Deleting an analysis

If you have the permissions to do so, you can delete an analysis from the **Analyses** page. When you delete an analysis, it doesn't affect any dashboards that are based on that analysis. They continue to show the deleted analysis, but you can't make changes to the analysis once you delete it. Navigate to the Analyses page and find the analysis that you want to remove. Choose the details icon (:) on the analysis, then choose **Delete**. Confirm your choice by choosing **Delete** again. You can't undo this action.

Adding and managing sheets

A *sheet* is a set of visuals that are viewed together in a single page. When you create an analysis, you place visuals in the workspace on a sheet. You can imagine this as a sheet from a newspaper, except that it is filled with data visualizations. You can add more sheets, and make them work separately or together in your analysis.

The top sheet, also called the default sheet, is the one on the far left. This sheet displays on top in an analysis or dashboard. Each analysis can contain up to 20 sheets.

You can share analyses and publish dashboards with multiple sheets. You can also schedule email reports for any combination of sheets in an analysis.

When you create a new analysis or a new sheet in an existing analysis, you choose whether to make the new sheet an **Interactive sheet** or a **Pixel perfect report**. This way, you can have analyses for interactive sheets only, analyses for pixel perfect reports only, or you can have an analysis that includes both interactive sheets and pixel perfect reports.

An *Interactive Sheet* is a collection of data expressed in visuals that users can interact with when the sheet is published to a dashboard. Amazon Quick authors can add different controls and filters to their interactive sheets. Dashboard viewers can use these to gain detailed information from the published data. For more information on interactive sheets, see [Working with interactive sheets in Amazon Quick Sight](#).

A *Paginated Report* is a collection of tables, charts, and visuals that are used to convey business critical information, such as daily transaction summaries or weekly business reports. In order to create pixel perfect reports in Quick Sight, add the **Pixel perfect reporting Add-on** to your Quick account. To get the **Pixel perfect reporting Add-on** and start working with pixel perfect reports, see [Working with pixel perfect reports in Amazon Quick Sight](#).

Use the following list of actions to work with sheets:

- To add a new sheet, choose the plus sign (+) to the right of the sheet tabs, choose the type of sheet that you want, and then choose **ADD**.
- To rename a sheet, choose the name of the sheet and start typing. **Rename** is also available from the sheet menu.
- To duplicate a sheet, choose the name of the sheet, then choose **Duplicate** from the sheet menu. You can only duplicate a sheet if **Autosave** is turned on.

- To duplicate an interactive sheet and convert it to a pixel perfect report, choose the name of the sheet, then choose **Duplicate to report** from the sheet menu. You can't convert a pixel perfect report to an interactive sheet.
- To delete a sheet, choose the name of the sheet, then choose **Delete** from the sheet menu. You can't delete the sheet if it's the only sheet in the analysis.
- To change the order of the sheets, choose the name of the sheet and drag it to a new position.
- To copy a visual to a new sheet, choose **Duplicate visual to** from the on-visual menu. Then choose the target sheet. Filters exist only on the sheet that you create them on. To duplicate filters, recreate them on the target sheet.
- To highlight specific data points across visuals in a sheet, go to the **Sheets** tab and select **Layout Settings**. Under the **Interactivity** section, select either **On selection** or **On hover** to turn highlighting on, or **No highlight** to turn it off. By default, sheet highlighting follows the same settings as analysis highlighting.

When you select or hover over a data point on a visual, related data across other visuals will stand out, while unrelated data is dimmed. Highlighting allows you to understand correlations, spot patterns, trends, and outliers, and facilitate stronger, more informed analyses.

You can use the parameter controls on the top sheet to control multiple sheets. To do this, open each sheet that you want to work with the parameter. Then add a filter that uses the same parameter used in the control on the top sheet. Or, if you want a new sheet to operate independently, you can add parameters and parameter controls to it that are separate from those on the top sheet.

Working with interactive sheets in Amazon Quick Sight

An *Interactive Sheet* is a collection of data expressed in visuals that users can interact with when the sheet is published to a dashboard. Amazon Quick authors can add different layouts, controls, and filters to their interactive sheets that dashboard viewers can use to gain detailed information from the published data. By default, every sheet in an analysis is an interactive sheet. If your account doesn't have the **Pixel perfect reporting Add-on**, you can only create and publish interactive sheets.

For more information on creating an interactive sheet, see [Starting an analysis in Quick Sight](#).

For more information on formatting interactive sheets, see the following topics.

Topics

- [Customizing dashboard layouts in Amazon Quick Sight](#)
- [Parameters in Amazon Quick](#)
- [Using custom actions for filtering and navigating](#)

Customizing dashboard layouts in Amazon Quick Sight

You can customize a dashboard's layout to organize your data to fit your business requirements. You can choose from three dashboard layouts. You can also change the size, background color, border color, and interactions of a visual to create a fully customized dashboard.

Use the following topics to learn more about customizing dashboards and visuals.

Topics

- [Types of layout](#)
- [Choosing a layout](#)
- [Customizing visuals in a free-form layout](#)
- [Conditional rules](#)

Types of layout

There are three dashboard layout designs you can choose from: **Tiled**, **Free-form**, and **Classic**.

Tiled layout

Visuals in a **Tiled** layout snap to a grid with standard spacing and alignment. You can make visuals any size and place them wherever you want within a dashboard, but visuals can't overlap.

Dashboards are displayed as designed, with options to fit to screen or view at actual size. You can also fit an entire dashboard to your window by choosing **Fit to window** for **View**. This option was previously called **Optimized**.

Note

On mobile devices, tiled layout dashboards appear as a single column in portrait mode or exactly as designed in landscape mode.

Free-form layout

Visuals in a **Free-form** layout can be placed anywhere in your dashboard using precise coordinates. You can drag a visual to the exact place you want, or you can enter the coordinates of the visual's location. Use the following procedure to enter the exact coordinates of the visual's location.

Dashboards are displayed the way that you choose to design them, with options to fit to screen or to view at its actual size. You can optimize free-form layouts for viewing at specific resolutions, with the default being 1,600 pixels. You can also fit an entire dashboard to a browser's window by choosing **Fit to window** for **View**.

Note

Dashboards with optimized resolutions might appear bigger or smaller on a viewer's computer if the viewer's computer resolution doesn't equal the set resolution of the dashboard.

Switching from **Free-form** to another layout might cause some visual elements to shift. On mobile devices, **Free-form** dashboards appear as published with no changes to the layout.

Classic layout

Visuals in a **Classic** layout snap to a grid with standard spacing and alignment. Dashboards hide data or change formatting to fit smaller screen sizes. For example, if you change a visual to make it considerably smaller, the on-visual menu and editors are hidden so that the chart elements have more room to display. Bar chart visuals can also display fewer data points.

If you reduce the size of the browser window, Amazon Quick Sight resizes and if necessary reorders visuals for optimal display. For example, smaller visuals that were side by side might be displayed sequentially. The original layout is restored when the size of the browser window is increased again.

Note

On mobile devices, classic layout dashboards appear as a single column or exactly as designed in landscape mode.

Choosing a layout

To change a dashboard's layout

1. Open the [Quick console](#).
2. From the Quick homepage, choose **Analyses**, and then choose the analysis that you want to change.
3. On the analysis page, choose **Edit** and then choose **Analysis Settings**.
4. Expand **Sheet layout** and choose the layout that you want to use.
5. When finished, choose **Apply**.

Customizing visuals in a free-form layout

You can use the free-form layout to fully customize the color, size, location, and visibility of each visual in a dashboard.

Organizing visuals

Besides dragging a visual to its preferred location within a dashboard, there are many different ways to move a visual to the exact location it needs to be.

To enter the coordinates of the visual's location

1. Choose the visual that you want.
2. On the menu in the upper-right corner of the visual, select the **Format visual** icon.
3. In the **Properties** pane that opens, choose **Placement**.
4. Enter the **X** and **Y** coordinates of the location you want to place your visual. You can also adjust the size of the visual by entering **Width** and **Height** values.

Selected visuals can also be moved pixel-by-pixel using your keyboard's arrow keys.

You can overlay visuals on top of one another to create multi-layered visuals that show data.

Visuals can be organized into multiple layers that can be manually moved to the front and back.

To move overlaid visuals to the front and back

1. Choose the visual that you want.
2. On the three-dot menu in the upper-right hand side of the visual, choose **Menu options**.
3. For **Menu options**, choose from the following:
 - **Send to back** sends the visual to the back.
 - **Send backward** sends the visual one layer back.
 - **Bring forward** rings the visual one layer forward.
 - **Bring to front** brings a visual to the front.

Changing a visual's background color

The colors of a visual's background, border, and selection frame can be customized in the **Display settings** pane of the **Properties** pane.

To change the color of a visual's background, border, or selection frame

1. Choose the visual that you want to change.
2. On the menu in the upper-right hand side of the visual, choose the **Properties** icon.
3. In the **Properties** pane that appears on the left, choose **Display settings**.
4. Navigate to the **Card style** section and perform one or more of the available actions:

- To change the color of a visual's background, choose the **Background** color box, and then choose the color that you want.
- To change the color of a visual's border, choose the **Border** color box, and then choose the color that you want.
- To change the color of a visual's selection frame, choose the **Selection** color box, and then choose the color that you want.

If you want to use a custom color for your visual's background, border, or selection frame, choose the color box of the property that you want to change, and then choose **Custom color**. In the **Custom color** window that appears, choose your custom color or enter the color's hexadecimal code. When you are finished, choose **Apply**.

You can also reset a visual's customized background back to its default appearance.

To reset the appearance of a visual

1. Choose the visual that you want to change.
2. On the menu in the upper-right hand side of the visual, choose the **Properties** icon.
3. In the **Properties** pane that appears on the left, choose **Display settings**.
4. Choose the color that you want to reset, and then choose **Reset to default**.

Hiding visual backgrounds, borders, and selection colors

You can also choose not to show the background border, or selection color of a visual. This is useful for when you want to overlap multiple visuals. You can hide a visual's background, border, and selection colors by choosing the eye icon next to the **Border**, **Background**, or **Selection** color boxes. You can also remove a visual's loading animation by clearing the **Show loading animation** box.

Disabling visual menus

Use the **Interactions** panel of the **Properties** pane to hide the **Context** menu and **On-visual** menu from selected visuals. You can hide secondary visual menus to make the visual less crowded or to make a visual act like an overlay.

The **Context** menu opens on data-point clicks. Common actions in the **Context menu** include **Focus**, **Exclude**, and **Drill-down**.

The **On-visual** menu appears on the top-right side of a visual. The **On-visual** menu is used to access the **Properties** pane, **Maximize** the visual, access the **Menu options** panel, and review an **Anomaly insight**.

You can turn off the secondary visual menus by clearing the **Context menu** and **On-visual menu** options.

Note

You can't preview changes to the **Interactions** panel in **Analyses**. Publish the dashboard to view your changes.

Conditional rules

This feature is currently available with the **Free-form** layout. Conditional rules are used to hide or show visuals when specific conditions are met. This can be useful when you have multiple versions of the same visual overlapped with each other and want the dashboard viewer to see a version that best represents the parameter value they select.

Conditional rules use parameters and parameter controls to hide and show visuals. Parameters are named variables that can transfer a value for use by an action or an object. This feature supports string and number parameters. To make the parameters accessible to the dashboard viewer, you add a parameter control. A parameter control allows users to choose a value to use in a predefined filter or URL action. For more information about parameters and parameter controls, see [Parameters in Amazon Quick](#).

Use the sections below to set up and use conditional rules.

Topics

- [Hiding a visual by default](#)
- [Setting a conditional rule](#)
- [Using conditional rules](#)

Hiding a visual by default

In the **Interactions** pane of the **Properties** pane, you can choose to hide a visual by default. Doing this can be useful if you want the viewer to only see visuals based on specific conditions.

To hide a visual by default

1. From the Quick homepage, choose **Analyses**, and then choose the analysis that you want to customize.
2. Choose the visual that you want to add a rule to.
3. On the menu in the upper-right hand side of the visual, choose **Properties**.
4. In the **Properties** pane that opens, choose **Interactions** and open the **Rules** dropdown.
5. In the **Rules** menu, choose **Hide this visual by default**.

Hidden visuals appear fully hidden in a viewing dashboard. In the **Analyses** pane, hidden visuals are visible with the message "Hidden based on rule". With this display, you can see where all of a dashboard's visuals are located.

Note

You can't create conditional rules that hide visuals that are already hidden by default or that show visuals that already appear by default. If you change the default appearance of a visual, existing rules that contradict the new default appearance will be disabled.

Setting a conditional rule

When you set up a conditional rule, you create a conditional statement that will hide or show a visual when a specific condition is met. You can currently create conditional rules that hide or show a visual. If you want to create a conditional rule that makes a hidden visual appear, choose **Hide this visual by default** in the **Rules** menu of the **Properties** pane.

Note

Before you begin, make a parameter and a corresponding parameter control to base your new conditional rule on. Supported parameters are string parameters and number parameters. For more information about parameters and parameter controls, see [Parameters in Amazon Quick](#).

To set a conditional rule

1. From the Quick homepage, choose **Analyses**, and then choose the analysis you want to customize.
2. Choose the visual that you want to add a rule to.
3. On the menu in the upper-right hand side of the visual, choose **Properties**.
4. In the **Properties** pane that appears on the left, choose **Interactions**, and then choose **Rules**.
5. Choose **ADD RULE**.
6. In the first menu in the **Add rule** pane, choose the parameter you want.
7. In the second menu in the **Add rule** pane, choose which condition you want. For string parameters, supported conditions are **Equals**, **Starts with**, **Contains**, and **Does not equal**. For number parameters, supported conditions are **Equals**, **Starts with**, **Contains**, and **Does not equal**.
8. Enter the value you want the conditional rule to meet.

Note

Values are case-sensitive.

9. Choose **Add rule** to apply the new conditional rule to the visual. To cancel the rule, choose **Cancel**.

Conditional rules can also be edited and deleted.

To edit a conditional rule

1. On the menu in the upper-right hand side of the visual, choose **Properties**.
2. In the **Properties** pane that appears on the left, choose **Interactions**, and then choose **Rules**.
3. Choose the menu icon on the right-hand side of the rule you want to edit, and choose **Edit**.
4. Make the changes that you want and choose **Save**.

To delete a conditional rule

1. On the menu in the upper-right hand side of the visual, choose **Properties**.
2. In the **Properties** pane that appears on the left, choose **Interactions**, and then choose **Rules**.

3. Choose the menu icon on the right-hand side of the rule you want to edit and choose **Delete**.

Using conditional rules

Once you have set up a conditional rule that is connected to a parameter and a parameter control, you can use the parameter control to enable or disable the conditional rules you have set.

To enable a conditional rule

1. From the Quick homepage, choose **Analyses**, and then choose the analysis you want to customize.
2. On the **Controls** bar, choose the dropdown icon.
3. Choose the parameter control associated with the conditional rule you created.
4. Choose the value associated with the conditional rule that you created from the parameter's menu. You can also enter the value that you want into the **Search value** box.

Note

Values are case-sensitive.

Selecting the correct value causes the visual to appear or disappear depending on the rule you set.

You can also bring a parameter control to the sheet your visual is on. This is useful when you want a parameter control to be next to the visual it is associated with or when you want to add a conditional rule to the control so it appears only when specific conditions are met.

To bring a parameter control to a sheet

1. From the Quick homepage, choose **Analyses**, and then choose the analysis you want to customize.
2. On the **Controls** bar, choose the control that you want to move.
3. At the upper right-hand side of the control, open the **Menu options** menu.
4. Choose **Move to sheet**.

To move a parameter control back to the Controls bar

1. On your dashboard, select the parameter control you want to move.
2. On the upper right-hand side of the control, open the **Menu options** menu.
3. Choose **Move to top of sheet**.

Parameters in Amazon Quick

Parameters are named variables that can transfer a value for use by an action or an object. By using parameters, you can create an easier way for a dashboard user to interact with dashboard features in a less technical way. Parameters can also connect one dashboard to another, allowing a dashboard user to drill down into data that's in a different analysis.

For example, a dashboard user can use a list to choose a value. That value sets a parameter that in turn sets a filter, calculation, or URL action to the chosen value. Then the visuals in the dashboard react to the user's choices.

To make the parameters accessible to the dashboard viewer, you add a parameter control. You can set up cascading controls, so that a selection in one control filters the options that display in another control. A control can appear as a list of options, a slider, or a text entry area. If you don't create a control, you can still pass a value to your parameter in the dashboard URL.

For a parameter to work, it needs to be connected to something in your analysis, regardless of whether it has a related control. You can reference parameters in the following:

- Calculated fields (except for multivalue parameters)
- Filters
- Dashboard and analysis URLs
- Actions
- Titles and descriptions throughout an analysis

Some ways that you can use parameters are the following:

- Using a calculation, you can transform data that is shown in an analysis.
- If you add a control with a filter to an analysis you are publishing, the dashboard users can filter the data without creating their own filters.
- Using controls and custom actions, you can let dashboard users set values for the URL actions.

Topics

- [Using a control with a parameter in Amazon Quick](#)
- [Creating parameter defaults in Amazon Quick](#)
- [Connecting to parameters in Amazon Quick](#)

Setting up parameters in Amazon Quick

Use the following procedure to create or edit a basic parameter.

To create or edit a basic parameter

1. Choose an analysis to work with, then decide which field you want to parameterize.
2. Choose the **Parameters** icon from the icon list at the top of the page.
3. Add a new parameter by choosing the plus sign (+ **Add**) near the top of the pane.

Edit an existing parameter by first choosing the v-shaped icon near the parameter name and then choosing **Edit parameter**.

4. For **Name**, enter an alphanumeric value for the parameter.
5. For **Data type**, choose **String**, **Number**, **Integer**, or **Datetime**, and then complete the following steps.

- If you choose **String**, **Number**, or **Integer**, do the following:

1. For **Values**, choose **Single value** or **Multiple values**.

Choose the single value option for parameters that can contain only one value. Choose multiple values for parameters that can contain one or more values. Multivalue parameters can't be datetime data types. They also don't support dynamic default values.

To switch an existing parameter between single and multiple values, delete and recreate the parameter.

2. (Optional) For **Static default value** or **Static multiple default values**, enter one or more values.

This type of static value is used during the first page load if a dynamic default value or URL parameter isn't provided.

3. (Optional) Choose **Show as blank by default**.

Select this option to show the default value for multivalue lists as blank. This option only applies to multivalue parameters.

- If you choose **Datetime**, do the following:

1. For **Time granularity**, choose **Day**, **Hour**, **Minute**, or **Second**.

2. For **Default date**, select either **Fixed date** or **Relative date**, and then do the following:

- If you select **Fixed date**, enter a date and time by using the date and time picker.
- If you select **Relative date**, choose a rolling date. You can choose **Today**, **Yesterday**, or you can specify the **Filter condition** (start of or end of), **Range** (this, previous, or next), and **Period** (year, quarter, month, week, or day).

6. (Optional) Choose **Set a dynamic default** to create a default that is user-specific.

A *dynamic default* is a per-user default value for the first page load of the dashboard. Use a dynamic default to create a personalized view for each user.

Calculated fields can't be used as dynamic defaults.

Dynamic defaults don't prevent a user from selecting a different value. If you want to secure the data, you can add row-level locking. For more information, see [Using row-level security with user-based rules to restrict access to a dataset](#).

This option only appears if you choose a single value parameter. Multivalue parameters can't have dynamic defaults.

Note

If you choose a multivalue parameter, the screen changes to remove the default options. Instead, you see a box with the text **Enter values you want to use for this control**. You can enter multiple values in this box, each on a single line. These values are used as the default selected values in the parameter control. The values here are unioned with what you choose to enter for the parameter control. For more information on parameter controls, see [Parameter Controls](#).

- ### 7. (Optional) Set a reserved value to determine the value of the **Select all** value. The *reserved value* of a parameter is the value that is assigned to a parameter when you choose **Select all** as its value. When you set up a specific reserved value for your parameter, that value is no longer

considered a valid parameter value in your dataset. The reserved value can't be used in any *parameter consumers*, such as filters, controls, and calculated fields, and custom actions. Also, it does not appear in the parameter control list. You can choose from **Recommended value**, **Null**, and **Custom value**. **Recommended value** is the default. If you choose **Recommended value**, the reserved value is set to the following values based on the value type:

- Strings: "ALL_VALUES"
- Numbers: "Long.MIN_VALUE"-9,223,372,036,854,775,808
- "Integers: Int.MIN_VALUE"-2147483648

To set a reserved value in your new parameter, choose the **Advanced settings** dropdown list in either the **Create a new parameter** page or the **Edit parameter** page and select the value that you want.

8. Choose **Create** or **Update** to complete creating or updating the parameter.

After you create a parameter, you can use it in a variety of ways. You can create a control (such as a button) so that you can choose a value for your parameter. For more information, see the following sections.

Using a control with a parameter in Amazon Quick

In dashboards, parameter controls appear at the top of the data sheet, which contains a set of visuals. Providing a control allows users to choose a value to use in a predefined filter or URL action. Dashboard users can use controls to apply filtering across all visuals datasets on a dashboard, without having to create the filters themselves.

The following rules apply:

- To create or edit a control for a parameter, make sure that the parameter exists.
- Multiselect list controls are compatible with analysis URLs, dashboard URLs, custom actions, and custom filters. The filter must be either equal or not equal to the values provided. No other comparisons are supported.
- Lists show up to 1,000 values. If there are more than 1,000 distinct values, a search box appears so you can filter the list. When the filtered list contains less than 1,001 values, the contents of the list appear as line items.

- The **Style** option displays only the style types that are appropriate for the parameter's data type and single or multivalue setting. If the style that you want to use isn't in the list, recreate your parameter with the appropriate settings and try again.
- If your parameter links to a dataset field, it must be an actual field. Calculated fields aren't supported.
- The values display alphabetically in the control, unless there are more than 1,000 distinct values. Then the control displays a search box instead. Each time you search for the value you want to use, it initiates a new query. If the results contain more than 1,000 values, you can scroll through the values with pagination. Wildcard search is supported. To learn more about wildcard search, see [Using wildcard search](#).

Use the following procedure to create or edit a control for an existing parameter.

To create or edit a control for an existing parameter

1. Choose an existing parameter's context menu, the  icon near the parameter name, and choose **Add control**.
2. Enter a name to give the new control a label. This label appears at the top of the workspace, and later at the top of the sheet that a dashboard displays on.
3. Choose a style for the control from the following:

- **Text field**

A text field lets you type in their own value. A text field works with numbers and text (strings).

- **Text field - multiline**

A multiline text field lets you type in their own values. With this option, you can choose to separate values you enter into the parameter control by a line break, comma, pipe (|), or semicolon. A text field works with numbers and text (strings).

- **Dropdown**

A dropdown list control that you can use to select a single value. A list control works with numbers and text (strings).

- **Dropdown multiselect**

A list control that you can use to select multiple values. A list control works with numbers and text (strings).

- **List**

A list control that you can use to select a single value. A list control works with numbers and text (strings).

- **List - multiselect**

A list control that you can use to select multiple values. A list control works with numbers and text (strings).

- **Slider**

A slider lets you select a numeric value by sliding the control from one end of the bar to another. A slider works with numbers.

- **Date-picker**

Using a date-picker, you can choose a date from a calendar control. When you choose to add a date-picker control, you can customize how to format dates in the control. To do so, for **Date format**, enter the date format that you want using the tokens described in [Customizing date formats in Quick](#).

4. (Optional) If you choose a dropdown control, the screen expands so you can choose the values to display. You can either specify a list of values, or use a field in a dataset. Choose one of the following:

- **Specific values**

To create a list of specific values, type in one per line, with no separating spaces or commas, as shown in the following screenshot.

In the control, the values display alphabetically, not in the order that you typed them.

- **Link to a data set field**

To link to a field, choose the dataset that contains your field, then choose the field from the list.

If you change the default values in the parameter, choose **Reset** on the control to show the new values.

The values that you choose here are unioned with the static default values in the parameter settings.

5. (Optional) Enable the option **Hide [ALL] option from the control if the parameter has a default configured**. Doing this shows only the data values and removes the option to select all items in the control. If you don't configure a static default on the parameter, this option doesn't work. You can add a default after adding a control by choosing the parameter, and selecting **Edit parameter**.
6. (Optional) You can limit the values displayed in the controls, so they only show values that are valid for what is selected in other controls. This is called a cascading control.

To create one, choose **Show relevant values only**. Choose one or more controls that can change what displays in this control.

When creating cascading controls, the following limitations apply.

- Cascading controls must be tied to dataset columns from the same dataset.
 - The child control must be a dropdown or list control.
 - For parameter controls, the child control must be linked to a dataset column.
 - For filter controls, the child control must be linked to a filter (instead of showing only specific values).
 - The parent control must be one of the following.
 - A string, integer, or numeric parameter control.
 - A string filter control (EXCLUDING Top-Bottom filters).
 - A non-aggregated numeric filter control.
 - A date filter control (EXCLUDING Top-Bottom filters).
7. When you finish choosing options for your control, choose **Add**.

The finished control appears at the top of the workspace. The context menu, shaped like a v, offers four options:

- **Reset** restores the user's selection to its default state.
- **Refresh list** applies only to drop-downs that are linked to a field in a dataset. Choosing **Refresh list** queries the data to check for changes. Data used in the control is cached.
- **Edit** reopens the control creation screen so that you can change your settings.

Once you have the **Edit control** pane open, you can click on different visuals and controls to view formatting data for the specific visual or control. For more information about formatting a visual, see [Formatting in Amazon Quick](#).

- **Delete** removes the control. You can recreate it by choosing the parameter context menu.

Configuring custom sort for controls

You can configure a custom sort order for parameter controls to change how values appear in the control list. By default, controls display values in user-defined order. You can customize this to sort in ascending or descending order or sort by a related field in the dataset.

To configure custom sort for a control

1. Choose the parameter control in the sheet.
2. Choose the pencil icon to open the **Format control** pane.
3. In the **Format control** pane, locate the **Sort** section.
4. Configure the sort options. Note that the sort options depend on whether the control uses specific values or is linked to a dataset field.

Sort options by control type

Sorting controls with specific values

If the control uses specific values, choose one of the following sort options:

- **Ascending (A–Z, 0–9)** – Sorts values in ascending order.
- **Descending (Z–A, 9–0)** – Sorts values in descending order.
- **User-defined order** – Displays the values in the exact order that you entered them, without any automatic sorting. This is the default.

Sorting controls linked to a dataset field

If the control is linked to a dataset field, you can sort by the control's own column or by another field in the same dataset.

- **Sort by control column** – Sorts values based on the field that the control is linked to. Choose a sort direction (**Ascending** or **Descending**) and optionally choose an aggregation function. Choose **No aggregation** to sort by the raw column values.
- **Sort by another field** – Sorts values based on a column in any analysis dataset. For calculated fields, only scalar (non-aggregated) calculated columns are available. Choose a sort-by field, a sort direction, and an aggregation function. This is useful for ordering values by a related metric, such as sorting regions by total revenue.

Note

The available aggregation functions depend on the data type of the selected column. For numeric fields, options include **No aggregation**, **Sum**, **Average**, **Count**, **Distinct count**, **Min**, **Max**, **Median**, **Percentile**, **Var**, and **Stdev**. For non-numeric fields, options include **No aggregation**, **Count**, and **Distinct count**.

In the workspace, you can also resize and rearrange your controls. The dashboard users see them as you do, except without being able to edit or delete them.

Creating parameter defaults in Amazon Quick

Use this section to learn more about the types of parameter defaults that are available, and how to set up each of them.

Each field can have a parameter and a control associated with it. When someone views a dashboard or email report, any sheet control that has a static default value configured uses the static default. The default value can change how data is filtered, how custom actions behave, and what text displays in a dynamic sheet title. Email reports also support dynamic defaults.

The simplest default is a static (unchanging) default, which shows the same value to everyone. As the designer of the dashboard, you choose the default value. It can't be changed by the person using the dashboard. However, that person can choose any value from the controls. Setting a default doesn't change this. To restrict the values that a person can select, consider using row-level security. For more information, see [Using row-level security with user-based rules to restrict access to a dataset](#).

To create or edit a static default value that applies to everyone's dashboard view

1. Choose the context menu (v) by the parameter that you want to edit, or create a new parameter by following the steps in [Setting up parameters in Amazon Quick](#).
2. Enter a value for **Static default value** to set a static default.

To display a different default depending on who is viewing the dashboard, you create a dynamic default parameter (DDP). Using dynamic defaults involves some preparation to map people to their assigned defaults. First, you need to create a database query or a data file that contains information about the people, the fields, and the default values to display. You add this to a dataset, then add the dataset to your analysis. Following, you can find procedures that you can use to gather information, create the dataset, and add the dynamic default to the parameter.

Use the following guidelines when creating a dataset for dynamic default values:

- We recommend that you use a single dataset to contain all dynamic default definitions for a logical grouping of users or groups. If you can, maintain them in a single table or file.
- We also recommend that the fields in your dataset have names that closely match the field names in the analysis. Not all dataset fields need to be part of the analysis, for example if you're using the same dataset for the defaults in multiple dashboards. The fields can be in any order.
- We don't recommend that you combine both user and group names in the same column or even in the same dataset. This kind of configuration is more work to maintain and troubleshoot.
- If you use a comma-delimited file to create your dataset, make sure to remove any space between values in the file. The following example shows the correct comma-separated value (CSV) format. Enclose text (strings) that include nonalphanumeric characters—like spaces, apostrophes, and so on—in single or double quotation marks. You can enclose fields that are dates or times in quotation marks, but it isn't required. You can enclose numeric fields in quotation marks, for example if the numbers contain special characters, as shown following.

```
"Value includes spaces","Field contains ' other characters",12345.6789,"20200808"
ValueWithoutSpaces,"1000,67","Value 3",2020-AUG-08
```

- After you create the dataset, make sure to double-check the data types that Quick selects for the fields.

Before you begin, you need a list of the user or group names for the people who are going to have dynamic defaults. To generate a list of users or groups, you can use the AWS CLI to get the

information. To run CLI commands, make sure that you have the AWS CLI installed and configured. For more information, see [Installing the AWS CLI](#) in the *AWS CLI User Guide*.

This is just one example of how to get a list of user or group names. Use whatever method works best for you.

To identify people for a dynamic default parameter (DDP)

- List either individual user names or group names:
 - To list individual user names, include a column that identifies the people for your DDP. This column should contain each person's system user name that they use to connect from your identity provider to Quick. This user name is often the same as a person's email alias before the @ sign, but not always.

To get a list of users, use the [ListUsers](#) Quick API operation or AWS CLI command. The CLI command is shown in the following example. Specify the AWS Region for your identity provider, for example `us-east-1`.

```
awsacct1="111111111111"
namespace="default"
region="us-east-1"

aws quicksight list-users --aws-account-id $awsacct1 --namespace $namespace --
region $region
```

The following example alters the previous command by adding a query that limits the results to active users.

```
awsacct1="111111111111"
namespace="default"
region="us-east-1"

aws quicksight list-users --aws-account-id $awsacct1 --namespace $namespace --
region $region --query 'UserList[?Active==`true`]'
```

The result set looks similar to the following sample. This example is an excerpt from JSON output (`--output json`). People who have federated user names have principal IDs that start with the word `federated`.

```
[
  {
    "Arn": "arn:aws:quicksight:us-east-1:111111111111:user/default/
anacasilva",
    "UserName": "anacarolinasilva",
    "Email": "anacasilva@example.com",
    "Role": "ADMIN",
    "Active": true,
    "PrincipalId": "federated/iam/AIDAJ64EIEIOPX5CEIEIO"
  },
  {
    "Arn": "arn:aws:quicksight:us-east-1:111111111111:user/default/Reader/
liujie-stargate",
    "UserName": "Reader/liujie-stargate",
    "Role": "READER",
    "Active": true,
    "PrincipalId": "federated/iam/AR0AIJSEIEIOMXTZEIEIO:liujie-stargate"
  },
  {
    "Arn": "arn:aws:quicksight:us-east-1:111111111111:user/default/embedding/
cxoportall",
    "UserName": "embedding/cxoportal",
    "Email": "saanvisarkar@example.com",
    "Role": "AUTHOR",
    "Active": true,
    "PrincipalId": "federated/iam/AR0AJTGEIEIOWB6BEIEIO:cxoportall"
  },
  {
    "Arn": "arn:aws:quicksight:us-east-1:111111111111:user/default/
zhangwei@example.com",
    "UserName": "zhangwei@example.com",
    "Email": "zhangwei@example.com",
    "Role": "AUTHOR",
    "Active": true,
    "PrincipalId": "user/d-96123-example-id-1123"
  }
]
```

- To list group names, include a column that identifies the groups containing the user names for your DDP. This column should contain the system group names that are used to connect from your identity provider to Quick. To identify groups that you can add to the dataset, use one or more of the following Quick API operations or CLI commands:

- [ListGroups](#) – Lists Quick groups by AWS account ID and namespace for the AWS Region that contains your identity provider.
- [ListGroupMemberships](#) – Lists the users in the specified Quick group.
- [ListUserGroups](#) – Lists the Quick groups that a Quick user is a member of.

Or you can ask your network administrator to query your identity provider to get this information.

The next two procedures provide instructions on how to finish creating a dataset for dynamic default values. The first procedure is for creating a dataset for a single-value DDP. The second one is for creating a dataset for a multivalue DDP.

To create a dataset for a single-value DDP

1. Create dataset columns with single-value parameters. The first column in the query or file should be for the people using the dashboard. This field can contain user names or group names. However, support for groups is only available in Quick Enterprise edition.
2. For each field that displays a dynamic default for a single-value parameter, add a column to the dataset. The name of the column doesn't matter—you can use the same name as the field or parameter.

Single-value parameters only work as specified if the combination of user entity and dynamic default is unique for that parameter's field. If there are multiple values a default field for a user entity, the single-value control for that field displays the static default instead. If no static default is defined, the control doesn't display a default value. Be careful if you use group names, because some user names can be members of multiple groups. If those groups have different default values, then this type of user name functions as a duplicate entry.

The following example shows a table that appears to contain two single-value parameters. We make this assumption because no user name is paired with multiple default values. To make this table easier to understand, we add the word 'default' in front of the field names from the analysis. Thus, you can read the table by making the following statement, changing the values for each row: When viewed by anacarolinasilva, the controls display a default region NorthEast and a default segment SMB.

Viewed-by	Default-region	Default-segment
anacarolinasilva	NorthEast	SMB
liujie	SouthEast	SMB
saanvisarkar	NorthCentral	SMB
zhangwei	SouthCentral	SMB

3. Import this data into Quick, and save it as a new dataset.
4. In your analysis, add the dataset that you created. The analysis needs to use at least one other dataset that matches the columns you defined for the defaults. For more information, see [Adding a dataset to an analysis](#).

To create a dataset for a multivalue DDP

1. Create dataset columns with multivalue parameters. The first column in the query or file should be for the people using the dashboard. This field can contain user names or group names. However, support for groups is only available in Quick Enterprise edition.
2. For each field that displays a dynamic default for a multivalue parameter, add a column to the dataset. The name of the column doesn't matter—you can use the same name as the field or parameter.

Unlike single-value parameters, multivalue parameters allow multiple values in the field that's associated with the parameter.

The following example shows a table that appears to contain a single-value parameter and a multivalue parameter. We can make this assumption because each user name has a unique value in one column, and some user names have multiple values in the other column. To make this table easier to understand, we add the word 'default' in front of the field names from the analysis. Thus, you can read the table by making the following statement, changing the values for each row: When viewed-by is liujie, the controls display a default-region value of SouthEast, and a default-city value of Atlanta. And if we read ahead one row, we see that liujie also has Raleigh in default-city.

Viewed-by	Default-region	Default-city
anacarolinasilva	NorthEast	New York
liujie	SouthEast	Atlanta
liujie	SouthEast	Raleigh
saanvisarkar	NorthCentral	Chicago
zhangwei	SouthCentral	Dallas
zhangwei	SouthCentral	Kansas City

In this example, the parameter that we apply `default-region` to works correctly whether it's a single-value or multivalue parameter. If it's a single-value parameter, two entries work for one user because both entries are the same value, `SouthEast`. If it's a multivalue parameter, it still works, except that only one value is selected by default. However, if we change the parameter that's using `default-city` as its default from a multivalue to a single-value parameter, we don't see these defaults selected. Instead, the parameter uses the static default, if there is one defined. For example, if the static default is set to `Atlanta`, `liujie` has `Atlanta` selected in that control, but not `Raleigh`.

In some cases, your static default value might also be used as a dynamic default. If so, make sure to test the control for a user name that doesn't use a default value that can be both.

If a user name belongs to multiple groups, the named user sees a set of default values that is a union of the two groups' default values.

3. Import this data into Quick, and save it as a new dataset.
4. In your analysis, add the dataset that you created. The analysis needs to use at least one other dataset that matches the columns you defined for the defaults. For more information, see [Adding a dataset to an analysis](#).

Use the following procedure to add a dynamic default parameter to your analysis. Before you begin, make sure that you have a dataset that contains the dynamic defaults for each user name

or group name. Also make sure that your analysis is using this dataset. For help with these requirements, see the procedures preceding.

To add a DDP to your analysis

1. In the Quick console, choose the **Parameters** icon at the top of the page and choose an existing parameter. Choose **Edit parameter** from the parameter's menu. To add a new parameter, choose the plus (+) sign near **Parameters**.
2. Choose **Set a dynamic default**.
3. Configure the following options with your settings:
 - **Dataset with default values and user information** – Choose the dataset that you created and added to your analysis.
 - **User name column** – To create defaults that are based on user names, choose the column in the dataset that contains the user names.
 - **Group name column** – To create defaults that are based on group names, choose the column in the dataset that contains the group names.
 - **Column for default value** – Choose the column that contains default values for this parameter.
4. Choose **Apply** to save your setting changes, and then choose **Update** to save the parameter changes. To exit without saving changes, choose **Cancel** instead.
5. Add a filter for each field that contains dynamic defaults to make the defaults work. To learn more about using filters with parameters, see [Using filters with parameters in Amazon Quick](#)

Amazon Quick uses the static default value for anyone whose user name doesn't exist in the dataset, doesn't have a default assigned, or doesn't have a unique default. Each person can have only one set of defaults. If you don't want to use dynamic defaults, you can set a static default instead.

Connecting to parameters in Amazon Quick

Use this section after you have a parameter set up, to connect it and make it work.

After you create a parameter, you can create consumers of the parameters. *Parameter consumers* are components that consume the value of a parameter, such as filters, controls, calculated fields, or custom actions.

You can navigate to each of these options in another way, as follows:

- To create a filter, choose the **Filter** icon at the top of the page. In short, you create a **Custom Filter** and enable **Use parameters**. The list shows only eligible parameters.
- To add a new control for the parameter, choose the **Parameters** icon at the top of the page. In short, choose your parameter, and then **Add control**.
- To use a parameter in a calculated field, either edit an existing calculated field, or add a new one by choosing **Add** at the top left. The parameter list appears below the field list.

 Note

You can't use multivalue parameters with calculated fields.

- To create a URL action, choose the **v**-shaped menu on a visual, and then choose **URL Actions**.

For more information on each of these topics, see the following sections.

Topics

- [Using filters with parameters in Amazon Quick](#)
- [Using calculated fields with parameters in Amazon Quick](#)
- [Using custom actions with parameters in Amazon Quick](#)
- [Using parameters in a URL](#)
- [Using parameters in titles and descriptions in Amazon Quick](#)

Using filters with parameters in Amazon Quick

Use this section to filter the data in an analysis or dashboard by a single-value parameter value. To use a multivalued parameter—one with a multiselect drop-down control—create a custom filter that is equal (or not equal) to the values.

Before using a filter with a parameter, you should already know how to work with filters.

1. Verify that your analysis has a parameter already created. Choose **Edit** from either the parameter or the control menu to find out what settings are in use.
2. Choose the **Filter** pane from the left of the screen. If there is already a filter for the field that you want to use, choose it to open its settings. Otherwise, create a filter for the field that you want to filter by parameter.

3. Choose **Use Parameters**.
4. Choose your parameters from the list or lists below **Use parameters**. For text (string) fields, first choose **Custom Filter**, and then enable **Use Parameters**.

For date fields, choose the **Start date** and **End date** parameters, as shown in the following screenshot.

For fields with other data types, choose **Select a parameter** and then choose your parameter from the list.

 Note

Parameters that can hold multiple values must use equal or not equal as the comparison type.

5. Choose **Apply** to save your changes.

Test your new filter by choosing the control near the top of the analysis. In this example, we use a basic parameter that has no defaults, and a dynamic control that is linked to the **Region** field in the sample dataset named **Sales Pipeline**. The control queries the data, returning all values.

If you delete or recreate a parameter that you are using in a filter, you can update the filter with the new parameter. To do this, open the filter, choose the new parameter that you want to use, and then choose **Apply**.

If you rename a parameter, you don't need to update the filter or any other consumers.

Using calculated fields with parameters in Amazon Quick

You can pass the value of a parameter to a calculated field in an analysis. When you create a calculation, you can choose existing parameters from the list of parameters under **Parameter list**. You can't create a calculated field that contains a multivalued parameter—those with a multiselect drop-down control.

For the formula, you can use any of the available functions. You can pass the viewer's selection from the parameter control, to the `ifElse` function. In return, you get a metric. The following shows an example.

```
ifelse(
```

```
`${KPIMetric}` = 'Sales',sum({Weighted Revenue})),  
  
`${KPIMetric}` = 'Forecast',sum({Forecasted Monthly Revenue})),  
  
`${KPIMetric}` = '# Active', distinct_count(ActiveItem),  
  
NULL  
  
)
```

The preceding example creates a metric (a decimal) that you can use in a field well. Then, when a user chooses a value from the parameter control, the visual updates to reflect their selection.

Using custom actions with parameters in Amazon Quick

A *custom action* enables you to launch URLs or filter visuals by selecting a data point in a visual or choosing the action name from the context menu. When you use a URL action with a parameter, you can pass or send parameters dynamically to the URL. To make this work, you set up a parameter, and then use it in the URL when you create a custom action with an action type of **URL action**. The parameters on both the sending and the receiving end must match in name and data type. All parameters are compatible with URL actions.

For details on creating a URL action, see [Creating and editing custom actions in Amazon Quick Sight](#). If you just want to use a parameter in a link without creating a URL action, see [Using parameters in a URL](#).

Using parameters in a URL

You can use a parameter name and value in a URL in Amazon Quick to set a default value for that parameter in a dashboard or analysis.

The following example shows the URL of a dashboard that sets a parameter for another dashboard.

```
https://us-east-2.quicksight.aws.amazon.com/sn/dashboards/abc123-abc1-abc2-abc3-  
abcdefef1234#p.myParameter=12345
```

In the previous example, the first part is the link to the target dashboard: `https://us-east-2.quicksight.aws.amazon.com/sn/dashboards/abc123-abc1-abc2-abc3-`

abcdefef1234. The hash sign (#) follows the first part to introduce the *fragments*, which contain the values that you want to set.

The values in the fragments aren't received or logged by AWS servers. This functionality keeps your data values more secure.

The fragment after # follows these rules:

- Parameters are prefixed with p.. The names are the parameter name, not the control name. You can view the parameter name by opening the analysis, and choosing **Parameter** on the left sidebar.
- The value is set using equals (=). The following rules apply:
 - Literal values don't use quotation marks.
 - Spaces inside values are automatically encoded by the browser, so you don't need to use escape characters when manually creating a URL.
 - To return all values, set the parameter equal to "[ALL]".
 - To assign the parameter's value to null, set it equal to %00. For example, p.population=%00.
 - In custom actions, target parameter names begin with \$, for example: <<\$passThroughParameter>>
 - In custom actions, parameter values display with angle brackets << >>, for example <<dashboardParameter1>>. The dashboard user sees the lookup value, not the variable.
- For a custom URL action, multivalue parameters only need one instance of the same parameter in the fragment, for example: p.city=<<\$city>>
- For a direct URL, multiple values for a single parameter have two instances of the same parameter in the fragment. For an example, see following.
- Ampersands (&) separate multiple parameters. For an example, see following.

The server converts the date to UTC and sends it to the backend as a string without a time zone. To use Universal Coordinated Time (UTC) dates, exclude the time zone. Following are some examples of date formats that work:

- 2017-05-29T00%3A00%3A00
- 2018-04-04 14:51 -08:00
- Wed Apr 04 2018 22:51 GMT+0000

```
https://us-east-2.quicksight.aws.amazon.com/sn/dashboards/abc123-  
abc1-abc2-abc3-abcdefef1234#p.shipdate=2018-09-30 08:01&p.city=New  
York&p.city=Seattle&p.teamMember=12&p.percentageRank=2.3
```

In the browser, this code becomes the following.

```
https://us-east-2.quicksight.aws.amazon.com/sn/dashboards/abc123-  
abc1-abc2-abc3-abcdefef1234#p.shipdate=2018-09-30%2008:01&p.city=New  
%20York&p.city=Seattle&p.teamMember=12&p.percentageRank=2.3
```

The previous example sets four parameters:

- `shipDate` is a date parameter: Sept 30, 2018.
- `city` is a multivalued string parameter: New York, and Seattle
- `teamMember` is an integer parameter: 12.
- `percentageRank` is a decimal parameter: 2.3.

The following example shows how to set values for a parameter that accepts multiple values.

```
https://us-east-2.quicksight.aws.amazon.com/sn/dashboards/abc123-abc1-abc2-abc3-  
abcdefef1234#p.MultiParam=WA&p.MultiParam=OR&p.MultiParam=CA
```

To pass values from one dashboard (or analysis) to another dashboard based on the user's data point selection, use custom URL actions. If you choose, you can also generate these URLs manually, and use them to share a specific view of the data.

For information on creating custom actions, see [Using custom actions for filtering and navigating](#).

Using parameters in titles and descriptions in Amazon Quick

When you create parameters in Amazon Quick, you can use them in titles and descriptions throughout your charts and analyses to dynamically display parameter values.

You can use parameters in the following areas of your analysis:

- Chart titles and subtitles

- Axis titles
- Legend titles
- Parameter control titles
- Sheet titles and descriptions

The following image shows a chart title that uses a parameter.

Use the following procedures to learn how to add parameters to areas throughout your analysis. For more information about parameters and how to create them, see [Parameters](#).

Adding parameters to chart titles and subtitles

Use the following procedure to learn how to add parameters to chart titles and subtitles.

To add a parameter to a chart title or subtitle

1. Open the **Properties** pane for the visual that you want to format.
2. In the **Properties** pane, choose the **Title** tab.
3. Select **Show title** or **Show subtitle**. These options might already be selected.
4. Choose the three dots at the right of **Edit title** or **Edit subtitle**, and then choose a parameter from the list.

The parameter is added to the title in the **Properties** pane. In the chart, the parameter value is displayed in the title.

For more information about editing titles and subtitles in visuals, see [Titles and subtitles on visual types in Quick](#).

Adding parameters to axis titles

Use the following procedure to learn how to add parameters to axis titles.

To add a parameter to an axis title

1. Open the **Properties** pane for the visual that you want to format.
2. In the **Properties** pane, choose the axis that you want to format.
3. Select **Show title**.
4. Choose the three dots at the right of the default axis title, and then choose a parameter from the list.

The parameter is added to the axis title in the **Properties** pane. In the chart, the parameter value is displayed in the axis title.

For more information about editing axis titles, see [Axes and grid lines](#).

Adding parameters to legend titles

Use the following procedure to learn how to add parameters to legend titles.

To add a parameter to a legend title

1. Open the **Properties** pane for the visual that you want to format.
2. In the **Properties** pane, choose **Legend**.
3. Select **Show legend title**.
4. Choose the three dots at the right of **Legend title**, and then choose a parameter from the list.

The parameter is added to the legend title in the **Properties** pane. In the chart, the parameter value is displayed in the legend title.

For more information about formatting legends, see [Legends on visual types in Quick](#).

Adding parameters to control titles

Use the following procedure to learn how to add parameters to parameter control titles.

To add a parameter to a parameter control title

1. Select the parameter control that you want to edit, choose the three dots at the right of the parameter control title, and then choose **Edit**.
2. In the **Edit control** page that opens, select **Show title**.
3. Choose the three dots at the right of **Display name**, and then choose a parameter from the list.

The parameter is added to the parameter control title.

For more information about using parameter controls, see [Parameter controls](#).

Adding parameters to sheet titles and descriptions

Use the following procedure to learn how to add parameters to sheet titles and descriptions in your analysis.

To add a parameter to a sheet title or description

1. On the analysis page, choose **Sheets** in the application bar and then choose **Add title** or **Add description**.

A sheet title or description appears on the sheet.

2. For **Sheet title** or for **Description**, choose the three dots at right, and then choose a parameter from the list.

The parameter is added to the sheet title or description and the parameter value appears in the text when you close the text box.

For more information about adding sheet titles and descriptions, see [Adding a title and description to an analysis](#).

Using custom actions for filtering and navigating

To add interactive options for dashboard subscribers (Quick readers), you create custom actions on one or more visuals in your analysis. Enhancing dashboards with custom actions helps people explore data by adding more context from within the dataset. It can make it easier to drill into the details and to find new insights in the same dashboard, a different dashboard, or a different application. You can add up to 10 custom actions to each visual in a dashboard.

Before you begin, it's helpful to do some planning. For example, identify fields that are good candidates for filtering, for opening a different sheet, for opening a URL, or for sending email. For each sheet, identify the widgets that display these fields. Then decide which widgets are going to contain actions. It's also a good idea to create a naming scheme so the names of the actions are consistent throughout the entire analysis. Consistent names make it easier for the person using your analysis to figure out what the action will do, plus they make it easier for you to maintain actions that you might be duplicating throughout the analysis.

Actions only exist on the dashboard widget where you create them and they work in the context of that widget's parent sheet and child fields that it displays. You can create actions only on specific types of widget: visuals and insights. You can't add them to other widgets, for example filter or list controls. Custom actions can only be activated from the widget where you create them.

To activate an action, the person using the analysis can left-click (select) or right-click (use the context menu) on a data point. A *data point* is an item in the dataset, for example a point on a line chart, a cell in a pivot table, a slice on a pie chart, and so on. If the person clicks a visual element, the *select* action is activated. This is the action that is currently a member of the **On select** category of the **Actions** in an analysis. If the person instead right-clicks a visual element, they can choose from a list of *menu* actions. Any action listed is currently a member of the **Menu option** category of the **Actions** in an analysis. The **On select** category can contain one and only one member action.

By default, the first action you create becomes the select action—the one activated by left-clicking. To remove an action from the **On select** category, change the action's **Activation** setting to **Menu option**. After you save that change, you can set a different action's **Activation** setting to **Select**.

You can choose from three **Action types** when you configure an action:

- **Filter action** – Filter data included in visual or in the entire sheet. By default, filters are available for all fields in the parent visual. Cascading filters are enabled by default. Filter actions work across multiple datasets by using automatically generated field mappings.

If the analysis uses more than one dataset, you can view the automatically generated field mappings for fields that exist in multiple datasets. To do this, choose **View field mapping** at the end of the action settings, while you're editing an action. If you are viewing a list of actions, choose **View field mapping** from the menu for each action. The field mappings appear in a new screen that shows the mapping between the initial dataset and all the other datasets in the visual. If no fields are automatically mapped, a message displays with a link to [Mapping and Joining Fields](#).

- **Navigation actions** – Enable navigation between different sheets in the same analysis.
- **URL actions** – Open a link to another web page. If you want to open a different dashboard, use a URL action. You can use a URL action to send data points and parameters to other URLs. You can include any available field or parameter.

If the URL uses the mailto scheme, running the action opens your default email editor.

Topics

- [Adding one-click interactive filters](#)
- [Creating and editing custom actions in Amazon Quick Sight](#)
- [Repairing custom actions](#)
- [Understanding field mapping for custom actions in Amazon Quick Sight](#)

Adding one-click interactive filters

One-click interactive filtering provides point-and-click filtering that cascades from the clickable visual to all the other visuals and insights on a sheet. Add this to your analysis to start with summaries and drill down into the metrics, all within the same dashboard sheet.

After you set this up, when you click a data point (for example, a point in a line chart), you instantly filter using all mapped fields on all the other visuals on that sheet. If you have multiple datasets, all target fields must be mapped for this to work. Also, you can only have one action that works by clicking a data point; all other actions work from the context menu.

Use the following procedure to create a one-click filter in an analysis.

To create a one-click filter on a visual or insight

1. In your analysis, choose a visual or insight that you want to add interactive filtering to.

2. Choose **Actions** from the Menu options dropdown in the upper right corner.
3. Choose **Filter same-sheet visuals**. Doing this immediately adds one-click filtering.
4. Repeat this process for each visual that you wish to make interactive.

Creating and editing custom actions in Amazon Quick Sight

You create one action for each task that you want to be able to add to a visual. The actions you create become part of the functionality of each visual or insight.

The following table defines when to use each type of action.

Action to perform	Type of action
Add or customize an interactive filter action, including one-click filters	Filter action
Open another sheet in the same dashboard	Navigation action
Open a sheet in a different dashboard in the same AWS account	URL action
Open a URL (https, http)	URL action
Send an email (mailto)	URL action

You can set the following attributes and options for a custom action:

- **Action name** – This is a descriptive name that you choose for the action. By default, actions are named **Action 1**, **Action 2**, and so on. If your custom action is activated from a context menu, this name displays in the menu when you right-click on a data point.

To make the action name dynamic, you can parameterize it. Use the plus icon near the action name header to display a list of available variables. Variables are enclosed in angle brackets << >>. Parameters are prefixed with a \$, for example <<\$parameterName>>. Field names have no prefix, for example <<fieldName>>.

- **Activation** – Available options are **Select** or **Menu option**. To use an action, you can *select* the data point (left-click) or navigate to the *menu option* in the context menu (right-click). Navigation

actions and URL actions listed in the middle of the context menu, just above **Color** options. Actions that are activated by menu are also available from the legend on a visual.

- **Action type** – The type of action that you want. Settings that are specific to an action type only display after you choose the action type.
- **Filter action** settings include the following:
 - **Filter scope** – The fields to filter on. To filter on all fields, choose **All fields**. Otherwise, choose **Select fields** and then turn off the items you don't want to target.

The default is **All fields**.

- **Target visuals** – The dashboard widgets to target. To apply the filter to all of them, choose **All visuals**. Otherwise, choose **Select visuals** and then turn off the items you don't want to target. When you apply a filter action to other visuals, the effect is called *cascading filters*.

The default is **All visuals**.

A cascading filter applies all the visuals that are set up in the **Target visuals** section of a specific filter action. Amazon Quick Sight initially evaluates your visuals and preconfigures the settings for you. But you can change the defaults if you wish to do so. You can set up multiple cascading filters on multiple visuals in the same sheet or analysis. When you are using the analysis or dashboard, you can use multiple cascading filters at the same time, although you activate each of these one at a time.

A filter action requires at least one target visual, because a filter action requires a source and a target. To filter only the current visual, create a regular filter instead by choosing **Filter** at left.

- **Navigation action** settings include the following:
 - **Target sheet** – The sheet to target.
 - **Parameters** – The parameters to send to the target sheet. Choose the plus icon to add an existing parameter.
- **URL action** settings include the following:
 - **URL** – The URL to open. URL actions can be deep links into another application. Valid URL schemes include https, http, and mailto.
 - **+ (Values)** – (Optional) The parameters to send to the target URL. Parameter names start with a \$. The parameters on both the sending and the receiving end must match in name and data type.

- **Open in** – Where to open the URL. You can choose **New browser tab**, **Same browser tab**, or **New browser window**.

Some types of actions enable you to include values from parameters or fields that are available in the visual or insight. You can type these in manually or choose + to select from a list. For the custom action to work, every field and parameter it references must be actively in use in the parent widget.

Use the following procedure to create, view, or edit a custom action in an analysis.

To create, view, or edit a custom action

1. With your analysis open, choose **Actions** from the **Menu options** dropdown in the upper right corner.

The existing actions, if any, display by activation type. To turn an existing action on or off, use the box to the right of the action's name.

2. (Optional) To edit or view an existing action, choose the menu icon next to the name of the action.

To edit the action, choose **Edit**.

To delete it, choose **Delete**.

3. To create a new action, choose either one of the following:
 - The add icon near the **Actions** heading
 - The **Define a custom action** button
4. For **Action name**, define an action name. To make the action name dynamic, use the plus icon to add parameter or field values.
5. For **Activation**, choose how the action runs.
6. For **Action type**, choose the action type you want to use.
7. For a **Filter action**, do the following:
 - a. For **Filter scope**, choose the scope of the filter.
 - b. For **Target visuals**, choose how far the filter cascades
8. For a **Navigation action**, do the following:

- a. For **Target sheet**, choose the target sheet.
 - b. For **Parameters**, choose the plus icon near the **Parameters** heading, select a parameter, and then choose a parameter value. You can choose all values, enter custom values, or select specific fields.
9. For a **URL action**, do the following:
- a. For **URL**, enter the hyperlink.
 - b. Choose the plus icon near the **URL** heading. Then, add variables from the list.
 - c. For **Open in**, choose how to open the URL.
10. After you are finished with the action, choose one of the following at the bottom of the **Actions** panel (you might need to scroll down):
- **Save** – Save your selections, and create the custom action.
 - **Close** – Close this custom action and discard your changes.
 - **Delete** – Delete this action.

Repairing custom actions

For a custom action to work, every field and parameter it references must be active in the parent widget. If a field is missing from the source widget, or if a parameter is missing from the analysis, the action for that field or parameter becomes unavailable. Menu actions are no longer included in the context menu. Select actions no longer respond to attempts to interact. However, in all other ways, the widget continues to function. No error displays to your users. You can fix broken filter actions and URL actions by adding the missing fields back to the broken visual or insight.

The following procedure explains how to fix an action that broke because someone removed a field or parameter without updating the action. These steps provide basic guidance how to fix this issue. However, use your own judgment on how or if you should make changes to the analysis. If you're not sure, it's better to ask a Amazon Quick administrator for assistance before you change anything. For example, there might be a way to restore a previous version of the analysis, which might be safer if you aren't sure what happened to it.

To remove a field from a broken action

1. From the start page, choose **Analyses**. Then choose the analysis to fix.

2. Choose the visual or insight where the action no longer works. Make sure that it's highlighted on the sheet.
3. Choose **Actions** from the Menu options dropdown in the upper right corner.
4. Locate the action you want to fix and choose **Edit**.
5. If the action type is **Filter action**, and you see an error that says *the field used by this action was removed*, check the settings for **Filter scope**. **Selected fields** can only display fields that are in the visual. To disable selected fields that are removed, choose one of the following:
 - Change the **Filter scope** setting to **All fields**. Doing this enables the widget to filter on every field.
 - If you want to use a list of **Selected fields**, verify the list of fields. If you need to include another field, you need to add it to the visual first.
6. If the action type is **Navigation action**, follow the guidance on the error message, which reflects the type of change that caused the error.
7. If the action type is **URL action**, check the **URL** setting for variables marked with double angle brackets (<<FIELD-OR-\$PARAMETER>). Open the list of available variables by choosing the plus icon. Remove any fields or parameters that aren't in the list. Be sure you also remove the matching *URL parameter* and its separator (? for the first URL parameter, or & for subsequent parameters). The following examples show (in **bold**) which part is removed if you were removing the field named **Product** from the visual.

```
https://www.example.com/examplefunction?q=<<Product>
```

```
https://www.example.com/examplefunction?q=<<Product>&uact=<<$CSN>
```

```
https://www.example.com/examplefunction?pass=yes&q=<<Product>+<<City>&oq=<<Product>+<<City>&uact=<<$CSN>
```

Make sure to test the new URL.

8. (Optional) To delete the action, scroll to the end and choose **Delete**.
9. When you are finished, confirm your changes to the action. Scroll to the bottom of the **Action** pane and choose **Save**.

If the error also exists in an associated dashboard, share and publish the dashboard again to propagate the fix.

Understanding field mapping for custom actions in Amazon Quick Sight

Automated field mapping is based on identical fields. Fields with the same name and data type map automatically across datasets. Their field names and data types must be an exact match. This works similar to a join, except that it is automatically generated based on names and data types for every matching field. If you are missing fields, you can create them by using calculated fields in the dataset that's missing a field. If you don't want to have some of the fields mapped to each other, you can rename or remove them from the dataset.

It's important to make sure that all target fields are mapped if they are enabled for use with a filter action (in the **Filter scope**). Doing this allows filtering to apply automatically. If some target fields aren't mapped, the automatic filtering doesn't work.

Mapping is generated only when you create or save a custom action. So after every change that affects the mapping, make sure to return to it and save it again. When you create an action, mapping is based on the fields as they exist at that point. When you save an action, any mapped fields that you renamed since you created the custom action stay mapped. However, if you alter the data type of a mapped field, the mapping is removed.

If your mapping is missing some fields, you can do one of the following to fix it:

- Only target the mapped fields, by removing the unmapped fields from the **Filter scope**.
- Remove the visual in question from the target visuals.
- Create calculated fields to supply the missing fields for the mapping, and then save your custom action.
- Edit the dataset and rename the fields or change their data types, and then save your custom action.
- Edit the dataset and rename the fields or change their data types, and then resave your custom action.

Note

The information that displays on the mapping screen shows the configuration from the most recent time you saved it. To refresh or update the view, save the action again.

If you add or edit datasets, they aren't automatically mapped or remapped. This causes the filtering to work incorrectly. For example, suppose that you add a new dataset, then create visuals for it.

The new visuals won't respond to filter actions, because there is no field mapping to connect them. When you make changes, remember to save your custom actions again to redo the field mappings.

If you remove a parameterized field or any other targeted field from the source visual, the action that uses it breaks. The action for the missing field either doesn't work when you select a data point, or it's hidden from the context menu.

For information about preparing your dataset for automated field mapping, see [Mapping fields](#).

Working with pixel perfect reports in Amazon Quick Sight

With Amazon Quick Sight Pixel Perfect Reports, you can create, schedule, and share highly formatted multipage PDF reports. You can also schedule data exports as CSV files using Quick Sight's existing web interface. This unifies historically separate systems for dashboards and reports.

Report creators can use Quick Sight's browser-based authoring experience to connect to a broad range of supported data sources and create highly formatted reports. They can specify the exact page size, length, and arrangement of images, charts, and tables with pixel-level precision. Authors can then use Quick Sight's scheduling mechanisms to set up and schedule highly personalized report delivery to end users, or archive reports for future use.

Pixel perfect reports are designed to be printed or distributed. Pixel perfect report content is formatted to fit paper sizes and it displays all the data in a table and pivot table, even if the data spans multiple pages. They are formatted for exact paper sizes and you can control page layout exactly. Each pixel perfect report can generate a PDF of up to 1,000 pages.

Pixel perfect reports provide all available data that is present when the report is published as a PDF or CSV. For example, let's say you have a table with 10,000 rows. A pixel perfect report presents the entire report across multiple pages for readers to view in its entirety. If you include this same table in an interactive dashboard report, the generated PDF includes a snapshot of the table that fills in a single page that can be scrolled through. These customized reports can be sent out in email bursts that generate up to thousands of personalized PDF or CSV reports to individual users and groups.

Note

Pixel perfect reports are not available in the eu-central-2 Europe (Zurich) region.

Topics

- [Getting started](#)
- [Creating reports from an analysis in Amazon Quick Sight](#)
- [Formatting reports in Amazon Quick Sight](#)
- [Consuming pixel perfect reports in Amazon Quick Sight](#)
- [Unsubscribe from paginated reporting in Quick Sight](#)

Getting started

To get started working with Amazon Quick Sight pixel perfect reports, first get the pixel perfect reporting add-on for your Amazon Quick account. Pricing for the add-on applies to your entire Quick account and isn't specific to a Region. After you subscribe to Quick reporting, authors can begin creating, scheduling, and sending pixel perfect reports.

Get the Quick pixel perfect reports add-on

Before you can work with pixel perfect reports in Amazon Quick Sight, you must add the **Pixel-Perfect Reports add-on** to your Quick subscription.

To get the pixel perfect reporting add-on in Amazon Quick Sight

1. On the Quick start page, choose your user name at the upper right, and then choose **Manage Quick**.
2. Choose **Manage subscriptions**, and then choose **Pixel-Perfect Reports**.
3. Choose the subscription plan that you want. You can choose between a monthly plan and an annual plan.
4. Review the Pixel-Perfect Reports add-on pricing information and then choose **Confirm subscription**.

After you get the pixel perfect reports add-on, it may take several minutes for your subscription to take effect. When your subscription takes effect, you will be able to begin creating pixel perfect reports in Amazon Quick Sight.

Creating reports from an analysis in Amazon Quick Sight

Pixel perfect reports are created at the sheet level of an analysis in Amazon Quick Sight. When you create a new analysis or a new sheet in an existing analysis, you choose whether to make the

new sheet an **Interactive dashboard** or a **Pixel perfect report**. This way, you can have analyses for interactive dashboards only, analyses for pixel perfect reports only, or you can have an analysis that includes both interactive dashboards and pixel perfect reports.

There are three ways to create a pixel perfect report. You can create a new report from a new sheet in an analysis, you can duplicate an interactive sheet in a dashboard, or you can duplicate a pixel perfect report that already exists. Use the procedures below to create a pixel perfect report.

Creating reports from an analysis in Amazon Quick Sight

To create a pixel perfect report from a new analysis

1. On the Quick homepage, choose **Analyses**, and then choose **New analysis**.
2. Choose the dataset that you want to include in your new analysis, and then choose **USE IN ANALYSIS** in the top right.
3. In the **New sheet** pop-up that appears, choose **Pixel perfect report**.
4. (Optional) Choose the paper size that you want for your pixel perfect report. You can choose from the following options:
 - US letter (8.5 x 11 in.)
 - US legal (8.5 x 14 in.)
 - A0 (841 x 1189 mm)
 - A1 (594 x 841 mm)
 - A2 (420 x 594 mm)
 - A3 (297 x 420 mm)
 - A4 (210 x 297 mm)
 - A5 (148 x 210 mm)
 - Japan B4 (257 x 364 mm)
 - Japan B5 (182 x 257 mm)

The default paper size is US letter (8.5 x 11 in.)

5. (Optional) Choose between a portrait and landscape arrangement for the sheet. The default option is portrait.
6. Choose **ADD**.

If you want to create a new pixel perfect report in an existing analysis, choose the plus sign (+) icon to the right of the sheet tabs in your analysis and follow steps 3-6 from the preceding procedure.

Creating reports from an existing dashboard in Amazon Quick Sight

You can also create a pixel perfect report by duplicating an interactive sheet and converting the duplicate sheet into a pixel perfect report.

To create a pixel perfect report from an interactive sheet

1. From the sheet that you want to duplicate in an analysis, choose the dropdown next to the name of the sheet that you want to convert.
2. Choose **Duplicate to report**.

You can convert an interactive sheet to a pixel perfect report, but you can't convert a pixel perfect report to an interactive sheet.

Duplicate an existing report in Amazon Quick Sight

This section will go over how to copy a report.

To copy a pixel perfect report

1. From the sheet that you want to duplicate in an analysis, choose the dropdown next to the name of the sheet that you want to convert.
2. Choose **Duplicate**.

Formatting reports in Amazon Quick Sight

Use this section to learn how to format a pixel perfect report in Amazon Quick Sight.

Topics

- [Working with sections](#)
- [Changing paper size, margins, and orientation](#)
- [Adding and removing page breaks to a report](#)
- [Adding and deleting visuals to a report](#)
- [Adding a text box to a report](#)

- [Setting up prompts for paginated reports](#)

Working with sections

A *section* is a container for different visuals that grow vertically to contain contents. Each section is rendered to completion, one after the other, accommodating configured page breaks and section settings. Headers and footers are special types of section that have a predefined size, location, and repetition throughout each page of a report.

Each section in a pixel perfect report can be formatted independently from other sections in the report. Visuals can be dragged and dropped anywhere you want, similar to a free-form layout in an interactive sheet. Visuals can also be overlapped, resized, or brought forward or to the back of the section. Additionally, you can change the margins within a section to make the grouping of visuals stand out from the rest of the report.

Every report in Quick Sight needs at least one section. You can add multiple sections to group different sets of visuals together, or to control the rendering order for different groupings of visuals.

Each pixel perfect report sheet supports up to 30 sections, including headers and footers.

Use the topics listed below to learn more about sections.

Topics

- [Adding, moving, and deleting sections](#)
- [Headers and footers](#)
- [Section padding](#)
- [Create repeating sections](#)

Adding, moving, and deleting sections

Add a new section

To add a new section to a pixel perfect report, use the following procedure.

To add a new section to a pixel perfect report

1. From the Quick homepage, choose **Analyses** and then choose the analysis that contains the report that you want to add a section to.

2. Choose the sheet that contains the pixel perfect report that you want to add a section to.
3. Choose the **ADD (+)** icon in the top left corner, and choose **Add section**.

You can also add a section by choosing the plus (+) icon at the bottom of an existing section and choosing **Add section**.

When you choose **Add section**, a new section is added to the bottom of the report.

You can't create a section inside of another section. If you select an existing section and then choose **Add section**, a new section will appear at the bottom of the report.

When you have multiple sections in a pixel perfect report, they can be arranged in any order that you want.

Move a section

To move a section in a report

1. Choose the section that you want to move, and then choose the three-dot icon in the right corner to open the on-section menu.
2. Choose where you want to move your section. You can choose from the following options:
 - **Move section to top**
 - **Move section up**
 - **Move section down**
 - **Move section to bottom**

In some cases, you aren't able to select some of the preceding options. For example, if your section is already at the bottom of the report, you can't select **Move down** or **Move section to bottom**.

Sections are named according to their ascending order in the report. When you move a section up or down in a report, every section affected by the move is renamed according to the new ascending order.

When you delete a section from a pixel perfect report, the names of the remaining sections may change depending on where the deleted section was located. For example, say you decide to delete Section 1. When you delete the section, the previous Section 2 will move up the report and become the new Section 1.

Delete a section

To delete a section from a report

1. Navigate to the section that you want to delete and choose the three-dot icon in the upper right corner to open the on-section menu.
2. Choose **Delete**.

Headers and footers

Headers and *Footers* are optional special sections located at the top and bottom of a pixel perfect report. Headers and footers are commonly used to display basic information like the date the report was created or the page number. You can interact with headers and footers the same way you interact with a regular section in a report.

By default, every report in Amazon Quick Sight has a header and a footer. To remove the header or footer from your report, use the following procedure.

To remove a header or footer from a pixel perfect report

1. In your pixel perfect report, navigate to the header or footer that you want to delete and open the **On-section**.
2. Choose **Delete**.

When you delete a header or footer from your report, you are deleting the header or footer from every page of the report. You can't have a header or footer on some pages but not others.

If you have removed the header or footer from your report but want them to be visible again, use the following procedure.

To add a header or footer to a pixel perfect report

1. Navigate to the pixel perfect report that you want to add a header or footer to and choose **Insert** from the top menu.
2. Choose **Add header** or **Add footer**.

Section padding

You can use section padding to change the margins of an individual section in a pixel perfect report. By default, all sections in a report use the page margins that are configured and applied to the entire report. You can also add section padding to a header or footer. With section padding, you can make a section stand out from other sections by creating another set of margins. Apply the new set of margins to the section on top of the page margins that the rest of the report uses.

To change the section padding of a section

1. Navigate to the section that you want to add section padding to and open the **Edit section**.
2. In the **Padding** section of the **Edit section**, enter the amount of padding you want in inches. You can customize the padding of every side of the section (top, bottom, left, and right).

You can't use section padding to decrease the margins of the section. For example, if the margins of the entire pixel perfect report are 1 inch, you can only add to that value with section padding.

Create repeating sections

Use repeating sections to create duplicates of specific sections of a report to show one or more-dimension values. The data in the repeating section is sliced to match the dimensions of the section. Repeating sections can be replicated at scale to decrease the amount of time it takes to build reports.

Use the following procedures to create and configure a repeating section in a report.

To define a repeating section

1. Navigate to the section that you want to add a repeating behavior to and choose the **Edit repeating section** (triple panel).
2. In the **Edit section** pane that opens, choose **ADD DIMENSION**, and then choose the dimension that you want to add.
3. To add additional dimensions, repeat Step 2. You can add up to 3 dimensions in each repeating section configuration.

Considerations for repeating sections

The following limits apply to repeating sections.

- Insight visuals aren't supported for repeating sections.
- Repeating sections dimensions that are only from the last dataset that was selected for use in the analysis.

After you create a repeating section, you can define sorting and limits to the repeating section configuration. You can also use text boxes to add system parameters to repeating sections.

Define sorting in a repeating section

To define sorting in a repeating section

1. Navigate to the section that you want to add a repeating behavior to and choose the **Edit repeating section** (triple panel).
2. In the **Edit section** that opens, choose the ellipsis (three dots) next to the dimension that you want to change.
3. Navigate to the **Repeating** tab and choose the ellipsis (three dots) next to the dimension that you want to sort, and then choose **Edit**.
4. For **Sort by**, use the dropdown to choose the dimension that you want to sort by.
5. For **Aggregation** dropdown, choose the aggregation that you want to specify.
6. For **Sort order**, choose **Ascending** or **Descending**.

Define limits in a repeating section

You can set limits to show only a certain number of distinct dimension values for each dimension of a repeating section. You can choose to show between 1 and 1000 distinct values. The default limit is 50.

To define limits in a repeating section

1. Navigate to the section that you want to add a repeating behavior to and choose the **Edit repeating section** (triple panel).
2. In the **Edit section** that opens, choose the ellipsis (three dots) next to the dimension that you want to change.
3. For **Limit to**, enter the number of values that you want to limit the sorting to. You can enter a number between 1 and 1000.

Considerations for limits

The following limitations apply to limits in repeating sections.

- An *instance* is defined as a distinct value of a dimension or a unique combination of values of multiple dimensions.
- If the number of unique instances for a dimension in a repeating section exceeds 1000, the PDF report is NOT generated. If this occurs, try one of the following options.
 - Define a limit for your dimension.
 - Create a sheet level filter to restrict the dimension values.
 - Use row level security (RLS) to restrict the dimension values.
 - Apply dataset filters.

Add system parameters to repeating sections

You can use text boxes to add system parameters to your paginated report's repeating section. This makes it possible to access dimensions that have been used to configure repeating sections. Repeating sections and dimensions need to be configured before you can access the dimensions in a text box. The system parameters can only be used within a repeating section.

To add system parameters to a repeating section from a text box

1. Choose the text box visual that you want, and then choose the **System parameters** icon in the far right of the text box toolbar.
2. From the dropdown that appears, choose the parameter that you want.

Add page breaks to repeating sections

Similar to section page breaks, you can add page breaks to repeating sections.

To add a page break to a repeating section

1. Navigate to the section that contains the repeating behavior that you want to change and choose the **Edit repeating section** (triple panel) icon.
2. In the **Repeating** tab of the **Edit section** pane that appears, check the box titled **Page break after each instance**.

An instance is defined as a distinct value of a dimension or a unique combination of values of multidimensions. If you clear the **Page break after each instance** checkbox, the page break is removed.

Changing paper size, margins, and orientation

After you create a pixel perfect report in Amazon Quick Sight, you can change the report format, orientation, and margins from the **Analysis settings** menu whenever you want.

To change the paper size of a pixel perfect report

1. From the Quick homepage, choose **Analyses**, and then choose the analysis that contains the pixel perfect report that you want to change.
2. Choose **Sheets** in the file menu and select **Layout Settings**.
3. Open the **Paper size** dropdown menu and choose the paper size that you want. Choose from the following options:
 - US letter (8.5 x 11 in.)
 - US legal (8.5 x 14 in.)
 - A0 (841 x 1189 mm)
 - A1 (594 x 841 mm)
 - A2 (420 x 594 mm)
 - A3 (297 x 420 mm)
 - A4 (210 x 297 mm)
 - A5 (148 x 210 mm)
 - Japan B4 (257 x 364 mm)
 - Japan B5 (182 x 257 mm)
4. Choose **Apply**.

To change the orientation of a report

1. From the Quick homepage, choose **Analyses**, and then choose the analysis that contains the pixel perfect report that you want to change.
2. Choose the **Settings** icon on the left.
3. Choose the orientation for your report, and then choose **Apply**.

To change the margins of a report

1. From the Quick start page, choose **Analyses**, and then choose the analysis that contains the pixel perfect report that you want to change.
2. Choose **Edit < Analysis Settings**.
3. Enter the margin values that you want your report to have, and then choose **Apply**.

Margin values are applied to every page of a pixel perfect report. You can't set custom settings for specific pages in a report, but you can set custom margins for sections using section padding. For more information on section padding, see [Section padding](#). Margin values are expressed in inches. The default margins for all reports are 0.5 inches.

Adding and removing page breaks to a report

You can add page breaks between sections of a pixel perfect report to organize the way data is rendered when the report is published by page. For example, let's say you have a report that contains two sections that are each 2.5 pages long. By default, Section 2 begins on the third page of the report directly following the end of Section 1. If you add a page break to the end of the Section 1, Section 2 begins on a new page, even if the last page of Section 1 only uses half of a page. This is useful when you don't want different sections to share pages, but you don't know how many pages each section will need.

To add or delete a page break

1. Select your section and choose the **Edit section** icon in the top left corner.
2. In the **Edit section** pane that opens on the left, select the **Page break after** check box.
3. Choose **Apply**.

When you check the **Page break after** box, a page break will appear at the end of the section. If you remove the check from the **Page break after** box, the page break is removed from the end of the section. Also, the proceeding section renders directly under the last page of the section, even if it causes the two sections to share a page.

You can also add or remove a page break from a report by choosing the plus (+) icon at the bottom of an existing section and choosing **Add page break** or **Remove page break**.

Adding and deleting visuals to a report

To add visuals to a section in a pixel perfect report

1. In your pixel perfect report, select the section that you want to add a visual to.
2. Choose the **ADD (+)** icon in **Visuals** pane.
3. Choose the visual type that you want to use in your report.

After you add a visual to a report, you can interact with it the same way you would if the visual was part of an interactive dashboard. You can drag and drop visuals anywhere you want, similar to a free-form layout in a Quick Sight interactive dashboard sheet. You can also overlap visuals, resize them, or bring them forward or to the back of the section. For more information on formatting visuals in Amazon Quick Sight, see [Formatting in Amazon Quick](#).

To delete a visual

1. In the section that you want to delete a visual from, select the visual that you want to delete.
2. Choose the three-dot icon in the upper right corner of the visual to open the on-visual menu.
3. Choose **Delete**.

When you delete a visual from a section of a pixel perfect report, you are only deleting that specific visual from the report. Any duplicate visuals that are located in different sections of the report will remain in the report.

Adding a text box to a report

You can add text boxes to your pixel perfect reports to add context to your reports. Text box visuals can also be used boxes to add hyperlinks to external websites. To customize the font, font style, text color, text spacing, text alignment, and text size, use the text box toolbar that appears when you select the visual.

To add a text box to a report

1. In your pixel perfect report, select the section that you want to add a text box to.
2. Choose the **Text box** icon in the task bar.
3. The new text box appears in the section of the report that you selected.

To edit a text box, select the text box and begin typing what you want. A toolbar appears that you can use to make changes to the formatting and style of the text.

To delete a text box

1. In the section that you want to delete a text box from, select the text box that you want to delete.
2. Choose the three-dot icon in the upper right corner of the visual to open the on-text box menu.
3. Choose **Delete**.

Text box system parameters

Use text boxes to add system parameters to your pixel perfect report's headers and footers. Text box system parameters appear on the far right side of the text box toolbar. You can add the following parameters to a header or footer of your report:

- Page numbers: The current page number of the report.
- Report print date: The date the report was generated.

To add a page number parameter to your text box, choose the number (#) icon on the far right side of the text box toolbar. To add a `PrintDate` parameter to your text box, choose the calendar icon on the far right side of the text box toolbar.

For more advanced parameter options, add an insight to your paginated report.

Setting up prompts for paginated reports

Amazon Quick authors can create prompts on pixel-perfect reports to allow dashboard users to filter data in on-demand and scheduled reports. *Prompts* behave the same way a filter or control behaves in an interactive sheet.

To define a prompt in a pixel perfect report

1. On a pixel perfect sheet, define a filter control or a parameter control. For more information on filter controls to sheets, see [Adding filter controls to analysis sheets](#). For more information on parameter controls, see [Using a control with a parameter in Amazon Quick](#).
2. In the new filter or parameter, choose the prompt values that you want. The new prompts are immediately reflected on the sheet.

3. To export the report with the new prompts, choose **File**, and then choose **Export to PDF**.

Prompts can't be moved to the sheet itself. Instead, they are displayed on the top panel.

After a prompt is created for a pixel-perfect report and is published as a dashboard, Quick authors can use the new prompt to configure and schedule reports that are sent to Quick dashboard viewers. Dashboard viewers can also use these prompts to create their own scheduled reports. For more information about reader generated reports, see [Creating a reader generated report in Amazon Quick Sight](#).

Consuming pixel perfect reports in Amazon Quick Sight

When an Amazon Quick author publishes and then sends a scheduled pixel perfect report, Quick will generate and save a snapshot of the report that is sent out. Whenever you go to view the pixel perfect report's dashboard, you will see the generated snapshot of the most recently sent report. If you try to view your report's dashboard but you haven't sent an email report yet, you are prompted to schedule your first report to see the dashboard snapshot. For more information on scheduling an email report, see [Scheduling and sending Quick Sight reports by email](#).

If a Quick author has set up a prompted report for a Quick Sight pixel perfect report, Quick readers can use the prompt to schedule their own on-demand reports for themselves. For more information about reader-generated reports, see [Creating a reader generated report in Amazon Quick Sight](#). For more information about prompts for pixel perfect reports, see [Setting up prompts for paginated reports](#).

Users can't interact with a published pixel perfect report the same way they can interact with a published interactive sheet. Unlike interactive sheets, pixel perfect reports generate static snapshots of data that is presented in groups of visuals or text boxes. These static snapshots are generated at the time that the report is sent, so that the audience can see the latest version of the data in the report. Pixel perfect reports are especially useful for generating invoices or weekly business reviews. Users can then compare the current pixel perfect reports with reports that were generated in the past to better track their business data.

Viewing a report's snapshot history

Every time you send out a scheduled pixel perfect report, Amazon Quick saves a copy of the generated snapshot that is sent out for your reference. You can view these snapshots at any time in the Quick console.

To view a report's snapshot history

1. From the Quick homepage, choose **Dashboards**, and then choose the dashboard whose snapshot history you want to see.
2. Choose the **Scheduling** icon in the top right toolbar, and then choose **Recent snapshots**.
3. In the **Recent snapshots** pane that appears on the right, choose the snapshot to view, and then choose the download button next to the file that you want to download.

Unsubscribe from paginated reporting in Quick Sight

You can unsubscribe from Quick Sight pixel perfect reporting at any time. Once you unsubscribe from pixel perfect reporting, you will lose the ability to create and schedule pixel perfect reports in Quick Sight. You are still able to access your existing paginated reports, but you won't be able to make changes or schedule new reports.

To unsubscribe from pixel perfect reporting in Amazon Quick Sight

1. From any page in Quick, choose your user name in the upper right, and choose **Manage Quick**.
2. Choose **Manage subscriptions** on the left.
3. On the **Manage subscriptions** page, locate the **Pixel-Perfect Reports** section and choose **Manage**.
4. Scroll down to your chosen subscription plan and choose **Cancel subscription**.

Working with items on sheets in Amazon Quick Sight analyses

Use this section to learn how to work with visuals and other items as you author sheets in Quick Sight

Topics

- [Adding visuals to Quick Sight analyses](#)
- [Using Topics on sheets in Amazon Quick Sight](#)
- [Visual types in Amazon Quick Sight](#)
- [Formatting in Amazon Quick](#)
- [Customizing data presentation](#)

Adding visuals to Quick Sight analyses

A *visual* is a graphical representation of your data. You can create a wide variety of visuals in an analysis, using different datasets and visual types.

After you have created a visual, you can modify it in a range of ways to customize it to your needs. Possible customizations include changing what fields map to visual elements, changing the visual type, sorting visual data, or applying a filter.

Quick Sight supports up to 50 datasets in a single analysis, and up to 50 visuals in a single sheet, and a limit of 20 sheets per analysis.

You can create a visual in several ways. You can select the fields that you want and use AutoGraph to let Amazon Quick Sight determine the most appropriate visual type. Or you can choose a specific visual type and choose fields to populate it. If you aren't sure what questions your data can answer for you, you can choose **Suggested** on the tool bar and choose a visual that Amazon Quick Sight suggests. Suggested visuals are ones that we think are of interest, based on a preliminary examination of your data. For more information about AutoGraph, see [Using AutoGraph](#).

You can add more visuals to the workspace by choosing **Add**, then **Add visual**. Visuals created after June 21, 2018, are smaller in size, fitting two on each row. You can resize the visuals and drag them to rearrange them.

To create a useful visual, it helps to know what question you are trying to answer as specifically as possible. It also helps to use the smallest dataset that can answer that question. Doing so helps you create simpler visuals that are easier to analyze.

Fields as dimensions and measures

In the **Visuals** pane, dimension fields have blue icons and measure fields have orange icons. *Dimensions* are text or date fields that can be items, like products. Or they can be attributes that are related to measures and can be used to partition them, like sales date for sales figures. *Measures* are numeric values that you use for measurement, comparison, and aggregation. You typically use a combination of dimension and measure fields to produce a visual, for example sales totals (a measure) by sales date (a dimension). For more information about the types of fields expected by the different visual types, see the specific visual type topics in the [Visual types in Amazon Quick Sight](#) section. For more information about changing a field's measure or dimension setting, see [Setting fields as a dimensions or measures](#).

Field limitations

You can only use one date field per visual. This limitation applies to all visual types.

You can't use the same field for more than one dimension field well or drop target on a visual. For more information about how expected field type is indicated by field wells and drop targets, see [Using visual field controls](#).

Searching for fields

If you have a long field list in the **Fields list** pane, you can search to locate a specific field. To do so, choose the search icon at the top of the **Data** pane and then enter a search term into the search box. Any field whose name contains the search term is shown. Search is case-insensitive and wildcards aren't supported. Choose the cancel icon (X) to the right of the search box to return to viewing all fields.

Adding a visual

Use the following procedure to create a new visual.

To create a new visual

1. Open the [Quick console](#).
2. On the Quick homepage, choose the analysis that you want to add a visual to.
3. On the analysis page, choose the dataset that you want to use from the dataset list at the top of the **Data** pane. For more information, see [Adding a dataset to an analysis](#).
4. Open the **Visualize** pane, choose **Add**, and then choose **Add visual**.

A new, blank visual is created and receives focus.

5. Use one of the following options:
 - Choose the fields to use from the **Data** pane at left. If the fields aren't visible, choose **Visualize** to display it. Amazon Quick Sight creates the visual, using the visual type it determines is most compatible with the data you selected.
 - Choose the dropdown arrow next to the **ADD** button to choose a visual type. After the visual is created, choose the fields that you want to populate it.
 1. Choose the icon of a visual type from the **Visual types** pane.

The field wells display the fields that are visualized.

2. From the **Data** pane, drag the fields that you want to use to the appropriate field wells. Typically, you want to use dimension or measure fields as indicated by the color of the

target field well. If you choose to use a dimension field to populate a **Value** field well, the **Count** aggregate function is automatically applied to it to create a numeric value.

Amazon Quick Sight creates the visual using the visual type you selected.

- Create a visual using a suggestion.

On the tool bar, choose **Suggested**, then choose a suggested visual.

Importing Amazon Quick Sight visuals to an analysis

Quick Sight authors can import Quick Sight visuals from one analysis or dashboard to a new analysis that has access privileges. When you import a visual from a Quick Sight analysis or dashboard to another Quick Sight analysis, the following dependencies are imported along with the visual.

- Datasets associated with the visual
- All parameters that are configured to the visual
- Calculated fields that are configured to the visual
- Filter definitions
- Visual properties
- Conditional formatting rules

Use the following sections to learn more about importing Quick Sight visuals.

Topics

- [Considerations](#)
- [Import a visual](#)

Considerations

Before you import a visual, review the following limitations.

- The Quick Sight author that wants to import a visual must have ownership privileges to the analysis that they want to import the visual to
- Filter controls can't be imported
- Importing visuals from multiple sheets at a time is not supported

- Some user configurations including filter configurations that are maintained against bookmarks and alerts are not supported

Import a visual

Use the following procedure to import a visual from a source dashboard or analysis to a different analysis.

1. Open the [Quick console](#).
2. Open the analysis that you want to import a visual to.
3. Choose **File**, and then choose **Import**. Alternatively, you can choose the **Import** icon in the **ADD** toolbar.
4. The **Asset explorer** modal opens. A list of all eligible source analyses and dashboards that you can access are displayed. Choose the artifact that you want to import a visual from, and then choose **LOAD**. Alternatively, enter the name of the source artifact that contains the visual that you want to import in the **Find source to insert** search bar. Choose the artifact that you want, and then choose **LOAD**.
5. In the **Select visuals to import** page that opens, choose the sheet that contains the visuals that you want to import, and then choose the visuals that you want to import. You can only import visuals from one sheet at a time. When you have chosen all visuals that you want to import, choose **IMPORT**.

After a successful import job, the imported visuals are added to the destination analysis. The imported visuals retain the original properties that were configured to them in the source dashboard or analysis. Imported visuals inherit the theme-level properties from the theme that is applied to the destination analysis.

Duplicating Quick Sight visuals

You can duplicate a visual to make a new copy of it on the same sheet or on a different sheet.

To duplicate a visual, on the v-shaped on-visual menu, choose **Duplicate visual to**, then choose the sheet where you want the visual to appear. The display automatically shows you the duplicated visual.

Duplicated visuals keep all the same filters and settings as the source visual. However, if you duplicate a visual onto a different sheet, all of its copied filters apply to the duplicate only. All

copied filters are scoped down to apply only to that visual. If you want the filters to apply to more visuals on the new sheet, edit the filter and change the setting.

Parameters and controls apply to all sheets. To make parameter controls work with a visual that you duplicate to a different sheet, add filters on the target sheet and connect them to the parameter. To do this, choose **Custom filter** as the filter type.

Renaming Amazon Quick Sight visuals

Use the following procedure to rename a visual.

To rename a visual

1. On the analysis page, choose the visual that you want to rename.
2. Select the visual name at the top left of the visual and enter a new name.
3. Press **Enter** or click outside of the visual name field to save the new name.

Viewing visual data in Amazon Quick Sight

Amazon Quick Sight offers a variety of ways to see the details of the data being displayed in a visual. The axes or rows and columns of the visual (depending on the visual type) have labels. Hovering over any graphical element in a visual displays the data associated with that element. Some visual types use visual cues to emphasize the element that you are hovering over and make it easier to differentiate. For example, the visual type might change the color of the element or highlight it.

Use the following sections to learn more about viewing data in visuals.

Topics

- [Viewing visual details](#)
- [Scrolling through visual data](#)
- [Focusing on visual elements](#)
- [Excluding visual elements](#)
- [Searching for specific values in your data in Quick Sight](#)

Viewing visual details

When viewing a visual, you can hover your cursor over any graphical element to get details on that element. For example, when you hover over a single bar on a bar chart, information about that specific bar displays in a tooltip.

Hovering your cursor over a single data point on a scatter plot also displays information about that specific data point.

You can customize the information that appears when you hover your cursor over data in a chart. For more information, see [Tooltips](#).

Scrolling through visual data

For bar charts, line charts, and pivot tables, the content of the visual can be larger than the size that you want the visual to be.

In these cases, scrub bars appear so you can either reduce the data that is displayed or scrub through it. This process is similar to the way that you can scrub through a video.

To reduce the length of the scrub bar, hover over one end of it until the cursor changes shape. Then drag the widget to make the scrub bar larger or smaller. To scroll through the data, click and hold the scrub bar and slide it toward the end that you want to see.

Focusing on visual elements

When viewing visuals, you can choose data that you want to focus on or exclude. To perform this choice, choose an element such as a bar or bubble, or a row or column header.

Focusing on or excluding data causes Quick Sight to create a filter and show only the data that you selected.

To remove the filter, choose **Filters** at left and then disable or delete the filter. You can also use **Undo** to remove a filter.

If your visual has a legend that shows categories (dimensions), you can click on the values in the legend to see a menu of available actions. For example, suppose that your bar chart has a field in the **Color** or **Group/Color** field well. The bar chart menu displays the actions that you can choose by clicking or right-clicking on a bar, such as the following:

- Focusing on, or excluding, visual elements
- Changing colors of visual elements
- Drilling down into a hierarchy
- Custom actions activated from the menu, including filtering or URL actions

Excluding visual elements

When viewing visuals, you can choose an element on the visual, and then choose to focus on the element. Elements to focus on can include, for example, a bar or bubble, or a row or column header in the case of a pivot table. The exception is that you can't exclude elements that are mapped to date fields. You can exclude multiple elements on a single chart.

Excluding the element creates a filter that removes only that element from the visual.

To see the excluded element again, you can either choose **Undo** on the application bar, or you can disable or delete the filter.

For more information about filters, see [Filtering data in Amazon Quick Sight](#).

Searching for specific values in your data in Quick Sight

When filtering your visual data, previewing anomalies, or using list or dropdown controls in a dashboard, you can quickly search for values that interest you.

You can search for specific values or all values that contain a specific search query. For example, searching for *al* in a list of U.S. states returns **Alabama**, **Alaska**, and **California**.

You can also use wildcard search to search for all values that match a specific character pattern. For example, you can search for all U.S. states that end with the letters *ia* and narrow the results down to California, Georgia, Pennsylvania, Virginia, and West Virginia.

To search for values in a filter or control, enter a search query in the search bar.

Using wildcard search

The following wildcard characters can be used to find values in Quick Sight filters, list and dropdown controls, and anomaly previews.

- ***** - Use an asterisk symbol to search for values that match zero to many characters in a specific position.
- **?** - Use a question mark to match a single character in a specific position.
- **** - Use a backslash to escape the *****, **?**, or **** wildcard characters and search for them in your query. For example, you can search for phrases that end with a question mark.

Following are examples of how supported wildcard characters can be used in a Quick Sight search query.

- **al** - This query searches for all values with **al** and returns Alabama, Alaska, and California.
- **al*** - This query searches for all values that begin with **al** and end with zero to multiple characters. It returns Alabama, and Alaska in a list of U.S. states.
- ***ia** - This query searches for all values that begin with zero to multiple characters and end with letters **ia**. It returns California, Georgia, Pennsylvania, Virginia, and West Virginia.
- ***al*** - This query searches for all values with zero to multiple characters before and after the letters **al**. It returns Alabama, Alaska, and California.
- **a?a?a?a** - This query searches for all values with a single character in the exact positions between the **a** letters. It returns Alabama.
- **a?a*a** - This query searches for all values with a single character between the first two **a** letters and multiple characters between the second two **a** letters. It returns Alabama and Alaska.
- **How*\?** - This query searches for values that begin with **How**, followed by zero to multiple characters, and end with a question mark. The backslash (****) in this query informs Quick Sight to

search for question marks in each value, rather than use the question mark symbol as a wildcard character. This query returns the questions, How are you? and, How is this possible?

- `\**` - This query searches for values that begin with an asterisk and are followed by zero to multiple characters. The backslash (\) in this query informs Quick Sight to search for an actual asterisk in the values, rather than use the asterisk symbol as a wildcard character. This query returns values such as `*all`, `*above`, and `*below`.
- `\\*` - This query searches for values with a backslash, followed by zero to multiple characters. The first backslash (\) in this query informs Quick Sight to search for the second backslash (\) in each value, rather than use the backslash symbol as a wildcard character. This query returns results such as `\Home`.
- `???` - This query searches for values that contain three characters. It returns values such as `ant`, `bug`, and `car`.

Exporting data from visuals

Note

Export files can directly return information from the dataset import. This makes the files vulnerable to CSV injection if the imported data contains formulas or commands. For this reason, export files can prompt security warnings. To avoid malicious activity, turn off links and macros when reading exported files.

Using the Amazon Quick console, you can export data from any type of chart or graph. The export contains only the data in the fields that are currently visible in the selected visualization. Any data that is filtered out is excluded from the export file. You can export data into the following formats:

- A text file containing comma-separated values (CSV), available for all visual types.
- A Microsoft Excel workbook file (.xlsx), available for pivot tables and table charts only.

The following rules apply:

- Exported files are downloaded to the default download directory configured in the browser that you're currently using.
- The downloaded file is named for the visualization that you exported it from. To make the file name unique, it has a sequential timestamp (a Unix epoch data type).

- Default limit for export to CSV format: 500 MB or 1M rows whichever comes first
- Default limit for export to Excel format:
 - from Pivot Table visual 400K cells or 50K rows
 - from Table visual 800K cells or 100K rows

 Note

With a subscription to Paginated Reporting, you are able to [schedule the export of visuals in CSV and Excel formats](#) and export up to 3M rows (CSV) and 16M cells (Excel).

- You can't export data from an insight, because insights consume the data, but don't contain the data.
- Quick Sight doesn't support exporting data from more than a single visualization at a time. To export data from additional visuals in the same analysis or dashboard, repeat this process for each visual. To export all the data from a dashboard or analysis, you need to connect to the original data source using valid credentials and a tool that you can use to extract data.

Use the following procedure to export data from a visualization in Amazon Quick Sight. Before you begin, open the analysis or dashboard that contains the data that you want to export.

To export data from a visualization

1. Choose the visualization that you want to export. Make sure that it is selected and highlighted.
2. At top right on the visual, open the menu and choose one of the following:
 - To export to CSV, choose **Export to CSV**.
 - To export to XSLX, choose **Export to Excel**. This option is available only for pivot tables and table charts.
3. Depending on your browser settings, one of the following happens:
 - The file automatically goes to your default **Download** location.
 - A dialog box appears so you can choose a file name and location.
 - A dialog box appears so you can choose to open the file with the default software or to save to.

Refreshing visuals in Quick Sight

When you work in an Quick Sight analysis or dashboard, visuals refresh and reload when you change something that affects them, such as updating a parameter or filter control. If you switch to a new sheet after a parameter or filter changes, only the visuals affected by the change refresh on the new sheet. Otherwise, visuals update every 30 minutes when you switch sheets. This is the default behavior for all analyses and dashboards.

If you want to refresh all visuals when you switch sheets, regardless of a change, you can do so for each analysis that you create.

To refresh all visuals each time that you switch sheets in an analysis

1. In Amazon Quick, open the analysis.
2. In the analysis, choose **Edit > Analysis Settings**.
3. In the **Analysis Settings** pane that opens, for **Refresh Options**, toggle on **Reload visuals each time I switch sheets**.
4. Choose **Apply**.

Deleting Amazon Quick Sight visuals

Use the following procedure to delete a visual.

To delete a visual

1. On the analysis page, choose the visual that you want to delete.
2. Choose the on-visual menu at the upper-right corner of the visual, and then choose **Delete**.

Using Topics on sheets in Amazon Quick Sight

You can use Quick Sight Topics as the data model for your analysis sheets. When you create an analysis from a Topic, you can select fields from any of the datasets in the Topic and Quick Sight automatically performs runtime inner joins based on the defined relationships. This eliminates the need to pre-join tables into a single flat dataset before building an analysis.

Creating an analysis from a Topic

To use a Topic as the data model for an analysis, use the following procedure.

To create an analysis from a Topic

1. On the Quick homepage, choose **Data** in the navigation pane, then choose the **Topics** tab.
2. Open the Topic you want to use.
3. Choose **Create analysis**.
4. Select **Interactive sheet** and choose **Create**.
5. In the analysis, the fields list shows columns from all datasets in the Topic. Select fields from multiple datasets and add them to a visual. Quick Sight performs runtime inner joins automatically based on the defined relationships.

The following rules apply when working with Topics in analysis sheets:

- You must have Owner or Viewer permissions on the Topic to use it in an analysis.
- When a visual references fields from multiple datasets, Quick Sight uses the defined relationships to determine the join path and performs inner joins at runtime.
- You can create calculated fields that reference columns from different datasets within the Topic.
- Row-level security (RLS) rules are enforced during runtime joins. Users see only the intersection of rows they are permitted to access in each dataset.
- Each dataset in the Topic can have its own independent refresh schedule. Visuals always reflect the latest data available in each dataset.

Note

Runtime joins in analysis sheets use inner join semantics only. Rows without matching keys in both datasets are excluded from visual results. If you need outer join behavior, use the Topic in Amazon Quick chat, where the LLM-powered chat agent can generate SQL with outer joins based on custom instructions.

For more information about creating and configuring Topics, see [Working with Amazon Quick Sight Topics](#).

Enabling legacy Topics in an analysis

Note

The following applies to legacy Topics only. For information about the differences between new Topics and legacy Topics, see [Working with legacy Topics](#).

For legacy Topics, you can enable a topic in an analysis to activate the ML-powered automated data prep, which speeds natural language topic creation. Automated data prep automatically selects high-value fields, chooses user-friendly field names and synonyms, and formats data for presentation.

Automated data prep binds the legacy Topic to your analysis and prepares an index for searching in natural language. Dashboard users find that the linked topic is automatically selected in the search bar, making it easier for them to query the dataset.

The following rules apply to working with legacy Topics in an analysis:

- You must be an owner of the underlying dataset before you can create a legacy Topic using that dataset or an analysis that uses that dataset.
- You must be an owner of a legacy Topic before you can link it to an analysis.

To enable a legacy Topic

1. Open the analysis that you want to use with automated data prep.
2. On the top navigation bar, choose the topic icon.
3. Choose one of the following:
 - To activate a new topic, select **Create new topic** and enter a topic title and optional description.
 - To activate an existing topic, select **Update existing topic** and choose the topic from the list.
4. Choose **ENABLE TOPIC** to confirm your choice.
5. When the topic is finished processing, you can use what it learned from the analysis to ask questions in natural language.

Now, when users navigate to the dashboard, the linked topic is automatically selected in the search bar.

After a legacy Topic is linked to an analysis, further updates to the analysis are not automatically synced to the topic. Authors need to manage updating topics manually from the **Topics** page.

Visual types in Amazon Quick Sight

Amazon Quick Sight offers a range of visual types that you can use to display your data. Use the topics in this section to learn more about the capabilities of each visual type.

Topics

- [Measures and dimensions](#)
- [Display limits](#)
- [Hiding or displaying the other category](#)
- [Customizing the number of data points to display](#)
- [Using AutoGraph](#)
- [Using bar charts](#)
- [Using box plots](#)

- [Creating maps and geospatial charts](#)
- [Using small multiples](#)
- [Using pie charts](#)

- [Using pivot tables](#)
- [Using radar charts](#)
- [Using Sankey diagrams](#)
- [Using scatter plots](#)
- [Using tables as visuals](#)
- [Using text boxes](#)
- [Using tree maps](#)
- [Using waterfall charts](#)
- [Using word clouds](#)

Measures and dimensions

We use the term *measure* to refer to numeric values that you use for measurement, comparison, and aggregation in visuals. A measure can be either a numeric field, like product cost, or a numeric aggregate on a field of any data type, like count of transaction IDs.

We use the term *dimension* or *category* to refer to text or date fields that can be items, like products, or attributes that are related to measures and can be used to partition them. Examples are sales date for sales figures or product manufacturer for customer satisfaction numbers. Amazon Quick Sight automatically identifies a field as a measure or a dimension based on its data type.

Numeric fields can act as dimensions, for example ZIP codes and most ID numbers. It's helpful to give such fields a string data type during data preparation. This way, Amazon Quick Sight understands that they are to be treated as dimensions and are not useful for performing mathematical calculations.

You can change whether a field is displayed as a dimension or measure on an analysis-by-analysis basis instead. For more information, see [Fields as dimensions and measures](#).

Display limits

All visual types limit the number of data points they display, so that the visual elements (like lines, bars, or bubbles) are still easy to view and analyze. The visual selects the first n number of rows for display up to the limit for that visual type. The selection is either according to sort order, if one has been applied, or in default order otherwise.

The number of data points supported varies by visual type. To learn more about display limits for a particular visual type, see the topic for that type.

The visual title identifies the number of data points displayed if you have reached the display limit for that visual type. If you have a large dataset and want to avoid running into the visual display limit, use one or more filters to reduce the amount of data displayed. For more information about using filters with visuals, see [Filtering data in Amazon Quick Sight](#).

For dashboards and analyses, Amazon Quick Sight supports the following:

- 50 datasets per dashboard
- 20 sheets per dashboard
- 30 visualization objects per sheet

Note

Amazon Quick Sight supports over 30 different *visual types* (categories of charts and visualizations such as bar charts, pie charts, and line charts). Each analysis sheet can contain up to 30 *visual instances* (individual chart objects) of any combination of types.

You can also choose to limit how many data points you want to display in your visual, before they are added to the **other** category. This category contains the aggregated data for all the data beyond the cutoff limit for the visual type you are using—either the one you impose, or the one based on display limits. You can use the on-visual menu to choose whether to display the **other** category. The **other** category doesn't show on scatter plots, heat maps, maps, tables (tabular reports), or key performance indicators (KPIs). It also doesn't show on line charts when the x-axis is a date. Drilling down into the **other** category is not supported.

Hiding or displaying the other category

Use the following procedure to hide or display the "other" category.

To hide or display the "other" category

1. On the analysis page, choose the visual that you want to modify.
2. Choose the on-visual menu at the upper-right corner of the visual, and then choose **Hide "other" category** or **Show "other" category**, as appropriate.

Customizing the number of data points to display

You can choose the number of data points to display on the main axis of some visuals. After this number is displayed in the chart, any additional data points are included in the "other" category. For example, if you choose to include 10 data points out of 200, 10 display in the chart and 190 become part of the "other" category.

To find this setting, choose the v-shaped on-visual menu, then choose **Format visual**. You can use the following table to determine which field well contains the data point setting and what number of data points the visual type displays by default.

Visual type	Where to find the data point setting	Default number of data points
Bar chart, horizontal	Y-axis – Number of data points displayed	10,000
Bar chart, vertical	X-axis – Number of data points displayed	10,000
Combo chart	X-axis – Number of data points displayed	2,500
Heat map	Rows – Number of rows displayed Columns – Number of columns displayed	100
Line chart	X-axis – Number of data points displayed	10,000
Pie chart	Group/Color – Number of slices displayed	20
Tree map	Group by – Number of squares displayed	100

Using AutoGraph

AutoGraph isn't a visual type itself, but instead lets you tell Amazon Quick to choose the visual type for you. When you create a visual by choosing AutoGraph and then selecting fields, Amazon Quick uses the most appropriate visual type for the number and data types of the fields you select.

Creating a visual using AutoGraph

Use the following procedure to create a visual using AutoGraph.

To create a visual using AutoGraph

1. On the analysis page, choose **Visualize** on the tool bar.
2. Choose **Add** on the application bar, and then choose **Add visual**.
3. On the **Visual types** pane, choose the AutoGraph icon.
4. On the **Fields list** pane, choose the fields that you want to use.

Using bar charts

Amazon Quick supports the following types of bar charts, with either horizontal or vertical orientation:

- **Single-measure** – A *single-measure bar chart* shows values for a single measure for a dimension.
- **Multi-measure** – A *multi-measure bar chart* shows values for multiple measure for a dimension.
- **Clustered** – A *clustered bar chart* shows values for a single measure for a dimension, grouped by another dimension.
- **Stacked** – A *stacked bar chart* is similar to a clustered bar chart in that it displays a measure for two dimensions. However, instead of clustering bars for each child dimension by the parent dimension, it displays one bar per parent dimension. It uses color blocks within the bars to show the relative values of each item in the child dimension. The color blocks reflect the value of each item in the child dimension relative to the total for the measure. A stacked bar chart uses a scale based on the maximum value for the selected measure.
- **Stacked 100 percent** – A *stacked 100 percent bar chart* is similar to a stacked bar chart. However, in a stacked 100 percent bar chart, the color blocks reflect the percentage of each item in the child dimension, out of 100 percent.

Bar charts show up to 10,000 data points on the axis for visuals that don't use group or color. For visuals that do use group or color, they show up to 50 data points on the axis and up to 50 data points for group or color. For more information about how Amazon Quick handles data that falls outside display limits, see [Display limits](#).

Creating single-measure bar charts

Use the following procedure to create a single-measure bar chart.

To create a single-measure bar chart

1. On the analysis page, choose **Visualize** on the toolbar at left.
2. On the application bar at upper left, choose **Add**, and then choose **Add visual**.
3. On the **Visual types** pane, choose the **Horizontal bar chart** or **Vertical bar chart** icon.
4. From the **Fields list** pane, drag a dimension to the **X-axis** or **Y-axis** field well.
5. From the **Fields list** pane, drag a measure to the **Value** field well.

Creating multi-measure bar charts

Use the following procedure to create a multi-measure bar chart.

To create a multi-measure bar chart

1. On the analysis page, choose **Visualize** on the toolbar at left.
2. On the application bar at upper-left, choose **Add**, and then choose **Add visual**.
3. On the **Visual types** pane, choose the **Horizontal bar chart** or **Vertical bar chart** icon.
4. From the **Fields list** pane, drag a dimension to the **X-axis** or **Y-axis** field well.
5. From the **Fields list** pane, drag two or more measures to the **Value** field well.

Creating clustered bar charts

Use the following procedure to create a clustered bar chart.

To create a clustered bar chart

1. On the analysis page, choose **Visualize** on the toolbar at left.
2. On the application bar at upper left, choose **Add**, and then choose **Add visual**.
3. On the **Visual types** pane, choose the **Horizontal bar chart** or **Vertical bar chart** icon.
4. From the **Fields list** pane, drag a dimension to the **X-axis** or **Y-axis** field well.
5. From the **Fields list** pane, drag a measure to the **Value** field well.
6. From the **Fields list** pane, drag a dimension to the **Group/Color** field well.

Creating stacked bar charts

Use the following procedure to create a stacked bar chart.

To create a stacked bar chart

1. On the analysis page, choose **Visualize** on the toolbar at left.
2. On the application bar at upper-left, choose **Add**, and then choose **Add visual**.
3. On the **Visual types** pane, choose the **Horizontal stacked bar chart** or **Vertical stacked bar chart** icon.
4. From the **Fields list** pane, drag a dimension to the **X-axis** or **Y-axis** field well.
5. From the **Fields list** pane, drag a dimension to the **Group/Color** field well.
6. From the **Fields list** pane, drag a measure to the **Value** field well.
7. (Optional) Add data labels and show totals:
 - a. On the menu in the upper-right corner of the visual, choose the **Format visual** icon.
 - b. In the **Visual** pane, choose **Data labels**.
 - c. Toggle the switch to display data labels.

Labels for each measure value appear in the chart and the option to show totals appears in the pane.

- d. Check **Show totals**.

Totals appear for each bar in the chart.

Creating stacked 100 percent bar charts

Use the following procedure to create a stacked 100 percent bar chart.

To create a stacked 100 percent bar chart

1. On the analysis page, choose **Visualize** on the toolbar at left.
2. On the application bar at upper-left, choose **Add**, and then choose **Add visual**.
3. On the **Visual types** pane, choose the **Horizontal stacked 100% bar chart** or **Vertical stacked 100% bar chart** icon.
4. From the **Fields list** pane, drag a dimension to the **X-axis** or **Y-axis** field well.
5. From the **Fields list** pane, drag two or more measures to the **Value** field well.

Bar chart features

To understand the features supported by bar charts, use the following table.

Feature	Supported?	Comments	For more information
Changing the legend display	Yes, with exceptions	Multi-measure and clustered bar charts display a legend, while single-measure horizontal bar charts don't.	Legends on visual types in Quick
Changing the title display	Yes		Titles and subtitles on visual types in Quick
Changing the axis range	Yes		Range and scale on visual types in Quick
Showing or hiding axis lines, grid lines, axis labels, and axis sort icons	Yes		Axes and grid lines on visual types in Quick
Changing the visual colors	Yes		Colors in visual types in Quick
Focusing on or excluding elements	Yes, with exceptions	You can focus on or exclude any bar on the chart, except when you are using a date field as the dimension for the axis. In that case, you can only focus on a bar, not exclude it.	Focusing on visual elements Excluding visual elements
Sorting	Yes	You can sort on the fields you choose for the axis and the values.	Sorting visual data in Amazon Quick

Feature	Supported?	Comments	For more information
Performing field aggregation	Yes	You must apply aggregation to the field or fields you choose for the value, and can't apply aggregation to the fields you choose for the axis or group/ color.	Changing field aggregation
Adding drill-downs	Yes	You can add drill-down levels to the axis and Group/Color field wells.	Adding drill-downs to visual data in Quick Sight
Showing data labels	Yes		Data labels on visual types in Quick
Showing stacked bar chart totals	Yes	Showing totals in a stacked bar chart is only available when you choose to show data labels.	Stacked bar charts

Using box plots

Box plots, also known as box and whisker plots, display data pooled from multiple sources into one visual, helping you make data-driven decisions. Use a box plot to visualize how data is distributed across an axis or over time, for example flights delayed over a 7-day time period. Typically, a box plot details information in quarters:

- **Minimum** – The lowest data point excluding outliers.
- **Maximum** – The highest data point excluding outliers.
- **Median** – The middle value of the dataset.
- **First Quartile** – The middle value between the smallest number and the median of the dataset. The first quartile doesn't include the minimum or the median.
- **Third Quartile** – The middle value between the largest number and the median of the dataset. The third quartile doesn't include the maximum or the median.

Outliers are extreme data points that aren't included in the calculation of a box plot's key values. Because outliers are calculated separately, their data points don't appear immediately after a box plot is created. Box plots display up to 10,000 data points. If a dataset contains more than 10,000 data points, a warning appears at the upper-right corner of the visual.

Box plots support up to five metrics and one group-by, but don't render if duplicate metrics are supplied.

Box plots support some calculated fields, but not all. Any calculated field that uses a window function, for example `avgOver1`, results in a SQL error.

Box plot visuals aren't compatible with MySQL 5.3 and earlier.

To create a basic box plot visual

1. Sign in to Amazon Quick at <https://quicksight.aws.amazon.com/>.
2. Open Quick and choose **Analyses** on the navigation pane at left.
3. Choose one of the following:
 - To create a new analysis, choose **New analysis** at upper right. For more information, see [Starting an analysis in Quick Sight](#).
 - To use an existing analysis, choose the analyses that you want to edit.
4. Choose **Add, Add visual**.
5. At lower left, choose the box plot icon from **Visual types**.
6. On the **Fields list** pane, choose the fields that you want to use for the appropriate field wells. Box plots require at least one unique measure field.
7. (Optional) Add drill-down layers by dragging one or more additional fields to the **Group/Color** field well. For more information about adding drill-downs, see [Adding drill-downs to visual data in Quick Sight](#).

To understand the features supported by box plots, see [Analytics formatting per type in Quick](#). For customization options, see [Formatting in Amazon Quick](#).

Using combo charts

Using a combo chart, you can create one visualization that shows two different types of data, for example trends and categories. Combo charts are also known as line and column (bar) charts, because they combine a line chart with a bar chart. Bar charts are useful for comparing categories.

Both bar charts and line charts are useful for displaying changes over time, although bar charts should show a greater difference between changes.

Amazon Quick supports the following types of combo charts:

- **Clustered bar combo charts** – display sets of single-color bars where each set represents a parent dimension and each bar represents a child dimension. Use this chart to make it easy to determine values for each bar.
- **Stacked bar combo charts** – display multi-color bars where each bar represents a parent dimension and each color represents a child dimension. Use this chart to make it easy to see relationships between child dimensions within a parent dimension. This chart shows the total value for the parent dimension and how each child adds to the total value. To determine the value for each child dimension, the chart reader must compare the size of the color section to the data labels for that axis.

Both types of combo chart require only one dimension on the **X axis**, but are usually more effective when also displaying at least one measure under **Lines**.

Use a combo chart only if you want to show a relationship between the bars and the lines. A good rule of thumb is that if you need to explain how the two chart types relate, you should probably use two separate charts instead.

Because each chart works differently, it can be helpful to understand the following points before you begin:

- The data points in each series render on different scales. Combo charts use a scale based on the maximum value for the selected measure.
- The distance between the numbers on the axis won't match between the lines and bars, even if you select the same scale for each chart type.
- For clarity, try to use different units for the measure in each data series.

The combo chart is like using two different types of visualization at the same time. Make sure that the data in the bars (or columns) directly relates to the data in the line or lines. This relationship is not technically enforced by the tool, so it's essential that you determine this relationship yourself. Without some relation between the lines and bars, the visual loses meaning.

You can use the combo chart visual type to create a single-measure or single-line chart. A single-measure combo chart shows one measure for one dimension.

To create a multi-measure chart, you can choose to add multiple lines, or multiple bars. A multi-measure bar chart shows two or more measures for one dimension. You can group the bars in clusters, or stack them.

For the bars, use a dimension for the axis and a measure for the value. The dimension is typically a text field that is related to the measure in some way and can be used to segment it to see more detailed information. Each bar in the chart represents a measure value for an item in the dimension you chose.

Bars and lines show up to 2,500 data points on the axis for visuals that don't use group or color. For visuals that do use group or color, bars show up to 50 data points on the axis and up to 50 data points for group or color, while lines show 200 data points on the axis and up to 25 data points for group or color. For more information about how Amazon Quick handles data that falls outside display limits, see [Display limits](#).

Combo chart features

To understand the features supported by combo charts, use the following table.

Feature	Supported?	Comments	For more information
Changing the legend display	Yes, with exceptions	Multi-measure combo charts display a legend, and single-measure combo charts don't.	Legends on visual types in Quick
Changing the title display	Yes		Titles and subtitles on visual types in Quick
Changing the axis range	Yes	You can set the range for the axis.	Range and scale on visual types in Quick
Showing or hiding axis lines, grid lines, axis labels, and axis sort icons	Yes		Axes and grid lines on visual types in Quick

Feature	Supported?	Comments	For more information
Changing the visual colors	Yes		Colors in visual types in Quick
Focusing on or excluding elements	Yes, with exceptions	You can focus on or exclude any bar on the chart, except when you are using a date field as the dimension for the axis. In that case, you can only focus on a bar, not exclude it.	Focusing on visual elements Excluding visual elements
Sorting	Yes	You can sort on the fields you choose for the axis and the values.	Sorting visual data in Amazon Quick
Performing field aggregation	Yes	You must apply aggregation to the field or fields you choose for the value. You can't apply aggregation to the fields you choose for the axis or group/color.	Changing field aggregation
Adding drill-downs	Yes	You can add drill-down levels to the axis and Group/Color field wells.	Adding drill-downs to visual data in Quick Sight
Synchronizing y-axis	Yes	Synchronize the y-axes for both bars and lines into a single axis.	Range and scale on visual types in Quick

Creating a combo chart

Use the following procedure to create a combo chart.

To create a combo chart

1. On the analysis page, choose **Visualize** on the tool bar.
2. Choose **Add** on the application bar, and then choose **Add visual**.
3. On the **Visual types** pane, choose one of the combo chart icons.
4. From the **Fields list** pane, drag the fields that you want to use to the appropriate field wells. Typically, you want to use dimension or measure fields as indicated by the target field well. If you choose to use a dimension field as a measure, the **Count** aggregate function is automatically applied to it to create a numeric value. You can create combo charts as follows:
 - Choose a dimension for the **X axis**.
 - To create a single-measure combo chart, choose one measure for either **Bars** or **Lines**.
 - To create a multi-measure combo chart, choose two or more measures for the **Bars** or **Lines** field well.
 - Optionally, add a dimension to the **Group/Color** field well. If you have a field in **Group/Color**, you can't have more than one field under **Bars**.

5. (Optional) Add drill-down layers by dragging one or more additional fields to the **X axis** or **Group/Color** field wells. For more information about adding drill-downs, see [Adding drill-downs to visual data in Quick Sight](#).

Using custom visual content

You can embed webpages and online videos, forms, and images in your Quick dashboards using the custom visual content chart type.

For example, you can embed the image of your company logo in your dashboards. You can also embed an online video from your organization's latest conference, or embed an online form asking readers of the dashboard if the dashboard is helpful.

After you create custom visual content, you can use navigation actions to navigate within them. You can also use parameters to control what appears in them.

The following limitations apply to custom visual content:

- Only `https` URL schemes are supported.
- Custom visual content isn't supported in email reports.
- Images and websites that use hotlink protection won't load in custom visuals.

To embed a webpage, video, online form, or image in your dashboard, choose the custom visual content icon in the **Visual types** pane.

For more information about adding visuals to a dashboard, see [Adding a visual](#).

Use the following procedures to learn how to embed custom visuals in your dashboards.

Best practices for using custom visual content

When embedding web content using the custom visual content chart type, we recommend the following:

- Choose web content from sources that support viewing or opening the content in an `IFrame`. If the source of the web content doesn't support being viewed or opened in an `IFrame`, the content doesn't appear in Quick, even if the URL is accurate.
- When possible, use embeddable URLs, especially for videos, online forms, spreadsheets, and documents. Embeddable URLs create a better experience for readers of your dashboard and make interacting with the content easier. You can usually find the embeddable URL for content when you choose to share the content from the source website.
- To embed internal URLs or URLs that you own, you might need to set them to be opened in an `IFrame`.

- When viewing custom visual content in an analysis or dashboard, make sure you enable all cookies. If third-party cookies are blocked in your browser, images that are part of the website that is embedded within the custom content visual do not render.

Note

Chrome has announced plans to deprecate all third-party cookies by the end of 2024. This means that websites that are embedded within Quick custom content visuals will no longer show any contents that rely on third-party cookies in Chrome. For more information about Chrome's plans to deprecate third party cookies, see [Chrome is deprecating third-party cookies](#).

Embedding images in a dashboard

You can embed an online image in a dashboard using the image URL. Use the following procedure to embed an image using the custom visual content chart type.

Embedded images don't appear in a browser that has third-party cookies blocked. To see embedded images in a dashboard, enable third-party cookies in your browser settings.

To embed an image in a dashboard

1. In the **Visual types** pane, choose the custom visual content icon.
2. In the visual, choose **Customize visual**.
3. In the **Properties** pane that opens, under **Custom content**, enter the image URL for the image that you want to embed.
4. Choose **Apply**.

The image appears as a webpage in the visual.

5. Choose **Show as image**.

If the URL is an image, the image appears in the visual.

If the URL is not an image, such as a URL to a slide show, gallery, or webpage, the following message appears: This URL doesn't appear to be an image. Update the URL to an image. To do so, open the image that you want to embed in a separate browser tab, or choose an embeddable URL for the image (usually found when you choose to share the image).

6. (Optional) For **Image sizing options**, choose one of the following options:

- **Fit to width** – This option fits the image to the width of the visual.
- **Fit to height** – This option fits the image to the height of the visual.
- **Scale to visual** – This option scales the image to the width and height of the visual. This option might contort the image.
- **Do not scale** – This option keeps the image at its original scale and doesn't fit the image to the dimensions of the visual. With this option, the image is centered in the visual and the parts of the image that are within the width and height of the visual appear. Some parts of the image might not appear if the visual is smaller than the image. If the visual is larger than the image, however, the image is centered in the visual and is surrounded by white space.

Embedding online forms in a dashboard

You can embed an online form in a dashboard using the embeddable URL. Use the following procedure to embed an online form using the custom visual content chart type.

To embed an online form in a dashboard

1. In the **Visual types** pane, choose the custom visual content icon.
2. In the visual, choose **Customize visual**.
3. In the **Properties** pane that opens, under **Custom content**, enter the form URL for the online form that you want to embed.

If possible, use an embeddable URL for the form. Using an embeddable URL creates a better experience for readers of your dashboard who might want to interact with the form. You can often find the embeddable URL when you choose to share the form on the site where you create it.

4. Choose **Apply**.

The form appears in the visual.

Embedding webpages in a dashboard

You can embed webpage in a dashboard using the URL. Use the following procedure to embed webpage using the custom visual content chart type.

To embed a webpage in a dashboard

1. In the **Visual types** pane, choose the custom visual content icon.
2. In the visual, choose **Customize visual**.
3. In the **Properties** pane that opens, under **Custom content**, enter the URL for the webpage that you want to embed.
4. Choose **Apply**.

The webpage appears in the visual.

Embedding online videos in a dashboard

You can embed an online video in a dashboard using the embeddable video URL. Use the following procedure to embed an online video using the custom visual content chart type.

To embed an online video in a dashboard

1. In the **Visual types** pane, choose the custom visual content icon.
2. In the visual, choose **Customize visual**.
3. In the **Properties** pane that opens, under **Custom content**, enter the embeddable URL for the video that you want to embed.

To find the embeddable URL for a video, share the video and copy the embed URL from IFrame code. The following is an example of an embed URL for a YouTube video: `https://www.youtube.com/embed/uniqueid`. For a Vimeo video, the following is an example of an embed URL: `https://player.vimeo.com/video/uniqueid`.

4. Choose **Apply**.

The video appears in the visual.

Using donut charts

Use donut charts to compare values for items in a dimension. The best use for this type of chart is to show a percentage of a total amount.

Each wedge in a donut chart represents one value in a dimension. The size of the wedge represents the proportion of the value for the selected measure that the item represents compared to the

whole for the dimension. Donut charts are best when precision isn't important and there are few items in the dimension.

To learn how to use donut charts in Amazon Quick, you can watch this video:

[Using Donut Charts](#)

To create a donut chart, use one dimension in the **Group/Color** field well. With only one field, the chart displays the division of values by row count. To display the division of dimension values by a metric value, you can add a metric field to the **Value** field well.

Donut charts show up to 20 data points for group or color. For more information about how Amazon Quick handles data that falls outside display limits, see [Display limits](#).

Donut chart features

To understand the features supported by donut charts, use the following table.

Feature	Supported?	Comments	For more information
Changing the legend display	Yes		Legends on visual types in Quick
Changing the title display	Yes		Titles and subtitles on visual types in Quick
Changing the axis range	Not applicable		Range and scale on visual types in Quick
Changing the visual colors	Yes		Colors in visual types in Quick
Focusing on or excluding elements	Yes, with exceptions	You can focus on or exclude a wedge in a donut chart, except when you are using a date field as a dimension . In that case, you can only focus on a wedge, not exclude it.	Focusing on visual elements Excluding visual elements

Feature	Supported?	Comments	For more information
Sorting	Yes	You can sort on the field that you choose for the value or the group or color.	Sorting visual data in Amazon Quick
Performing field aggregation	Yes	You must apply aggregation to the field that you choose for the value, and can't apply aggregation to the field that you choose for group or color.	Changing field aggregation
Adding drill-downs	Yes	You can add drill-down levels to the Group/Color field well.	Adding drill-downs to visual data in Quick Sight
Choosing size	Yes	You can choose how thick the donut chart is: small, medium, and large.	Formatting in Amazon Quick
Showing totals	Yes	You can choose to display or hide the aggregate of the Value field. By default, this displays the total count of the Group/Color field, or the total sum of the Value field.	Formatting in Amazon Quick

Creating a donut chart

Use the following procedure to create a donut chart.

To create a donut chart

1. On the analysis page, choose **Visualize** on the tool bar.
2. Choose **Add** on the application bar, and then choose **Add visual**.
3. On the **Visual types** pane, choose the donut chart icon.

4. From the **Fields list** pane, drag the fields that you want to use to the appropriate field wells. Typically, you want to use dimension or measure fields as indicated by the target field well. If you choose to use a dimension field as a measure, the **Count** aggregate function is automatically applied to it to create a numeric value.

To create a donut chart, drag a dimension to the **Group/Color** field well. Optionally, drag a measure to the **Value** field well.

5. (Optional) Add drill-down layers by dragging one or more additional fields to the **Group/Color** field well. For more information about adding drill-downs, see [Adding drill-downs to visual data in Quick Sight](#).

Using funnel charts

Use a funnel chart to visualize data that moves across multiple stages in a linear process. In a funnel chart, each stage of a process is represented in blocks of different shapes and colors. The first stage, known as the *head*, is the largest block and is followed by the smaller stages, known as the *neck*, in a funnel shape. The size of the block representing each stage in a funnel chart is a percentage of the total, and is proportionate to its value. The bigger the size of the block, the bigger its value.

Funnel charts are often useful in business contexts because you can view trends or potential problem areas in each stage, such as bottlenecks. For example, they can help you visualize the amount of the potential revenue in each stage of a sale, from first contact to final sale and on through maintenance.

To create a basic funnel chart visual

1. Open Amazon Quick and choose **Analyses** on the navigation pane at left.
2. Choose one of the following:
 - To create a new analysis, choose **New analysis** at upper right. For more information, see [Starting an analysis in Quick Sight](#).
 - To use an existing analysis, choose the analysis that you want to edit.
3. Choose **Add (+), Add Visual**.
4. At lower left, choose the funnel chart icon from **Visual types**.
5. On the **Fields list** pane, choose the fields that you want to use for the appropriate field wells. Funnel charts require one dimension in **Group**.

6. (Optional) Add drill-down layers by dragging one or more additional fields to the **Group/Color** field well. For more information about adding drill-downs, see [Adding drill-downs to visual data in Quick Sight](#).

To understand the features supported by funnel charts, see [Analytics formatting per type in Quick](#). For customization options, see [Formatting in Amazon Quick](#).

Using gauge charts

Use gauge charts to compare values for items in a measure. You can compare them to another measure or to a custom amount.

A gauge chart is similar to a nondigital gauge, for example a gas gauge in an automobile. It displays how much there is of the thing you are measuring. In a gauge chart, this measurement can exist alone or in relation to another measurement. Each color section in a gauge chart represents one value. In the following example, we are comparing actual sales to the sales goal, and the gauge shows that we must sell an additional 33.27% to meet the goal.

To learn how to use gauge charts in Amazon Quick, you can watch this video:

[Using Gauge Charts](#)

To create a gauge chart, you need to use at least one measure. Put the measure in the **Value** field well. If you want to compare two measures, put the additional measure in the **Target value** field well. If you want to compare a single measure to a target value that isn't in your dataset, you can use a calculated field that contains a fixed value.

You can choose a variety of formatting options for the gauge chart, including the following settings in **Format visual**.

- **Value displayed** – Hide value, display actual value, or display a comparison of two values
- **Comparison method** – Compare values as a percent, the actual difference between values, or difference as a percent
- **Axis style** –
 - **Show axis label** – Show or hide the axis label
 - **Range** – The numeric minimum and maximum range to display in the gauge chart
 - **Reserve padding (%)** – Added to the top of the range (target, actual value, or max)
- **Arc style** – Degrees the arc displays (180° to 360°)

- **Thickness** – Thickness of the arc (small, medial, or large)

Gauge chart features

To understand the features supported by gauge charts, use the following table.

Feature	Supported?	Comments	For more information
Changing the legend display	Yes		Legends on visual types in Quick
Changing the title display	Yes		Titles and subtitles on visual types in Quick
Formatting gauge	Yes	You can customize the value displayed, the comparison method, the axis style, the arc style, and the thickness of the gauge.	
Changing the axis range	No		
Changing the visual colors	Yes	The foreground color the filled area; it represents the Value . The background color the unfilled area; it represents the Target value if one is selected.	Colors in visual types in Quick
Focusing on or excluding elements	No		
Sorting	No		Sorting visual data in Amazon Quick

Feature	Supported?	Comments	For more information
Performing field aggregation	Yes		Changing field aggregation
Adding drill-downs	No		

Creating a gauge chart

Use the following procedure to create a gauge chart.

To create a gauge chart

1. On the analysis page, choose **Visualize** on the tool bar.
2. Choose **Add** on the application bar, and then choose **Add visual**.
3. On the **Visual types** pane, choose the gauge chart icon.
4. From the **Fields list** pane, drag the fields that you want to use to the appropriate field wells. To create a gauge chart, drag a measure to the **Value** field well. To add a comparison value, drag a different measure to the **Target value** field well.

Using heat maps

Use heat maps to show a measure for the intersection of two dimensions, with color-coding to easily differentiate where values fall in the range. Heat maps can also be used to show the count of values for the intersection of the two dimensions.

Each rectangle on a heat map represents the value for the specified measure for the intersection of the selected dimensions. Rectangle color represents where the value falls in the range for the measure, with darker colors indicating higher values and lighter colors indicating lower ones.

Heat maps and pivot tables display data in a similar tabular fashion. Use a heat map if you want to identify trends and outliers, because the use of color makes these easier to spot. Use a pivot table if you want to further analyze data on the visual, for example by changing column sort order or applying aggregate functions across rows or columns.

To create a heat map, choose at least two fields of any data type. Amazon Quick populates the rectangle values with the count of the x-axis value for the intersecting y-axis value. Typically, you choose a measure and two dimensions.

Heat maps show up to 50 data points for rows and up to 50 data points for columns. For more information about how Amazon Quick handles data that falls outside display limits, see [Display limits](#).

Heat map features

To understand the features supported by heat maps, use the following table.

Feature	Supported?	Comments	For more information
Changing the legend display	Yes		Legends on visual types in Quick
Changing the title display	Yes		Titles and subtitles on visual types in Quick
Changing the axis range	Not applicable		Range and scale on visual types in Quick
Changing the visual colors	No		Colors in visual types in Quick
Focusing on or excluding elements	Yes, with exceptions	You can focus on or exclude a rectangle in a heat map, except when you are using a date field as the rows dimension. In that case, you can only focus on a rectangle, not exclude it.	Focusing on visual elements Excluding visual elements
Sorting	Yes	You can sort by the fields you choose for the columns and the values.	Sorting visual data in Amazon Quick

Feature	Supported?	Comments	For more information
Performing field aggregation	Yes	You must apply aggregation to the fields you choose for the value, and can't apply aggregation to the fields you choose for the rows or columns.	Changing field aggregation
Adding drill-downs	Yes	You can add drill-down levels to the Rows and Columns field wells.	Adding drill-downs to visual data in Quick Sight
Conditional formatting	No		Conditional formatting on visual types in Quick

Creating a heat map

Use the following procedure to create a heat map.

To create a heat map

1. On the analysis page, choose **Visualize** on the tool bar.
2. Choose **Add** on the application bar, and then choose **Add visual**.
3. On the **Visual types** pane, choose the heat map icon.
4. From the **Fields list** pane, drag the fields that you want to use to the appropriate field wells. Typically, you want to use dimension or measure fields as indicated by the target field well. If you choose to use a dimension field as a measure, the **Count** aggregate function is automatically applied to it to create a numeric value.

To create a heat map, drag a dimension to the **Rows** field well, a dimension to the **Columns** field well, and a measure to the **Values** field well.

5. (Optional) Add drill-down layers by dragging one or more additional fields to the **Rows** or **Columns** field wells. For more information about adding drill-downs, see [Adding drill-downs to visual data in Quick Sight](#).

Using Highcharts

Use Highcharts visuals to create custom chart types and visuals that use the [Highcharts Core library](#). Highcharts visuals provide Quick authors direct access to the [Highcharts API](#).

To configure a Highcharts visual, Quick authors need to add a Highcharts JSON schema to the visual in Quick. Authors can use Quick expressions to reference Quick fields, and formatting options in the JSON schema that they use to generate the Highcharts visual. The JSON **Chart code** editor provides contextual assistance for autocomplete and real time validation to ensure that the input JSON schemas are configured properly. To maintain security, the Highcharts visual editor does not accept CSS, JavaScript, or HTML code input.

For more information about Highcharts visuals in Amazon Quick, see the [Highcharts Visual QuickStart Guide](#) in [DemoCentral](#).

The following image shows a lipstick chart that is configured in the **Chart code** JSON editor of a Highcharts visual in Quick.

For more examples of visuals that you can create with the Highcharts visual in Quick, see [Highcharts demos](#).

Considerations

Before you start creating Highcharts visuals in Amazon Quick, review the following limitations that apply to Highcharts visuals.

- The following JSON values are not supported in the Highcharts **Chart code** JSON editor:
 - Functions
 - Dates
 - Undefined values
- Links to GeoJSON files or other images are not supported for Highcharts visuals.
- Field colors are not available for Highcharts visuals. Default theme colors are applied to all Highcharts visuals.

Creating a Highcharts visual

Use the following procedure to create a Highcharts visual in Amazon Quick.

1. Open the [Quick console](#).
2. Open the Quick analysis that you want to add a Highcharts visual to.
3. On the application bar, choose **Add**, and then choose **Add visual**.
4. On the **Visual types** pane, choose the Highcharts visual icon. An empty visual appears on the analysis sheet and the **Properties** pane opens on the left.
5. In the **Properties** pane, expand the **Display settings** section and perform the following actions:
 - a. For **Edit title**, choose the paintbrush icon, enter the title that you want the visual to have, and then choose **SAVE**. Alternatively, choose the eyeball icon to hide the title.
 - b. (Optional) For **Edit subtitle**, choose the paintbrush icon, enter the subtitle that you want the visual to have, and then choose **SAVE**. Alternatively, choose the eyeball icon to hide the subtitle.
 - c. (Optional) For **Alt text**, add the alt text that you want the visual to have.

6. Expand the **Data point limit** section. For **Number of data points to show**, enter the number of data points that you want the visual to show. Highcharts visuals can show up to 10,000 data points.
7. Expand the **Chart code** section.
8. Enter a JSON schema into the **Chart code** JSON editor. The editor provides contextual assistance and real time validation to ensure that your input JSON is configured properly. Any errors that Quick identifies can be viewed in the **Errors** dropdown. The example below shows a JSON schema that creates a lipstick chart that shows current year sales by industry.

```
{
  "xAxis": {
    "categories": ["getColumn", 0]
  },
  "yAxis": {
    "min": 0,
    "title": {
      "text": "Amount ($)"
    }
  },
  "tooltip": {
    "headerFormat": "<span style='font-size:10px'>{point.key}</span><table>",
    "pointFormat": "<tr><td style='color:{series.color};padding:0'>{series.name}:</td><td style='padding:0'><b>${point.y:.0f}</b></td></tr>",
    "footerFormat": "</table>",
    "shared": true,
    "useHTML": true
  },
  "plotOptions": {
    "column": {
      "borderWidth": 0,
      "grouping": false,
      "shadow": false
    }
  },
  "series": [
    {
      "type": "column",
      "name": "Current Year Sales",
      "color": "rgba(124,181,236,1)",
      "data": ["getColumn", 1],
      "pointPadding": 0.3,
      "pointPlacement": 0.0
    }
  ]
}
```

```
}  
]  
}
```

9. Choose **APPLY CODE**. Quick converts the JSON schema into a visual that appears in the analysis. To make changes to the rendered visual, update the appropriate properties in the JSON schema and choose **APPLY CODE**.
10. (Optional) Open the **Reference** dropdown to access links to helpful Highcharts reference material.

When you are happy with the rendered visual, close the properties pane. For more information about Quick Sight specific expressions that can be used to configure a Highcharts visual, see [Amazon Quick JSON expression language for Highcharts visuals](#).

Interactive Highchart features

Highchart visualizations in Amazon Quick Sight support custom actions, highlighting, and custom field color consistencies, allowing you to create interactive and visually cohesive charts that integrate seamlessly with other Quick Sight visuals.

Custom actions

With custom actions, you can define specific behaviors for any data point in your Highchart visualizations. This feature seamlessly integrates with Quick Sight's existing action framework, enabling you to create interactive charts that respond to user clicks. The system currently supports single data point selection, giving you precise control over user interactions. Custom actions can be implemented across various chart types, including line charts, bar charts, and stacked bar charts, among others.

To implement custom actions, you'll need to modify your Highcharts JSON configuration. Add an event block to your series configuration, specifying the click event and the corresponding action. For example:

```
{  
  "series": [{  
    "type": "line",  
    "data": ["getColumn", 1],  
    "name": "value",  
    "events": {
```

```

    "click": [
      "triggerClick", { "rowIndex": "point.index" }
    ]
  }
}]

```

This configuration enables click events on your chart's data points, allowing Quick Sight to handle custom actions based on the selected data.

Cross-visual highlighting

Cross-visual highlighting enhances the interactivity of your dashboards by creating visual connections between different charts. When a user selects elements in one chart, related elements in other visuals are automatically highlighted, while unrelated elements are dimmed. This feature helps users quickly identify relationships and patterns across multiple visualizations, improving data comprehension and analysis.

To enable cross-visual highlighting and maintain field color consistency, use the `quicksight` clause in your Highcharts JSON configuration. This clause acts as a bridge between Highcharts rendering and Quick's visual interaction system. Here's an example of how to set it up:

```

{
  "quicksight": {
    "pointRender": ["updatePointAttributes", {
      "opacity": ["case",
        ["dataMarkMatch", ["getColumnName", 0], "series.name"],
        1, // Full opacity for matching elements
        0.1 // Dim non-matching elements
      ],
      "color": ["getColumnColorOverrides", ["getColumnName", 0], "series.name"]
    }]
  }
}

```

This configuration uses Quick Sight's JSON expression language to dynamically modify visual properties like opacity and color based on user interactions and predefined color schemes.

For more complex scenarios, you can set up highlighting based on multiple conditions. This allows for more nuanced interactivity in your visualizations. The following example highlights elements based on either the quarter or day of the week:

```
{
  "quicksight": {
    "pointRender": ["updatePointAttributes", {
      "opacity": ["case",
        ["||",
          ["dataMarkMatch", "quarter", "series.name"],
          ["dataMarkMatch", "day_of_week", "point.name"]
        ],
        1, // Full opacity for matching elements
        0.1 // Dim non-matching elements
      ],
    }]
  }
}
```

Field-level color consistency

Maintaining visual coherence across your dashboard is crucial for effective data interpretation. The field-level color consistency feature ensures that colors assigned to specific dimensions persist across all visuals in your dashboard. This consistency helps users quickly recognize and track particular data categories across different chart types and views, enhancing the overall user experience and data comprehension.

Amazon Quick JSON expression language for Highcharts visuals

Highcharts visuals accept most [valid JSON values](#), standard arithmetic operators, string operators, and conditional operators. The following JSON values are not supported for Highcharts visuals:

- Functions
- Dates
- Undefined values

Quick authors can use JSON expression language create JSON schemas for a highcharts visual. JSON expression language is used to bind JSON to APIs or datasets to allow dynamic population and modification of JSON structures. Developers can also use JSON expression language to inflate and transform JSON data with concise and intuitive expressions.

With JSON expression language, expressions are represented as arrays, where the first element specifies the operation and subsequent elements are the arguments. For example, ["unique",

[1, 2, 2]] applies the unique operation to the array [1, 2, 2], resulting in [1, 2]. This array-based syntax allows for flexible expressions, that allow complex transformations on JSON data.

JSON expression language supports *nested expressions*. Nested expressions are expressions that contain other expressions as arguments. For example ["split", ["toUpper", "hello world"], " "] first converts the string hello world into an uppercase, then splits it into array of words, resulting in ["HELLO", "WORLD"].

Use the following sections to learn more about JSON expression language for Highcharts visuals in Amazon Quick.

Arithmetics

The following table shows arithmetic expressions that can be used with JSON expression language.

Operation	Expression	Input	Output
Addition	["+", operand1, operand2]	{ sum: ["+", 2, 4] }	{ sum: 6 }
Subtraction	["-", operand1, operand2]	{ difference: ["-", 10, 3] }	{ difference: 7 }
Multiplication	["*", operand1, operand2]	{ product: ["*", 5, 6] }	{ product: 30 }

Operation	Expression	Input	Output
Division	<code>["/", operand1, operand2]</code>	<code>{ quotient: ["/", 20, 4] }</code>	<code>{ quotient: 5 }</code>
Modulo	<code>["%", operand1, operand2]</code>	<code>{ remainder: ["%", 15, 4] }</code>	<code>{ remainder: 3 }</code>
Exponentiation	<code>["**", base, exponent]</code>	<code>{ power: ["**", 2, 3] }</code>	<code>{ power: 8 }</code>
Absolute Value	<code>["abs", operand]</code>	<code>{ absolute: ["abs", -5] }</code>	<code>{ absolute: 5 }</code>
Square Root	<code>["sqrt", operand]</code>	<code>{ sqroot: ["sqrt", 16] }</code>	<code>{ sqroot: 4 }</code>
Logarithm (base 10)	<code>["log10", operand]</code>	<code>{ log: ["log10", 100] }</code>	<code>{ log: 2 }</code>
Natural Logarithm	<code>["ln", operand]</code>	<code>{ ln: ["ln", Math.E] }</code>	<code>{ ln: 1 }</code>
Round	<code>["round", operand]</code>	<code>{ rounded: ["round", 3.7] }</code>	<code>{ rounded: 4 }</code>
Floor	<code>["floor", operand]</code>	<code>{ floor: ["floor", 3.7] }</code>	<code>{ floor: 3 }</code>
Ceiling	<code>["ceil", operand]</code>	<code>{ ceiling: ["ceil", 3.2] }</code>	<code>{ ceiling: 4 }</code>

Operation	Expression	Input	Output
Sine	<code>["sin", operand]</code>	<code>{ sine: ["sin", 0] }</code>	<code>{ sine: 0 }</code>
Cosine	<code>["cos", operand]</code>	<code>{ cosine: ["cos", 0] }</code>	<code>{ cosine: 1 }</code>
Tangent	<code>["tan", operand]</code>	<code>{ tangent: ["tan", Math.PI] }</code>	<code>{ tangent: 0 }</code>

Array operations

JSON expression language allows generic array manipulation for the following functions:

- **map** – Applies a mapping function to each element of an array and returns a new array with the transformed values.

For example, `["map", [1, 2, 3], ["*", ["item"], 2]]` maps each element of the array `[1, 2, 3]` by multiplying it by 2.

- **filter** – Filters an array based on a given condition and returns a new array containing only the elements that satisfy the condition

For example, `["filter", [1, 2, 3, 4, 5], ["==", ["%", ["item"], 2], 0]]` filters the array `[1, 2, 3, 4, 5]` to include only the even numbers.

- **reduce** – Reduces an array to a single value by applying a reducer function to each element and accumulating the result.

For example, `["reduce", [1, 2, 3, 4, 5], ["+", ["acc"], ["item"]], 0]` reduces the array `[1, 2, 3, 4, 5]` to the sum of its elements.

- **get** – Retrieves a value from an object or an array by specifying a key or index.

For example, `["get", ["item"], "name"]` retrieves the value of the "name" property from the current item.

- **unique** – Given an array returns only unique items inside this array.

For example, `["unique", [1, 2, 2]]` returns `[1, 2]`.

Amazon Quick expressions

Amazon Quick offers additional expressions to enhance the functionality of Highcharts visuals. Use the following sections to learn more about common Quick expressions for highcharts visuals. For more information about JSON expression language in Amazon Quick, see the [Highcharts Visual QuickStart Guide](#) in [DemoCentral](#).

Topics

- [getColumn](#)
- [formatValue](#)

getColumn

Use the getColumn expressions to return values from specified column indices. For example, the following table shows a list of products alongside their category, and price.

Product name	Category	Price
Product A	Technology	100
Product B	Retail	50
Product C	Retail	75

The following getColumn query generates an array that shows all product names alongside their price.

```
{
  product name: ["getColumn", 0],
  price: ["getColumn", 2]
}
```

The following JSON is returned:

```
{
```

```
product name: ["Product A", "Product B", "Product C"],  
price: [100, 50, 75]  
}
```

You can also pass multiple columns at once to generate an array of arrays, shown in the following example.

Input

```
{  
  values: ["getColumn", 0, 2]  
}
```

Output

```
{  
  values: [["Product A", 100], ["Product B", 50], ["Product C", 75]]  
}
```
