IP Address Manager

Amazon Virtual Private Cloud

Amazon Virtual Private Cloud: IP Address Manager

Table of Contents

What is IPAM?

Amazon VPC IP Address Manager (IPAM) is a VPC feature that makes it easier for you to plan, track, and monitor IP addresses for your AWS workloads. You can use IPAM automated workflows to more efficiently manage IP addresses.

You can use IPAM to do the following:

- Organize IP address space into routing and security domains
- Monitor IP address space that's in use and monitor resources that are using space against business rules
- View the history of IP address assignments in your organization
- Automatically allocate CIDRs to VPCs using specific business rules
- Troubleshoot network connectivity issues
- Enable cross-region and cross-account sharing of your Bring Your Own IP (BYOIP) addresses
- Provision Amazon-provided contiguous IPv6 CIDR blocks to pools for VPC creation

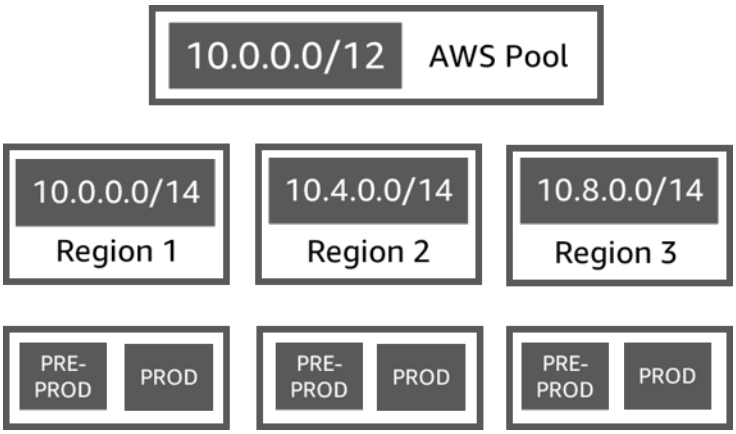
This guide consists of the following sections:

- How IPAM works: IPAM concepts and terminology.
- Getting started with IPAM: Steps to enable company-wide IP address management with AWS Organizations, create an IPAM, and plan IP address usage.
- Managing IP address space in IPAM: Steps to manage your IPAM, scopes, pools, and allocations.
- Tracking IP address usage in IPAM: Steps to monitor and track IP address usage with IPAM.
- Tutorials for Amazon VPC IP Address Manager: Detailed step-by-step tutorials for creating an IPAM and pools, allocating VPC CIDRs, and bringing your own public IP address CIDRs to IPAM.

How IPAM works

This topic explains some of the key concepts to help you get started with IPAM.

The following diagram shows an IPAM pool hierarchy for multiple AWS Regions within a top-level IPAM pool. Each AWS Regional pool has two IPAM development pools within it, one pool for pre-production and one pool production resources. For more information about IPAM concepts, see the descriptions below the diagram.



To use Amazon VPC IP Address Manager, you first create an IPAM.

When you create the IPAM, you choose which AWS Region to create it in. When you create an IPAM, AWS VPC IPAM automatically creates two scopes for the IPAM. The scopes, together with pools and allocations, are key components of your IPAM.

- A **scope** is the highest-level container within IPAM. When you create IPAM, a default public scope and a default private scope are automatically created for you. Each scope represents the IP space for a single network. The **private scope** is intended for all the IP addresses that can't be advertised to the internet. The **public scope** is generally intended for all the IP addresses that can be advertised to the internet from AWS. Note that when provisioning BYOIPv6 addresses to an IPAM pool, you can configure the addresses to not be publicly advertisable though they are in the public scope. Scopes enable you to reuse IP addresses across multiple unconnected networks without causing IP address overlap or conflict. Within a scope, you create IPAM pools.
- A **pool** is a collection of contiguous IP address ranges (or CIDRs). IPAM pools enable you to organize your IP addresses according to your routing and security needs. You can have multiple pools within a top-level pool. For example, if you have separate routing and security needs for development and production applications, you can create a pool for each. Within IPAM pools, you allocate CIDRs to AWS resources.

- An **allocation** is a CIDR assignment from an IPAM pool to another resource or IPAM pool. When you create a VPC and choose an IPAM pool for the VPC's CIDR, the CIDR is allocated from the CIDR provisioned to the IPAM pool. You can monitor and manage the allocation with IPAM.

IPAM can manage and monitor public and private IPv6 space. For more information about public and private IPv6 addresses, see IPv6 addresses in the *Amazon VPC User Guide*.

To get started and create an IPAM, see Getting started with IPAM.

Getting started with IPAM

Follow the steps in this section to get started with IPAM. This section is intended to get you started quickly with IPAM, but you may find that what you can achieve with the steps in this section doesn't fit your needs. For information about different ways you can use IPAM, see Plan for IP address provisioning and Tutorials for Amazon VPC IP Address Manager.

In this section, you'll begin by accessing IPAM and deciding if you want to delegate an IPAM account. By the end of this section, you will have created an IPAM, created multiple pools of IP addresses, and allocated a CIDR in a pool to a VPC.

Tasks

- Access IPAM
- Configure integration options for your IPAM
- Create an IPAM
- Plan for IP address provisioning
- Allocate CIDRs from an IPAM pool

Access IPAM

As with other AWS services, you can create, access, and manage your IPAM using the following methods:

- **AWS Management Console**: Provides a web interface that you can use to create and manage your IPAM. See https://console.aws.amazon.com/ipam/.
- **AWS Command Line Interface (AWS CLI)**: Provides commands for a broad set of AWS services, including Amazon VPC. The AWS CLI is supported on Windows, macOS, and Linux. To get the AWS CLI, see AWS Command Line Interface.
- **AWS SDKs**: Provide language-specific APIs. The AWS SDKs take care of many of the connection details, such as calculating signatures, handling request retries, and handling errors. For more information, see AWS SDKs.
- **Query API**: Provides low-level API actions that you call using HTTPS requests. Using the Query API is the most direct way to access IPAM. However, it requires your application to handle low-level details such as generating the hash to sign the request, and handling errors. For more information, see Amazon IPAM actions in the Amazon EC2 API Reference.

This guide primarily focuses on using the AWS Management Console to create, access, and manage your IPAM. In each description of how to complete a process in the console, we include links to the *AWS CLI Command Reference* so that you can do the same tasks by using the AWS CLI.

If you are a first-time user of IPAM, review How IPAM works to learn about the role of IPAM in Amazon VPC and then continue with the instructions in Configure integration options for your IPAM.

Configure integration options for your IPAM

This section describes your options for how you can integrate IPAM with AWS Organizations, other AWS accounts, or use it with a single AWS account.

Before you begin using IPAM, you must choose one of the options in this section to enable IPAM to monitor CIDRs associated with EC2 networking resources and store metrics:

- To enable IPAM to integrate with AWS Organizations to enable the Amazon VPC IPAM service to manage and monitor networking resources created by all AWS Organizations member accounts, see Integrate IPAM with accounts in an AWS Organization.
- After you integrate with AWS Organizations, to integrate IPAM with accounts outside of your organization, see Integrate IPAM with accounts outside of your organization.
- To use a single AWS account with IPAM and enable the Amazon VPC IPAM service to manage and monitor the networking resources you create with the single account, see Use IPAM with a single account.

If you do not choose one of these options, you can still create IPAM resources, such as pools, but you won't see metrics in your dashboard and you will not be able to monitor the status of resources.

Contents

Integrate IPAM with accounts in an AWS Organization

Optionally, you can follow the steps in this section to integrate IPAM with AWS Organizations and delegate a member account as the IPAM account.

The IPAM account is responsible for creating an IPAM and using it to manage and monitor IP address usage.

Integrating IPAM with AWS Organizations and delegating an IPAM admin has the following benefits:

- **Share your IPAM pools with your organization**: When you delegate an IPAM account, IPAM enables other AWS Organizations member accounts in the organization to allocate CIDRs from IPAM pools that are shared using AWS Resource Access Manager (RAM). For more information on setting up an organization, see What is AWS Organizations? in the *AWS Organizations User Guide*.
- **Monitor IP address usage in your organization**: When you delegate an IPAM account, you give IPAM permission to monitor IP usage across all of your accounts. As a result, IPAM automatically imports CIDRs that are used by existing VPCs across other AWS Organizations member accounts into IPAM.

If you do not delegate an AWS Organizations member account as an IPAM account, IPAM will monitor resources only in the AWS account that you use to create the IPAM.

Note

When integrating with AWS Organizations:

- You must enable integration with AWS Organizations by using IPAM in the AWS management console or the enable-ipam-organization-admin-account AWS CLI command. This ensures that the `AWSServiceRoleForIPAM` service-linked role is created. If you enable trusted access with AWS Organizations by using the AWS Organizations console or the register-delegated-administrator AWS CLI command, the `AWSServiceRoleForIPAM` service-linked role isn't created, and you can't manage or monitor resources within your organization.
- **The IPAM account must be an AWS Organizations member account.** You cannot use the AWS Organizations management account as the IPAM account. To check whether your IPAM is already integrated with AWS Organizations, use the steps below and view the details of the integration in *Organization settings*.

- IPAM charges you for each active IP address that it monitors in your organization's member accounts. For more information about pricing, see IPAM pricing.
- You must have an account in AWS Organizations and a management account set up with one or more member accounts. For more information about account types, see Terminology and concepts in the *AWS Organizations User Guide*. For more information on setting up an organization, see Getting started with AWS Organizations.
- The IPAM account must use an IAM role that has an IAM policy attached to it that permits the `iam:CreateServiceLinkedRole` action. When you create the IPAM, you automatically create the AWSServiceRoleForIPAM service-linked role.
- The user associated with the AWS Organizations management account must use an IAM role that has the following IAM policy actions attached:
  - `ec2:EnableIpamOrganizationAdminAccount`
  - `organizations:EnableAwsServiceAccess`
  - `organizations:RegisterDelegatedAdministrator`
  - `iam:CreateServiceLinkedRole`

  For more information on creating IAM roles, see Creating a role to delegate permissions to an IAM user in the *IAM User Guide*.
- The user associated with the AWS Organizations management account may use an IAM role that has the following IAM policy actions attached to list your current AWS Orgs delegated administrators: `organizations:ListDelegatedAdministrators`

AWS Management Console

To select an IPAM account

1. Using the AWS Organizations management account, open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the AWS Management Console, choose the AWS Region in which you want to work with IPAM.
3. In the navigation pane, choose **Organization settings**.
4. The **Delegate** option is only available if you've logged in to the console as the AWS Organizations management account. Choose **Delegate**.

5. Enter the AWS account ID for an IPAM account. The IPAM administrator must be an AWS Organizations member account.
6. Choose **Save changes**.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

- To delegate an IPAM admin account using AWS CLI, use the following command: enable-ipam-organization-admin-account

When you delegate an Organizations member account as an IPAM account, IPAM automatically creates a service-linked IAM role in all member accounts in your organization. IPAM monitors the IP address usage in these accounts by assuming the service-linked IAM role in each member account, discovering the resources and their CIDRs, and integrating them with IPAM. The resources within all member accounts will be discoverable by IPAM regardless of their Organizational Unit. If there are member accounts that have created a VPC, for example, you'll see the VPC and its CIDR in the Resources section of the IPAM console.

> **Important**
>
> The role of the AWS Organizations management account that delegated the IPAM admin is now complete. To continue using IPAM, the IPAM admin account must log into Amazon VPC IPAM and create an IPAM.

Integrate IPAM with accounts outside of your organization

This section describes how to integrate your IPAM with AWS accounts outside of your organization. To complete steps in this section, you must have already completed the steps in Integrate IPAM with accounts in an AWS Organization and delegated an IPAM account.

Integrating IPAM with AWS accounts outside of your organization enables you to do the following:

- Manage IP addresses outside of your organization from a single IPAM account.
- Share IPAM pools with third-party services hosted by other AWS accounts in other AWS Organizations.

After you integrate IPAM with AWS accounts outside of your organization, you can share an IPAM pool directly with the desired accounts of other organizations.

Contents

Considerations and limitations

This section contains considerations and limitations for integrating IPAM with accounts outside of your organization:

- When you share a resource discovery with another account, the only data that is exchanged is IP address and account status monitoring data. You can view this data before sharing using the get-ipam-discovered-resource-cidrs and get-ipam-discovered-accounts CLI commands or GetIpamDiscoveredResourceCidrs and GetIpamDiscoveredAccounts APIs. For resource discoveries that monitor resources across an organization, no organization data (such as the names of Organizational Units in your organization) are shared.
- When you create a resource discovery, the resource discovery monitors all visible resources in the owner account. If the owner account is a third-party service AWS account that creates resources for multiple of their own customers, those resources will be discovered by the resource discovery. If the third-party AWS service account shares the resource discovery with an end-user AWS account, the end-user will have visibility into the resources of the other customers of the third-party AWS service. For that reason, the third-party AWS service should exercise caution creating and sharing resource discoveries or use a separate AWS account for each customer.

Process overview

This section explains how to integrate your IPAM with AWS accounts outside of your organization. It refers to topics that are covered in other sections of this guide. Keep this page visible, and open the topics linked below in a new window so that you can return to this page for guidance.

When you integrate IPAM with AWS accounts outside of your organization, there are 4 AWS accounts involved in the process:

- **Primary Org Owner** - The AWS Organizations management account for organization 1.
- **Primary Org IPAM Account** - The IPAM delegated administrator account for organization 1.

- **Secondary Org Owner** - The AWS Organizations management account for organization 2.
- **Secondary Org Admin Account** - The IPAM delegated administrator account for organization 2.

Steps

1. Primary Org Owner delegates a member of their organization as the Primary Org IPAM Account (see Integrate IPAM with accounts in an AWS Organization).
2. Primary Org IPAM Account creates an IPAM (see Create an IPAM).
3. Secondary Org Owner delegates a member of their organization as the Secondary Org Admin Account (see Integrate IPAM with accounts in an AWS Organization).
4. Secondary Org Admin Account creates a resource discovery and shares it with the Primary Org IPAM Account using AWS RAM (see Create a resource discovery to integrate with another IPAM and Share a resource discovery with another AWS account). The resource discovery must be created in the same home Region as the Primary Org IPAM.
5. Primary Org IPAM Account accepts the resource share invitation using AWS RAM (see Accepting and rejecting resource share invitations in the *AWS RAM User Guide*).
6. Primary Org IPAM Account associates the resource discovery with their IPAM (see Associate a resource discovery with an IPAM).
7. Primary Org IPAM Account can now monitor and/or manage IPAM resources created by the accounts in Secondary Org.
8. (Optional) Primary Org IPAM Account shares IPAM pools with member accounts in Secondary Org (see Share an IPAM pool using AWS RAM).
9. (Optional) If Primary Org IPAM Account wants to stop discovering resources in Secondary Org, it can disassociate the resource discovery from the IPAM (see Disassociate a resource discovery).
10. (Optional) If the Secondary Org Admin Account wants to stop participating in the Primary Org's IPAM, they can unshare the shared resource discovery (see Update a resource share in AWS RAM in the *AWS RAM User Guide*) or delete the resource discovery (see Delete a resource discovery).

Use IPAM with a single account

If you choose not to Integrate IPAM with accounts in an AWS Organization, you can use IPAM with a single AWS account.

When you create an IPAM in the next section, a service-linked role is automatically created for the Amazon VPC IPAM service in AWS Identity and Access Management (IAM).

Service-linked roles are a type of IAM role that allows AWS services to access other AWS services on your behalf. They simplify the permission management process by automatically creating and managing the necessary permissions for specific AWS services to perform their required actions, streamlining the setup and administration of these services.

IPAM uses the service-linked role to monitor and store metrics for CIDRs associated with EC2 networking resources. For more information on the service-linked role and how IPAM uses it, see Service-linked roles for IPAM.

Important

If you use IPAM with a single AWS account, you must ensure that the AWS account you use to create the IPAM uses a IAM role with a policy attached to it that permits the `iam:CreateServiceLinkedRole` action. When you create the IPAM, you automatically create the AWSServiceRoleForIPAM service-linked role. For more information on managing IAM policies, see Editing IAM policies in the *IAM User Guide*.

Once the single AWS account has permission to create the IPAM service-linked role, go to Create an IPAM.

Create an IPAM

Follow the steps in this section to create your IPAM. If you have delegated an IPAM administrator, these steps should be completed by the IPAM account.

Important

When you create an IPAM, you will be asked to allow IPAM to replicate data from source accounts into an IPAM delegate account. To integrate IPAM with AWS Organizations, IPAM needs your permission to replicate resource and IP usage details across accounts (from member accounts to the delegated IPAM member account) and across AWS Regions (from operating Regions to the home Region of your IPAM). For single account IPAM users, IPAM needs your permission to replicate resource and IP usage details across operating Regions to the home Region of your IPAM.

When you create the IPAM, you choose the AWS Regions where the IPAM is allowed to manage IP address CIDRs. These AWS Regions are called *operating Regions*. IPAM discovers and monitors resources only in the AWS Regions that you select as operating Regions. IPAM doesn't store any data outside of the operating Regions that you select.

The following example hierarchy shows how the AWS Regions that you assign when you create the IPAM will impact the Regions that will be available for pools that you create later.

- **IPAM operating in AWS Region 1 and AWS Region 2**
  - Private scope
    - Top-level IPAM pool
      - Regional IPAM pool in **AWS Region 2**
        - Development pool
          - Allocation for a VPC in **AWS Region 2**

You can only create one IPAM per AWS Region. For more information about increasing quotas related to IPAM, see Quotas for your IPAM.

AWS Management Console

To create an IPAM

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the AWS Management Console, choose the AWS Region in which you want to create the IPAM. Create the IPAM in your main Region of operations.
3. On the service home page, choose **Create IPAM**.
4. Select **Allow Amazon VPC IP Address Manager to replicate data from source account(s) into the IPAM delegate account**. If you do not select this option, you cannot create an IPAM.
5. Choose an **IPAM tier**. For more information about the features available in each tier and the costs associated with the tiers, see the IPAM tab on the Amazon VPC pricing page.
6. Under **Operating regions**, select the AWS Regions in which this IPAM can manage and discover resources. The AWS Region in which you are creating your IPAM is selected as one of the operating Regions by default. For example, if you're creating this IPAM in AWS Region `us-east-1` but you want to create Regional IPAM pools later that provide CIDRs

to VPCs in `us-west-2`, select `us-west-2` here. If you forget an operating Region, you can return at a later time and edit your IPAM settings.

> **Note**
>
> If you are creating an IPAM in the Free Tier, you can select multiple operating Regions for your IPAM, but the only IPAM feature that will be available across operating Regions is Public IP insights. You cannot use other features in the Free Tier, like BYOIP, across the IPAM's operating Regions. You can only use them in the IPAM's home Region. To use all IPAM features across operating Regions, create an IPAM in the Advanced Tier.

7. Choose if you want to enable **Private IPv6 GUA CIDRs**. For more information about this option, see Enable provisioning private IPv6 GUA CIDRs.
8. Choose if you want to enable **Metering mode**. For more information about this option, see Enable cost distribution.
9. Choose **Create IPAM**.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

Use the following AWS CLI commands to create, modify, and view details related to your IPAM:

1. Create the IPAM: create-ipam
2. View the IPAM that you've created: describe-ipams
3. View the scopes that are created automatically: describe-ipam-scopes
4. Modify an existing IPAM: modify-ipam

When you have completed these steps, IPAM has done the following:

- Created your IPAM. You can see the IPAM and the currently selected operating Regions by choosing IPAMs in the left navigation pane of the console.
- Created one private and one public scope. You can see the scopes by choosing **Scopes** in the navigation pane. For more information about scopes, see How IPAM works.

Plan for IP address provisioning

Follow the steps in this section to plan for IP address provisioning by using IPAM pools. If you have configured an IPAM account, these steps should be completed by that account. The pool creation process is different for pools in public and private scopes. This section includes steps for creating a regional pool in the private scope. For BYOIP and BYOASN tutorials, see Tutorials.

Important

To use IPAM pools across AWS accounts, you must integrate IPAM with AWS Organizations or some features may not work properly. For more information, see Integrate IPAM with accounts in an AWS Organization.

In IPAM, a pool is a collection of contiguous IP address ranges (or CIDRs). Pools enable you to organize your IP addresses according to your routing and security needs. You can create pools for AWS Regions outside of your IPAM Region. For example, if you have separate routing and security needs for development and production applications, you can create a pool for each.

In the first step in this section, you'll create a top-level pool. Then, you'll create a Regional pool within the top-level pool. Within the Regional pool, you can create additional pools as needed, such as a production and development environment pools. By default, you can create pools up to a depth of 10. For information on IPAM quotas, see Quotas for your IPAM.

Note

The terms *provision* and *allocate* are used throughout this user guide and the IPAM console. *Provision* is used when you add a CIDR to an IPAM pool. *Allocate* is used when you associate a CIDR from an IPAM pool with a resource.

The following is an example hierarchy of the pool structure that you will create by completing the steps in this section:

- IPAM operating in AWS Region 1 and AWS Region 2
  - Private scope
    - Top-level pool

- Regional pool in AWS Region 1
  - Development pool
    - Allocation for a VPC

This structure serves as an example of how you might want to use IPAM, but you can use IPAM to suit the needs of your organization. For more information on best practices, see Amazon VPC IP Address Manager Best Practices.

If you are creating a single IPAM pool, complete the steps in Create a top-level IPv4 pool and then skip to Allocate CIDRs from an IPAM pool.

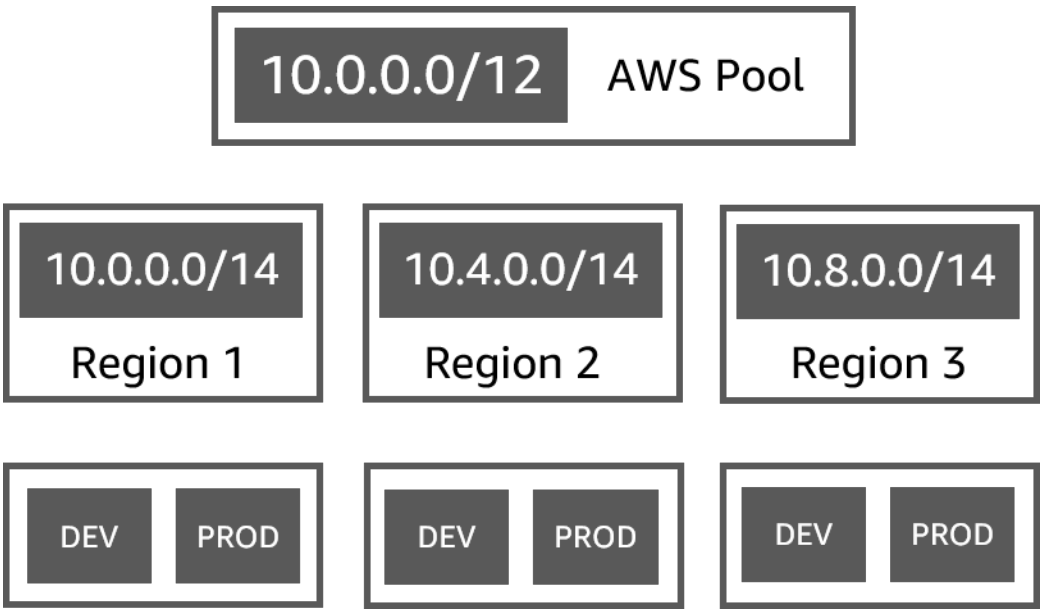
Contents

Example IPAM pool plans

You can use IPAM to suit the needs of your organization. This section provides examples of how you might organize your IP addresses.

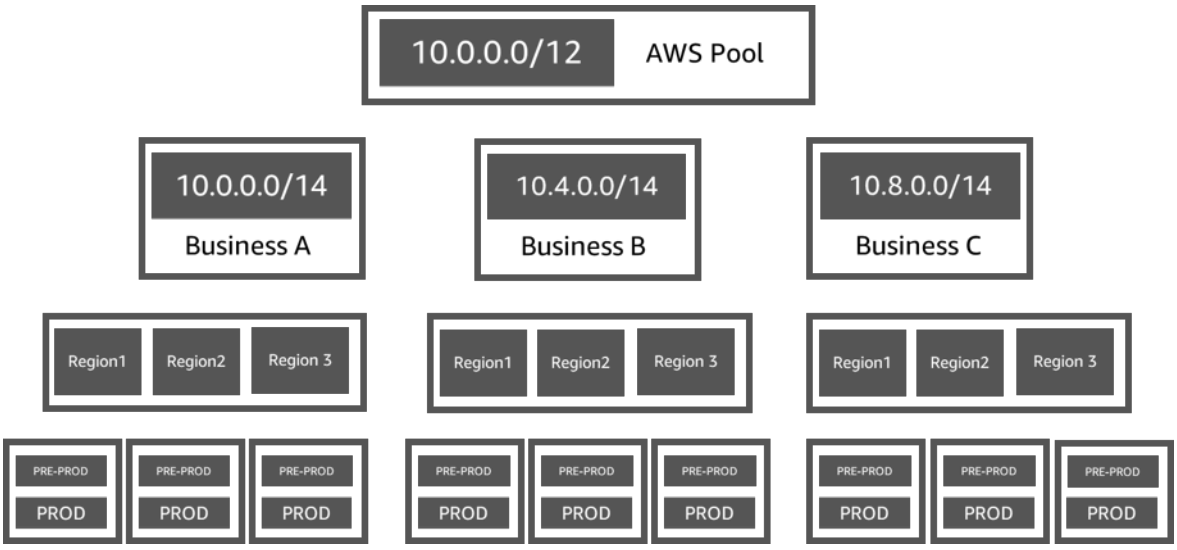
IPv4 pools in multiple AWS Regions

The following example shows an IPAM pool hierarchy for multiple AWS Regions within a top-level pool. Each AWS Regional pool has two IPAM development pools within it, one pool for development resources and one pool for production resources.



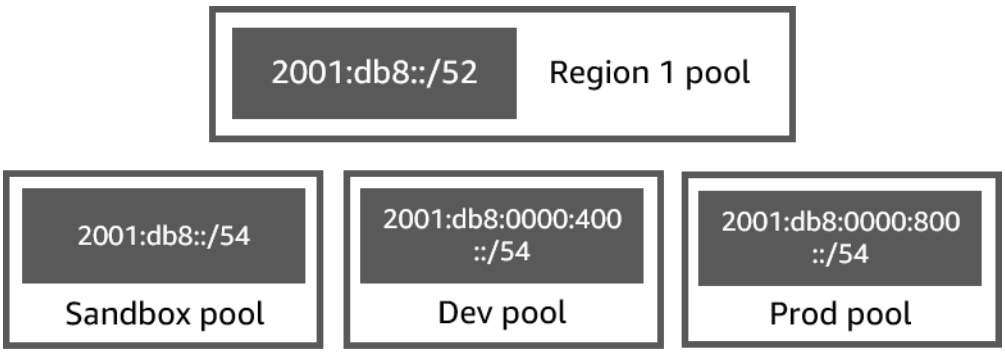
IPv4 pools for multiple lines of business

The following example shows an IPAM pool hierarchy for multiple lines of business within a top-level pool. Each pool for each line of business contains three AWS Regional pools. Each Regional pool has two IPAM development pools within it, one pool for pre-production resources and one pool for production resources.



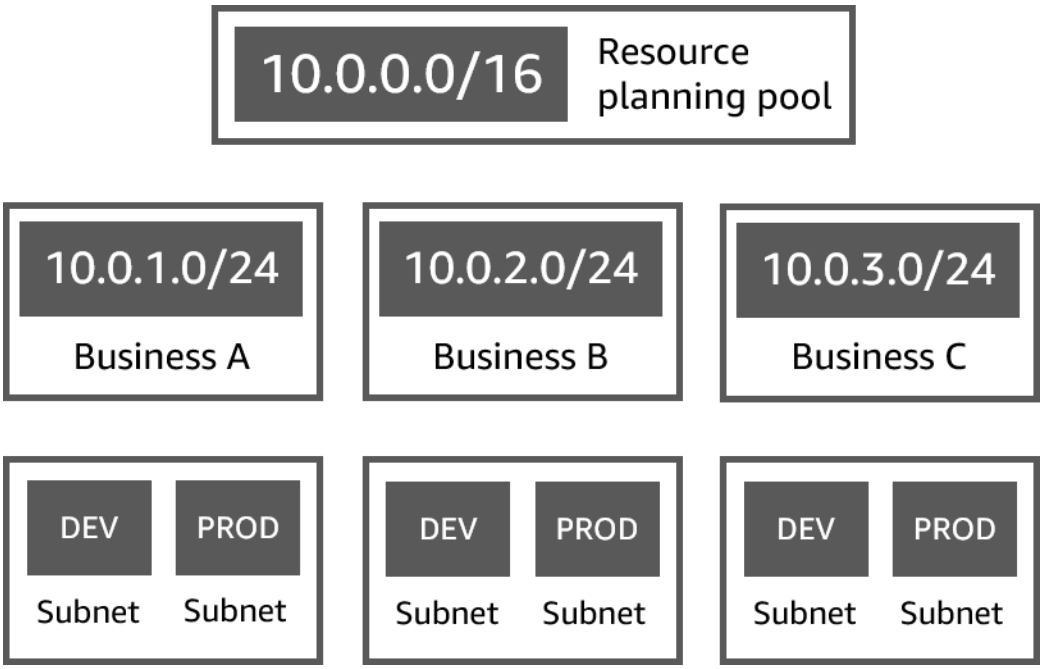
IPv6 pools in an AWS Region

The following example shows an IPAM IPv6 pool hierarchy for multiple lines of business within a Regional pool. Each Regional pool has three IPAM pools within it, one pool for sandbox resources, one pool for development resources, and one pool for production resources.



Subnet pools for multiple lines of business

The following example shows a resource planning pool hierarchy for multiple lines of business and dev/ prod subnet pools. For more information on subnet IP address space planning using IPAM, see Tutorial: Plan VPC IP address space for subnet IP allocations.



Create IPv4 pools

Follow the steps in this section to create an IPv4 IPAM pool hierarchy.

The following example shows the hierarchy of the pool structure that you can create with instructions in this guide. In this section, you are creating an IPv4 IPAM pool hierarchy:

- IPAM operating in AWS Region 1 and AWS Region 2
  - Private scope

- Top-level pool (10.0.0.0/8)
  - Regional pool in AWS Region 2 (10.0.0.0/16)
    - Development pool (10.0.0.0/24)
      - Allocation for a VPC (10.0.0.0/25)

In the preceding example, the CIDRs that are used are examples only. They illustrate that each pool within the top-level pool is provisioned with a portion of the top-level CIDR.

Contents

Create a top-level IPv4 pool

Follow the steps in this section to create an IPv4 top-level IPAM pool. When you create the pool, you provision a CIDR for the pool to use. You then assign that space to an allocation. An allocation is a CIDR assignment from an IPAM pool to another IPAM pool or to a resource.

The following example shows the hierarchy of the pool structure that you can create with instructions in this guide. At this step, you are creating the top-level IPAM pool:

- IPAM operating in AWS Region 1 and AWS Region 2
  - Private scope
    - **Top-level pool (10.0.0.0/8)**
      - Regional pool in AWS Region 1 (10.0.0.0/16)
        - Development pool for non-production VPCs (10.0.0.0/24)
          - Allocation for a VPC (10.0.0.0/25)

In the preceding example, the CIDRs that are used are examples only. They illustrate that each pool within the top-level pool is provisioned with a portion of the top-level CIDR.

When you create an IPAM pool, you can configure rules for the allocations that are made within the IPAM pool.

Allocation rules enable you to configure the following:

- Whether IPAM should automatically import CIDRs into the IPAM pool if it finds them within this pool's CIDR range
- The required netmask length for allocations within the pool
- The required tags for resources within the pool
- The required locale for resources within the pool. The locale is the AWS Region where an IPAM pool is available for allocations.

Allocation rules determine whether resources are compliant or noncompliant. For additional information about compliance, see Monitor CIDR usage by resource.

> **Important**
>
> There is an additional implicit rule that is not displayed in the allocation rules. If the resource is in an IPAM pool that is a shared resource in AWS Resource Access Manager (RAM), the resource owner must be configured as a principal in AWS RAM. For more information about sharing pools with RAM, see Share an IPAM pool using AWS RAM.

The following example shows how you might use allocation rules to control access to an IPAM pool:

Example

When you create your pools based on routing and security needs, you might want to allow only certain resources to use a pool. In such cases, you can set an allocation rule stating that any resource that wants a CIDR from this pool must have a tag that matches the allocation rule tag requirements. For example, you could set an allocation rule stating that only VPCs with the tag *prod* can get CIDRs from an IPAM pool. You could also set a rule stating that CIDRs allocated from this pool can be no larger than /24. In this case, creating a resource using a CIDR larger than /24 from this pool violates an allocation rule on the pool and creation fails. Existing resources with a CIDR larger than /24 are flagged as noncompliant.

Important

This topic covers how to create a top-level IPv4 pool with an IP address range provided by AWS. If you want to bring your own IPv4 address range to AWS (BYOIP), there are prerequisites. For more information, see Tutorial: Bring your IP addresses to IPAM.

AWS Management Console

To create a pool

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.
3. Choose **Create pool**.
4. Under **IPAM scope**, choose the private scope you want to use. For more information about scopes, see How IPAM works.

   By default, when you create a pool, the default private scope is selected. Pools in the private scope must be IPv4 pools. Pools in the public scope can be IPv4 or IPv6 pools. The public scope is intended for all public space.
5. (Optional) Add a **Name tag** for the pool and a description for the pool.
6. Under **Source**, choose **IPAM scope**.
7. Under **Address family**, choose **IPv4**.
8. Under **Resource planning**, leave **Plan IP space within the scope** selected. For more information about using this option to plan for subnet IP space within a VPC, see Tutorial: Plan VPC IP address space for subnet IP allocations.
9. For the **Locale**, choose **None**. You will set the locale on the Regional pool.

   The locale is the AWS Region where you want this IPAM pool to be available for allocations. For example, you can only allocate a CIDR for a VPC from an IPAM pool that shares a locale with the VPC's Region. Note that when you have chosen a locale for a pool, you cannot modify it. If the home Region of the IPAM is unavailable due to an outage and the pool has a locale different than the home Region of the IPAM, the pool can still be used to allocate IP addresses.
10. (Optional) You can create a pool without a CIDR, but you won't be able to use the pool for allocations until you've provisioned a CIDR for it. To provision a CIDR, choose **Add new**

CIDR. Enter an IPv4 CIDR to provision for the pool. If you want to bring your own IPv4 or IPv6 IP address range to AWS there are prerequisites. For more information, see Tutorial: Bring your IP addresses to IPAM.

11. Choose optional allocation rules for this pool:

- **Automatically import discovered resources**: This option is not available if the **Locale** is set to **None**. If selected, IPAM will continuously look for resources within the CIDR range of this pool and automatically import them as allocations into your IPAM. Note the following:
  - The CIDRs that will be allocated for these resources must not already be allocated to other resources in order for the import to succeed.
  - IPAM will import a CIDR regardless of its compliance with the pool's allocation rules, so a resource might be imported and subsequently marked as noncompliant.
  - If IPAM discovers multiple CIDRs that overlap, IPAM will import the largest CIDR only.
  - If IPAM discovers multiple CIDRs with matching CIDRs, IPAM will randomly import one of them only.

  Warning
  - After you create an IPAM, when you create a VPC, choose the IPAM-allocated CIDR block option. If you do not, the CIDR you choose for your VPC may overlap with an IPAM CIDR allocation.
  - If you have a VPC already allocated in an IPAM pool, a VPC with an overlapping CIDR cannot be automatically imported. For example, if you have a VPC with a 10.0.0.0/26 CIDR allocated in an IPAM pool, a VPC with a 10.0.0.0/23 CIDR (that would cover the 10.0.0.0/26 CIDR) cannot be imported.
  - It takes some time for existing VPC CIDR allocations to be auto-imported into IPAM.

- **Minimum netmask length**: The minimum netmask length required for CIDR allocations in this IPAM pool to be compliant and the largest size CIDR block that can be allocated from the pool. The minimum netmask length must be less than the maximum netmask length. Possible netmask lengths for IPv4 addresses are 0 - 32. Possible netmask lengths for IPv6 addresses are 0 - 128.

- **Default netmask length**: A default netmask length for allocations added to this pool. For example, if the CIDR that's provisioned to this pool is **`10.0.0.0/8`** and you enter **16** here, any new allocations in this pool will default to a netmask length of /16.
- **Maximum netmask length**: The maximum netmask length that will be required for CIDR allocations in this pool. This value dictates the smallest size CIDR block that can be allocated from the pool.
- **Tagging requirements**: The tags that are required for resources to allocate space from the pool. If the resources have their tags changed after they have allocated space or if the allocation tagging rules are changed on the pool, the resource may be marked as noncompliant.
- **Locale**: The locale that will be required for resources that use CIDRs from this pool. Automatically imported resources that do not have this locale will be marked noncompliant. Resources that are not automatically imported into the pool will not be allowed to allocate space from the pool unless they are in this locale.

> **Note**
>
> Allocation rules apply only to the managed resources within that pool. The rules do not apply to resources in pools within a pool.

12. (Optional) Choose **Tags** for the pool.
13. Choose **Create pool**.
14. See Create a Regional IPv4 pool.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

Use the following AWS CLI commands to create or edit a top-level pool in your IPAM:

1. Create a pool: create-ipam-pool.
2. Edit the pool after you create it to modify the allocation rules: modify-ipam-pool.

Create a Regional IPv4 pool

Follow the steps in this section to create a Regional pool within your top-level pool. If you need only a top-level pool, and don't need additional Regional and development pools, skip to Allocate CIDRs from an IPAM pool.

> **Note**
>
> The pool creation process is different for pools in public and private scopes. This section includes steps for creating a regional pool in the private scope. For BYOIP and BYOASN tutorials, see Tutorials.

The following example shows the hierarchy of the pool structure that you create by following the instructions in this guide. At this step, you are creating the Regional IPAM pool:

- IPAM operating in AWS Region 1 and AWS Region 2
  - Private scope
    - Top-level pool (10.0.0.0/8)
      - **Regional pool in AWS Region 1 (10.0.0.0/16)**
        - Development pool for non-production VPCs (10.0.0.0/24)
          - Allocation for a VPC (10.0.0.0/25)

In the preceding example, the CIDRs that are used are examples only. They illustrate that each pool within the top-level pool is provisioned with a portion of the top-level CIDR.

AWS Management Console

To create a Regional pool within a top-level pool

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.
3. Choose **Create pool**.
4. Under **IPAM scope**, choose the same scope that you used when you created the top-level pool. For more information about scopes, see How IPAM works.
5. (Optional) Add a **Name tag** for the pool and a description for the pool.

6. Under **Source**, choose **IPAM pool**. Then choose the top-level pool that you created in the previous section.
7. If you are creating this pool in the public scope, you'll see an option for **Address family**. Choose **IPv4**.
8. Under **Resource planning**, leave **Plan IP space within the scope** selected. For more information about using this option to plan for subnet IP space within a VPC, see Tutorial: Plan VPC IP address space for subnet IP allocations.
9. Choose the locale for the pool. Choosing a locale ensures there are no cross-region dependencies between your pool and the resources allocating from it. The available options come from the operating Regions that you chose when you created your IPAM.

   The locale is the AWS Region where you want this IPAM pool to be available for allocations. For example, you can only allocate a CIDR for a VPC from an IPAM pool that shares a locale with the VPC's Region. Note that when you have chosen a locale for a pool, you cannot modify it. If the home Region of the IPAM is unavailable due to an outage and the pool has a locale different than the home Region of the IPAM, the pool can still be used to allocate IP addresses.

   > **Note**
   >
   > If you are creating a pool in the Free Tier, you can only choose the locale that matches the home Region of your IPAM. To use all IPAM features across locales, upgrade to the Advanced Tier.

10. If you are creating this pool in the public scope, you'll see an option for **Service**. Choose **EC2 (EIP/VPC)**. The service you select determines the AWS service where the CIDR will be advertisable. Currently, the only option is **EC2 (EIP/VPC)**, which means that the CIDRs allocated from this pool will be advertisable for the Amazon EC2 service (for Elastic IP addresses) and the Amazon VPC service (for CIDRs associated with VPCs).
11. (Optional) Choose a CIDR to provision for the pool. You can create a pool without a CIDR, but you won't be able to use the pool for allocations until you've provisioned a CIDR for it. You can add CIDRs to a pool at any time by editing the pool.
12. You have the same allocation rule options here as you did when you created the top-level pool. See Create a top-level IPv4 pool for an explanation of the options that are available when you create pools. The allocation rules for the Regional pool are not inherited from

the top-level pool. If you do not apply any rules here, there will be no allocation rules set for the pool.

13. (Optional) Choose **Tags** for the pool.
14. When you've finished configuring your pool, choose **Create pool**.
15. See Create a development IPv4 pool.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

Use the following AWS CLI commands to create a Regional pool in your IPAM:

1. Get the ID of the scope that you want to create the pool in: describe-ipam-scopes
2. Get the ID of the pool that you want to create the pool in: describe-ipam-pools
3. Create the pool: create-ipam-pool
4. View the new pool: describe-ipam-pools

Repeat these steps to create additional pools within the top-level pool, as needed.

Create a development IPv4 pool

Follow the steps in this section to create a development pool within your Regional pool. If you need only a top-level and Regional pool, and don't need development pools, skip to Allocate CIDRs from an IPAM pool.

The following example shows the hierarchy of the pool structure that you can create with the instructions in this guide. At this step, you are creating a development IPAM pool:

- IPAM operating in AWS Region 1 and AWS Region 2
  - Private scope
    - Top-level pool (10.0.0.0/8)
      - Regional pool in AWS Region 1 (10.0.0.0/16)
        - **Development pool for non-production VPCs (10.0.0.0/24)**
          - Allocation for a VPC (10.0.1.0/25)

In the preceding example, the CIDRs that are used are examples only. They illustrate that each pool within the top-level pool is provisioned with a portion of the top-level CIDR.

AWS Management Console

To create a development pool within a Regional pool

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.
3. Choose **Create pool**.
4. Under **IPAM scope**, choose the same scope that you used when you created the top-level and Regional pools. For more information about scopes, see How IPAM works.
5. (Optional) Add a **Name tag** for the pool and a description for the pool.
6. Under **Source**, choose **IPAM pool**. Then choose the Regional pool.
7. Under **Resource planning**, leave **Plan IP space within the scope** selected. For more information about using this option to plan for subnet IP space within a VPC, see Tutorial: Plan VPC IP address space for subnet IP allocations.
8. (Optional) Choose a CIDR to provision for the pool. You can only provision a CIDR that was provisioned to the top-level pool. You can create a pool without a CIDR, but you won't be able to use the pool for allocations until you've provisioned a CIDR for it. You can add CIDRs to a pool at any time by editing the pool.
9. You have the same allocation rule options here as you did when you created the top-level and Regional pool. See Create a top-level IPv4 pool for an explanation of the options that are available when you create pools. The allocation rules for the pool are not inherited from the pool above it in the hierarchy. If you do not apply any rules here, no allocation rules will be set for the pool.
10. (Optional) Choose **Tags** for the pool.
11. When you've finished configuring your pool, choose **Create pool**.
12. See Allocate CIDRs from an IPAM pool.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

Use the following AWS CLI commands to create a Regional pool in your IPAM:

1. Get the ID of the scope that you want to create the pool in: describe-ipam-scopes
2. Get the ID of the pool that you want to create the pool in: describe-ipam-pools
3. Create the pool: create-ipam-pool
4. View the new pool: describe-ipam-pools

Repeat these steps to create additional development pools within the Regional pool, as needed.

Create IPv6 address pools in your IPAM

AWS offers IPv6 connectivity across many of its services, including EC2, VPC, and S3, enabling you to use the increased address space and enhanced security features of IPv6. IPv6 was designed to resolve this fundamental limitation of IPv4. By moving to a 128-bit address space, IPv6 offers a large number of unique IP addresses. This massive address expansion enables the continued proliferation of connected technologies, from smartphones and IoT devices to cloud infrastructure.

In addition, you can use IPAM to ensure that you are using contiguous IPv6 CIDRs for VPC creation. Contiguously-allocated CIDRs are CIDRs that are allocated sequentially. They enable you to simplify your security and networking rules; the IPv6 CIDRs can be aggregated in a single entry across networking and security constructs like access control lists, route tables, security groups, and firewalls.

Follow the steps in this section to create an IPAM IPv6 pool hierarchy. When you create the pool, you can provision a CIDR for the pool to use. The pool assigns space within that CIDR to allocations within the pool. An allocation is a CIDR assignment from an IPAM pool to another resource or IPAM pool.

> **Note**
>
> Both public and private IPv6 addressing is available in AWS. AWS considers public IP addresses those advertised on the internet from AWS, while private IP addresses are not and cannot be advertised on the internet from AWS. If you want your private networks to support IPv6 and have no intention of routing traffic from these addresses to the internet, create your IPv6 pool in a private scope. For more information about public and private IPv6 addresses, see IPv6 addresses in the *Amazon VPC User Guide*.

The following example shows the hierarchy of the pool structure that you can create with instructions in this guide. In this section, you are creating an IPv6 IPAM pool hierarchy:

- IPAM operating in AWS Region 1 and AWS Region 2
  - Scope
    - Regional pool in AWS Region 1 (2001:db8::/52)
      - Development pool (2001:db8::/54)
        - Allocation for a VPC (2001:db8::/56)

In the preceding example, the CIDRs that are used are examples only. They illustrate that the Development pool within the Regional pool is provisioned with a portion of the Regional pool CIDR.

Contents

Create a Regional IPv6 address pool in your IPAM

Follow the steps in this section to create an IPv6 regional IPAM pool. When you provision an Amazon-provided IPv6 CIDR block to a pool, it must be provisioned to a pool with a locale (AWS Region) selected. When you create the pool, you can provision a CIDR for the pool to use or add it later. You then assign that space to an allocation. An allocation is a CIDR assignment from an IPAM pool to another IPAM pool or to a resource.

The following example shows the hierarchy of the pool structure that you can create with instructions in this guide. At this step, you are creating the IPv6 regional IPAM pool:

- IPAM operating in AWS Region 1 and AWS Region 2
  - Scope
    - **Regional pool in AWS Region 1 (2001:db8::/52)**
      - Development pool (2001:db8::/54)
        - Allocation for a VPC (2001:db8::/56)

In the preceding example, the CIDRs that are used are examples only. They illustrate that each pool within the IPv6 regional pool is provisioned with a portion of the IPv6 regional CIDR.

When you create an IPAM pool, you can configure rules for the allocations that are made within the IPAM pool.

Allocation rules enable you to configure the following:

- The required netmask length for allocations within the pool
- The required tags for resources within the pool
- The required locale for resources within the pool. The locale is the AWS Region where an IPAM pool is available for allocations.

Allocation rules determine whether resources are compliant or noncompliant. For additional information about compliance, see Monitor CIDR usage by resource.

Note

There is an additional implicit rule that is not displayed in the allocation rules. If the resource is in an IPAM pool that is a shared resource in AWS Resource Access Manager (RAM), the resource owner must be configured as a principal in AWS RAM. For more information about sharing pools with RAM, see Share an IPAM pool using AWS RAM.

The following example shows how you might use allocation rules to control access to an IPAM pool:

Example

When you create your pools based on routing and security needs, you might want to allow only certain resources to use a pool. In such cases, you can set an allocation rule stating that any resource that wants a CIDR from this pool must have a tag that matches the allocation rule tag requirements. For example, you could set an allocation rule stating that only VPCs with the tag *prod* can get CIDRs from an IPAM pool.

Note

- This topic covers how to create an IPv6 regional pool with an IPv6 address range provided by AWS or with a private IPv6 range. If you want to bring your own public IPv4 or IPv6 IP address ranges to AWS (BYOIP), there are prerequisites. For more information, see Tutorial: Bring your IP addresses to IPAM.

- If you are creating an IPv6 pool in a private scope, you can use a private IPv6 GUA or ULA range. To use a private GUA range, you have to have first enabled the option on your IPAM (see Enable provisioning private IPv6 GUA CIDRs).

AWS Management Console

To create a pool

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.
3. Choose **Create pool**.
4. Under **IPAM scope**, choose a private or public scope. If you want your private networks to support IPv6 and have no intention of routing traffic from these addresses to the internet, choose a private scope. For more information about scopes, see How IPAM works.

   By default, when you create a pool, the default private scope is selected.
5. (Optional) Add a **Name tag** for the pool and a description for the pool.
6. Under **Source**, choose **IPAM scope**.
7. For **Address family**, select **IPv6**. If you're creating this pool in the public scope, all CIDRs in this pool will be publicly advertisable.
8. Under **Resource planning**, leave **Plan IP space within the scope** selected. For more information about using this option to plan for subnet IP space within a VPC, see Tutorial: Plan VPC IP address space for subnet IP allocations.
9. Choose the **Locale** for the pool. If you want to provision an Amazon-provided IPv6 CIDR block to a pool, it must be provisioned to a pool with a locale (AWS Region) selected. Choosing a locale ensures there are no cross-region dependencies between your pool and the resources allocating from it. The available options come from the operating Regions that you chose for the IPAM when you created it. You can add additional operating Regions at any time.

   The locale is the AWS Region where you want this IPAM pool to be available for allocations. For example, you can only allocate a CIDR for a VPC from an IPAM pool that shares a locale with the VPC's Region. Note that when you have chosen a locale for a pool, you cannot modify it. If the home Region of the IPAM is unavailable due to an outage and the pool has

a locale different than the home Region of the IPAM, the pool can still be used to allocate IP addresses.

> **Note**
>
> If you are creating a pool in the Free Tier, you can only choose the locale that matches the home Region of your IPAM. To use all IPAM features across locales, upgrade to the Advanced Tier.

10. (Optional) If you are creating an IPv6 pool in the public scope, under **Service**, choose **EC2 (EIP/VPC)**. The service you select determines the AWS service where the CIDR will be advertisable. Currently, the only option is **EC2 (EIP/VPC)**, which means that the CIDRs allocated from this pool will be advertisable for the Amazon EC2 service (for Elastic IP addresses) and the Amazon VPC service (for CIDRs associated with VPCs).
11. (Optional) If you are creating an IPv6 pool in the public scope, under **Public IP source** option, choose **Amazon owned** to have AWS provide an IPv6 address range for this pool. As noted at the top of this page, this topic covers how to create an IPv6 regional pool with an IP address range provided by AWS. If you want to bring your own IPv4 or IPv6 address range to AWS (BYOIP), there are prerequisites. For more information, see Tutorial: Bring your IP addresses to IPAM.
12. (Optional) You can create a pool without a CIDR, but you won't be able to use the pool for allocations until you've provisioned a CIDR for it. To provision a CIDR, do one of the following:

    - If you are creating an IPv6 pool in the public scope with **Public IP source Amazon-owned**, to provision a CIDR, under **CIDRs to provision**, choose **Add Amazon-owned CIDR** and choose the netmask size between /40 and /52 for the CIDR. When you choose a netmask length in the dropdown menu, you see the netmask length as well as the number of /56 CIDRs that the netmask represents. By default, you can add one Amazon-provided IPv6 CIDR block to the Regional pool. For information on increasing the default limit, see Quotas for your IPAM.
    - If you are creating an IPv6 pool in a private scope, you can use a private IPv6 GUA or ULA range:
        - For important details about private IPv6 addressing, see Private IPv6 addresses in the *Amazon VPC User Guide*.

- To use a private IPv6 ULA range, under **CIDRs to provision**, choose **Add ULA CIDR by netmask** and choose a netmask size or choose **Input private IPv6 CIDR** and enter a ULA range. Valid IPv6 ULA space is anything under fd00::/8 that does not overlap with the Amazon reserved range fd00::/16.
- To use a private IPv6 GUA range, you have to have first enabled the option on your IPAM (see Enable provisioning private IPv6 GUA CIDRs). Once you've enabled private IPv6 GUA CIDRs, enter an IPv6 GUA in **Input private IPv6 CIDR**.

13. Choose optional allocation rules for this pool:

- **Minimum netmask length**: The minimum netmask length required for CIDR allocations in this IPAM pool to be compliant and the largest size CIDR block that can be allocated from the pool. The minimum netmask length must be less than the maximum netmask length. Possible netmask lengths for IPv6 addresses are 0 - 128.
- **Default netmask length**: A default netmask length for allocations added to this pool. For example, if the CIDR that's provisioned to this pool is `2001:db8::/52` and you enter 56 here, any new allocations in this pool will default to a netmask length of /56.
- **Maximum netmask length**: The maximum netmask length that will be required for CIDR allocations in this pool. This value dictates the smallest size CIDR block that can be allocated from the pool. For example, if you enter /56 here, the smallest netmask length that can be allocated for CIDRs from this pool is /56.
- **Tagging requirements**: The tags that are required for resources to allocate space from the pool. If the resources have their tags changed after they have allocated space or if the allocation tagging rules are changed on the pool, the resource may be marked as noncompliant.
- **Locale**: The locale that will be required for resources that use CIDRs from this pool. Automatically imported resources that do not have this locale will be marked noncompliant. Resources that are not automatically imported into the pool will not be allowed to allocate space from the pool unless they are in this locale.

14. (Optional) Choose **Tags** for the pool.
15. Choose **Create pool**.
16. See Create a development IPv6 address pool in your IPAM.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

Use the following AWS CLI commands to create or edit an IPv6 regional pool in your IPAM:

1. If you want to enable provisioning private IPv6 GUA CIDRs, modify the IPAM with modify-ipam and include the option to `enable-private-gua`. For more information, see Enable provisioning private IPv6 GUA CIDRs.
2. Create a pool with create-ipam-pool.
3. Provision a CIDR to the pool: provision-ipam-pool-cidr.
4. Edit the pool after you create it to modify the allocation rules: modify-ipam-pool.

Create a development IPv6 address pool in your IPAM

Follow the steps in this section to create a development pool within your IPv6 Regional pool. If you only need a Regional pool and don't need development pools, skip to Allocate CIDRs from an IPAM pool.

The following example shows the hierarchy of the pool structure that you can create with the instructions in this guide. At this step, you are creating a development IPAM pool:

- IPAM operating in AWS Region 1 and AWS Region 2
  - Scope
    - Regional pool in AWS Region 1 (2001:db8::/52)
      - **Development pool (2001:db8::/54)**
        - Allocation for a VPC (2001:db8::/56)

In the preceding example, the CIDRs that are used are examples only. They illustrate that each pool within the top-level pool is provisioned with a portion of the top-level CIDR.

AWS Management Console

To create a development pool within an IPv6 Regional pool

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.

3. Choose **Create pool**.
4. Under **IPAM scope**, choose a scope. For more information about scopes, see How IPAM works.
5. (Optional) Add a **Name tag** for the pool and a description for the pool.
6. Under **Source**, choose **IPAM pool**. Then, under **Source pool**, choose the IPv6 Regional pool.
7. Under **Resource planning**, leave **Plan IP space within the scope** selected. For more information about using this option to plan for subnet IP space within a VPC, see Tutorial: Plan VPC IP address space for subnet IP allocations.
8. (Optional) Choose a CIDR to provision for the pool. You can only provision a CIDR that was provisioned to the top-level pool. You can create a pool without a CIDR, but you won't be able to use the pool for allocations until you've provisioned a CIDR for it. You can add CIDRs to a pool at any time by editing the pool.
9. You have the same allocation rule options here as you did when you created the IPv6 Regional pool. See Create a Regional IPv6 address pool in your IPAM for an explanation of the options that are available when you create pools. The allocation rules for the pool are not inherited from the pool above it in the hierarchy. If you do not apply any rules here, no allocation rules will be set for the pool.
10. (Optional) Choose **Tags** for the pool.
11. When you've finished configuring your pool, choose **Create pool**.
12. See Allocate CIDRs from an IPAM pool.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

Use the following AWS CLI commands to create an IPv6 Regional pool in your IPAM:

1. Get the ID of the scope that you want to create the pool in: describe-ipam-scopes
2. Get the ID of the pool that you want to create the pool in: describe-ipam-pools
3. Create the pool: create-ipam-pool
4. View the new pool: describe-ipam-pools

Repeat these steps to create additional development pools within the IPv6 Regional pool, as needed.

Allocate CIDRs from an IPAM pool

One important feature of IPAM is the ability to allocate and manage IP address space. When creating a VPC, you must specify an IP address CIDR block, which defines the range of IP addresses available for that VPC. IPAM simplifies this process by providing a global view of your entire IP address inventory, helping you strategically assign and reuse IP prefixes across multiple VPCs.

This address space allocation is crucial for ensuring there are no overlapping IP ranges, which could cause routing conflicts and connectivity issues. IPAM also enables you to reserve IP address space for future VPC expansion, avoiding the need for complex renumbering later.

Follow the steps in this section to allocate a CIDR from an IPAM pool to a resource.

> **Note**
>
> The terms *provision* and *allocate* are used throughout this user guide and the IPAM console. *Provision* is used when you add a CIDR to an IPAM pool. *Allocate* is used when you associate a CIDR from an IPAM pool with a resource.

You can allocate CIDRs from an IPAM pool in the following ways:

- Use an AWS service that's integrated with IPAM, such as Amazon VPC, and select the option to use an IPAM pool for the CIDR. IPAM automatically creates the allocation in the pool for you.
- Manually allocate a CIDR within an IPAM pool to reserve it for later use with an AWS service that's integrated with IPAM, such as Amazon VPC.

This section walks you through both options: how to use the AWS services integrated with IPAM to provision an IPAM pool CIDR, and how to manually reserve IP address space.

Contents

Create a VPC that uses an IPAM pool CIDR

With Amazon Virtual Private Cloud (Amazon VPC), you can launch AWS resources in a logically isolated virtual network that you've defined. This virtual network closely resembles a traditional

network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

A *virtual private cloud* (VPC) is a virtual network dedicated to your AWS account. It is logically isolated from other virtual networks in the AWS Cloud. You can specify an IP address range for the VPC, add subnets, add gateways, and associate security groups.

Follow the steps in Create a VPC in the *Amazon VPC User Guide*. When you reach the step to choose a CIDR for the VPC, you will have an option to use a CIDR from an IPAM pool.

If you choose the option to use an IPAM pool when you create the VPC, AWS allocates a CIDR in the IPAM pool. You can view the allocation in IPAM by choosing a pool in the content pane of the IPAM console and viewing the Resources tab for the pool.

> **Note**
>
> For complete instructions using the AWS CLI, including creating a VPC, see the Tutorials for Amazon VPC IP Address Manager section.

Manually allocate a CIDR to a pool to reserve IP address space

Follow the steps in this section to manually allocate a CIDR to a pool. You might do this to reserve a CIDR within an IPAM pool for later use. You can also reserve space in your IPAM pool to represent an on-premises network. IPAM manages that reservation for you and indicates if any CIDRs overlap with your on-premises IP space.

AWS Management Console

To manually allocate a CIDR

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.
3. By default, the default private scope is selected. If you don't want to use the default private scope, from the dropdown menu at the top of the content pane, choose the scope you want to use. For more information about scopes, see How IPAM works.
4. In the content pane, choose a pool.
5. Choose **Actions** > **Create custom allocation**.

6. Choose whether to add a specific CIDR to allocate (for example, `10.0.0.0/24` for IPv4 or `2001:db8::/52` for IPv6) or add a CIDR by size by choosing the netmask length only (for example, `/24` for IPv4 or `/52` for IPv6).
7. (Optional) To tag the allocation, expand the **Tags** section and enter the key and value for each tag you want to add.
8. Choose **Allocate**.
9. You can view the allocation in IPAM by choosing **Pools** in the navigation pane, choosing a pool, and viewing the **Allocations** tab for the pool.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

Use the following AWS CLI commands to manually allocate a CIDR to a pool:

1. Get the ID of the IPAM pool that you want to create the allocation in: describe-ipam-pools.
2. Create the allocation: allocate-ipam-pool-cidr. (Optional) To tag the allocation at creation, include the `--tag-specifications` parameter. For example:

```
aws ec2 allocate-ipam-pool-cidr --ipam-pool-id ipam-pool-0533048da7eba92f6
 --netmask-length 24 --tag-specifications 'ResourceType=ipam-pool-
allocation,Tags=[{Key=Environment,Value=Production}]'
```

3. View the allocation: get-ipam-pool-allocations.

To release a manually allocated CIDR, see Release an allocation.

Managing IP address space in IPAM

The tasks in this section are optional. Note that this section is a grouping of procedures all related to working with IPAM. The procedures are ordered alphabetically.

If you want to complete the tasks in this section, and you have delegated an IPAM account, the tasks should be completed by the IPAM administrator.

Follow the steps in this section to manage your IP address space in IPAM.

Contents

- Work with resource discoveries

Automate prefix list updates with IPAM

A managed prefix list is a set of CIDR blocks that you can reference in security group rules and route tables instead of specifying individual IP addresses. For example, instead of creating separate security group rules for `10.1.0.0/16`, `10.2.0.0/16`, and `10.3.0.0/16`, you can create one prefix list containing all three CIDRs and reference it in a single rule.

There are two types:

- **Customer-managed prefix lists**: IP ranges you define and manage
- **AWS-managed prefix lists**: IP ranges for AWS services (like S3 or CloudFront)

This IPAM feature automates the management of **customer-managed prefix lists** by keeping your CIDR entries synchronized with your network changes.

The problem this solves

Without automation, network teams spend significant time manually updating prefix lists when infrastructure changes and maintaining consistent prefix lists across environments and Regions.

IPAM solves this by letting you create rules that automatically populate prefix lists. You can use two approaches: reference CIDRs from your IPAM pools, or create rules based on your actual AWS resources—such as ' include all VPCs tagged with env=prod', 'include all subnets in us-east-1', or 'include all Elastic IP addresses owned by account 123456789'. When you add or remove these resources, IPAM automatically updates the prefix list with their CIDRs.

How it works

You create rules that tell IPAM which IP addresses to include in a prefix list. For example, "include all VPC CIDRs tagged with env=prod". When you add or remove production VPCs, IPAM automatically updates the prefix list.

When to use it

- **Security groups**: Create a rule "include all VPCs tagged env=prod" so when you add new production VPCs, they're automatically allowed in your security group rules

- **Multi-region**: Deploy the same IPAM rules in multiple regions to keep identical prefix lists without manually copying CIDR entries
- **Dynamic infrastructure**: When you create/delete VPCs or subnets, their CIDRs are automatically added/removed from prefix lists without manual updates

Prerequisites

Before you begin, ensure you have:

- An IPAM with Advanced Tier enabled
- A customer-managed prefix list (or create one during setup)
- IAM permissions for IPAM and EC2 prefix list operations

Setup steps

Step 1: Create an IPAM prefix list resolver

Define which CIDRs to include in your prefix list by creating an IPAM prefix list resolver.

AWS Management Console

To create an IPAM prefix list resolver

1. Open the IPAM console.
2. In the navigation pane, choose **Prefix list resolvers**.
3. Choose **Create prefix list resolver**.
4. In **Step 1: Configure resolver details**, choose the following:
   - **IPAM**: An IPAM instance
   - **Address family**: IPv4 or IPv6
   - **Name tag - optional**: A descriptive name
   - **Description - optional**: A description
   - **Tags**: Resource tags
5. Choose **Next**.
6. In **Step 2: Configure rules**, choose **Add rule**. You can add up to 99 rules.

> **Important**
>
> You can create a prefix list resolver without any CIDR selection rules, but it will generate empty versions (containing no CIDRs) until you add rules.

7. Choose one of the rule types:

- **Static CIDR**: A fixed list of CIDRs that do not change (like a manual list replicated across Regions)
- **IPAM pool CIDR**: CIDRs from specific IPAM pools (like all CIDRs from your IPAM production pool)

  If you choose this option, choose the following:

  - **IPAM scope**: Select the IPAM scope to search for resources
  - **Conditions:**
    - **Property**
      - **IPAM pool ID**: Select an IPAM pool that contains the resources
      - **CIDR** (like 10.24.34.0/23)
    - **Operation**: Equals/Not equals
    - **Value**: The value on which to match the condition
- **Scope resource CIDR**: CIDRs from AWS resources like VPCs, subnets, EIPs within an IPAM scope

  If you choose this option, choose the following:

  - **IPAM scope**: Select the IPAM scope to search for resources
  - **Resource type**: Select a resource, like a VPC or subnet.
  - **Conditions**:
    - **Property**:
      - Resource ID: The unique ID of a resource (like vpc-1234567890abcdef0)
      - Resource owner (like 111122223333)
      - Resource region (like us-east-1)
      - Resource tag (like key: name, value: dev-vpc-1)
      - CIDR (like 10.24.34.0/23)

- **Operation**: Equals/Not equals
- **Value**: The value on which to match the condition

8. Choose **Next**.
9. Choose **Validate and create**.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

Use the following AWS CLI commands to create an IPAM prefix list resolver:

- Use the create-ipam-prefix-list-resolver command and save the returned resolver ID for step 2.

Step 2: Create a resolver target to connect to a prefix list

Link your resolver to an existing prefix list by creating a resolver target. Use the resolver ID returned from Step 1.

AWS Management Console

To create an IPAM prefix list resolver target

1. In the IPAM console, choose **Prefix list resolvers**.
2. Choose the resolver you created in Step 1.
3. On the resolver details page, choose the **Targets** tab.
4. Choose **Create target**.
5. Configure the target:
   - **Region**: Select the Region where the existing managed prefix list exists or where you will create one.
   - **Prefix list**: Choose an existing managed prefix list or create a new one
6. Under **Desired version**, select one of the following:
   - **Always track latest version**: Choose this for automatic updates when you want your prefix lists to stay current with infrastructure changes without manual intervention.

- **Track specific version**: Choose this for stability when you need predictable, controlled updates and want to manually approve changes to your prefix lists.

7. Choose **Create target**.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

Use the following AWS CLI commands to create an IPAM prefix list resolver target:

- Use the create-ipam-prefix-list-resolver-target command with the resolver ID from step 1 and your existing prefix list ID.

IPAM now automatically updates your prefix list based on your rules. The prefix list will be populated with CIDRs matching your criteria.

Step 3: Monitor versions and synchronization

As a result of creating a prefix list resolver and target, the prefix list resolver generates CIDR versions based on your rules and then the target syncs those CIDRs from the resolver to a specific managed prefix list. Each version is a snapshot of what CIDRs matched your rules at that moment in time. The version number increments every time the CIDR list changes due to infrastructure changes.

Version example:

Initial State (Version 1)

Production environment:

- vpc-prod-web (10.1.0.0/16) - tagged env=prod
- vpc-prod-db (10.2.0.0/16) - tagged env=prod

Resolver rule: Include all VPCs tagged env=prod

Version 1 CIDRs: 10.1.0.0/16, 10.2.0.0/16

Infrastructure Change (Version 2)

New VPC added:

- vpc-prod-api (10.3.0.0/16) - tagged env=prod

IPAM automatically detects the change and creates a new version.

Version 2 CIDRs: 10.1.0.0/16, 10.2.0.0/16, 10.3.0.0/16

This section explains how you can monitor version creation with the AWS console or AWS CLI and synchronization success with the AWS CLI.

Also, we encourage you to set CloudWatch alarms on failure metrics as you may need to reassess and adjust CIDR selection rules to stay within the limits for version and prefix list size. For a list of CloudWatch metrics related to IPAM prefix lists, see IPAM prefix list resolver metrics.

AWS Management Console

To view versions created and monitor the target synchronization

1. In the IPAM console, choose **Prefix list resolvers**.
2. Choose the resolver you created in Step 1.
3. On the resolver details page, choose the **Versions** tab. Here you'll see any versions that have been created by the resolver along with any CIDRs in the version.
4. On the resolver details page, choose the **Monitoring** tab. In this view, IPAM prefix list resolver metrics are presented in graph form:
   - Prefix list resolver version creation success
   - Prefix list resolver version creation failure
5. From the **Monitoring** tab, you can also configure a CloudWatch alarm by choosing **Create alarm for prefix list resolver version creation**. You're taken to the CloudWatch console with the alarm partially configured for the metric. For more information about how to finish creating the alarm, see Create a CloudWatch alarm based on a static threshold in the *Amazon CloudWatch User Guide*.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

Use the following AWS CLI commands to monitor versions and synchronization:

1. Use the get-ipam-prefix-list-resolver-version-entries command to view the latest version created by resolver.
2. Use the describe-ipam-prefix-list-resolver-targets command to monitor resolver target sync status.

The monitor command shows:

- state - current sync state (create-complete, modify-complete, and more)
- lastSyncedVersion - last successfully synced version
- desiredVersion - target version to sync to
- stateMessage - error details if sync failed

> **Important**
>
> To support rollback workflows, IPAM retains copies of the previous 10 prefix list resolver versions for each of its targets. Additionally, IPAM deletes versions older than this threshold if they remain unreferenced for an additional 7 days.

Step 4: (Optional) Enable and disable IPAM prefix list sync

If a managed prefix list has been configured as an IPAM prefix list target and you want to make changes to the prefix list without needing permission to access the IPAM prefix list resolver target, you can modify the managed prefix list and disable synchronization with the IPAM prefix list resolver. When disabled, the prefix list CIDRs are not automatically updated and you can make changes to them. When enabled, the prefix list CIDRs are automatically updated based on the associated resolver's CIDR selection rules.

Change the monitoring state of VPC CIDRs

Follow the steps in this section to change the monitoring state of a VPC CIDR. You may want to change a VPC CIDR from monitored to ignored if you do not want IPAM to manage or monitor the VPC and allow the CIDR allocated to the VPC to be available for use. You may want to change a VPC CIDR from ignored to monitored if you want IPAM to manage and monitor the VPC CIDR.

Note

- You cannot ignore VPC CIDRs in the public scope.
- If a CIDR is ignored, you are still charged for the active IP addresses in the CIDR. For more information, see Pricing for IPAM.
- If a CIDR is ignored, you can still view the history of IP addresses in the CIDR. For more information, see View IP address history.

You can change the monitoring state of a VPC CIDR to monitored or ignored:

- **Monitored**: The VPC CIDR has been detected by IPAM and is being monitored for overlap with other CIDRs and allocation rule compliance.
- **Ignored**: The VPC CIDR has been chosen to be exempt from monitoring. Ignored VPC CIDRs are not evaluated for overlap with other CIDRs or Allocation rule compliance. Once a VPC CIDR is chosen to be ignored, any space allocated to it from an IPAM pool is returned to the pool and the VPC CIDR is not imported again through auto-import (if the auto-import Allocation rule is set on the pool).

AWS Management Console

To change the monitoring status of a CIDR allocated to a VPC

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Resources**.
3. From the dropdown menu at the top of the content pane, choose the private scope you want to use.
4. In the content pane, choose the VPC and view the details of the VPC.
5. Under **VPC CIDRs**, select one of the CIDRs allocated to the VPC and choose **Actions** > **Mark as ignored** or **Unmark as ignored**.
6. Choose **Mark as ignored** or **Unmark as ignored**.

Command line

Use the following AWS CLI commands to change the monitoring state of a VPC CIDR:

1. Get a scope ID: describe-ipam-scopes
2. View the current monitoring state for the VPC CIDR: get-ipam-resource-cidrs
3. Change the state of the VPC CIDR: modify-ipam-resource-cidr
4. View the new monitoring state for the VPC CIDR: get-ipam-resource-cidrs

Create additional scopes

Follow the steps in this section to create an additional scope.

A scope is the highest-level container within IPAM. When you create an IPAM, IPAM creates two default scopes for you. Each scope represents the IP space for a single network. The private scope is intended for all private space. The public scope is intended for all public space. Scopes enable you to reuse IP addresses across multiple unconnected networks without causing IP address overlap or conflict.

When you create an IPAM, default scopes (one private and one public) are created for you. You can create additional private scopes. You cannot create additional public scopes.

You can create additional private scopes if you require support for multiple disconnected private networks. Additional private scopes allow you to create pools and manage resources that use the same IP space.

> **Important**
>
> If IPAM discovers resources with private IPv4 or private IPv6 CIDRs, the resource CIDRs are imported into the default private scope and do not appear in any additional private scopes you create. You can move CIDRs from the default private scope to another private scope. For information, see Move VPC CIDRs between scopes.

AWS Management Console

To create an additional private scope

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Scopes**.
3. Choose **Create scope**.
4. Choose the IPAM that you want to add the scope to.

5. Add a description for the scope.
6. Choose **Create scope**.
7. You can view the scope in IPAM by choosing **Scopes** in the navigation pane.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

Use the following AWS CLI commands to create an additional private scope:

1. View your current scopes: describe-ipam-scopes
2. Create a new private scope: create-ipam-scope
3. View your current scopes to view the new scope: describe-ipam-scopes

Delete an IPAM

You may want to delete an IPAM if it is no longer needed, if you need to restructure your IP address management, or if you want to start fresh with a new IPAM configuration. Deleting an IPAM can help simplify your IP address management and align with changing business or operational requirements.

Follow the steps in this section to delete an IPAM. For information on increasing the default number of IPAMs you can have rather than deleting an existing IPAM, see Quotas for your IPAM.

> **Note**
>
> Deleting an IPAM removes all monitored data associated with the IPAM including the historical data for CIDRs.

AWS Management Console

To delete an IPAM

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **IPAMs**.
3. In the content pane, select your IPAM.

4. Choose **Actions** > **Delete IPAM**.
5. Do one of the following:

   - Choose **Cascade delete** to delete the IPAM, private scopes, pools in private scopes, and any allocations in the pools in private scopes. You cannot delete the IPAM with this option if there is a pool in your public scope. If you use this option, IPAM does the following:
     - Deallocates any CIDRs allocated to VPC resources (such as VPCs) in pools in private scopes.

       > **Note**
       >
       > No VPC resources are deleted as a result of enabling this option. The CIDR associated with the resource will no longer be allocated from an IPAM pool, but the CIDR itself will remain unchanged.

     - Deprovisions all IPv4 CIDRs provisioned to IPAM pools in private scopes.
     - Deletes all IPAM pools in private scopes.
     - Deletes all non-default private scopes in the IPAM.
     - Deletes the default public and private scopes and the IPAM.
   - If you don't choose the **Cascade delete** checkbox, before you can delete an IPAM, you must do the following:
     - Release allocations within the IPAM pools. For more information, see Release an allocation.
     - Deprovision CIDRs provisioned to pools within the IPAM. For more information, see Deprovision CIDRs from a pool.
     - Delete any additional non-default scopes. For more information, see Delete a scope.
     - Delete your IPAM pools. For more information, see Delete a pool.
6. Enter **`delete`** and then choose **Delete**.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

Use the following AWS CLI commands to delete an IPAM:

1. View current IPAMs: describe-ipams
2. Delete an IPAM: delete-ipam
3. View your updated IPAMs: describe-ipams

To create a new IPAM, see Create an IPAM.

Delete a pool

An IPAM pool in AWS represents a defined range of IP addresses that can be allocated and managed within a specific AWS environment or organization. Pools are used to organize IP address space, enable automated IP address management, and enforce IP address governance policies across your cloud infrastructure.

You may want to delete an IPAM pool to remove unused or unnecessary IP address space and reclaim it for other purposes. You cannot delete an IP address pool if there are allocations in it. You must first release the allocations and Deprovision CIDRs from a pool before you can delete the pool.

Follow the steps in this section to delete an IPAM pool.

AWS Management Console

To delete a pool

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.
3. From the dropdown menu at the top of the content pane, choose the scope that you want to use. For more information about scopes, see How IPAM works.
4. In the content pane, choose the pool whose CIDR you want to delete.
5. Choose **Actions** > **Delete pool**.
6. Enter **`delete`** and then choose **Delete**.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

Use the following AWS CLI commands to delete a pool:

1. View pools and get an IPAM pool ID: describe-ipam-pools
2. Delete a pool: delete-ipam-pool
3. View your pools: describe-ipam-pools

To create a new pool, see Create a top-level IPv4 pool.

Delete a scope

You may want to delete an IPAM scope if it no longer serves its intended purpose, such as when you restructure your network, consolidate regions, or adjust your IP address allocation. Deleting unused scopes can help streamline your IPAM configuration and optimize your IP address management within AWS.

Note

You can't delete a scope if either of the following is true:

- The scope is a default scope. When you create an IPAM, two default scopes (one public, one private) are created automatically, and cannot be deleted. To see if a scope is a default scope, view the **Scope type** in the details of the scope.
- There are one or more pools in the scope. You must first Delete a pool before you can delete the scope.

AWS Management Console

To delete a scope

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Scopes**.
3. In the content pane, choose the scope that you want to delete.
4. Choose **Actions** > **Delete scope**.
5. Enter **`delete`** and then choose **Delete**.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

Use the following AWS CLI commands to delete a scope:

1. View scopes: describe-ipam-scopes
2. Delete a scope: delete-ipam-scope
3. View updated scopes: describe-ipam-scopes

To create a new scope, see Create additional scopes. To delete the IPAM, see Delete an IPAM.

Deprovision CIDRs from a pool

You may want to deprovision a pool CIDR to free up IP address space, simplify IP address management, prepare for network changes, or meet compliance requirements. Deprovisioning a pool CIDR allows for better control and optimization of your IP address allocations within IPAM, while ensuring unused IP space is reclaimed and made available for future use. You can't deprovision the CIDR if there are allocations in the pool. To remove allocations, see the section called “Release an allocation”.

Follow the steps in this section to deprovision CIDRs from an IPAM pool. When you deprovision all pool CIDRs, the pool can no longer be used for allocations. You must first provision a new CIDR to the pool before you can use the pool for allocations.

AWS Management Console

To deprovision a pool CIDR

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.
3. From the dropdown menu at the top of the content pane, choose the scope that you want to use. For more information about scopes, see How IPAM works.
4. In the content pane, choose the pool whose CIDRs you want to deprovision.
5. Choose the **CIDRs** tab.
6. Select one or more CIDRs and choose **Deprovision CIDRs**.

7. Choose **Deprovision CIDR**.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

Use the following AWS CLI commands to deprovision a pool CIDR:

1. Get an IPAM pool ID: describe-ipam-pools
2. View your current CIDRs for the pool: get-ipam-pool-cidrs
3. Deprovision CIDRs: deprovision-ipam-pool-cidr
4. View your updated CIDRs: get-ipam-pool-cidrs

To provision a new CIDR to the pool, see Deprovision CIDRs from a pool. If you want to delete the pool, see Delete a pool.

Edit an IPAM pool

You may want to edit a pool to do one of the following:

- Change the allocation rules for the pool. For more information about allocation rules, see Create a top-level IPv4 pool.
- Modify the pool's name, description, or other metadata to improve organization and visibility within IPAM.
- Change pool options like auto-import discovered resources to optimize IPAM's automated IP address management.

Follow the steps in this section to edit an IPAM pool.

AWS Management Console

To edit a pool

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.

3. By default, the default private scope is selected. If you don't want to use the default private scope, from the dropdown menu at the top of the content pane, choose the scope you want to use. For more information about scopes, see How IPAM works
4. In the content pane, choose the pool whose CIDR you want to edit.
5. Choose **Actions** > **Edit**.
6. Make any changes you need to the pools. For information about pool configuration options, see Create a top-level IPv4 pool.
7. Choose **Update**.

Command line

Use the following AWS CLI commands to edit a pool:

1. Get an IPAM pool ID: describe-ipam-pools
2. Modify the pool: modify-ipam-pool

Enable cost distribution

When you enable cost distribution, you distribute the charges for active IP addresses to the accounts using the IP addresses rather than to the IPAM owner. This is useful for large organizations where the delegated IPAM admin manages the IP addresses centrally using IPAM and each account is responsible for their own usage, eliminating the need for manual billing calculations.

The cost distribution option is available when you create an IPAM or modify an IPAM under **Metering mode**, where:

- **IPAM owner** (default): The AWS account which owns the IPAM is charged for all active IP addresses managed in IPAM.
- **Resource owner**: The AWS account that owns the IP address is charged for the active IP address.

Requirements

- Your IPAM must be integrated with AWS Organizations.
- The IPAM must have been created by the delegated IPAM admin in your AWS Organization.

- The IPAM's home region must be a Region that's enabled by default. It cannot be an opt-in Region.

How charging works

- Even though you can distribute IP address charges within an organization, all IPAM charges are consolidated to the organization's payer account through AWS Organizations consolidated billing.
- When cost distribution is enabled, organization member accounts can still view their individual IPAM usage and charges in their account bills.
- The IPAM ARN will appear on individual account bills when cost distribution is enabled, which allows resource owners to track their IPAM active IP usage. If you use AWS Data Exports, IPAM charges appear with the associated IPAM ARN in both consolidated and individual account bills.
- Only accounts within the delegated administrator's organization can receive charges for the resources that they own. IP address costs outside of the organization are charged to the IPAM owner.

Time restrictions

- You have 24 hours to opt out after enabling cost distribution. After 24 hours, you cannot change the setting for 7 days. After 7 days, you can disable cost distribution.

Integrate VPC IPAM with Infoblox infrastructure

Amazon VPC IPAM and Infoblox integration connects your AWS VPC IP Address Manager (IPAM) with Infoblox, enabling you to manage AWS IP addresses through your existing Infoblox workflows while gaining cloud-native AWS capabilities.

This integration solves a common enterprise challenge: avoiding duplicate IP management systems. Instead of learning new tools and maintaining separate processes for AWS and on-premises networks, you can designate Infoblox as the management authority for VPC IPAM scopes and continue using your familiar Infoblox interface for all IP address operations.

Integration process overview

The following steps provide an overview of the complete integration process:

1. **Configure IPAM scope** (described in this document): Amazon VPC IPAM delegated admin creates a new scope or modifies an existing scope to use Infoblox as its external authority.
2. **Configure Infoblox** (described outside of this document): See Next steps.
3. **Create top-level pool**: Amazon VPC IPAM delegated admin creates a pool in the scope that's linked to Infoblox. The pool starts with no CIDR assigned.
4. **Provision CIDR from external authority**: Amazon VPC IPAM delegated admin provisions a CIDR for the pool. You can request any available CIDR (Infoblox chooses from allowed range) or request a specific CIDR (Infoblox accepts or rejects based on availability). IPAM automatically coordinates with Infoblox to obtain and provision the approved CIDR.
5. **Continue with standard IPAM operations**: Create child pools and VPCs from the allocated CIDR using standard Amazon VPC IPAM procedures.

When to use this integration

Use this integration if you already use or plan to use Infoblox for on-premises network management and want to extend your existing IP management practices to AWS without maintaining separate systems.

Prerequisites

Before configuring this integration, ensure you have:

- **VPC IPAM Advanced Tier**: enabled in your AWS account. For more information, see VPC IPAM Advanced Tier.
- **Required IAM permissions**: listed below
- **Infoblox resource identifier**: from your Infoblox administrator

IAM role for Infoblox

Create an IAM role for the Infoblox principal to assume, or use an existing role. The role needs these permissions:

- `ec2:DescribeIpamPools`
- `ec2:DescribeIpams`
- `ec2:DescribeIpamScopes`

- `ec2:GetIpamPoolAllocations`
- `ec2:GetIpamPoolCidrs`
- `ec2:GetIpamResourceCidrs`

For instructions on how to add these permissions to an IAM role or policy, see Adding and removing IAM identity permissions in the *IAM User Guide*.

> **Note**
>
> Infoblox may require permissions for VPC IPAM discovery in addition to these permissions required to enable this integration.

Configure Infoblox integration in the VPC IPAM

You can enable Infoblox integration when you create or modify scopes in the AWS VPC IPAM console or AWS CLI.

> **Important**
>
> Infoblox integration is available only for private scopes, not public scopes.

Creating a new scope with Infoblox integration

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **IPAM**, and then choose **Scopes**.
3. Choose **Create scope**.
4. For **Scope settings**, do the following:
   - **IPAM ID** is automatically populated.
   - (Optional) For **Name tag**, enter a name for the scope.
   - (Optional) For **Description**, enter a description for the scope.
5. For **Scope Authority**, choose **Infoblox IPAM**.
6. For **Infoblox resource identifier**, enter the Infoblox resource identifier in the format `<version>.identity.account.<entity_realm>.<entity_id>`.

7. Verify that you have the required IAM permissions as displayed in the information box.
8. Choose **Create scope**.

The related AWS CLI command for this is create-ipam-scope.

Modifying existing scopes

To change the scope authority from **Amazon VPC IPAM** to **Infoblox IPAM** for an existing scope, edit the scope settings and follow the same configuration steps in the previous procedure.

The related AWS CLI command for this is modify-ipam-scope.

Next steps

This completes the Amazon VPC IPAM configuration needed for the integration. After configuring the scope authority, you can create a top-level IPAM pool within the scope. For more information, see Create a top-level IPv4 pool.

The integration also requires configuring an Infoblox source pool, verifying discovery job status, setting up the private scope to be managed by Infoblox, enabling Infoblox management for Amazon VPC IPAM, and creating pools either from the Infoblox integration or directly from the Infoblox portal.

For information about the Infoblox side of the integration, see the *AWS IPAM Integration User Guide* in the Infoblox documentation.

Enable provisioning private IPv6 GUA CIDRs

If you want your private networks to support IPv6 and have no intention of routing traffic from these addresses to the internet, you can provision a private IPv6 ULA or GUA range to an IPAM pool in a private scope.

For important details about private IPv6 addressing, see Private IPv6 addresses in the *Amazon VPC User Guide*.

There are two types of private IPv6 addresses:

- **IPv6 ULA ranges**: IPv6 addresses as defined in RFC4193. These address ranges will always start with "fc" or "fd", which makes them easily identifiable. Valid IPv6 ULA space is anything under fd00::/8 that does not overlap with the Amazon reserved range fd00::/16.

- **IPv6 GUA ranges**: IPv6 addresses as defined in RFC3587. The option to use IPv6 GUA ranges as private IPv6 addresses is disabled by default and must be enabled before you can use it.

To use an IPv6 ULA address ranges, you choose the IPv6 option when you provision a CIDR to an IPAM pool and enter the IPv6 ULA range. To use your own IPv6 GUA ranges as private IPv6 addresses, however, you must first complete the steps in this section. The option is disabled by default.

Note

- When you use private IPv6 GUA ranges, we require that you use IPv6 GUA ranges owned by you.
- IPAM discovers resources with IPv6 ULA and GUA addresses and monitors pools for overlapping IPv6 ULA and GUA address space.
- If you want to connect to the internet from a resource that has a private IPv6 address, you can do it, but you must route traffic through a resource in another subnet with a public IPv6 address to accomplish it.
- If you have a private IPv6 GUA range allocated to a VPC, you cannot use public IPv6 GUA space that overlaps the private IPv6 GUA space in the same VPC.
- Communication between resources with private IPv6 ULA and GUA address ranges is supported (such as across Direct Connect. VPC peering, transit gateway, or VPN connections).
- A private GUA IPv6 range cannot be converted to a publicly-advertised IPv6 GUA range.

AWS Management Console

To enable provisioning private IPv6 GUA CIDRs

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **IPAMs**.
3. Choose your IPAM and choose **Actions** > **Edit**.
4. Under **Private IPv6 GUA CIDRs**, choose **Enable provisioning GUA CIDR space into private IPv6 IPAM pools**.
5. Choose **Save changes**.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

Use the following AWS CLI commands to enable provisioning private IPv6 GUA CIDRs:

1. View current IPAMs with describe-ipams
2. Modify the IPAM with modify-ipam and include the option to `enable-private-gua`.

Once you enable the option to provision private IPv6 GUA CIDRs, you can provision a private IPv6 GUA CIDR to a pool. For more information, see Provision CIDRs to a pool.

Enforce IPAM use for VPC creation with SCPs

> **Note**
>
> This section is only applicable to you if you've enabled IPAM to integrate with AWS Organizations. For more information, see Integrate IPAM with accounts in an AWS Organization.

This section describes how to create a service control policy in AWS Organizations that requires members in your organization to use IPAM when they create a VPC. Service control policies (SCPs) are a type of organization policy that enable you to manage permissions in your organization. For more information, see Service control policies in the *AWS Organizations User Guide*.

Enforce IPAM when creating VPCs

Follow the steps in this section to require members in your organization to use IPAM when creating VPCs.

To create an SCP and restrict VPC creation to IPAM

1. Follow the steps in Create a service control policy in the *AWS Organizations User Guide* and enter the following text in the JSON editor:

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [{
       "Effect": "Deny",
        "Action": ["ec2:CreateVpc", "ec2:AssociateVpcCidrBlock"],
        "Resource": "arn:aws:ec2:*:*:vpc/*",
        "Condition": {
            "Null": {
                "ec2:Ipv4IpamPoolId": "true"
            }
        }
     }]
}
```

2. Attach the policy to one or more organizational units in your organization. For more information, see Attach policies and Detach policies in the *AWS Organizations User Guide*.

Enforce an IPAM pool when creating VPCs

Follow the steps in this section to require members in your organization to use a specific IPAM pool when creating VPCs.

To create an SCP and restrict VPC creation to an IPAM pool

1. Follow the steps in Create a service control policy in the *AWS Organizations User Guide* and enter the following text in the JSON editor:

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [{
        "Effect": "Deny",
        "Action": ["ec2:CreateVpc", "ec2:AssociateVpcCidrBlock"],
        "Resource": "arn:aws:ec2:*:*:vpc/*",
        "Condition": {
            "StringNotEquals": {
```

```
                "ec2:Ipv4IpamPoolId": "ipam-pool-0123456789abcdefg"
            }
          }
    }]
}
```

2. Change the `ipam-pool-0123456789abcdefg` example value to the IPv4 pool ID you would like to restrict users to.
3. Attach the policy to one or more organizational units in your organization. For more information, see Attach policies and Detach policies in the *AWS Organizations User Guide*.

Enforce IPAM for all but a given list of OUs

Follow the steps in this section to enforce IPAM for all but a given list of Organizational Units (OUs). The policy described in this section requires OUs in the organization except for the OUs that you specify in `aws:PrincipalOrgPaths` to use IPAM to create and expand VPCs. The listed OUs can either use IPAM when creating VPCs or specify an IP address range manually.

To create an SCP and enforce IPAM for all but a given list of OUs

1. Follow the steps in Create a service control policy in the *AWS Organizations User Guide* and enter the following text in the JSON editor:

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [{
 "Effect": "Deny",
     "Action": ["ec2:CreateVpc", "ec2:AssociateVpcCidrBlock"],
     "Resource": "arn:aws:ec2:*:*:vpc/*",
     "Condition": {
         "Null": {
        "ec2:Ipv4IpamPoolId": "true"
                },
         "ForAnyValue:StringNotLike": {
             "aws:PrincipalOrgPaths": [
                 "o-a1b2c3d4e5/r-ab12/ou-ab12-11111111/ou-ab12-22222222/",
                 "o-a1b2c3d4e5/r-ab12/ou-ab13-22222222/ou-ab13-33333333/"
             ]
```

```
                }
            }
        }]
}
```

2. Remove the example values (like `o-a1b2c3d4e5/r-ab12/ou-ab12-11111111/ou-ab12-22222222/`) and add the AWS Organizations entity paths of the OUs that you want to have the option (but not require) to use IPAM. For more information about entity path, see Understand the AWS Organizations entity path and aws:PrincipalOrgPaths in the *IAM User Guide*.
3. Attach the policy to your organization root. For more information, see Attach policies and Detach policies in the *AWS Organizations User Guide*.

Exclude organizational units from IPAM

If your IPAM is integrated with AWS Organizations, you can exclude an organizational unit (OU) from being managed by IPAM. When you exclude an OU, IPAM will not manage the IP addresses in accounts in that OU. This feature gives you more flexibility in how you use IPAM.

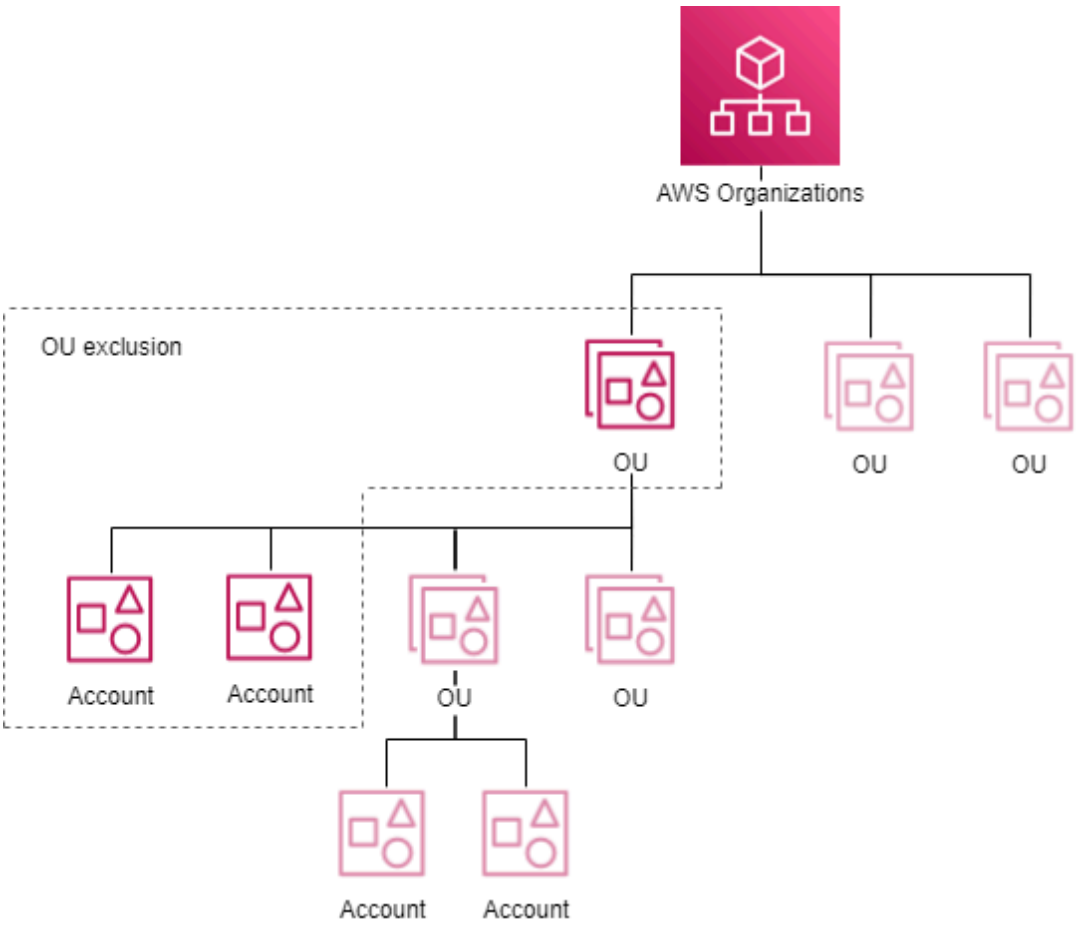
You can use OU exclusions in the following ways:

- **Enable IPAM for specific parts of your business**: If you have multiple business units or subsidiaries in AWS Organizations, you can now use IPAM just for the ones that need it.
- **Keep your sandbox accounts separate**: You can exclude your sandbox accounts from IPAM, focusing only on the accounts that really matter for your IP management.

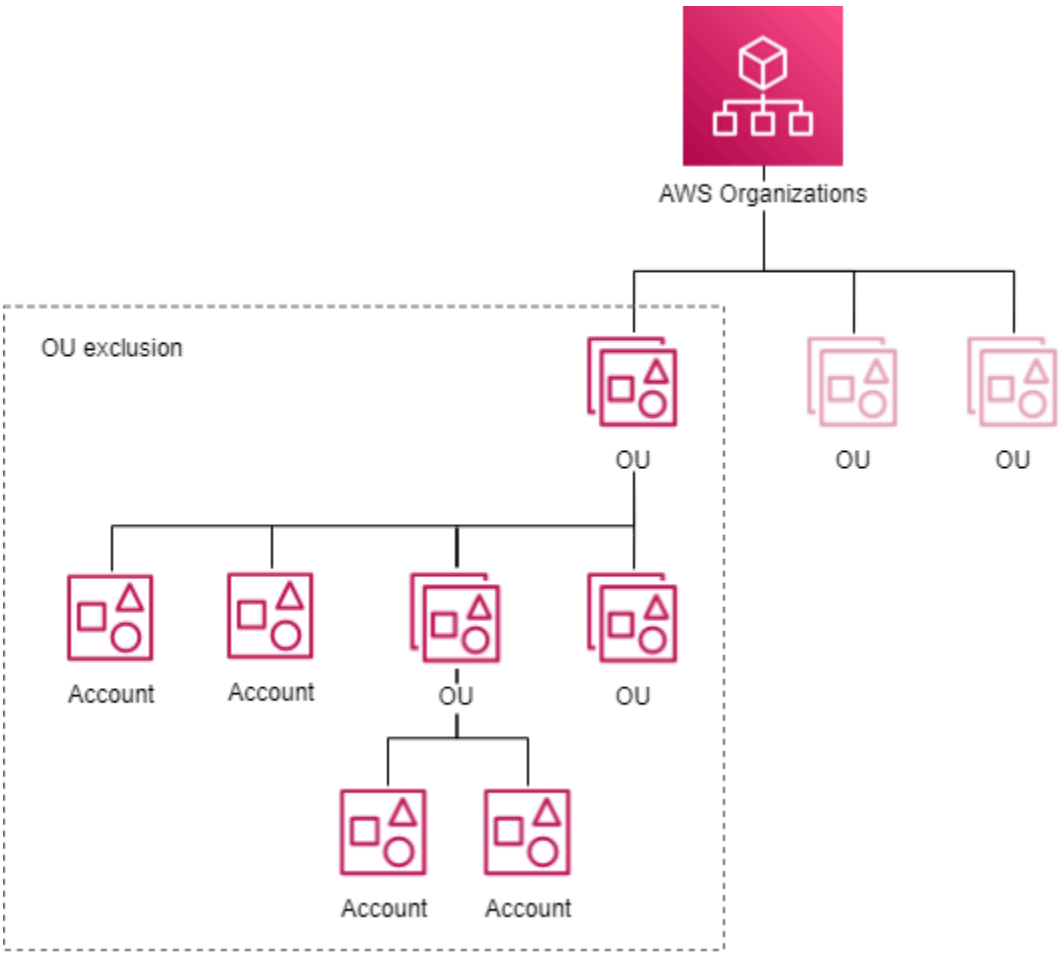
How OU exclusions work

The diagrams in this section demonstrate two use cases for adding OU exclusions in IPAM.

The first diagram shows the impact of adding an organization unit (OU) exclusion on a parent OU only. As a result, IPAM will not manage the IP addresses in accounts in the parent OU. IPAM will manage the IP addresses in accounts in the other OUs outside the exclusion.



The second diagram shows the impact of adding an organization unit (OU) exclusion on a parent OU *and* all child OUs. As a result, IPAM will not manage the IP addresses in accounts in the parent OU or in accounts in any child OUs. IPAM will manage the IP addresses in accounts in the OUs outside of the exclusion.



Add or remove OU exclusions

Complete the steps in this section to add or remove OU exclusions.

Note

- The delegated IPAM admin account is not excluded even if it's within an OU that's excluded.
- Your IPAM must be integrated with AWS Organizations to add an OU exclusion. The Organization must have OUs in it.
- You must be the delegated IPAM admin to view, add, or remove OU exclusions.
- It takes time for IPAM to discover recently created organizational units.
- There is a default quota for the number of exclusions you can add per resource discovery. For more information, see *Organizational unit exclusions per resource discovery* in Quotas for your IPAM.

- If you share a resource discovery with another account, that account can see the OU exclusions on it, which contains information such as the Org ID, Root ID, and organizational unit IDs of the resource discovery owner's Organization.

AWS Management Console

To add or remove OU exclusions

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Resource discoveries**.
3. Choose your default resource discovery.
4. Choose **Edit**.
5. Under **Organizational unit exclusions**, do the following:

   - **To add an OU exclusion**:
     - If you want to exclude the OU and all its child OUs:
       - Find the OU in the table and select the checkbox. All child OUs are automatically selected.
     - If you want to exclude only parent OU accounts:
       - Find the OU in the table and select the checkbox. All child OUs are automatically selected. Deselect all child OUs.
     - Alternatively, you can use the **Actions** column to select only a parent OU or parent and child OUs:
       - **Select all child OUs**: Include any child OUs in the exclusion. As a result of choosing an OU, the OU is added on screen. Each OU contains the ID and the entity path of the OU exclusion.
       - **Select only this OU**: Include only this OU in the exclusion. As a result of choosing an OU, the OU is added on screen. Each OU contains the ID and the entity path of the OU exclusion.
       - **Copy OU entity path**: Copy the organization entity path to use as needed.
     - If you know the AWS Organizations entity path already or you want to build it:
       - Choose **Input organizational unit exclusion** and enter the entity path of the OU exclusion. Build the path for the OU(s) using AWS Organizations IDs separated by a `/`. Include all child OUs by ending the path with `/*`.

- Example 1
  - Path to a child OU: `o-a1b2c3d4e5/r-f6g7h8i9j0example/ou-ghi0-awsccccc/ou-jkl0-awsddddd/`
  - In this example, `o-a1b2c3d4e5` is the organization ID, `r-f6g7h8i9j0example` is the root ID, `ou-ghi0-awsccccc` is an OU ID, and `ou-jkl0-awsddddd` is a child OU ID.
  - IPAM will not manage the IP addresses in accounts in the child OU.
- Example 2
  - Path where all child OUs will be part of the exclusion: `o-a1b2c3d4e5/r-f6g7h8i9j0example/ou-ghi0-awsccccc/*`
  - In this example, IPAM will not manage the IP addresses in accounts in the OU (`ou-ghi0-awsccccc`) or in accounts in any OUs that are children of the OU.

- **To remove an OU exclusion**:
  - Choose the **X** next to an OU that's already been added. The `/*` after the OU ID indicates that it's a parent OU and that child OUs are part of the OU exclusion.

6. Choose **Save changes**.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

1. View resource discovery details to get the ID of the default resource discovery for the next step with describe-ipam-resource-discoveries.

   Input:

   ```
   aws ec2 describe-ipam-resource-discoveries
   ```

   Output:

   ```
   {

       "IpamResourceDiscoveries": [
   ```

```
        {

            "OwnerId": "111122223333",

            "IpamResourceDiscoveryId": "ipam-res-disco-1234567890abcdef0",

            "IpamResourceDiscoveryArn": "arn:aws:ec2::111122223333:ipam-
resource-discovery/ipam-res-disco-1234567890abcdef0",
            "IpamResourceDiscoveryRegion": "us-east-1",

            "OperatingRegions": [

                {

                    "RegionName": "us-east-1"

                },

                {

                    "RegionName": "us-west-1"

                },

                {

                    "RegionName": "us-west-2"

                }

            ],

            "IsDefault": true,

            "State": "modify-complete",

            "Tags": []

        }

    ]
```

```
}
```

2. Add or remove an organizational unit exclusion from a resource discovery with modify-ipam-resource-discovery and the `--add-organizational-unit-exclusions` or `--remove-organizational-unit-exclusions` options. You'll need enter an AWS Organizations entity path. Build the path for the OU(s) using AWS Organizations IDs separated by a `/`. Include all child OUs by ending the path with `/*`. You can't include the same entity path more than once in the add or remove parameters.

   - Example 1
     - Path to a child OU: `o-a1b2c3d4e5/r-f6g7h8i9j0example/ou-ghi0-awsccccc/ou-jkl0-awsddddd/`
     - In this example, `o-a1b2c3d4e5` is the organization ID, `r-f6g7h8i9j0example` is the root ID, `ou-ghi0-awsccccc` is an OU ID, and `ou-jkl0-awsddddd` is a child OU ID.
     - IPAM will not manage the IP addresses in accounts in the child OU.
   - Example 2
     - Path where all child OUs will be part of the exclusion: `o-a1b2c3d4e5/r-f6g7h8i9j0example/ou-ghi0-awsccccc/*`
     - In this example, IPAM will not manage the IP addresses in accounts in the OU (`ou-ghi0-awsccccc`) or in accounts in any OUs that are children of the OU.

   Note

   The resulting set of exclusions must not "overlap", meaning two or more OU exclusions must not exclude the same OU.
   Example of non-overlapping entity paths:

   - Path 1 ="o-1/r-1/ou-1/"
   - Path 2 ="o-1/r-1/ou-1/ou-2/"

   These paths are do not overlap because Path 1 only excludes the accounts under ou-1 and Path 2 only excludes accounts under ou-2.
   Example of overlapping entity paths:

   - Path 1 ="o-1/r-1/ou-1/*"

- Path 2 ="o-1/r-1/ou-1/ou-2/"

These paths overlap because Path 1 represents both "o-1/r-1/ou-1/" and "o-1/r-1/ou-1/ou-2/", and "o-1/r-1/ou-1/ou-2/" overlaps with Path 2.

Input:

```
aws ec2 modify-ipam-resource-discovery \
    --ipam-resource-discovery-id ipam-res-disco-1234567890abcdef0 \
    --add-organizational-unit-exclusions OrganizationsEntityPath='o-a1b2c3d4e5/
r-f6g7h8i9j0example/ou-ghi0-awsccccc/*' \
    --remove-organizational-unit-exclusions OrganizationsEntityPath='o-
a1b2c3d4e5/r-f6g7h8i9j0example/ou-ghi0-awsccccc/ou-jkl0-awsddddd/' \
    --region us-east-1
```

Output:

```
{
    "IpamResourceDiscovery": {
        "OwnerId": "111122223333",
        "IpamResourceDiscoveryId": "ipam-res-disco-1234567890abcdef0",
        "IpamResourceDiscoveryArn": "arn:aws:ec2::111122223333:ipam-resource-
discovery/ipam-res-disco-1234567890abcdef0",
        "IpamResourceDiscoveryRegion": "us-east-1",
        "OperatingRegions": [
            {
                "RegionName": "us-east-1"
            }
        ],
        "IsDefault": false,
        "State": "modify-in-progress",
        "OrganizationalUnitExclusions": [
            {
                "OrganizationsEntityPath": "o-a1b2c3d4e5/r-f6g7h8i9j0example/ou-
ghi0-awsccccc/*"
            }
        ]
    }
}
```

Modify IPAM tier

IPAM offers two tiers: Free Tier and Advanced Tier. Switching to the Advanced Tier of Amazon VPC IP Address Manager provides more granular control over your IP address management. This can be beneficial as your network complexity grows, allowing you to better optimize and manage your IP address space. For more information about the features available in the Free Tier and the costs associated with the Advanced Tier, see the IPAM tab in the Amazon VPC pricing page.

Note

Before you can switch from the Advanced Tier to the Free Tier, you must:

- Delete private scope pools.
- Delete non-default private scopes.
- Delete pools with locales different than the IPAM home Region.
- Delete non-default resource discovery associations.
- Delete pool allocations to accounts that are not the IPAM owner.

AWS Management Console

To modify the IPAM tier

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **IPAMs**.
3. In the content pane, select your IPAM.
4. Choose **Actions** > **Edit**.

Note

If you are in the Free Tier, you will see **Your estimated IPAM total active IP count is....**
The total active IP count is the number of active IP addresses in your IPAM that you would be charged if you switched from the Free Tier to the Advanced Tier. An active IP address is defined as an IP address or a prefix associated with an Elastic Network Interface (ENI) that is attached to a resource such as an EC2 Instance.

- This metric is only available to customers in the Free Tier.
- If your IPAM is integrated with AWS Organizations, the active IP count covers all the Organization accounts.
- You cannot view a breakdown of the active IP count by IP type (public/private) or class (IPv4/IPv6).
- IPAM only counts IPs from ENIs owned by monitored accounts. The count may be inaccurate for shared subnets. IP addresses are excluded if the subnet owner or ENI owner is not covered by IPAM.

5. Choose the **IPAM tier** you want to use for the IPAM.
6. Choose **Save changes**.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

Use the following AWS CLI commands to view and modify an IPAM tier:

1. View current IPAMs: describe-ipams
2. Modify the IPAM tier: modify-ipam
3. View your updated IPAMs: describe-ipams

Modify IPAM operating Regions

Operating Regions are AWS Regions where the IPAM is allowed to manage IP address CIDRs. IPAM only discovers and monitors resources in the AWS Regions you select as operating Regions.

Adding an operating region to an IPAM allows you to manage IP address space across multiple AWS Regions. This can improve IP address utilization, enable regional segmentation, and support geographically distributed infrastructure. Expanding the IPAM's Regional scope provides greater flexibility and control over your overall IP address management.

AWS Management Console

To modify the IPAM operating Regions

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **IPAMs**.
3. In the content pane, select your IPAM.
4. Choose **Actions** > **Edit**.
5. Under **IPAM settings**, choose the **Operating Regions** you want to use for the IPAM.
6. Choose **Save changes**.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

Use the following AWS CLI commands to view and modify IPAM operating Regions:

1. View current IPAMs: describe-ipams
2. Add or remove IPAM operating Regions: modify-ipam
3. View your updated IPAMs: describe-ipams

Provision CIDRs to a pool

Follow the steps in this section to provision CIDRs to a pool. If you already provisioned a CIDR when you created the pool, you might need to provision additional CIDRs if a pool is nearing full allocation. To monitor pool usage, see Monitor CIDR usage with the IPAM dashboard.

> **Note**
>
> The terms *provision* and *allocate* are used throughout this user guide and the IPAM console. *Provision* is used when you add a CIDR to an IPAM pool. *Allocate* is used when you associate a CIDR from an IPAM pool with a VPC or Elastic IP address.

AWS Management Console

To provision CIDRs to a pool

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.
3. By default, the default private scope is selected. If you don't want to use the default private scope, from the dropdown menu at the top of the content pane, choose the scope you want to use. For more information about scopes, see How IPAM works.
4. In the content pane, choose the pool that you want to add a CIDR to.
5. Choose **Actions** > **Provision CIDRs**.
6. Do one of the following:
   - If you are provisioning a CIDR to a pool in the public scope, enter the **Netmask**.
   - If you are provisioning a CIDR to an IPv4 pool in the private scope, enter the **CIDR**.
   - If you are provisioning a CIDR to an IPv6 pool in the private scope, note the following:
     - For important details about private IPv6 addressing, see Private IPv6 addresses in the *Amazon VPC User Guide*.
     - To use a private IPv6 ULA range, under **CIDRs to provision**, choose **Add ULA CIDR by netmask** and choose a netmask size or choose **Input private IPv6 CIDR** and enter a ULA range. Valid ranges for private IPv6 ULA are /9 to /60 starting with fd80::/9.
     - To use a private IPv6 GUA range, you have to have first enabled the option on your IPAM (see Enable provisioning private IPv6 GUA CIDRs). Once you have enabled private IPv6 GUA CIDRs, enter an IPv6 GUA in **Input private IPv6 CIDR**.

   Note

   - By default, you can add one Amazon-provided IPv6 CIDR block to a Regional pool. For information on increasing the default limit, see Quotas for your IPAM.
   - The CIDR you want to provision must be available in the scope.
   - If you are provisioning CIDRs to a pool within a pool, then the CIDR space you want to provision must be available in the pool.
7. Choose **Provision**.

8. You can view the CIDR in IPAM by choosing **Pools** in the navigation pane, choosing a pool, and viewing the CIDRs tab for the pool.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

Use the following AWS CLI commands to provision CIDRs to a pool:

1. Get the ID of an IPAM pool: describe-ipam-pools
2. Get the CIDRs that are provisioned to the pool: get-ipam-pool-cidrs
3. Provision a new CIDR to the pool: provision-ipam-pool-cidr
4. Get the CIDRs that are provisioned to the pool and view the new CIDR: get-ipam-pool-cidrs

Move VPC CIDRs between scopes

Moving CIDRs between scopes allows you to optimize IP address allocation, organize by Region, separate concerns, enforce compliance, and adapt to infrastructure changes. This flexibility helps manage your IP address space efficiently as your workloads evolve.

Follow the steps in this section to move a VPC CIDR from one scope to another.

Important

- You can only move VPC CIDRs. When you move a VPC CIDR, the VPC's subnet CIDRs are moved automatically as well.
- You can only move VPC CIDRs from one private scope to another. You cannot move VPC CIDRs out of a public scope to a private scope or from a private scope to a public scope.
- The same AWS account must own both scopes.
- If a VPC CIDR is currently allocated from a pool in a private scope, the move request succeeds, but the VPC CIDR will not be moved until you release the VPC CIDR allocation from the current pool. For information on releasing an allocation, see Release an allocation.

AWS Management Console

To move a CIDR allocated to a VPC

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Resources**.
3. From the dropdown menu at the top of the content pane, choose the scope you want to use.
4. In the content pane, choose a VPC and view the details of the VPC.
5. Under **VPC CIDRs**, select one of the CIDRs allocated to the resource and choose **Actions** > **Move CIDR to different scope**.
6. Select the scope you want to move the VPC CIDR to.
7. Choose **Move CIDR to different scope**.

Command line

Use the following AWS CLI commands to move a VPC CIDR:

1. Get a VPC CIDR in current scope: get-ipam-resource-cidrs
2. Move a VPC CIDR: modify-ipam-resource-cidr
3. Get a VPC CIDR in the other scope: get-ipam-resource-cidrs

Define public IPv4 allocation strategy with IPAM policies

An IPAM policy is a set of rules that define how public IPv4 addresses from IPAM pools are allocated to AWS resources. Each rule maps an AWS service to IPAM pools that the service will use to get IP addresses. A single policy can have multiple rules and be applied to multiple AWS Regions. If the IPAM pool run out of addresses then the services fallback to Amazon-provided IP addresses. A policy can be applied to an individual AWS account or an entity within AWS Organizations. If you bring your own IP (BYOIP), this helps reduce your AWS public IPv4 costs.

When to use IPAM policies

Use IPAM policies to:

- Reduce public IPv4 costs by using BYOIP addresses
- Centrally control which IP pools your AWS resources use

- Ensure consistent IP allocation across your organization

How it works

When you create an AWS resource that needs a public IP address in an account with IPAM policies enforced:

- IPAM checks your policy rules in order.
- If a rule matches the resource type, IPAM allocates an IP from the specified pool.
- If the pool is empty and overflow is enabled, Amazon provides an IP address.
- If no rules match, the default behavior applies.

Supported services and resources

You can create IPAM policies to define how public IPv4 addresses from IPAM pools are allocated to the following AWS services and resources:

- Elastic IP addresses (EIPs)
- Application Load Balancers (ALBs)
- Amazon Relational Database Service (RDS)
- Regional NAT gateways

> **Important**
>
> If you choose a specific IPAM pool or EIP allocation ID when creating an AWS resource, that will override the IPAM policy.

Prerequisites

- An IPAM in the delegated administrator account with advanced tier enabled
- A public IPAM pool with IPv4 addresses
- IAM permissions for IPAM and EC2 operations

Terminology

IPAM policy

An IPAM policy is a set of rules that define how public IPv4 addresses from IPAM pools are allocated to AWS resources. Each rule maps an AWS service to IPAM pools that the service will use to get IP addresses. A single policy can have multiple rules and be applied to multiple AWS Regions. If the IPAM pool run out of addresses then the services fallback to Amazon-provided IP addresses. A policy can be applied to an individual AWS account or an entity within AWS Organizations. A policy can be applied to an individual AWS account or an entity within AWS Organizations.

Allocation rules

Optional configurations within an IPAM policy that map AWS resource types to specific IPAM pools. If no rules are defined, the resource types default to using Amazon-provided IP addresses.

Target

An individual AWS account or an entity within an AWS Organization to which an IPAM policy can be applied.

Step 1: Create an IPAM policy

Using the AWS Console:

Follow these steps to create an IPAM policy using the AWS Console:

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the left navigation pane, choose **Policies**.
3. Choose **Create policy**.
4. Enter a **Name** for your policy (optional).
5. Select the **IPAM** to associate with this policy.
6. (Optional) Add tags.
7. Choose **Create policy**.

Using the AWS CLI:

Use the create-ipam-policy command.

Step 2: Add allocation rules

After creating the policy, you need to add allocation rules that define how IP addresses are allocated:

Using the AWS Console:

Follow these steps to add allocation rules using the AWS Console:

1. In the left navigation pane, choose **Policies**.
2. Choose the policy you created in the previous step.
3. In your policy details page, choose the **Allocation rules** tab.
4. Choose **Create allocation rules**.
5. Configure the **Service configuration**:
   - **Locale**: Choose the AWS Region (us-east-1) or Local Zone where you want this policy to apply.
   - **Resource type**: Select the AWS service or resource type for this policy (Elastic IP addresses, RDS database instances, Application Load Balancers, or NAT gateways in regional availability mode).
6. Configure **Rules configuration**:
   - **IPAM pool**: Select the IPAM pool that will provide IP addresses.
   - Review the pool details (locale, public IP source, space available, and CIDR ranges available).
7. (Optional) Choose **Add new rule** to create additional rules.
8. Choose **Create allocation rule**.

Using the AWS CLI:

Use the modify-ipam-policy-allocation-rules command.

Step 3: Enable the policy

Specify which accounts should use this policy.

Using the AWS Console:

Follow these steps to enable the policy using the AWS Console:

1. In your policy details page, choose the **Targets** tab.

2. Choose **Manage policy targets**.
3. Do one of the following:

   - For single account usage (IPAM not integrated with AWS Organizations), choose **Enable for your account**.
   - For IPAM integrated with AWS Organizations (when you're the delegated admin):
     - In the **Organizational structure** section, select the accounts or organizational units where you want to apply this policy.
     - Check the **Enabled** checkbox for each target.
     - Choose **Save Changes**.
     - **Important**: Enabling this policy will replace any active IPAM policies on the selected accounts or organizational units.

Using the AWS CLI:

Use the enable-ipam-policy command based on your setup:

For single account usage (IPAM not integrated with AWS Organizations):

```
aws ec2 enable-ipam-policy \
    --ipam-policy-id ipam-policy-12345678
```

For IPAM integrated with AWS Organizations (when you're the delegated admin), set a policy to target an account in the AWS Organization:

```
aws ec2 enable-ipam-policy \
    --ipam-policy-id ipam-policy-12345678 \
    --organization-target-id 123456789012
```

For IPAM integrated with AWS Organizations (when you're the delegated admin), set a policy to target an organizational unit:

```
aws ec2 enable-ipam-policy \
    --ipam-policy-id ipam-policy-12345678 \
    --organization-target-id ou-123
```

> **Important**
>
> Enabling this policy will replace any active IPAM policies on the selected accounts or organizational units.

Step 4: Test your policy

Create a new resource of the type you configured (like an EIP) in one of the target accounts. The resource will automatically use an IP address from your IPAM pool.

> **Important**
>
> If you choose a specific IPAM pool or EIP allocation ID when creating an AWS resource, that will override the IPAM policy.

Step 5: Monitor usage

Check your IPAM pool in the console to see IP addresses being allocated to your resources.

View IPAM pool allocations

There are two ways to view IPAM pool allocations:

- **By pool** – Use get-ipam-pool-allocations to view all allocations in a specific pool that you own or that has been shared with you. This includes allocations that are not directly owned by you.
- **Across all pools** – Use describe-ipam-pool-allocations to view only allocations that you directly own. This command works across all pools without requiring a pool ID.

To find pools that you own or that are shared with you, use describe-ipam-pools.

AWS Management Console

To view IPAM pool allocations

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.

3. By default, the default private scope is selected. If you don't want to use the default private scope, from the scope dropdown menu in the content pane, choose the scope you want to use. For more information about scopes, see How IPAM works.
4. In the content pane, choose the pool.
5. Choose the **Allocations** tab to view all allocations in the pool.

> **Note**
>
> The console shows all allocations in the selected pool, including allocations owned by other accounts. To view only allocations that you directly own across all pools, use the command line.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

View allocations in a specific pool

Use get-ipam-pool-allocations to view all allocations in a specific pool. This includes allocations owned by other accounts if the pool is shared with you.

1. Get the ID of the IPAM pool: describe-ipam-pools.
2. View allocations in the pool: get-ipam-pool-allocations.

```
aws ec2 get-ipam-pool-allocations --ipam-pool-id ipam-pool-0533048da7eba92f6
```

3. (Optional) View a specific allocation in the pool:

```
aws ec2 get-ipam-pool-allocations --ipam-pool-id ipam-pool-0533048da7eba92f6 --
ipam-pool-allocation-id ipam-pool-alloc-0e6186d73999e1f12
```

> **Note**
>
> This command shows all allocations in the pool, including allocations owned by other accounts.

View your allocations across all pools

Use describe-ipam-pool-allocations to view only allocations that you directly own across all pools.

1. View all of your allocations:

```
aws ec2 describe-ipam-pool-allocations
```

2. (Optional) View specific allocations by ID:

```
aws ec2 describe-ipam-pool-allocations --ipam-pool-allocation-ids ipam-pool-alloc-0e6186d73999e1f12
```

3. (Optional) Filter by tag:

```
aws ec2 describe-ipam-pool-allocations --filters
 Name=tag:Environment,Values=Production
```

> **Note**
>
> This command returns only allocations that you directly own.

To allocate a new CIDR, see Allocate CIDRs from an IPAM pool. To release an allocation, see Release an allocation.

Modify an IPAM pool allocation

You can modify the description of an IPAM pool allocation using the console or the AWS CLI. Refer to the modify-ipam-pool-allocation documentation for more API details.

AWS Management Console

To modify an IPAM pool allocation

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.

3. By default, the default private scope is selected. If you don't want to use the default private scope, from the dropdown menu at the top of the content pane, choose the scope you want to use. For more information about scopes, see How IPAM works.
4. In the content pane, choose the pool that contains the allocation you want to modify.
5. Choose the **Allocations** tab.
6. Select the allocation and choose **Actions**, **Modify allocation**.
7. Modify the description.

> **Note**
>
> To remove the description, leave the field blank.

8. Choose **Save**.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

Use the following AWS CLI commands to modify an IPAM pool allocation:

1. Get the allocation ID: get-ipam-pool-allocations
2. Modify the allocation description: modify-ipam-pool-allocation

```
aws ec2 modify-ipam-pool-allocation --ipam-pool-allocation-id ipam-pool-alloc-0e6186d73999e1f12 --description "Updated description"
```

> **Note**
>
> To remove the description, pass a null value. To manage tags on an allocation, use the create-tags and delete-tags commands.

To release an allocation, see Release an allocation.

Release an allocation

If you are planning to delete a pool, you might need to release a pool allocation. An allocation is a CIDR assignment from an IPAM pool to another resource or IPAM pool.

You cannot delete pools if the pools have CIDRs provisioned, and you cannot deprovision CIDRs if the CIDRs are allocated to resources.

Note

- To release a manual allocation, use the steps in this section or call the ReleaseIpamPoolAllocation API.
- To release an allocation in a private scope, you must ignore or delete the resource CIDR. For more information, see Change the monitoring state of VPC CIDRs. After some time, Amazon VPC IPAM will automatically release the allocation on your behalf.

  Example

  Example

  If you have a VPC CIDR in a private scope, to release the allocation you must either ignore or delete the VPC CIDR. After some time, Amazon VPC IPAM will automatically release the VPC CIDR allocation from the IPAM pool.
- To release an allocation in a public scope, you must delete the resource CIDR. You cannot ignore public resource CIDRs. For more information, see *Cleanup* in Bring your own public IPv4 CIDR to IPAM using only the AWS CLI or *Cleanup* in Bring your own IPv6 CIDR to IPAM using only the AWS CLI. After some time, Amazon VPC IPAM will automatically release the allocation on your behalf.

For Amazon VPC IPAM to release allocations on your behalf, all account permissions must be properly configured for either single-account use or multi-account use.

When you release a CIDR that's managed by your IPAM, Amazon VPC IPAM recycles the CIDR back into an IPAM pool. If you are using IPAM in the Advanced Tier, it takes a few minutes for the CIDR to become available for future allocations. If you are using IPAM in the Free Tier, it will take up to

48 hours for the CIDR to become available for future allocations. For more information about pools and allocations, see How IPAM works.

> **Warning**
>
> When you release an allocation, all tags associated with the allocation are permanently deleted. You can't recover deleted tags.

AWS Management Console

To release a pool allocation

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.
3. From the dropdown menu at the top of the content pane, choose the scope you want to use. For more information about scopes, see How IPAM works.
4. In the content pane, choose the pool that the allocation is in.
5. Choose the **Allocations** tab.
6. Select one or more allocations. You can identify allocations by their **Resource type**:
   - **custom**: A custom allocation.
   - **vpc**: A VPC allocation.
   - **ipam-pool**: An IPAM pool allocation.
   - **ec2-public-ipv4-pool**: A public IPv4 pool allocation.
   - **subnet**: A subnet allocation.
7. Choose **Actions** > **Release custom allocation**.
8. Choose **Deallocate CIDR**.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

Use the following AWS CLI commands to release a pool allocation:

1. Get an IPAM pool ID: describe-ipam-pools

2. View your current allocations in the pool: get-ipam-pool-allocations
3. Release an allocation: release-ipam-pool-allocation
4. View your updated allocations: get-ipam-pool-allocations

To add a new allocation, see Allocate CIDRs from an IPAM pool. To delete the pool after releasing allocations, you must first Deprovision CIDRs from a pool.

Share an IPAM pool using AWS RAM

Follow the steps in this section to share an IPAM pool using AWS Resource Access Manager (RAM). When you share an IPAM pool with RAM, "principals" can allocate CIDRs from the pool to AWS resources, such as VPCs, from their respective accounts. A principal is a concept in RAM that means any AWS account, IAM role or organizational unit in AWS Organizations. For more information, see Sharing your AWS resources in the *AWS RAM User Guide*.

Note

- You can only share an IPAM pool with AWS RAM if you've integrated IPAM with AWS Organizations. For more information, see Integrate IPAM with accounts in an AWS Organization. You cannot share an IPAM pool with AWS RAM if you are a single account IPAM user.
- You must enable resource sharing with AWS Organizations in AWS RAM. For more information, see Enable resource sharing within AWS Organizations in the *AWS RAM User Guide*.
- RAM sharing is only available in the home AWS Region of your IPAM. You must create the share in the AWS Region that the IPAM is in, not in the Region of the IPAM pool.
- The account that creates and deletes IPAM pool resource shares must have the following permissions in the IAM policy attached to their IAM role:
  - `ec2:PutResourcePolicy`
  - `ec2:DeleteResourcePolicy`
- You can add multiple IPAM pools to a RAM share.
- While you can share IPAM pools with any AWS account outside an AWS Organization, IPAM will only monitor the IP addresses in accounts outside the Organization if the account owner has gone through the process of sharing their resource discovery with

the delegated IPAM admin as described in Integrate IPAM with accounts outside of your organization.

AWS Management Console

To share an IPAM pool using RAM

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.
3. By default, the default private scope is selected. If you don't want to use the default private scope, from the dropdown menu at the top of the content pane, choose the scope you want to use. For more information about scopes, see How IPAM works.
4. In the content pane, choose the pool you want to share and choose **Actions** > **View details**.
5. Under **Resource sharing**, choose **Create resource share**. As a result, the AWS RAM console opens. You'll create the shared pool in AWS RAM.
6. Choose **Create a resource share**.
7. Add a **Name** for the shared resource.
8. Under **Select resource type**, select IPAM pools and choose one or more IPAM pools.
9. Choose **Next**.
10. Choose one of the permissions for the resource share:
    - **AWSRAMDefaultPermissionsIpamPool**: Choose this permission to allow principals to view the CIDRs and allocations in the shared IPAM pool and allocate/release CIDRs in the pool.
    - **AWSRAMPermissionIpamPoolByoipCidrImport**: Choose this permission to allow principals to import BYOIP CIDRs into the shared IPAM pool. You will need this permission only if you have existing BYOIP CIDRs and you want to import them to IPAM and share them with principals. For additional information on BYOIP CIDRs to IPAM, see Tutorial: Transfer a BYOIP IPv4 CIDR to IPAM.
11. Choose the principals that are allowed to access this resource. If principals will be importing existing BYOIP CIDRs to this shared IPAM pool, add the BYOIP CIDR owner account as principal.
12. Review the resource share options and the principals you'll be sharing with and choose **Create**.

Command line

The command(s) in this section link to the *AWS CLI Command Reference*. There you'll find detailed descriptions of the options you can use when you run the command(s).

Use the following AWS CLI commands to share an IPAM pool using RAM:

1. Get the ARN of the IPAM: describe-ipam-pools
2. Create the resource share: create-resource-share
3. View the resource share: get-resource-shares

As a result of creating the resource share in RAM, other principals can now allocate CIDRs to resources using the IPAM pool. For information on monitoring resources created by principals, see Monitor CIDR usage by resource. For more information on how to create a VPC and allocate a CIDR from a shared IPAM pool, see Create a VPC in the *Amazon VPC User Guide*.

Work with resource discoveries

A resource discovery is an IPAM component that enables IPAM to manage and monitor resources that belong to the account that owns the resource discovery. This enables IPAM to maintain an up-to-date inventory of IP address usage across your workloads, facilitating IP address management and planning.

A resource discovery is created by default when you create an IPAM. You can also create a resource discovery independently of an IPAM and integrate it with an IPAM owned by another account or organization. If the resource discovery owner is the delegated administrator of an organization, IPAM will monitor resources for all members of the organization.

Note

Creating, sharing, and associating resource discoveries is part of the process of integrating IPAM with accounts outside of your organizations (see Integrate IPAM with accounts outside of your organization). If you are not creating an IPAM and integrating it with accounts outside your organization, you do not need to create, share, or associate resource discoveries.

Note that this section is a grouping of procedures all related to working with resource discoveries.

Contents

Create a resource discovery to integrate with another IPAM

This section describes how to create a resource discovery. A resource discovery is created by default when you create an IPAM. The default quota for resource discoveries per Region is 1. For more information about IPAM quotas, see Quotas for your IPAM.

> **Note**
>
> Creating, sharing, and associating resource discoveries is part of the process of integrating IPAM with accounts outside of your organizations (see Integrate IPAM with accounts outside of your organization). If you are not creating an IPAM and integrating it with accounts outside your organization, you do not need to create, share, or associate resource discoveries.

If you are integrating an IPAM with accounts outside of your organizations, this is a required step that must be completed by the **Secondary Org Admin Account**. For more information about the roles involved in this process, see Process overview.

AWS Management Console

To create a resource discovery

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Resource discoveries**.
3. Choose **Create resource discovery**.

4. Select **Allow Amazon VPC IP Address Manager to replicate data from source account(s) into the IPAM delegate account**. If you do not select this option, you cannot create a resource discovery.
5. (Optional) Add a **Name** tag to the resource discovery. A tag is a label that you assign to an AWS resource. Each tag consists of a key and an optional value. You can use tags to search and filter your resources or track your AWS costs.
6. (Optional) Add a description.
7. Under **Operating regions**, select the AWS Regions in which resources will be discovered. The current Region will automatically be set as one of the operating Regions. If you're creating the resource discovery so that you can share it with an IPAM in operating Region `us-east-1`, make sure you select `us-east-1` here. If you forget an operating Region, you can return at a later time and edit your resource discovery settings.

   > **Note**
   >
   > In most cases, the resource discovery should have the same operating Regions as the IPAM or you will only get resource discovery in that one Region.

8. (Optional) Choose any additional **Tags** for the pool.
9. Choose **Create**.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

- Create a resource discovery: create-ipam-resource-discovery

View resource discovery details

Viewing the details of a resource discovery in AWS IPAM can provide valuable insights, such as:

- Identifying the specific AWS resources that have been imported and their associated IP address allocations.
- Monitoring the status and progress of the resource discovery process.
- Troubleshooting any issues or discrepancies between IPAM and the discovered resources.

- Analyzing the IP address utilization and trends.

This information can help you optimize your IP address management and ensure alignment between IPAM and your actual resource deployments.

AWS Management Console

To view resource discovery details

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Resource discoveries**.
3. Choose a resource discovery.
4. Under **Resource discovery details**, view details related to the resource discovery, such as Default, which indicates whether the resource discovery is the default. The default resource discovery is the resource discovery automatically created when you create an IPAM.
5. In the tabs, view the details of a resource discovery:

   - **Discovered resources** - Resources monitored under a resource discovery. IPAM monitors CIDRs from the following resource types VPCs, Public IPv4 pools, VPC subnets, and Elastic IP addresses.
     - **Name (Resource ID)** – Resource discovery ID.
     - **IPs allocated** – The percentage of IP address space in use. To convert the decimal to a percentage, multiply the decimal by 100. Note the following:
       - For resources that are VPCs, this is the percentage of IP address space in the VPC that's taken up by subnet CIDRs.
       - For resources that are subnets, if the subnet has an IPv4 CIDR provisioned to it, this is the percentage of IPv4 address space in the subnet that's in use. If the subnet has an IPv6 CIDR provisioned to it, the percentage of IPv6 address space in use is not represented. The percentage of IPv6 address space in use cannot currently be calculated.
       - For resources that are public IPv4 pools, this is the percentage of IP address space in the pool that's been allocated to Elastic IP addresses (EIPs).
     - **CIDR** – Resource CIDR.
     - **Region** – Resource Region.
     - **Owner ID** – Resource owner ID.

    - **Sample time** – The last successful resource discovery time.
  - **Discovered accounts**: AWS accounts being monitored under a resource discovery. If you have integrated IPAM with AWS Organizations, all accounts in the organization are discovered accounts.
    - **Account ID** – The account ID.
    - **Region** – The AWS Region that the account information is returned from.
    - **Last attempted discovery time** – The last attempted resource discovery time.
    - **Last successful discovery time** – The last successful resource discovery time.
    - **Status** – Resource discovery failure reason.
  - **Operating regions** – The operating Regions for the resource discovery.
  - **Resource sharing** – If the resource discovery has been shared, the resource share ARN is listed.
    - **Resource share ARN** – Resource share ARN.
    - **Status** – The current status of the resource share. Possible values are:
      - **Active** – Resource share is active and available for use.
      - **Deleted** – Resource share is deleted and is no longer available for use.
      - **Pending** – An invitation to accept the resource share is waiting for a response.
    - **Created at** – When the resource share was created.
  - **Tags** – A tag is a label that you assign to an AWS resource. Each tag consists of a key and an optional value. You can use tags to search and filter your resources or track your AWS costs.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

- View resource discovery details: describe-ipam-resource-discoveries

Share a resource discovery with another AWS account

Follow the steps in this section to share a resource discovery using AWS Resource Access Manager. For more information about AWS RAM, see Sharing your AWS resources in the *AWS RAM User Guide*.

Note

Creating, sharing, and associating resource discoveries is part of the process of integrating IPAM with accounts outside of your organizations (see Integrate IPAM with accounts outside of your organization). If you are not creating an IPAM and integrating it with accounts outside your organization, you do not need to create, share, or associate resource discoveries.

When you create an IPAM that monitors accounts outside your organization, the Secondary Org Admin Account shares their resource discovery with the Primary Org IPAM Account using AWS RAM. You must first share a resource discovery with the Primary Org IPAM Account before the Primary Org IPAM Account can associate the resource discovery with their IPAM. For more information about the roles involved in this process, see Process overview.

Note

- When you create a resource share using AWS RAM to share a resource discovery, you must create the resource share in the home Region of the Primary Org IPAM.
- The account that creates and deletes a resource share for a resource discovery must have the following permissions in their IAM policy:
  - ec2:PutResourcePolicy
  - ec2:DeleteResourcePolicy
- If you share a resource discovery with another account, that account can see any OU exclusions on it, which contains information such as the Org ID, Root ID, and organizational unit IDs of the resource discovery owner's Organization.

If you are integrating an IPAM with accounts outside of your organizations, this is a required step that must be completed by the **Secondary Org Admin Account**.

AWS Management Console

To share a resource discovery

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Resource discoveries**.

3. Choose the **Resource sharing** tab.
4. Choose **Create resource share**. The AWS RAM console opens, which is where you will create the resource share.
5. In the AWS RAM console, choose **Settings**.
6. Choose **Enable sharing with AWS Organizations**, and then choose **Save settings**.
7. Choose **Create a resource share**.
8. Add a **Name** for the shared resource.
9. Under **Select resource type**, select **IPAM Resource Discovery**, and choose the resource discovery.
10. Choose **Next**.
11. Under **Associate permissions**, you can view the default permission that will be enabled for principals that are granted access to this resource share:
    - AWSRAMPermissionIpamResourceDiscovery
    - Actions allowed by this permission:
      - ec2:AssociateIpamResourceDiscovery
      - ec2:GetIpamDiscoveredAccounts
      - ec2:GetIpamDiscoveredPublicAddresses
      - ec2:GetIpamDiscoveredResourceCidrs
12. Specify the principals that are allowed access to the shared resource. For **Principals**, choose the Primary Org IPAM Account, and then choose **Add**.
13. Choose **Next**.
14. Review the resource share options and the principals that you'll be sharing with. Then choose **Create resource share**.
15. After a resource discovery is shared, it must be accepted by the Primary Org IPAM Account and then associated with an IPAM by the Primary Org IPAM Account. For more information, see Associate a resource discovery with an IPAM.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

1. Create the resource share: create-resource-share

2. View the resource share: get-resource-shares

Associate a resource discovery with an IPAM

This section describes how to associate a resource discovery with an IPAM. When you associate a resource discovery with an IPAM, the IPAM monitors all resources CIDRs and accounts discovered under the resource discovery. When you create an IPAM, a default resource discovery is created for your IPAM and automatically associated with your IPAM.

The default quota for resource discovery associations is 5. For more information (including how to adjust this quota), see Quotas for your IPAM.

> **Note**
>
> Creating, sharing, and associating resource discoveries is part of the process of integrating IPAM with accounts outside of your organizations (see Integrate IPAM with accounts outside of your organization). If you are not creating an IPAM and integrating it with accounts outside your organization, you do not need to create, share, or associate resource discoveries.

If you are integrating an IPAM with accounts outside of your organizations, this is a required step that must be completed by the **Primary Org IPAM Account**. For more information about the roles involved in this process, see Process overview.

AWS Management Console

To associate a resource discovery

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **IPAMs**.
3. Select **Associated discoveries**, and then choose **Associate resource discoveries**.
4. Under **IPAM resource discoveries**, choose a resource discovery that's been shared with you by the **Secondary Org Admin Account**.
5. Choose **Associate**.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

- Associate a resource discovery: associate-ipam-resource-discovery

Disassociate a resource discovery

This section describes how to disassociate a resource discovery from an IPAM. When you disassociate a resource discovery from an IPAM, the IPAM no longer monitors all resources CIDRs and accounts discovered under the resource discovery.

> **Note**
>
> You cannot disassociate a default resource discovery association. A default resource discovery association is one that is created automatically when you create an IPAM. The default resource discovery association is deleted, however, if you delete the IPAM.

This step must be completed by the **Primary Org IPAM Account**. For more information about the roles involved in this process, see Process overview.

AWS Management Console

To disassociate a resource discovery

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **IPAMs**.
3. Select **Associated discoveries,** and then choose **Disassociate resource discoveries**.
4. Under **IPAM resource discoveries**, choose a resource discovery that's been shared with you by the **Secondary Org Admin Account**.
5. Choose **Disassociate**.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

- To disassociate a resource discovery: disassociate-ipam-resource-discovery

Delete a resource discovery

This section describes how to delete a resource discovery.

> **Note**
>
> You cannot delete a default resource discovery. A default resource discovery is one that is created automatically when you create an IPAM. The default resource discovery is deleted, however, if you delete the IPAM.

This step must be completed by the **Secondary Org Admin Account**. For more information about the roles involved in this process, see Process overview.

AWS Management Console

To delete a resource discovery

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Resource discoveries**.
3. Select a resource discovery and choose **Actions** > **Delete resource discovery**.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

- To delete a resource discovery: delete-ipam-resource-discovery

Tracking IP address usage in IPAM

Amazon VPC IP Address Manager offers IP address usage tracking features that can benefit anyone who manages complex network environments. IPAM provides visibility into IP address allocation, utilization, and consumption trends across AWS. This helps you identify unused or inefficiently used IP addresses, optimization of the address space and preventing potential IP address exhaustion.

IPAM tracks IP address usage at the CIDR, scope, and IPAM levels, providing detailed reporting and analytics. This is valuable for large-scale deployments, multi-account setups, and evolving network requirements.

By using IPAM's usage tracking, you can make informed decisions, improve IP address management, and ensure efficient utilization of IP resources.

> **Note**
>
> The tasks described in this section are optional. If you want to complete the tasks in this section, and you have delegated an IPAM account, the tasks should be completed by the IPAM account.

Contents

Monitor CIDR usage with the IPAM dashboard

The IPAM dashboard in Amazon VPC IP Address Manager allows you to monitor CIDR usage for several key scenarios:

- **Identify unused or underutilized IP address space**: The dashboard provides visibility into CIDR utilization, enabling you to identify CIDRs with available capacity that can be reclaimed or reallocated.
- **Optimize IP address management**: By closely tracking CIDR usage, you can make informed decisions about expanding, contracting, or reassigning IP address blocks to meet changing business and infrastructure requirements.
- **Prevent IP address exhaustion**: Monitoring CIDR usage helps you anticipate when you may need to acquire additional IP address space, allowing you to proactively plan and avoid service disruptions due to IP address depletion.
- **Ensure compliance and governance**: The IPAM dashboard can help you demonstrate IP address usage patterns to meet regulatory requirements or internal policies around IP address management.
- **Troubleshoot network issues**: Detailed CIDR usage data can assist in identifying the root causes of network connectivity problems or resource conflicts.

By closely monitoring CIDR usage through the IPAM dashboard, you can enhance the efficiency, resilience, and compliance of your IP address management within AWS.

AWS Management Console

To monitor CIDR usage using the IPAM dashboard

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Dashboard**.
3. By default, when you view the dashboard, the default private scope is selected. If you don't want to use the default private scope, from the dropdown menu at the top of the content pane, choose the scope you want to use. For more information about scopes, see How IPAM works.
4. The dashboard presents an overview of your IPAM pools and CIDRs within a scope. You can add, remove, resize, and move widgets to customize the dashboard.

    - **Scope**: The details for this scope. A scope is the highest-level container within IPAM. An IPAM contains two default scopes, one private and one public. Each scope represents the IP space for a single network. You may have multiple private scopes, but you can only have one public scope.
        - **Scope ID**: The ID for this scope.

    - **Scope type**: The type of scope.
    - **IPAM ID**: The ID of the IPAM that the scope is in.
    - **IPAM pools in this scope**: The ID of the IPAM that the scope is in.
    - **View networking resources in this scope**: Takes you to the **Resources** section of the IPAM console.
    - **Search the history of an IP address in this scope**: Takes you to the **Search IP history** section of the IPAM console.
- **Resource CIDR types**: The types of resource CIDRs in the scope.
    - **Subnet**: The number of CIDRs for subnets.
    - **VPC**: The number of CIDRs for VPCs.
    - **EIPs**: The number of CIDRs for Elastic IP addresses.
    - **Public IPv4 pools**: The number of CIDRs for public IPv4 pools.
- **Management state**: The management state of the CIDRs.
    - **Unmanaged CIDRs**: The number of resource CIDRs for unmanaged resources in this scope.
    - **Ignored CIDRs**: The number of resource CIDRs that you have chosen to be exempt from monitoring with IPAM in the scope. IPAM does not evaluate ignored resources for overlap or compliance within a scope. When a resource is chosen to be ignored, any space that's allocated to it from an IPAM pool is returned to the pool, and the resource will not be imported again through automatic import (if the automatic import allocation rule is set on the pool).
    - **Managed CIDRs**: The number of resource CIDRs for manageable resources (VPCs or public IPv4 pools) that are allocated from an IPAM pool in the scope.
- **Overlapping resource CIDRs**: The number of overlapping and nonoverlapping CIDRs. Overlapping CIDRs can lead to incorrect routing in your VPCs.
    - **Overlapping CIDRs**: The number of CIDRs that currently overlap within the IPAM pools in this scope. Overlapping CIDRs can lead to incorrect routing in your VPCs.
    - **Nonoverlapping CIDRs**: The number of resource CIDRs that do not overlap within the IPAM pools in this scope.
- **Compliant resource CIDRs**: The number of compliant resource CIDRs.
    - **Compliant CIDRs**: The number of resource CIDRs that comply with the allocation rules for IPAM pools in the scope.

    - **Noncompliant CIDRs**: The number of resource CIDRs that do not comply with the allocation rules for the IPAM pools in the scope.
- **Overlap status**: The number of CIDRs that overlap over time.
    - **OverlappingResourceCidrs**: The number of CIDRs that overlap within the IPAM pools in this scope. Overlapping CIDRs can lead to incorrect routing in your VPCs.
- **Compliance status**: The number of CIDRs that comply versus do not comply with the allocation rules for IPAM pools in the scope over time.
    - **CompliantResourceCidrs**: The number of resource CIDRs that comply with the allocation rules.
    - **NoncompliantResourceCidrs**: The number of resource CIDRs that do not comply with the allocation rules.
- **VPC utilization**: VPCs (IPv4 and IPv6) with the highest or lowest IP utilization. You can use this information to configure Amazon CloudWatch alarms to be alerted if an IP utilization threshold is breached. For more information, see IPAM resource utilization metrics.
- **Subnet utilization**: Subnets (IPv4 only) with the highest or lowest IP utilization. You can use this information to decide if you want to keep or delete resources that are underutilized. For more information, see IPAM resource utilization metrics.
- **VPCs with highest IPs allocated**: The VPCs that have the highest percentage of IP address space allocated to subnets. This is useful to show you if you need to provision additional IP address space to the VPCs.
- **Subnets with highest IPs allocated**: The subnets that have the highest percentage of IP address space allocated to resources. This is useful to show you if you need to provision additional IP address space to the subnets.
- **Pool assignment**: The percentage of IP space that has been assigned to resources and manual allocations in the scope over time.
- **Pool allocation**: The percentage of a pool's IP space that has been allocated to other pools in the scope over time.

Command line

The information displayed in the dashboard comes from metrics stored in Amazon CloudWatch. For more information about the metrics stored in Amazon CloudWatch, see Monitor IPAM with

Amazon CloudWatch. Use the Amazon CloudWatch options in the AWS CLI Reference to view metrics for allocations in your IPAM pools and scopes.

If you find that the CIDR that's provisioned for a pool is almost fully allocated, you might need to provision additional CIDRs. For more information, see Provision CIDRs to a pool.

Monitor CIDR usage by resource

The **Resources** view in Amazon VPC IP Address Manager provides a centralized overview of IP address utilization across your AWS resources. This enables you to quickly identify which resources are consuming IP addresses, track address allocation trends, and optimize your IP address management to align with your evolving infrastructure and business needs.

In IPAM, a resource is an AWS service entity that is assigned an IP address or CIDR block. IPAM manages some resources, but only monitors other resources, so it's important to understand the difference between the two:

- **Managed resource**: A managed resource has a CIDR allocated from an IPAM pool. IPAM monitors the CIDR for potential IP address overlap with other CIDRs in the pool, and monitors the CIDR's compliance with a pool's allocation rules. IPAM supports managing the following type of resources:
  - Elastic IP addresses
  - Public IPv4 pools

    > **Note**
    >
    > Public IPv4 pools and IPAM pools are managed by distinct resources in AWS. Public IPv4 pools are single account resources that enable you to convert your publicly-owned CIDRs to Elastic IP addresses. IPAM pools can be used to allocate your public space to public IPv4 pools.

  - VPCs
- **Monitored resource**: If a resource is monitored by IPAM, the resource has been detected by IPAM and you can view details about the resource's CIDR when you use `get-ipam-resource-cidrs` with the AWS CLI, or when you view **Resources** in the navigation pane. IPAM supports monitoring the following resources:
  - Elastic IP addresses

- Public IPv4 pools
- VPCs
- VPC subnets

AWS Management Console

To monitor CIDR usage by resource

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Resources**.
3. From the IP dropdown menu at the top of the content pane, choose the IP address protocol that you want to use: IPv4 or IPv6.
4. From the scope dropdown menu at the top of the content pane, choose the scope that you want to use. For more information about scopes, see How IPAM works.
5. Use the resource CIDR map to view available, allocated, and overlapping IP address space in a scope:

   - **Available**: An IP address range is available for allocation.
   - **Compliant and nonoverlapping**: An IP address range is allocated to a resource managed by IPAM.
   - **Occupied**: An IP address range is allocated to a resource.
   - **Overlapping**: An IP address range has been allocated to multiple resources and is overlapping.
   - **Noncompliant**: An IP address range is not compliant. There is a resource using the IP address range that is not compliant with the allocation rules set up for the pool.

   In the CIDR map, choose an IP address block at the bottom of the map to view the resources in smaller CIDR blocks. Choose an IP address block at the top of the map to view the resources in larger CIDR blocks.
6. In the table, you can view the following details about resources in the scope:

   - **Name (Resource ID)**: The name and resource ID of the resource.
   - **CIDR**: The CIDR associated with the resource.
   - **Management state**: The state of the resource.

- **Managed**: The resource has a CIDR allocated from an IPAM pool and is being monitored by IPAM for potential CIDR overlap and compliance with pool allocation rules.
- **Unmanaged**: The resource does not have a CIDR allocated from an IPAM pool and is not being monitored by IPAM for potential CIDR compliance with pool allocation rules. The CIDR is monitored for overlap.
- **Ignored**: The resource has been chosen to be exempt from monitoring. Ignored resources are not evaluated for overlap or allocation rule compliance.

  When a resource is chosen to be ignored, any space allocated to it from an IPAM pool is returned to the pool. The resource will not be imported again through automatic import (if the automatic import allocation rule is set on the pool).
- **-**: This resource is not one of the types of resources that IPAM can manage.

- **Compliance status**: The compliance status of the CIDR.
  - **Compliant**: A managed resource complies with the allocation rules of the IPAM pool.
  - **Noncompliant**: The resource CIDR does not comply with one or more of the allocation rules of the IPAM pool.

    Example

    If a VPC has a CIDR that does not meet the netmask length parameters of the IPAM pool, or if the resource is not in the same AWS Region as the IPAM pool, it will be flagged as noncompliant.
  - **Unmanaged**: The resource does not have a CIDR allocated from an IPAM pool and is not being monitored by IPAM for potential CIDR compliance with pool allocation rules. The CIDR is monitored for overlap.
  - **Ignored**: The resource has been chosen to be exempt from monitoring. Ignored resources are not evaluated for overlap or allocation rule compliance.

    When a resource is chosen to be ignored, any space allocated to it from an IPAM pool is returned to the pool. The resource will not be imported again through automatic import (if the automatic import allocation rule is set on the pool).
  - **-**: This resource is not one of the types of resources that IPAM can manage.
- **Overlap status**: The overlap status of CIDR.

- **Nonoverlapping**: The resource CIDR does not overlap with another CIDR in the same scope.
- **Overlapping**: The resource CIDR overlaps with another CIDR in the same scope. Note that if a resource CIDR is overlapping, it could be overlapping with a manual allocation.
- **Ignored**: The resource has been chosen to be exempt from monitoring. IPAM does not evaluate ignored resources for overlap or allocation rule compliance.

  When a resource is chosen to be ignored, any space allocated to it from an IPAM pool is returned to the pool. The resource will not be imported again through automatic import (if the automatic import allocation rule is set on the pool).
- **-**: This resource is not one of the types of resources that IPAM can manage.

- **IPs allocated**: For resources that are VPCs, this is the percentage of IP address space in the VPC that's taken up by subnet CIDRs. For resources that are subnets, if the subnet has an IPv4 CIDR provisioned to it, this is the percentage of IPv4 address space in the subnet that's in use. If the subnet has an IPv6 CIDR provisioned to it, the percentage of IPv6 address space in use is not represented. The percentage of IPv6 address space in use cannot currently be calculated. For resources that are public IPv4 pools, this is the percentage of IP address space in the pool that's been allocated to Elastic IP addresses (EIPs).
- **Region**: The AWS Region of the resource.
- **Owner ID**: The AWS account ID of the person that created this resource.
- **Resource type**: Whether the resource is a VPC, subnet, Elastic IP address, or public IPv4 pool.
- **Pool ID**: The ID of the IPAM pool that the resource is in.

7. Use **Filter resources** to filter the resources table by column property, like VPC ID or compliance status.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

Use the following AWS CLI commands to monitor CIDR usage by resource:

1. Get the scope ID: describe-ipam-scopes
2. Request resource information: get-ipam-resource-cidrs

Monitor IPAM with Amazon CloudWatch

IPAM automatically stores metrics related to IP address usage (such as the IP address space available in your IPAM pools and the number of resource CIDRs that comply with allocation rules) and resource utilization in the `AWS/IPAM` Amazon CloudWatch namespace in the home Region of your IPAM.

Integrating IPAM with CloudWatch enhances your ability to monitor, analyze, and optimize your IP address management within AWS.

Use cases include:

- **Tracking IP address utilization trends**: CloudWatch can monitor CIDR pool usage, scope allocation, and other IPAM metrics, helping you proactively identify potential IP address exhaustion risks.
- **Setting utilization-based alerts**: You can configure CloudWatch alarms to notify you when CIDR utilization reaches predetermined thresholds, enabling timely intervention and optimization.
- **Monitoring IPAM events**: CloudWatch can capture and analyze IPAM-related events, such as CIDR allocations, deallocations, and scope modifications, providing visibility into IP address management activities.
- **Generating custom dashboards**: By combining IPAM data with other AWS metrics, you can create comprehensive dashboards to visualize and analyze your IP address landscape alongside related infrastructure and performance indicators.

Contents

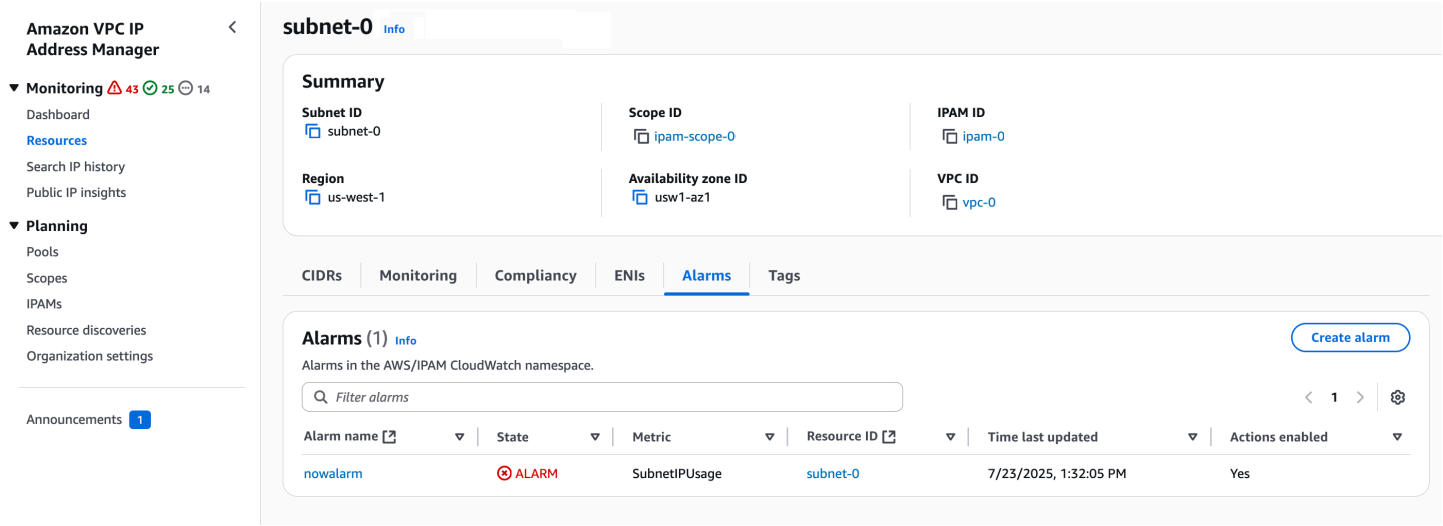
Manage alarms from IPAM console

You can create and manage Amazon CloudWatch alarms directly from the IPAM console. Alarms for IPAM metrics or IPAM resource utilization metrics that are in an INSUFFICIENT_DATA or ALARM state will appear as warning bars at the top of the console and as visual indicators in the left navigation next to **Monitoring**.

To manage alarms for specific resources, choose **Resources**, then choose a VPC, subnet, or pool. When the resource details page opens, choose the **Alarms** tab.

The **Alarms** tab displays all CloudWatch alarms associated with the selected resource. From this tab, you can view alarm details, monitor current states, and access alarm configuration options. The tab shows alarms from the `AWS/IPAM` namespace that are relevant to the resource you're viewing.

The following screenshot shows the alarm management interface in the IPAM console:



The **Alarms** tab provides a detailed summary of the CloudWatch alarms in the `AWS/IPAM` Amazon CloudWatch namespace in the home Region of your IPAM:

- **Alarm name**: User-defined name of the CloudWatch alarm.
- **State**: Current state of the CloudWatch alarm:
  - **ALARM**: Metric is outside defined threshold.
  - **OK**: Metric is within defined threshold.
  - **INSUFFICIENT_DATA**: Not enough data to determine alarm state.
- **Metric**: The specific CloudWatch metric being monitored by the alarm.
- **Resource ID**: The unique identifier of the AWS resource that the alarm is monitoring.
- **Time last updated**: Date and time when the alarm state was last changed or evaluated.
- **Actions enabled**: Indicates whether CloudWatch actions are enabled for the alarm:
  - **Yes**: Alarm can trigger configured actions when conditions are met.
  - **No**: Alarm is monitoring but not executing actions.

In addition, if you're viewing the utilization graphs on the **Monitoring** tab for a VPC, subnet, or pool, you can choose the option to create an alarm for the resource utilization. You're then redirected to the CloudWatch console with the resource and metric details pre-populated. From there, you can configure an alarm threshold to, for example, be notified when utilization reaches a specific percentage.

IPAM metrics

IPAM publishes data about your IPAM, pools, and scopes to Amazon CloudWatch. You can use these metrics to create alarms for IPAM pools to notify you if the address pools are nearing exhaustion or if resources fail to comply with allocation rules set on a pool. Creating alarms and setting up notifications with Amazon CloudWatch is outside the scope of this section. For more information, see Using Amazon CloudWatch alarms in the *Amazon CloudWatch User Guide*.

The metrics and dimensions that IPAM sends to Amazon CloudWatch are listed below.

IPAM metrics

The `AWS/IPAM` namespace includes the following IPAM metrics.

Metric name	Description
TotalActiveIpCount	The total active IP count is the number of active IP addresses in your IPAM that you would be charged if you switched from the Free Tier to the Advanced Tier. An active IP address is defined as an IP address or a prefix associated with an Elastic Network Interface (ENI) that is attached to a resource such as an EC2 Instance. • This metric is only available to customers in the Free Tier. • If your IPAM is integrated with AWS Organizations, the active IP count covers all the Organization accounts. • You cannot view a breakdown of the active IP count by IP type (public/private) or class (IPv4/IPv6). • IPAM only counts IPs from ENIs owned by monitored accounts. The count may be inaccurate for shared subnets. IP addresses are excluded if the subnet owner or ENI owner is not covered by IPAM.

IPAM pool metrics

The `AWS/IPAM` namespace includes the following pool metrics for IPAM.

Metric name	Description
CompliantResourceCidrs	The number of managed resource CIDRs that comply with the allocation rules of the IPAM pool. For more information about allocation rules, see Create a top-level IPv4 pool.
NoncompliantResourceCidrs	The number of managed resource CIDRs that do not comply with the allocation rules of the IPAM pool. For more informati on about allocation rules, see Create a top-level IPv4 pool.
PercentAllocated	The percentage of a pool's IP space that has been allocated to other pools.
PercentAssigned	The percentage of a pools IP space that has been allocated to resources, including manual allocations.
PercentAvailable	The percentage of a pool's IP space that has not been allocated to other pools or resources.

IPAM scope metrics

The `AWS/IPAM` namespace includes the following scope metrics for IPAM.

Metric name	Description
CompliantResourceCidrs	The number of resource CIDRs that comply with the allocation rules for IPAM pools in the scope.
ManagedResourceCidrs	The number of resource CIDRs for manageable resources (VPCs or public IPv4 pools) that are allocated from an IPAM pool in the scope.
NoncompliantResourceCidrs	The number of resource CIDRs that do not comply with the allocation rules for the IPAM pools in the scope.

Metric name	Description
OverlappingResourceCidrs	The number of resource CIDRs that overlap in the scope.
UnmanagedResourceCidrs	The number of resource CIDRs in the scope that are currently associated with manageable resources but are not managed by IPAM.

IPAM public IP metrics

The `AWS/IPAM` namespace includes the following public IP metrics for IPAM.

Metric name	Description
AmazonOwnedContigIPs	The number of IP addresses within CIDRs that are provisioned to Amazon-provided contiguous public IPv4 pools owned by the IPAM.
AllocatedAmazonOwnedContigIPs	The number of IP addresses that have been allocated from an Amazon-provided contiguous public IPv4 pool CIDR block.
UnallocatedAmazonOwnedContigIPs	The number of IP addresses within the Amazon-provided contiguous public IPv4 pool CIDR block owned by the IPAM.
AssociatedAmazonOwnedContigIPs	The number of Elastic IP addresses that have been allocated from an Amazon-provided contiguous public IPv4 pool CIDR block that are associated with an elastic network interface.
UnassociatedAmazonOwnedContigIPs	The number of Elastic IP addresses that have been allocated from an Amazon-provided contiguous public IPv4 pool CIDR block that are not associated with an elastic network interface.

IPAM prefix list resolver metrics

We encourage you to set CloudWatch alarms on failure metrics as you may need to reassess and adjust IPAM prefix list resolver rules to stay within the limits for version and prefix list size.

Metric name	Description
IpamPrefixListResolverSyncFailure	Prefix list resolver failed to sync with target. This may happen if a quota such as 'CIDR entries per prefix list resolver version' is exceeded, the target prefix list is not found, or sync is disabled on the target managed prefix list.
IpamPrefixListResolverSyncSuccess	Prefix list resolver successfully synced with target.
IpamPrefixListResolverVersionCreationSuccess	Version creation succeeded.
IpamPrefixListResolverVersionCreationFailure	Version creation failed. This may happen if you've reached your 'CIDR entries per prefix list resolver version' quota.

Metric dimensions

To filter the IPAM metrics, use the following dimensions.

Dimension	Description
AddressFamily	The IP address family for resource CIDRs (IPv4 or IPv6).
Locale	The AWS Region where an IPAM pool is available for allocations.
PoolID	The ID of a pool.
ScopeID	The ID of a scope.

For information about monitoring VPCs with Amazon CloudWatch, see CloudWatch metrics for your VPCs in the *Amazon Virtual Private Cloud User Guide*.

IPAM resource utilization metrics

IPAM publishes IP utilization metrics for resources that the IPAM monitors to Amazon CloudWatch. These resources include:

- VPCs (IPv4 and IPv6)
- Subnets (IPv4)
- Public IPv4 pools

IPAM calculates and publishes IP utilization metrics separately by IP address family (IPv4 or IPv6). The IP utilization of a resource is calculated across all of its CIDRs of the same address family.

For each resource type and address family combination, IPAM uses three rules to determine which metrics to publish:

- Up to 50 resources with the highest IP utilization. You can use this information to configure alarms to be alerted if an IP utilization threshold is breached.
- Up to 50 resources with the lowest IP utilization. You can use this information to decide if you want to keep or delete resources that are underutilized.
- Up to 50 other resources. You can use this information to consistently track the IP utilization of resources that may not be captured within the high or low utilization group.
  - Up to 50 VPCs containing a CIDR allocated from an IPAM pool (prioritized by total size of CIDR blocks).
  - Up to 50 subnets whose VPC contains a CIDR allocated from an IPAM pool (prioritized by total size of CIDR blocks).
  - Up to 50 public IPv4 pools containing a CIDR allocated from an IPAM pool (prioritized by total size of CIDR blocks).

After applying each rule, the metrics are aggregated and published under the same metric name for each resource type. See below for detailed information on the metric names and their dimensions.

Important

There is a unique limit for each resource type, address family, and rule combination. The default value of each limit is 50. You can adjust these limits by contacting the AWS Support Center as described in AWS service quotas in the *AWS General Reference*.

Example

Let's say that your IPAM monitors 2,500 VPCs and 10,000 subnets, all with IPv4 and IPv6 CIDRs. IPAM publishes the following IP utilization metrics:

- Up to 150 metrics for VPC IPv4 IP utilization, including:
  - The 50 VPCs with the highest IPv4 IP utilization
  - The 50 VPCs with the lowest IPv4 utilization
  - Up to 50 VPCs containing an IPv4 CIDR allocated from an IPAM pool
- Up to 150 metrics for VPC IPv6 utilization, including:
  - The 50 VPCs with the highest IPv6 IP utilization
  - The 50 VPCs with the lowest IPv6 utilization
  - Up to 50 VPCs containing an IPv6 CIDR allocated from an IPAM pool
- Up to 150 metrics for subnet IPv4 utilization, including:
  - The 50 subnets with the highest IPv4 IP utilization
  - The 50 subnets with the lowest IPv4 IP utilization
  - Up to 50 subnets whose VPC contains an IPv4 CIDR allocated from an IPAM pool

VPC metrics

The VPC metric name and description is listed below.

Metric name	Description
VpcIPUsage	The total IPs covered by CIDRs in the VPC's subnets divided by the total IPs covered by CIDRs in the VPC. This is calculated across all VPC CIDRs in the same IPAM Scope and separately for IPv4 and IPv6 CIDRs.

The dimensions you can use to filter VPC metrics are listed below.

Dimension	Description
AddressFamily	The IP address family for resource CIDRs (IPv4 or IPv6).

Dimension	Description
OwnerID	The ID of the VPC owner.
Region	The AWS Region where the VPC is located.
ScopeID	The ID of the IPAM scope that the VPC belongs to.
VpcID	The ID of the VPC.

Subnet metrics

The subnet metric name and description is listed below.

Metric name	Description
SubnetIPUsage	The number of active IPs divided by total IPs in the subnet's IPv4 CIDR.

The dimensions you can use to filter subnet metrics are listed below.

Dimension	Description
AddressFamily	The IP address family for resource CIDRs (IPv4 only).
OwnerID	The ID of the subnet owner.
Region	The AWS Region where the subnet is located.
ScopeID	The ID of the IPAM scope that the subnet belongs to.
SubnetID	The ID of the subnet.
VpcID	The ID of the VPC that the subnet belongs to.

Public IPv4 pool metrics

The public IPv4 pool metric name and description is listed below.

Metric name	Description
PublicIPv4PoolIPUsage	The number of EIPs from the public IPv4 Pool divided by total IPs in the pool.

The dimensions you can use to filter the public IPv4 pool metrics are listed below.

Dimension	Description
OwnerID	The ID of the public IPv4 pool owner.
PublicIPv4PoolID	The ID of the public IPv4 pool.
Region	The AWS Region where the public IPv4 pool is located.
ScopeID	The ID of the IPAM scope that the public IPv4 pool belongs to.

Public IP insight metrics

The public IP insight metric names and descriptions are listed below.

Metric name	Description
AmazonOwnedElasticIPs	The number of Amazon-owned Elastic IP addresses that you have provisioned or assigned to resources in your AWS account.
AssociatedAmazonOwnedElasticIPs	The number of Amazon-owned Elastic IP addresses that you have associated with resources in your AWS account.
AssociatedBringYourOwnIPs	The number of public IPv4 addresses that you have brought to AWS using Bring your own IP addresses (BYOIP) and have associated with resources in your AWS account.
BringYourOwnIPs	The number of public IPv4 addresses that you have brought to AWS using Bring your own IP addresses (BYOIP).
EC2PublicIPs	The number of public IPv4 addresses assigned to EC2 instances when the instances were launched into a default subnet or

Metric name	Description
	into a subnet configured to automatically assign a public IPv4 address.
ServiceManagedBringYourOwnIPs	The number of public IPv4 addresses that you have brought to AWS using Bring your own IP addresses (BYOIP) that are provisioned and managed by an AWS service.
ServiceManagedIPs	The number of public IPv4 addresses provisioned and managed by an AWS service.
UnassociatedAmazonOwnedElasticIPs	The number of Amazon-owned Elastic IP addresses that you have not associated with resources in your AWS account.
UnassociatedBringYourOwnIPs	The number of public IPv4 addresses that you have brought to AWS using Bring your own IP addresses (BYOIP) and have not associated with any resources in your AWS account.

The dimensions you can use to filter the public IP insight metrics are listed below.

Dimension	Description
IpamId	The ID of the IPAM that the IP address belongs to.
Region	The AWS Region where the public IP address is located.

Quick tip for creating alarms

To quickly create an Amazon CloudWatch alarm for resources with high IP address utilization, open the CloudWatch console, choose **Metrics**, **All metrics**, choose the **Query** tab, choose the **Namespace** `AWS/IPAM > VPC IP Usage Metrics`, `AWS/IPAM > Subnet IP Usage Metrics`, or `AWS/IPAM > Public IPv4 Pool IP Usage Metrics`, choose the **Metric name** `MAX(VpcIPUsage)`, `MAX(SubnetIPUsage)`, or `MAX(PublicIPv4PoolIPUsage)`, and choose **Create alarm**. For more information, see Create alarms on Metrics Insights queries in the *Amazon CloudWatch User Guide*.

Monitor BGP route protection

IPAM BGP route protection monitors Resource Public Key Infrastructure (RPKI) validity for all Bring Your Own IP (BYOIP) prefixes across accounts and Regions from a single dashboard, detects route overlaps that may indicate hijacking, and, with delegated RPKI, eliminates manual Route Origin Authorization (ROA) management at ARIN, RIPE, APNIC, and LACNIC. You go from logging into Regional Internet Registry (RIR) portals per-prefix to zero manual ROA operations.

The problem this solves

Customers who bring their own IP addresses to AWS must manually manage BGP route protection at their Regional Internet Registry. This means logging into RIR portals (ARIN, RIPE, APNIC) for every prefix, tracking expiration dates across dozens or hundreds of ROAs, and relying on third-party tools to detect route hijacks. For ROA management, customers either use their RIR's hosted portal or run open-source tools like Krill (NLnet Labs) to operate their own RPKI certificate authority (CA). Many customers skip ROA creation entirely or create them once and forget to renew. There's no integrated solution that combines route monitoring, RPKI management, and IP address management in one place.

With delegated RPKI, you no longer have to provide authenticity or ownership proof of CIDRs or prefixes when provisioning, because AWS verifies it on your behalf. At the same time, AWS creates ROAs for each new CIDR that you provision.

How it works

BGP route protection is built from three layers, each building on the previous one:

- **Route discovery**: IPAM discovers all BYOIP routes across accounts and Regions. You see prefix, ASN, advertisement status, and RPKI validity in one dashboard.
- **Route protection findings**: IPAM evaluates each route against published ROA data. It flags conflicting ROAs, missing ROAs, permissive configurations, and overlapping announcements from other ASNs. Without this, you have no way to detect sub-prefix hijacks or expired ROAs until traffic is already misrouted.
- **Delegated RPKI**: You authorize AWS to manage ROAs on your behalf through a one-time setup with your RIR. From that point, IPAM auto-creates ROAs when you provision CIDRs, auto-renews them before expiration, and manages ROAs for on-premises prefixes you haven't brought to AWS. Without delegation, you must manually track expiration dates across dozens of ROAs and renew them at each RIR portal individually.

When to use it

Consider BGP route protection if any of the following apply:

- You have BYOIP prefixes and want to know if they're protected against hijacking.
- You want to stop manually creating and renewing ROAs at your RIR.
- You want a single dashboard showing RPKI posture across all accounts and Regions.
- You need to manage ROAs for on-premises IP space from the same console as your AWS IPs.

BGP route protection is not needed if any of the following apply:

- You only use AWS-owned IP space (Elastic IP addresses, service-managed prefixes). AWS manages ROAs for those automatically.
- Your BYOIP prefixes are not advertised to the internet (private use only within AWS). No BGP announcements means no hijack risk.
- Your organization already runs a mature RPKI CA (such as Krill) with full automation and monitoring. In that case, delegated RPKI would duplicate what you already have, though the monitoring dashboard may still add value for centralized visibility.

Getting started options

You don't have to enable everything at once. Each capability works independently:

- **Monitoring**: View all BYOIP routes that IPAM automatically discovers from your provisioned prefixes, including advertisement status, RPKI validity, ROA strength, route overlaps, and ROA expiration. Free Tier customers can call the route discovery API; Advanced Tier adds the full dashboard with RPKI findings and overlap detection. No RIR setup is needed. Start here to understand your current posture before making changes.
- **Delegate RPKI**: Delegate ROA management to AWS through a one-time Internet Registry Association setup with your RIR. Once active, ROAs are created on provisioning and renewed automatically. Delegated RPKI supports batch updates for managing multiple prefixes atomically. Start here if you're already managing ROAs manually and want to eliminate that operational burden.

You can start with monitoring, evaluate your posture, and add delegated RPKI later without disrupting existing routes.

Tier requirements

Capability	Free Tier	Advanced Tier
Route discovery (view routes)	Yes	Yes
Route protection findings (RPKI status, overlaps)	No	Yes
Delegated RPKI (automated ROA managemen t)	No	Yes
On-premises ROA management (routing policy registrations)	No	Yes

For pricing details, see the IPAM tab on the Amazon VPC pricing page.

Supported Regional Internet Registries

RIR	Coverage	Notes
ARIN	North America, parts of the Caribbean	Most common for US-based customers
RIPE NCC	Europe, Middle East, Central Asia	
APNIC	Asia Pacific	
LACNIC	Latin America, Caribbean	Delegated RPKI supported. Automatic CIDR discovery and ROA pre-creation are not available during initial setup.
AFRINIC	Africa	Route discovery and findings only. Delegated RPKI not supported.

Key concepts

ROA (Route Origin Authorization)

A cryptographically signed object that authorizes a specific ASN to advertise a specific IP prefix. ROAs have three key attributes: CIDR, ASN, and max-length. Max-length indicates the longest (most-specific) subnet that the ASN is authorized to announce.

Strict ROA

Max-length matches the prefix length exactly. Only this exact prefix is RPKI-valid when announced by the authorized ASN. More-specific announcements from any ASN are RPKI-invalid. This is the recommended default.

Permissive ROA

Max-length is greater than the prefix length. The authorized ASN can announce more-specific subnets that are also RPKI-valid. This is useful for traffic engineering but offers weaker protection against sub-prefix hijacking.

Internet Registry Association

The trust relationship between your IPAM and your RIR. Once active, AWS can publish and manage ROAs for your IP space.

Routing policy registration (RPR)

A set of ROAs for a prefix, managed by IPAM for IP space that hasn't been brought to AWS. An RPR consists of a prefix and a list of ASNs, mapping to multiple ROAs (one per ASN). RPRs cover on-premises prefixes.

ROA auto-renewal

When delegated RPKI is active, AWS renews ROAs before expiration automatically. No tracking or manual action is needed.

What happens without BGP route protection

- **No ROA at all**: Your prefix has RPKI status *Unknown*. Networks that enforce RPKI validation may still accept it, but you have zero protection against route hijacks. Any ASN can announce your prefix or a more-specific prefix, and validating networks have no basis to reject it.

- **Permissive ROA**: Your prefix is RPKI-valid, but so are more-specific announcements from the same ASN. An attacker who compromises your ASN credentials can announce more-specific prefixes that are also valid, splitting your traffic.
- **Expired ROA**: Your prefix transitions from *Valid* to *Unknown* silently. Traffic continues flowing, but the prefix is no longer protected against route hijack because validating networks cannot distinguish your legitimate announcement from an unauthorized one.
- **No overlap detection**: A third party announces your prefix or a sub-prefix. Without monitoring, you don't know until customers report connectivity issues, which can take hours or days.

Console visualizations

The Route monitoring dashboard (**IPAM** > **Monitoring** > **Route monitoring**) shows three charts:

- **RPKI Coverage**: A pie chart showing Valid, Invalid, and Unknown across all advertised routes.
- **ROA Strength**: A pie chart showing the Strict versus Permissive distribution.
- **Routes with Overlaps**: A count of routes with conflicting more-specific advertisements from different ASNs.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

- View discovered routes: get-ipam-discovered-routes
- View route protection findings: get-ipam-route-protection-findings
- Create an Internet Registry Association: create-ipam-internet-registry-association
- Enable an Internet Registry Association: enable-ipam-internet-registry-association
- View ROAs: get-ipam-route-origin-authorizations
- View association CIDRs: get-ipam-internet-registry-association-cidrs
- Create a routing policy registration: create-ipam-routing-policy-registration
- Batch modify registrations: batch-modify-ipam-routing-policy-registrations
- View registration deltas: get-ipam-routing-policy-registration-deltas

To see examples of how you can use the AWS CLI to set up BGP route protection, see Tutorial: Set up delegated RPKI for BYOIP prefixes.

View IP address history

Follow the steps in this section to view the history of an IP address or CIDR in an IPAM scope. You can use the historical data to analyze and audit your network security and routing policies. IPAM automatically retains IP address monitoring data for up to three years.

You can use the IP historical data to search for the status change of IP addresses or CIDRs for the following types of resources:

- VPCs
- VPC subnets
- Elastic IP addresses
- EC2 instances
- EC2 network interfaces attached to instances

Important

Although IPAM doesn't monitor Amazon EC2 instances or EC2 network interfaces that are attached to instances, you can use the Search IP history feature to search for historical data on EC2 instance and network interface CIDRs.

Note

- If you move a resource from one IPAM scope to another, the previous history record ends and a new history record is created under the new scope. For more information, see Move VPC CIDRs between scopes.
- If you delete or transfer a resource to an AWS account that's not monitored by your IPAM, any new history related to the resource will not be visible and your IPAM won't monitor the resource. The IP address of the resource, however, will still be searchable.
- If you Integrate IPAM with accounts outside of your organization, the IPAM owner can view the IP address history of all resource CIDRs owned by those accounts.

AWS Management Console

To view the history of a CIDR

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Search IP history**.
3. Enter an IPv4 or IPv6 IP address or CIDR. This must be a specific CIDR for the resource.
4. Choose an IPAM scope ID.
5. Choose a date/time range.
6. If you want to filter the results by VPC, enter a VPC ID. Use this option if the CIDR appears in multiple VPCs.
7. Choose **Search**.

Command line

The commands in this section link to the *AWS CLI Command Reference*. The documentation provides detailed descriptions of the options that you can use when you run the commands.

- View the history of a CIDR: get-ipam-address-history

To see examples of how you can use the AWS CLI to analyze and audit IP address usage, see Tutorial: View IP address history using the AWS CLI.

The results of the search are organized into the following columns:

- **Sampled end time**: Sampled end time of the resource-to-CIDR association within the IPAM scope. Changes are picked up in periodic snapshots, so the end time might have occurred before this specific time.
- **Sampled start time**: Sampled start time of the resource-to-CIDR association within the IPAM scope. Changes are picked up in periodic snapshots, so the start time might have occurred before this specific time.

Example

To help explain the times that you see under Sampled start time and Sampled end time, let's look at an example use case:

At 2:00 PM, a VPC was created with CIDR 10.0.0.0/16. At 3:00 PM, you create an IPAM and IPAM pool with CIDR 10.0.0.0/8, and select the auto-import option to allow IPAM to discover and import any CIDRs that fall within the 10.0.0.0/8 IP address range. Because IPAM picks up changes to CIDRs in periodic snapshots, it doesn't discover the existing VPC CIDR until 3:05 PM. When you search for the ID of this VPC using the Search IP history feature, the Sampled start time for your VPC is 3:05 PM, which is when IPAM discovered it, not 2:00 PM, which is when you created the VPC. Now, let's say that you decide to delete the VPC at 5:00 PM. When the VPC is deleted, the CIDR 10.0.0.0/16 that was allocated to the VPC is recycled back into the IPAM pool. IPAM takes its periodic snapshot at 5:05 PM and picks up the change. When you search for the ID of this VPC in Search IP history, 5:05 PM is the Sampled end time for the VPC's CIDR, not 5:00 PM, which is when the VPC was deleted.

- **Resource ID**: The ID generated when the resource was associated with the CIDR.
- **Name:** The name of the resource (if applicable).
- **Compliance status**: The compliance status of the CIDR.
  - **Compliant**: A managed resource complies with the allocation rules of the IPAM pool.
  - **Noncompliant**: The resource CIDR does not comply with one or more of the allocation rules of the IPAM pool.

    Example

    If a VPC has a CIDR that does not meet the netmask length parameters of the IPAM pool, or if the resource is not in the same AWS Region as the IPAM pool, it will be flagged as noncompliant.
  - **Unmanaged**: The resource does not have a CIDR allocated from an IPAM pool and is not being monitored by IPAM for potential CIDR compliance with pool allocation rules. The CIDR is monitored for overlap.
  - **Ignored**: The managed resource has been chosen to be exempt from monitoring. Ignored resources are not evaluated for overlap or allocation rule compliance.

    When a resource is chosen to be ignored, any space allocated to it from an IPAM pool is returned to the pool and the resource will not be imported again through automatic import (if the automatic import allocation rule is set on the pool).
  - **-**: This resource is not one of the types of resources that IPAM can monitor or manage.
- **Overlap status**: The overlap status of CIDR.
  - **Nonoverlapping**: The resource CIDR does not overlap with another CIDR in the same scope.

  - **Overlapping**: The resource CIDR overlaps with another CIDR in the same scope. Note that if a resource CIDR is overlapping, it could be overlapping with a manual allocation.
  - **Ignored**: The managed resource has been chosen to be exempt from monitoring. IPAM does not evaluate ignored resources for overlap or allocation rule compliance.

    When a resource is chosen to be ignored, any space allocated to it from an IPAM pool is returned to the pool and the resource will not be imported again through automatic import (if the automatic import allocation rule is set on the pool).
  - **-**: This resource is not one of the types of resources that IPAM can monitor or manage.
- **Resource type**
  - **vpc**: The CIDR is associated with a VPC.
  - **subnet**: The CIDR is associated with a VPC subnet.
  - **eip**: The CIDR is associated with an Elastic IP address.
  - **instance**: The CIDR is associated with an EC2 instance.
  - **network-interface**: The CIDR is associated with a network interface.
- **VPC ID**: The ID of the VPC that this resource belongs to (if applicable).
- **Region**: The AWS Region of this resource.
- **Owner ID**: The AWS account ID of the user that created this resource (if applicable).

View public IP insights

You can use **Public IP insights** to see the following:

- If your IPAM is integrated with accounts in an AWS Organization, you can view all public IPv4 addresses used by services across all AWS Regions for your entire AWS Organization.
- If your IPAM is integrated with a single account, you can view all public IPv4 addresses used by services across all AWS Regions in your account.

A public IPv4 address is an IPv4 address that is routable from the internet. A public IPv4 address is necessary for a resource to be directly reachable from the internet over IPv4.

> **Note**
>
> AWS charges for all public IPv4 addresses, including public IPv4 addresses associated with running instances and Elastic IP addresses. For more information, see the **Public IPv4 Address** tab on the Amazon VPC pricing page.

You can view insights into the following public IPv4 address types:

- **Elastic IP addresses (EIPs)**: Static, public IPv4 addresses provided by Amazon that you can associate with an EC2 instance, elastic network interface, or AWS resource.
- **EC2 public IPv4 addresses**: Public IPv4 addresses assigned to an EC2 instance by Amazon (if the EC2 instance is launched into a default subnet or if the instance is launched into a subnet that's been configured to automatically assign a public IPv4 address).
- **BYOIPv4 addresses**: Public IPv4 addresses in the IPv4 address range that you've brought to AWS using Bring your own IP addresses (BYOIP).
- **Service-managed IPv4 addresses**: Public IPv4 addresses automatically provisioned on AWS resources and managed by an AWS service. For example, public IPv4 addresses on Amazon ECS, Amazon RDS, or Amazon WorkSpaces.

Public IP insights shows you all public IPv4 addresses used by services across Regions. You can use these insights to identify public IPv4 address usage and view recommendations to release unused Elastic IP addresses.

- **Public IP types**: The number of public IPv4 addresses organized by type.
  - **Amazon-owned EIPs**: Elastic IP addresses that you have provisioned or assigned to resources in your AWS account.
  - **EC2 public IPs**: Public IPv4 addresses assigned to EC2 instances when the instances were launched into a default subnet or into a subnet that's been configured to automatically assign a public IPv4 address.
  - **BYOIP**: Public IPv4 addresses that you have brought to AWS using Bring your own IP addresses (BYOIP).
  - **Service managed IPs**: Public IPv4 addresses provisioned and managed by an AWS service.
  - **Service managed BYOIP**: Public IPv4 addresses brought to AWS and managed by an AWS service.

  - **Amazon-owned contiguous EIPs**: Elastic IP addresses allocated from an Amazon-provided contiguous public IPv4 IPAM pool.
- **EIP usage**: The number of Elastic IP addresses organized by how they are used.
  - **Associated Amazon-owned EIPs**: Elastic IP addresses that you have provisioned in your AWS account and that you have associated with an EC2 instance, network interface, or AWS resource.
  - **Associated BYOIP**: Public IPv4 addresses you have brought to AWS using BYOIP that you have associated with a network interface.
  - **Unassociated Amazon-owned EIPs**: Elastic IP addresses that you have provisioned in your AWS account but you have not associated with a network interface.
  - **Unassociated BYOIP**: Public IPv4 addresses you have brought to AWS using BYOIP but you have not associated with a network interface.
  - **Associated Amazon-owned contiguous EIPs**: Elastic IP addresses allocated from an Amazon-provided contiguous public IPv4 IPAM pool and associated with a resource.
  - **Unassociated Amazon-owned contiguous EIPs**: Elastic IP addresses allocated from an Amazon-provided contiguous public IPv4 IPAM pool and unassociated with a resource.
- **Amazon-owned IPv4 contiguous IPs usage**: A table that shows contiguous public IPv4 address usage over time and related Amazon-owned IPv4 IPAM pools.
- **Public IP addresses**: A table of public IPv4 addresses and their attributes.
  - **IP address**: The public IPv4 address.
  - **Associated**: Whether or not the address is associated with an EC2 instance, network interface, or AWS resource.
    - **Associated**: The public IPv4 address is associated with an EC2 instance, network interface, or AWS resource.
    - **Unassociated**: The public IPv4 address is not associated to any resource and is idle in your AWS account.
  - **Address type**: The IP address type.
    - **Amazon-owned EIP**: The public IPv4 address is an Elastic IP address.
    - **BYOIP**: The public IPv4 address was brought to AWS using BYOIP.
    - **EC2 public IP**: The public IPv4 address was assigned automatically to an EC2 instance.
    - **Service managed BYOIP**: The public IPv4 address was brought to AWS using Bring your own IP (BYOIP).

  - **Service managed IP**: The public IPv4 address was provisioned and is managed by an AWS service.
- **Service**: The service that the IP address is associated with.
  - **AGA**: An AWS Global Accelerator. If a custom routing accelerator is used, its public IPs are not listed. To view these public IPs, see Viewing your custom routing accelerators.
  - **Database Migration Service**: An AWS Database Migration Service (DMS) replication instance.
  - **Redshift**: An Amazon Redshift cluster.
  - **RDS**: An Amazon Relational Database Service (RDS) instance.
  - **Load balancer (EC2)**: An Application Load Balancer or a Network Load Balancer.
  - **NAT gateway (VPC)**: An Amazon VPC public NAT gateway.
  - **Site-to-Site VPN**: An AWS Site-to-Site VPN virtual private gateway.
  - **Other**: Other service that is not currently identifiable.
- **Name (EIP ID)**: If this public IPv4 address is an Elastic IP address allocation, this is the name and ID of the EIP allocation.
- **Network interface ID**: If this public IPv4 address is associated with a network interface, this is the ID of the network interface.
- **Instance ID**: If this public IPv4 address is associated with an EC2 instance, this is the instance ID.
- **Security groups**: If this public IPv4 address is associated with an EC2 instance, this is the name and ID of the security group assigned to the instance.
- **Public IPv4 pool**: If this is an Elastic IP address from an IP address pool owned and managed by Amazon, the value is "-". If this is an Elastic IP address from an IP address range which you own and have brought to Amazon (using BYOIP), the value is the public IPv4 pool ID.
- **Network border group**: If the IP address is advertised, this is the AWS Region from which the IP address is advertised.
- **Owner ID**:The AWS account number of resource owner.
- **Sample time**: The last successful resource discovery time.
- **Resource discovery ID**: ID of the resource discovery that has discovered this public IPv4 address.
- **Service resource**: Resource ARN or ID.

If an Elastic IP address is allocated to your account but is not associated with a network interface, a banner appears informing you that you have unassociated EIPs in your account and you should release them.

> **Important**
>
> Public IP insights was recently updated. If you see an error related to not having permissions to call GetIpamDiscoveredPublicAddresses, the managed permission attached to a resource discovery that was shared with you needs to be updated. Contact the person who created the resource discovery and ask them to update the managed permission `AWSRAMPermissionIpamResourceDiscovery` to the default version. For more information, see Update a resource share in the *AWS RAM User Guide* .

AWS Management Console

To view public IP address insights

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Public IP insights**.
3. To view details for a public IP address, select an IP address by choosing it.
4. View the following information about the IP address:

   - **Details**: The same information visible in the columns of the main Public IP insights pane, such as the **Address type** and **Service**.
   - **Inbound security group rules**: If this IP address is associated with an EC2 instance, these are the security group rules that control the inbound traffic to the instance.
   - **Outbound security group rules**: If this IP address is associated with an EC2 instance, these are the security group rules that control the outbound traffic from the instance.
   - **Tags**: Key and value pairs that act as metadata for organizing your AWS resources.

Command line

Use the following command to get the public IP addresses that have been discovered by IPAM: get-ipam-discovered-public-addresses

Tutorials for Amazon VPC IP Address Manager

The following tutorials show you how to perform common IPAM tasks using the AWS CLI. To get the AWS CLI, see Access IPAM. For more information about the IPAM concepts that are mentioned in these tutorials, see How IPAM works.

Contents

Getting started with IPAM using the AWS CLI

This tutorial guides you through the process of setting up and using Amazon VPC IP Address Manager (IPAM) with the AWS CLI using a single AWS account. By the end of this tutorial, you will have created an IPAM, created a hierarchy of IP address pools, and allocated a CIDR to a VPC.

Prerequisites

Before you begin this tutorial, make sure you have:

- An AWS account with permissions to create and manage IPAM resources.
- The AWS CLI installed and configured with appropriate credentials. For information about installing the AWS CLI, see Installing or updating the latest version of the AWS CLI. For information about configuring the AWS CLI, see Configuration basics.
- Basic understanding of IP addressing and CIDR notation.
- Basic knowledge of Amazon VPC concepts.

- Approximately 30 minutes to complete the tutorial.

Create an IPAM

The first step is to create an IPAM with operating regions. An IPAM helps you plan, track, and monitor IP addresses for your AWS workloads.

Create an IPAM with operating regions in us-east-1 and us-west-2:

```
aws ec2 create-ipam \
  --description "My IPAM" \
  --operating-regions RegionName=us-east-1 RegionName=us-west-2
```

This command creates an IPAM and enables it to manage IP addresses in the specified regions. The operating regions are the AWS Regions where the IPAM is allowed to manage IP address CIDRs.

Verify that your IPAM was created:

```
aws ec2 describe-ipams
```

Take note of the IPAM ID from the output, as you'll need it for subsequent steps.

Wait for the IPAM to be fully created and available (approximately 20 seconds):

```
sleep 20
```

Get the IPAM scope ID

When you create an IPAM, AWS automatically creates a private and a public scope. For this tutorial, we'll use the private scope.

Retrieve the IPAM details and extract the private scope ID:

```
aws ec2 describe-ipams --ipam-id ipam-0abcd1234
```

Replace `ipam-0abcd1234` with your actual IPAM ID.

From the output, identify and note the private scope ID from the `PrivateDefaultScopeId` field. It will look something like `ipam-scope-0abcd1234`.

Create a top-level IPv4 pool

Now, let's create a top-level pool in the private scope. This pool will serve as the parent for all other pools in our hierarchy.

Create a top-level IPv4 pool:

```
aws ec2 create-ipam-pool \
  --ipam-scope-id ipam-scope-0abcd1234 \
  --address-family ipv4 \
  --description "Top-level pool"
```

Replace `ipam-scope-0abcd1234` with your actual private scope ID.

Wait for the pool to be fully created and available:

```
aws ec2 describe-ipam-pools --ipam-pool-ids ipam-pool-0abcd1234 --query
 'IpamPools[0].State' --output text
```

Replace `ipam-pool-0abcd1234` with your actual top-level pool ID. The state should be `create-complete` before proceeding.

After the pool is available, provision a CIDR block to it:

```
aws ec2 provision-ipam-pool-cidr \
  --ipam-pool-id ipam-pool-0abcd1234 \
  --cidr 10.0.0.0/8
```

Wait for the CIDR to be fully provisioned:

```
aws ec2 get-ipam-pool-cidrs --ipam-pool-id ipam-pool-0abcd1234 --query "IpamPoolCidrs[?
Cidr=='10.0.0.0/8'].State" --output text
```

The state should be `provisioned` before proceeding.

Create a regional IPv4 pool

Next, create a regional pool within the top-level pool. This pool will be specific to a particular AWS Region.

Create a regional IPv4 pool:

```
aws ec2 create-ipam-pool \
  --ipam-scope-id ipam-scope-0abcd1234 \
  --source-ipam-pool-id ipam-pool-0abcd1234 \
  --locale us-east-1 \
  --address-family ipv4 \
  --description "Regional pool in us-east-1"
```

Replace `ipam-scope-0abcd1234` with your actual private scope ID and `ipam-pool-0abcd1234` with your top-level pool ID.

Wait for the regional pool to be fully created and available:

```
aws ec2 describe-ipam-pools --ipam-pool-ids ipam-pool-1abcd1234 --query
 'IpamPools[0].State' --output text
```

Replace `ipam-pool-1abcd1234` with your actual regional pool ID. The state should be `create-complete` before proceeding.

After the pool is available, provision a CIDR block to it:

```
aws ec2 provision-ipam-pool-cidr \
  --ipam-pool-id ipam-pool-1abcd1234 \
  --cidr 10.0.0.0/16
```

Wait for the CIDR to be fully provisioned:

```
aws ec2 get-ipam-pool-cidrs --ipam-pool-id ipam-pool-1abcd1234 --query "IpamPoolCidrs[?
Cidr=='10.0.0.0/16'].State" --output text
```

The state should be `provisioned` before proceeding.

Create a development IPv4 pool

Now, create a development pool within the regional pool. This pool will be used for development environments.

Create a development IPv4 pool:

```
aws ec2 create-ipam-pool \
  --ipam-scope-id ipam-scope-0abcd1234 \
  --source-ipam-pool-id ipam-pool-1abcd1234 \
```

```
  --locale us-east-1 \
  --address-family ipv4 \
  --description "Development pool"
```

Replace `ipam-scope-0abcd1234` with your actual private scope ID and `ipam-pool-1abcd1234` with your regional pool ID.

Note: It's important to include the `--locale` parameter to match the parent pool's locale.

Wait for the development pool to be fully created and available:

```
aws ec2 describe-ipam-pools --ipam-pool-ids ipam-pool-2abcd1234 --query
 'IpamPools[0].State' --output text
```

Replace `ipam-pool-2abcd1234` with your actual development pool ID. The state should be `create-complete` before proceeding.

After the pool is available, provision a CIDR block to it:

```
aws ec2 provision-ipam-pool-cidr \
  --ipam-pool-id ipam-pool-2abcd1234 \
  --cidr 10.0.0.0/24
```

Wait for the CIDR to be fully provisioned:

```
aws ec2 get-ipam-pool-cidrs --ipam-pool-id ipam-pool-2abcd1234 --query "IpamPoolCidrs[?
Cidr=='10.0.0.0/24'].State" --output text
```

The state should be `provisioned` before proceeding.

Create a VPC using an IPAM pool CIDR

Finally, create a VPC that uses a CIDR from your IPAM pool. This demonstrates how IPAM can be used to allocate IP address space to AWS resources.

Create a VPC using an IPAM pool CIDR:

```
aws ec2 create-vpc \
  --ipv4-ipam-pool-id ipam-pool-2abcd1234 \
  --ipv4-netmask-length 26 \
  --tag-specifications 'ResourceType=vpc,Tags=[{Key=Name,Value=IPAM-VPC}]'
```

Replace `ipam-pool-2abcd1234` with your actual development pool ID.

The `--ipv4-netmask-length 26` parameter specifies that you want a /26 CIDR block (64 IP addresses) allocated from the pool. This netmask length is chosen to ensure it's smaller than the pool's CIDR block (/24).

Verify that your VPC was created:

```
aws ec2 describe-vpcs --filters "Name=tag:Name,Values=IPAM-VPC"
```

Verify the IPAM pool allocation

Check that the CIDR was allocated from your IPAM pool:

```
aws ec2 get-ipam-pool-allocations \
  --ipam-pool-id ipam-pool-2abcd1234
```

Replace `ipam-pool-2abcd1234` with your actual development pool ID.

This command shows all allocations from the specified IPAM pool, including the VPC you just created.

Troubleshooting

Here are some common issues you might encounter when working with IPAM:

- **Permission errors**: Ensure that your IAM user or role has the necessary permissions to create and manage IPAM resources. You may need the `ec2:CreateIpam`, `ec2:CreateIpamPool`, and other related permissions.
- **Resource limit exceeded**: You can create only one IPAM per AWS Region. If you already have an IPAM, you'll need to delete it before creating a new one or use the existing one.
- **CIDR allocation failures**: When provisioning CIDRs to pools, ensure that the CIDR you're trying to provision doesn't overlap with existing allocations in other pools.
- **API request timeouts**: If you encounter "RequestExpired" errors, it might be due to network latency or time synchronization issues. Try the command again.
- **Incorrect state errors**: If you receive "IncorrectState" errors, it might be because you're trying to perform an operation on a resource that's not in the correct state. Wait for the resource to be fully created or provisioned before proceeding.

- **Allocation size errors**: If you receive "InvalidParameterValue" errors about allocation size, ensure that the netmask length you're requesting is appropriate for the pool size. For example, you can't allocate a /25 CIDR from a /24 pool.
- **Dependency violations**: When cleaning up resources, you might encounter "DependencyViolation" errors. This is because resources have dependencies on each other. Make sure to delete resources in the reverse order of creation and deprovision CIDRs before deleting pools.

Clean up resources

When you're done with this tutorial, you should clean up the resources you created to avoid incurring unnecessary charges.

1. Delete the VPC:

```
aws ec2 delete-vpc --vpc-id vpc-0abcd1234
```

2. Deprovision the CIDR from the development pool:

```
aws ec2 deprovision-ipam-pool-cidr --ipam-pool-id ipam-pool-2abcd1234 --cidr
 10.0.0.0/24
```

3. Delete the development pool:

```
aws ec2 delete-ipam-pool --ipam-pool-id ipam-pool-2abcd1234
```

4. Deprovision the CIDR from the regional pool:

```
aws ec2 deprovision-ipam-pool-cidr --ipam-pool-id ipam-pool-1abcd1234 --cidr
 10.0.0.0/16
```

5. Delete the regional pool:

```
aws ec2 delete-ipam-pool --ipam-pool-id ipam-pool-1abcd1234
```

6. Deprovision the CIDR from the top-level pool:

```
aws ec2 deprovision-ipam-pool-cidr --ipam-pool-id ipam-pool-0abcd1234 --cidr
 10.0.0.0/8
```

7. Delete the top-level pool:

```
aws ec2 delete-ipam-pool --ipam-pool-id ipam-pool-0abcd1234
```

8. Delete the IPAM:

```
aws ec2 delete-ipam --ipam-id ipam-0abcd1234
```

Replace all IDs with your actual resource IDs.

> **Note**
>
> You may need to wait between these operations to allow the resources to be fully deleted before proceeding to the next step. If you encounter dependency violations, wait a few seconds and try again.

Next steps

Now that you've learned how to create and use IPAM with the AWS CLI, you might want to explore more advanced features:

- Plan for IP address provisioning – Learn how to plan your IP address space effectively
- Monitor CIDR usage by resource – Understand how to monitor IP address usage
- Share an IPAM pool using AWS RAM – Learn how to share IPAM pools across AWS accounts
- Integrate IPAM with accounts in an AWS Organization – Discover how to use IPAM across your organization

Tutorial: Create an IPAM and pools using the console

In this tutorial, you create an IPAM, integrate with AWS Organizations, create IP address pools, and create a VPC with a CIDR from an IPAM pool.

This tutorial shows you how you can use IPAM to organize IP address space based on different development needs. After you complete this tutorial, you'll have one IP address pool for pre-production resources. You can then create other pools based on your routing and security needs, such as a pool for production resources.

While you can use IPAM as a single user, integrating with AWS Organizations enables you to manage IP addresses across accounts in your organization. This tutorial covers integrating IPAM with accounts in an organization. It does not cover how to Integrate IPAM with accounts outside of your organization.

> **Note**
>
> For the purposes of this tutorial, the instructions will tell you to name IPAM resources in a particular way, create IPAM resources in specific Regions, and use specific IP address CIDR ranges for your pools. This is intended to streamline the choices available in IPAM and get you started with IPAM quickly. After you complete this tutorial, you might decide to create a new IPAM and configure it differently.

Contents

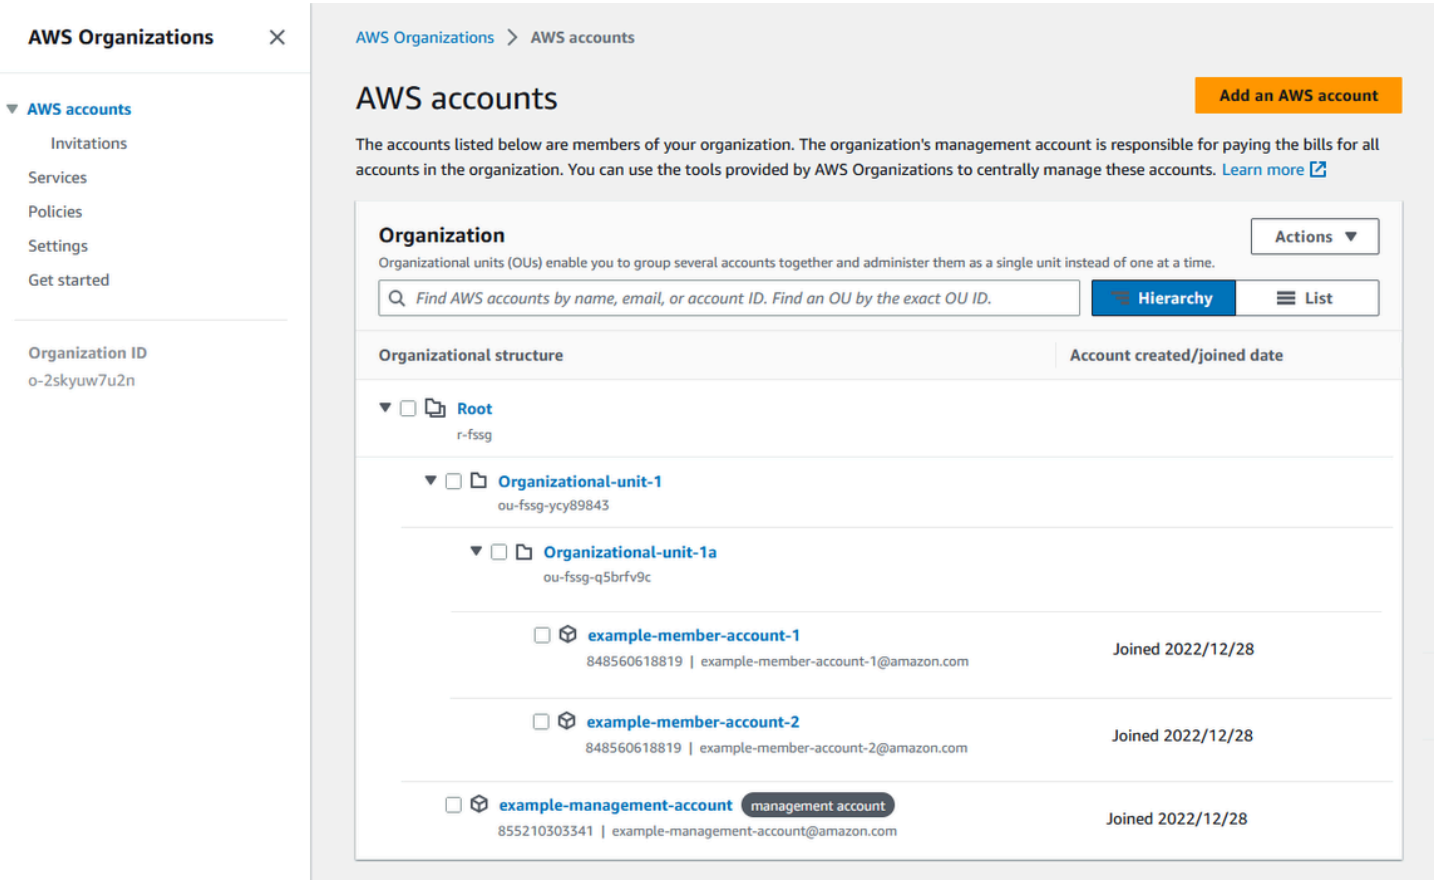
Prerequisites

Before you begin, you must have set up an AWS Organizations account with at least one member account. For how-to instructions, see Creating and managing an organization in the *AWS Organizations User Guide*.

How AWS Organizations integrates with IPAM

This section shows an example of the AWS Organizations accounts you use in this tutorial. There are three accounts in your organization that you use when you integrate with IPAM in this tutorial:

- The management account (called **example-management-account** in the following image) to log into the IPAM console and delegate an IPAM admin. You cannot use the organization's management account as your IPAM admin.
- A member account (called *example-member-account-1* in the following image) as the IPAM admin account. The IPAM admin account is responsible for creating an IPAM and using it to manage and monitor IP address usage across the organization. Any member account in your organization can be delegated as the IPAM admin.
- A member account (called *example-member-account-2* in the following above) as the developer account. This account creates a VPC with a CIDR allocated from an IPAM pool.



In addition to the accounts, you'll need the ID of the organizational unit (**ou-fssg-q5brfv9c** in the preceding image) that contains the member account you'll use as the developer account. You need this ID so that, in a later step, when you share your IPAM pool, you can share it with this OU.

> **Note**
>
> For more information about AWS Organizations account types like *management* and *member* accounts, see AWS Organizations terminology and concepts.

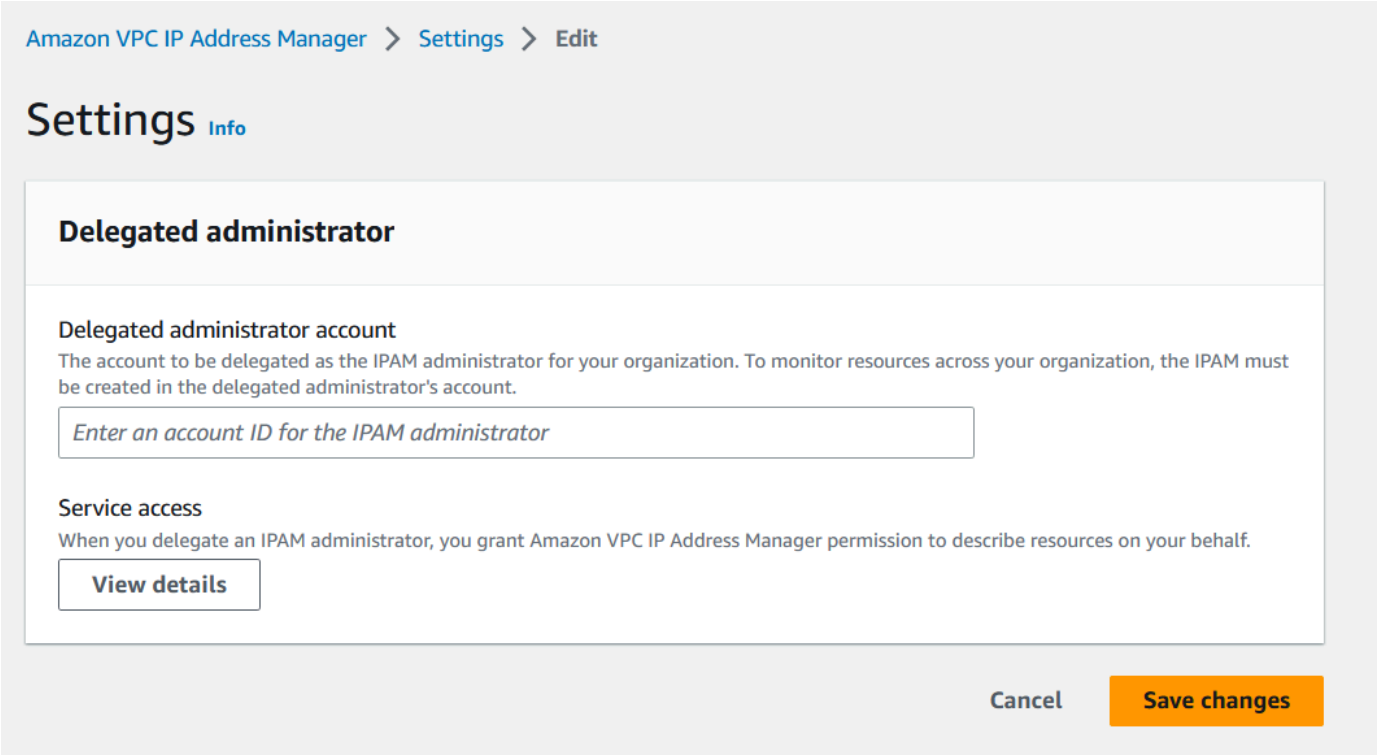
Step 1: Delegate an IPAM administrator

In this step, you'll delegate an AWS Organizations member account as the IPAM admin. When you delegate an IPAM admin, a service-linked role is automatically created in each of your AWS Organizations member accounts. IPAM monitors the IP address usage in these accounts by assuming the service-linked role in each member account. It can then discover the resources and their CIDRs regardless of their Organizational Unit.

You cannot complete this step unless you have the required AWS Identity and Access Management (IAM) permissions. For more information, see Integrate IPAM with accounts in an AWS Organization.

To delegate an IPAM admin account

1. Using the AWS Organizations management account, open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the AWS Management Console, choose the AWS Region in which you want to work with IPAM.
3. In the navigation pane, choose **Organization settings**.
4. Choose **Delegate**. The **Delegate** option is available only if you logged in to the console as the AWS Organizations management account.
5. Enter the AWS account ID for an organization member account. The IPAM administrator must be an AWS Organizations member account, not the management account.



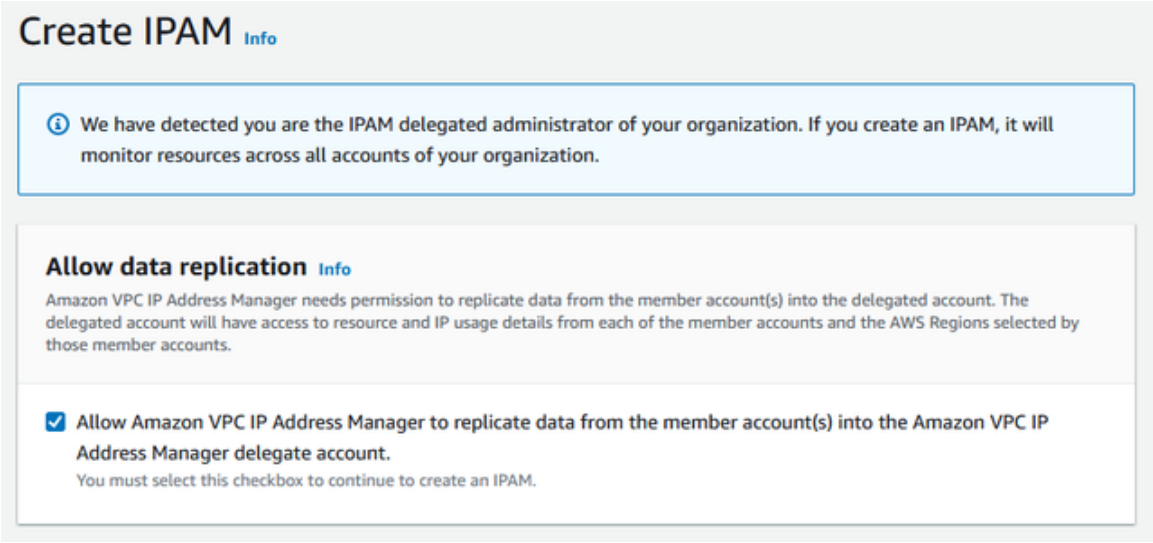
6. Choose **Save changes**. The **Delegated administrator** information is populated with details related to the member account.

Step 2: Create an IPAM

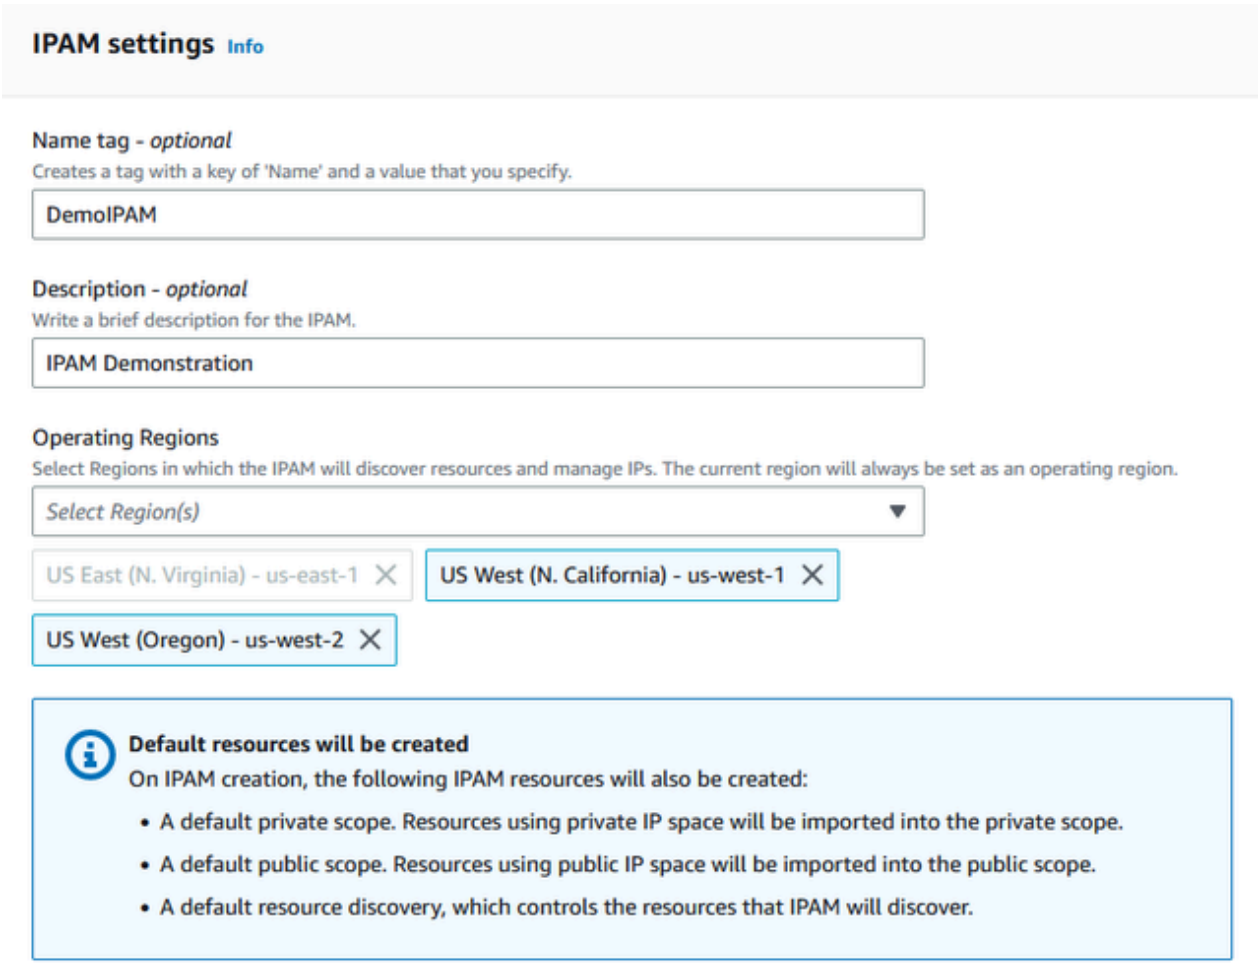
In this step you'll create an IPAM. When you create an IPAM, IPAM automatically creates two scopes for the IPAM: the private scope that's intended for all private space, and the public scope that's intended for all public space. The scopes, together with pools and allocations, are key components of your IPAM. For more information, see How IPAM works.

To create an IPAM

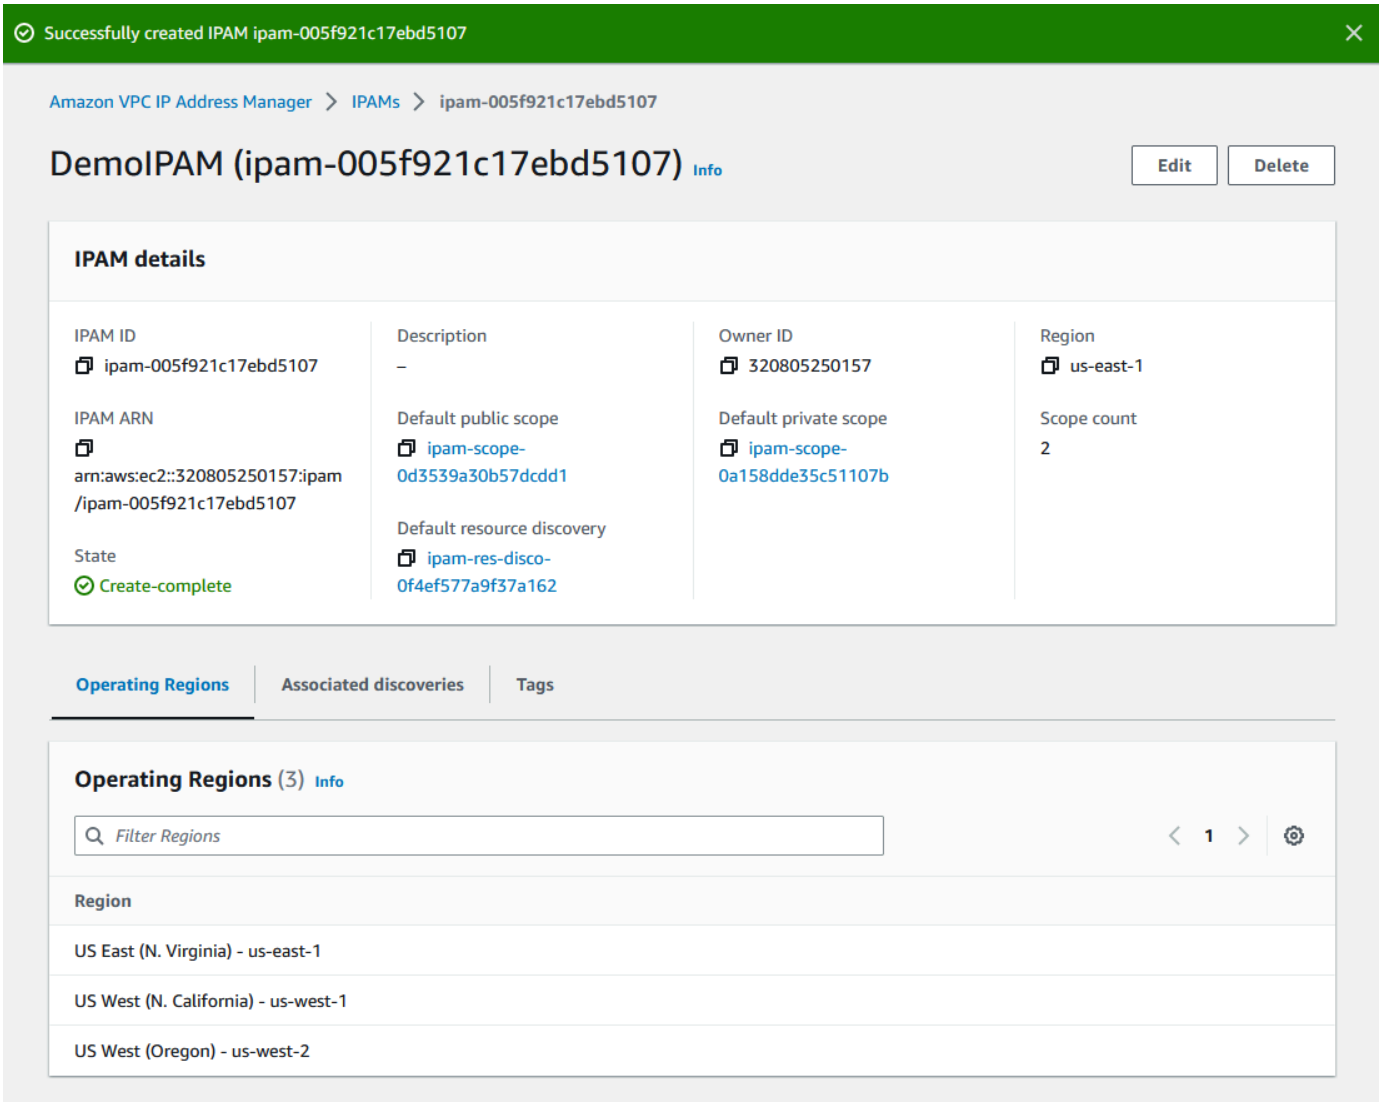
1. Using the AWS Organizations member account delegated as the IPAM admin in the previous step, open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the AWS Management Console, choose the AWS Region in which you want to create the IPAM. Create the IPAM in your main Region of operations.
3. On the service home page, choose **Create IPAM**.
4. Select **Allow Amazon VPC IP Address Manager to replicate data from source account(s) into the IPAM delegate account**. If you do not select this option, you cannot create an IPAM.



5. Under **Operating Regions**, choose the AWS Regions in which this IPAM can manage and discover resources. The AWS Region in which you are creating your IPAM is automatically selected as one of the operating Regions. In this tutorial, the home Region of our IPAM is us-east-1, so we'll choose us-west-1 and us-west-2 as additional operating Regions. If you forget an operating Region, you can edit your IPAM settings later and add or remove Regions.



6. Choose **Create IPAM**.



Step 3: Create a top-level IPAM pool

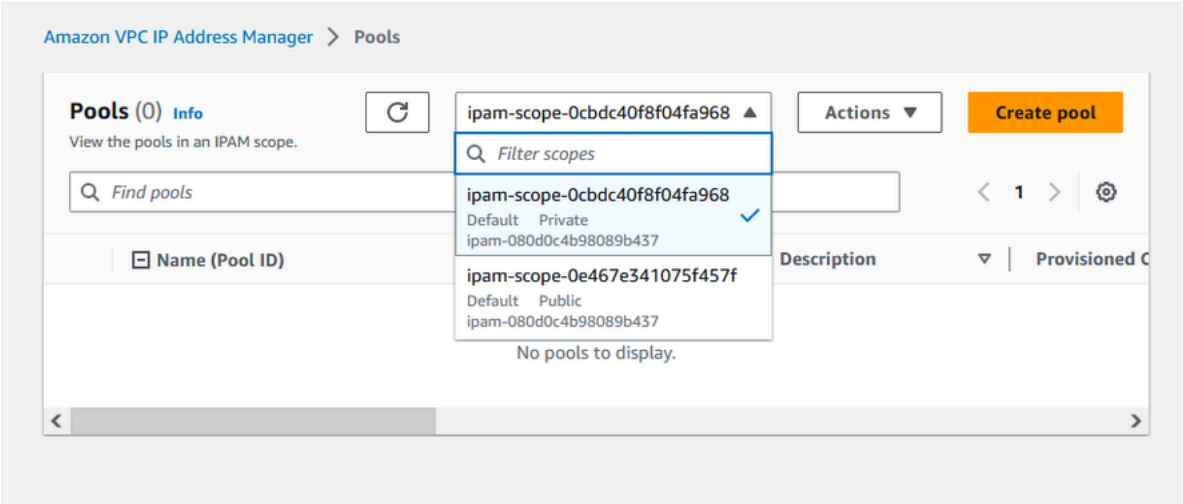
In this tutorial, you create a hierarchy of pools starting with the top-level IPAM pool. In the subsequent steps, you'll create a pair of Regional pools and a pre-production development pool in one of the regional pools.

For more information about pool hierarchies that you can build with IPAM, see Example IPAM pool plans.

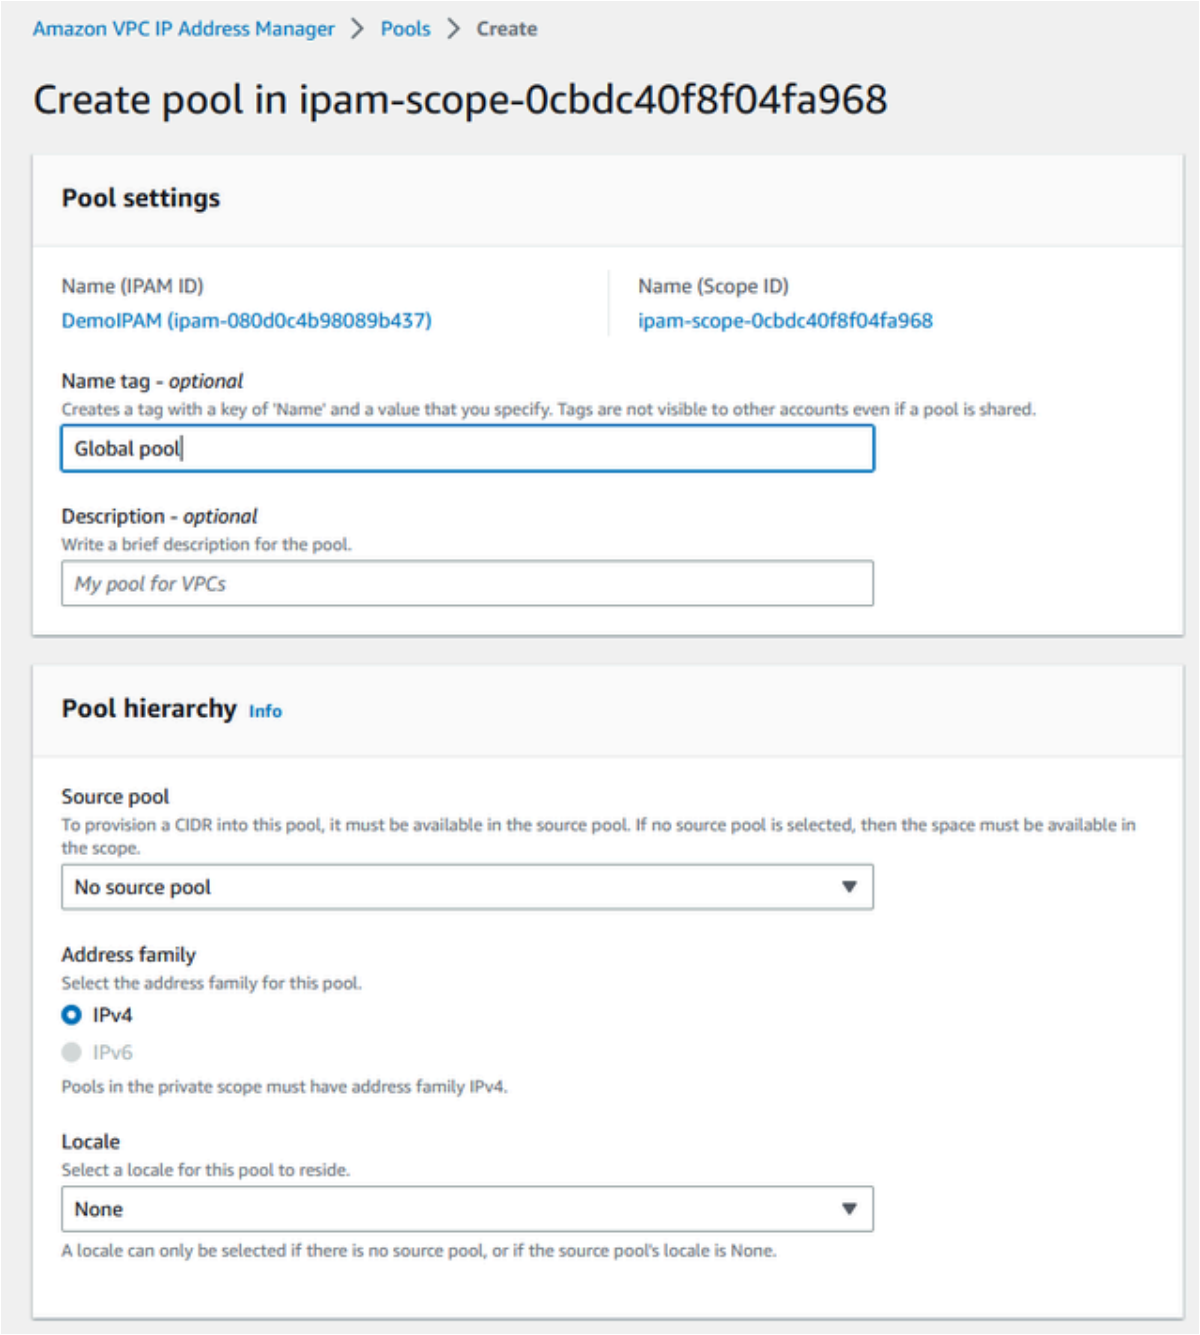
To create a top-level pool

1. Using the IPAM admin account, open the IPAM console at https://console.aws.amazon.com/ipam/.

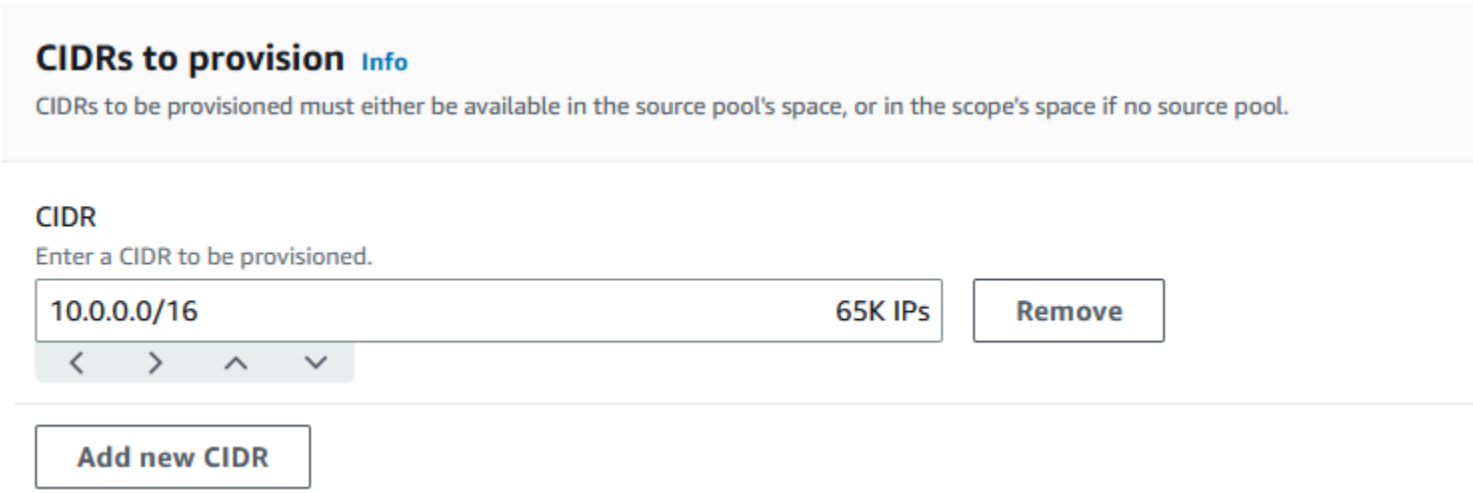
2. In the navigation pane, choose **Pools**.
3. Choose the private scope.



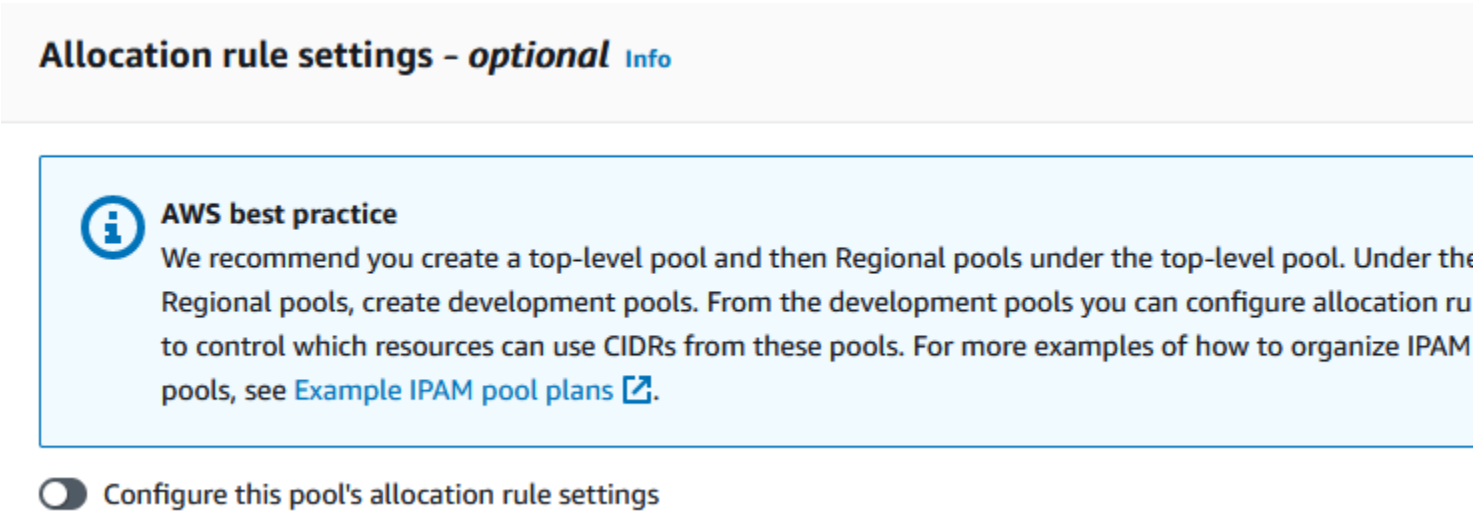
4. Choose **Create pool**.
5. Under **IPAM scope**, leave the private scope selected.
6. (Optional) Add a **Name tag** for the pool and a description for the pool, such as "Global pool".
7. Under **Source**, choose **IPAM scope**. Because this is our top level pool, it will not have a source pool.
8. Under **Address family**, choose **IPv4**.
9. Under **Resource planning**, leave **Plan IP space within the scope** selected. For more information about using this option to plan for subnet IP space within a VPC, see Tutorial: Plan VPC IP address space for subnet IP allocations.
10. For the **Locale**, choose **None**. Locales are the AWS Regions where you want this IPAM pool to be available for allocations. You'll set the locale for the Regional pools that you create in the next section of this tutorial.



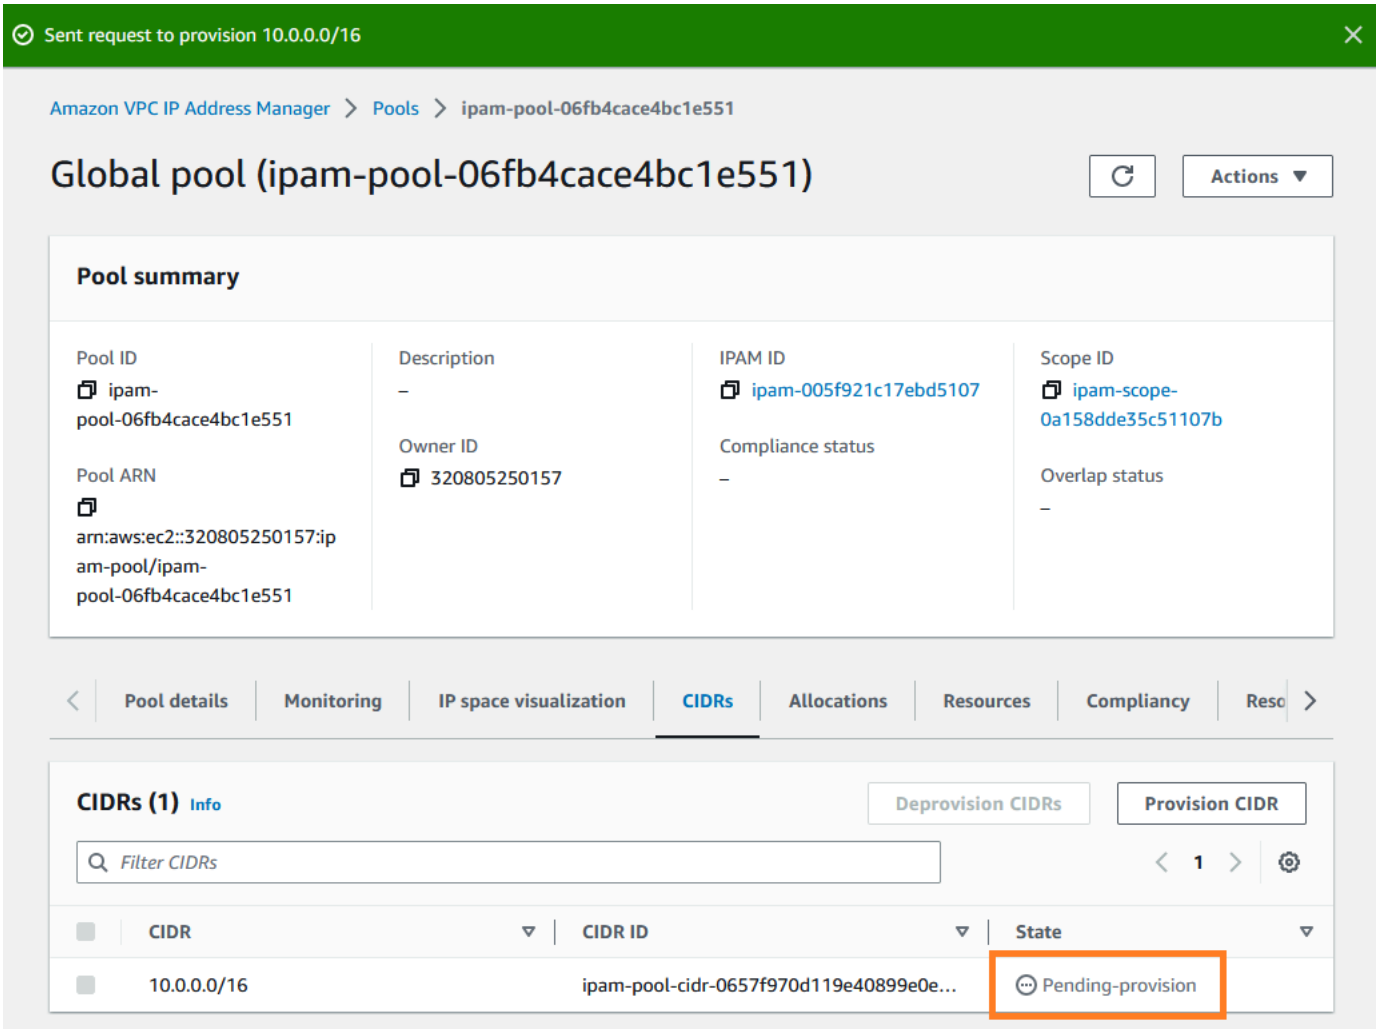
11. Choose a CIDR to provision for the pool. In this example, we provision 10.0.0.0/16.



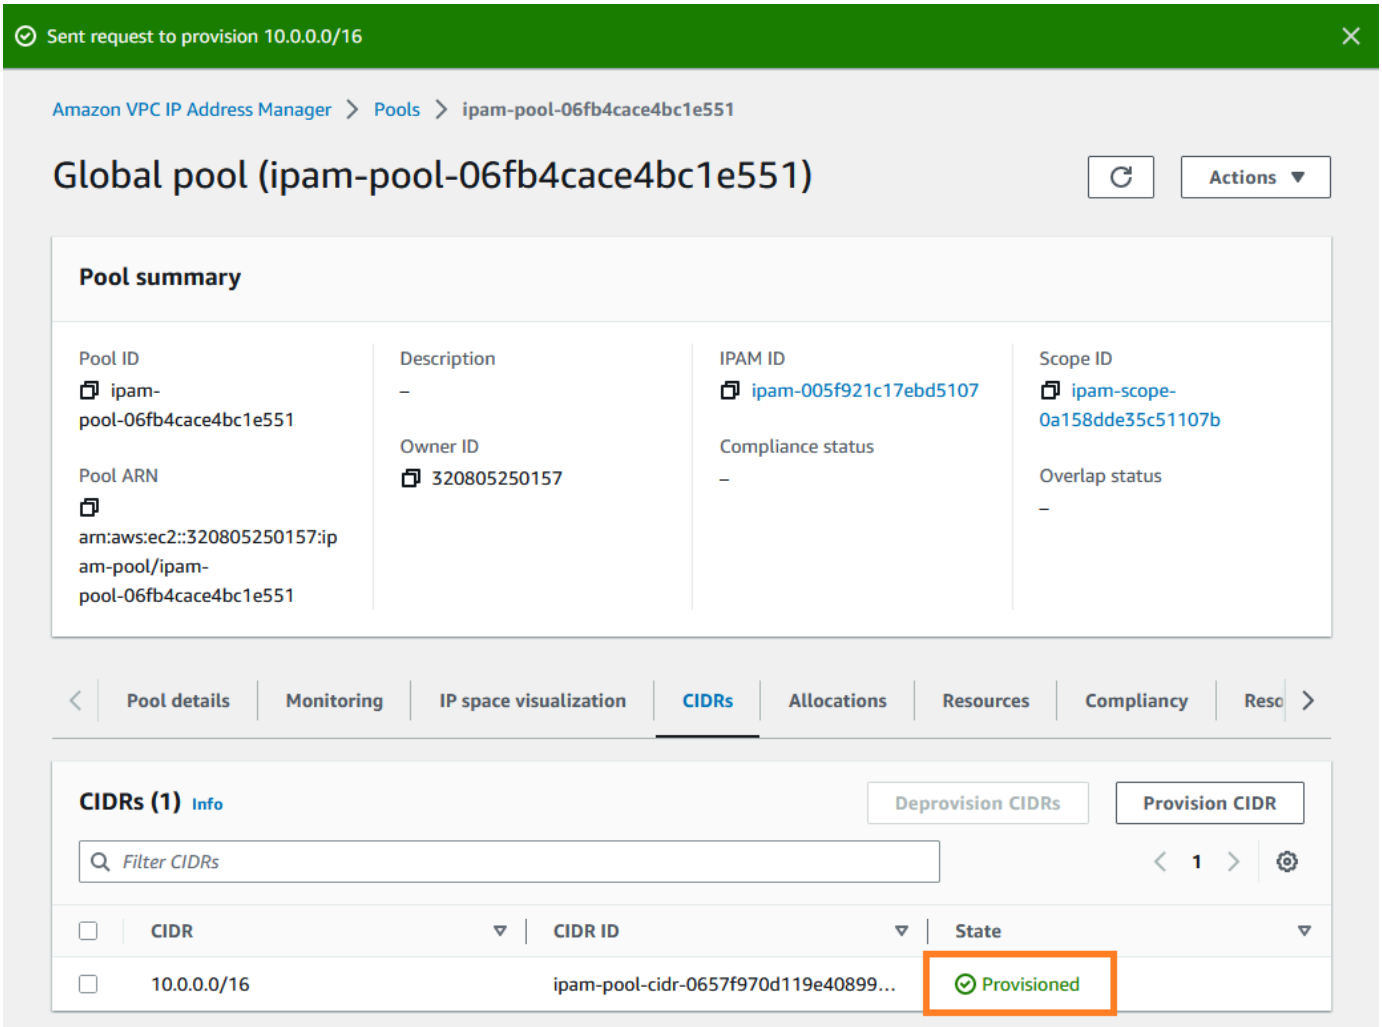
12. Leave **Configure this pool's allocation rule settings** disabled. This is our top-level pool, and you will not be allocating CIDRs to VPCs directly from this pool. Instead, you will allocate them from a sub-pool that you create from this pool.



13. Choose **Create pool**. The pool is created and the CIDR is in a **Pending-provision** state:



14. Wait for the state to be **Provisioned** before you go to the next step.



Now that you have created your top-level pool, you'll create Regional pools in us-west-1 and us-west-2.

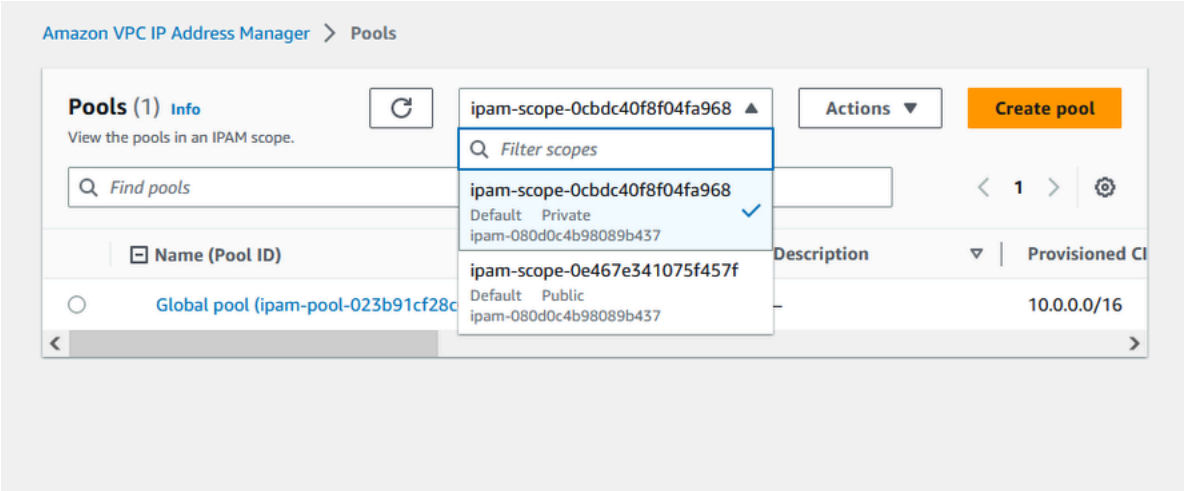
Step 4: Create Regional IPAM pools

This section shows you how to organize your IP addresses using two Regional pools. In this tutorial, we're following one of the example IPAM pool plans and creating two Regional pools which can be used by the member accounts in your organization for allocating CIDRs to their VPCs.

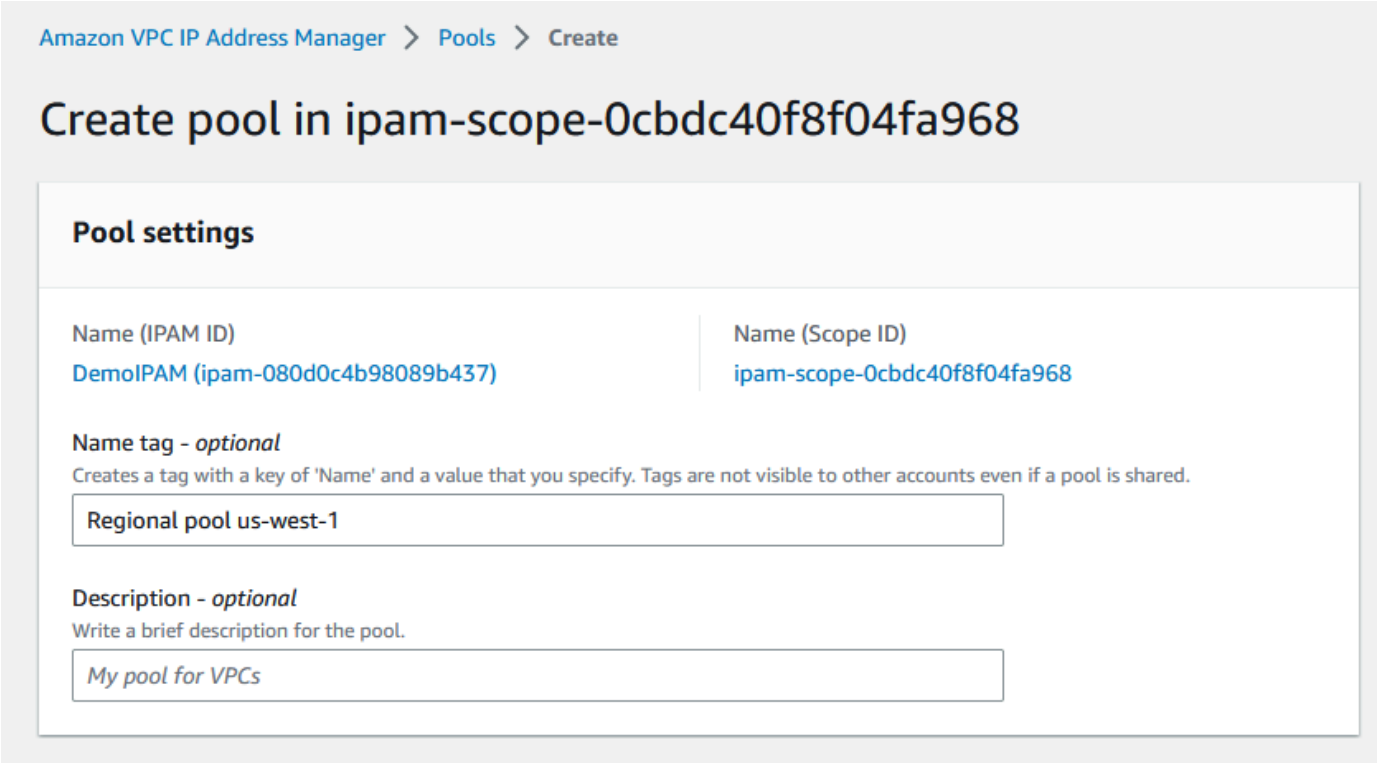
To create a Regional pool

1. Using the IPAM admin account, open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.

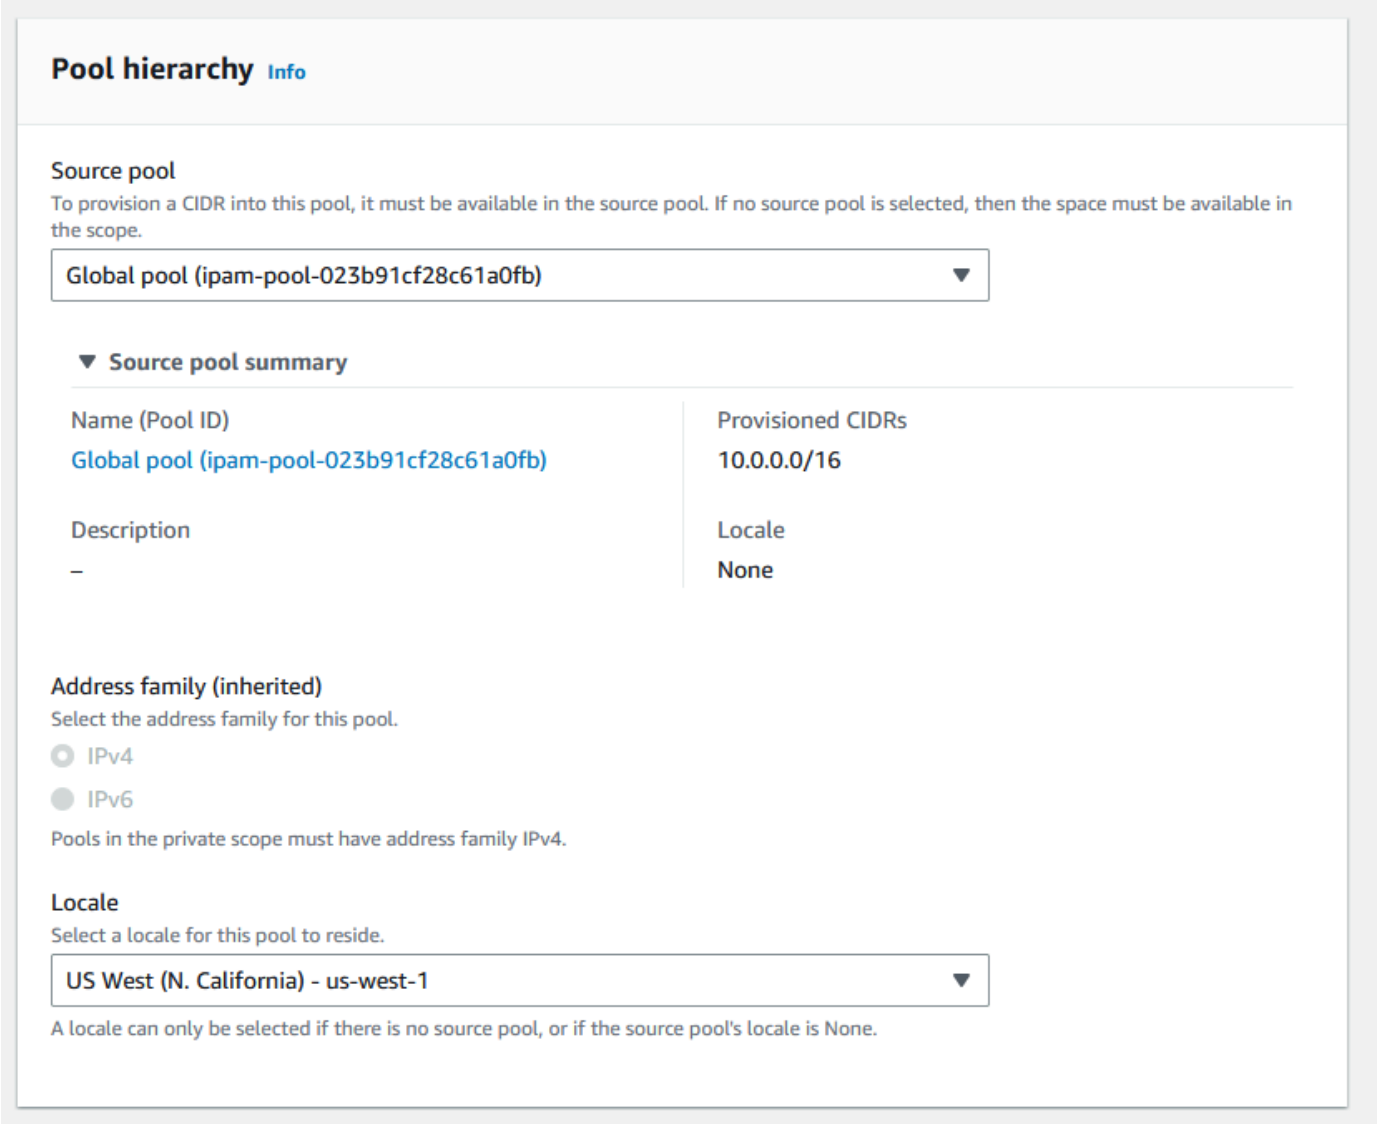
3. Choose the private scope.



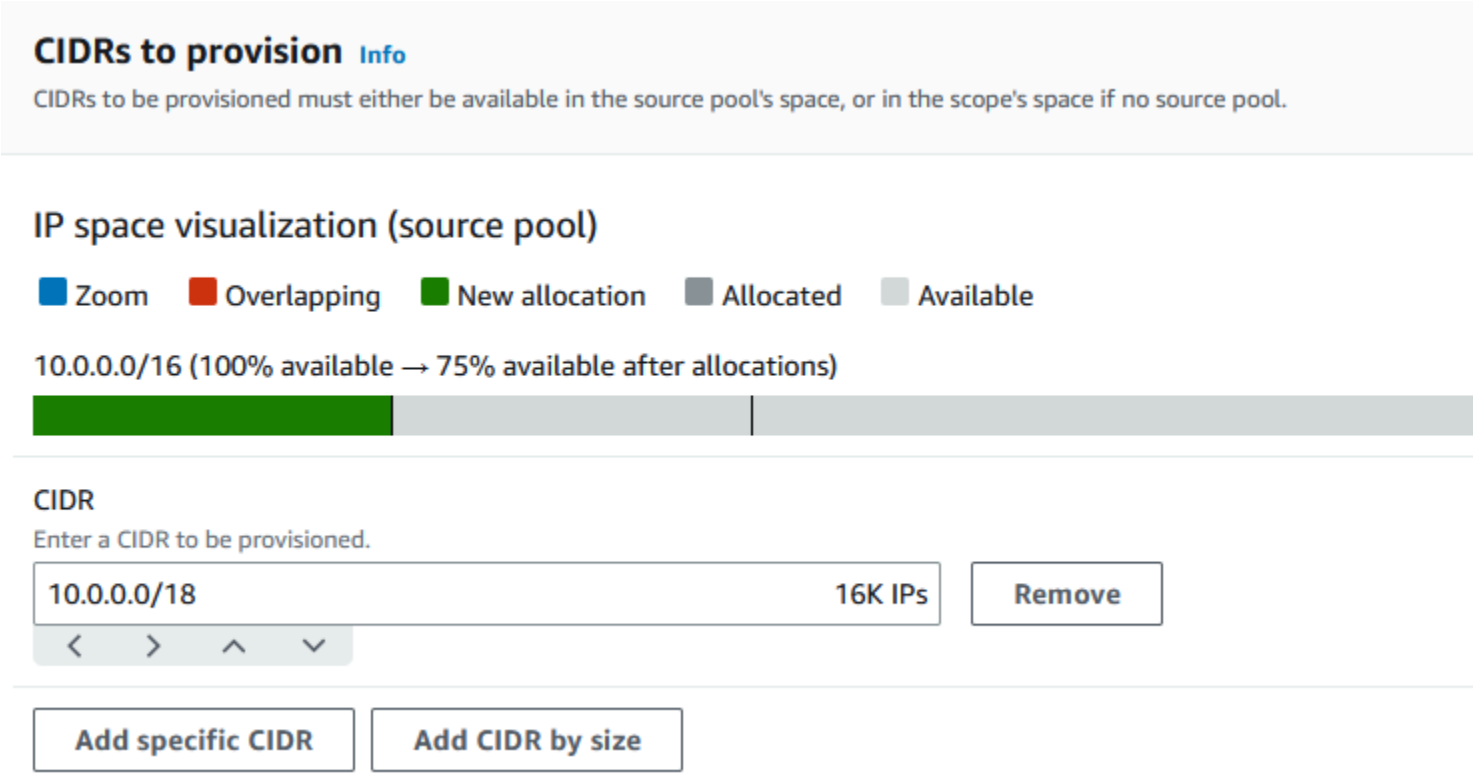
4. Choose **Create pool**.
5. Under **IPAM scope**, leave the private scope selected.
6. (Optional) Add a **Name tag** for the pool and a description for the pool, such as **Regional pool us-west-1**.



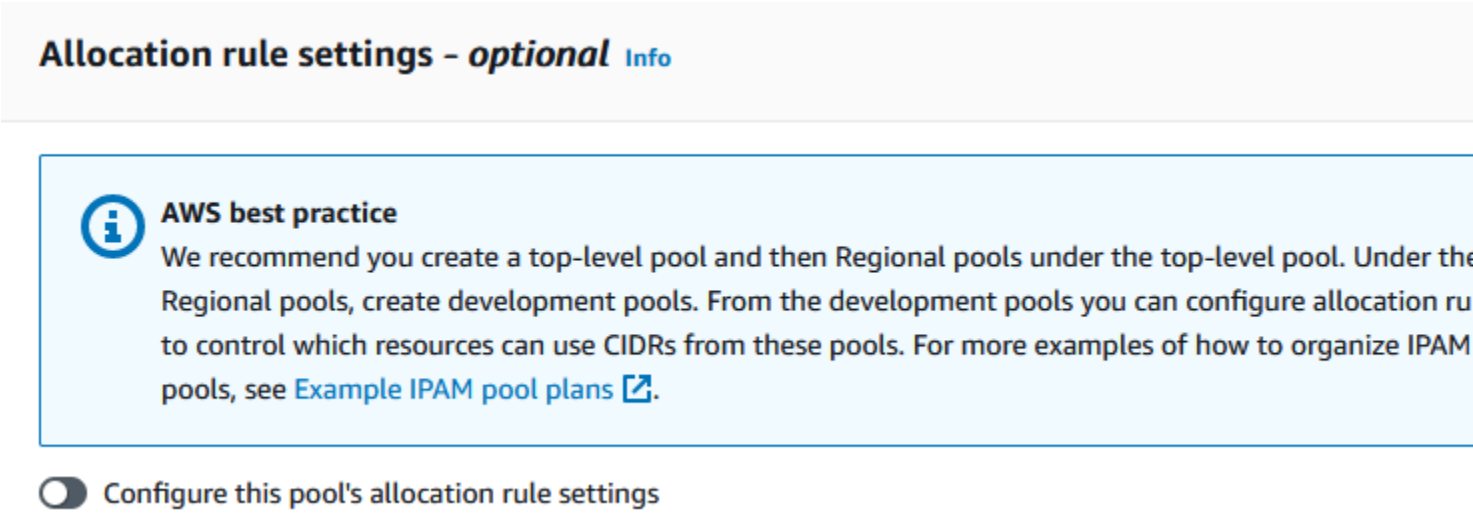
7. Under **Source**, select **IPAM pool** and select the top-level pool ("Global pool") that you created in Step 3: Create a top-level IPAM pool. Then, under **Locale**, choose **us-west-1**.



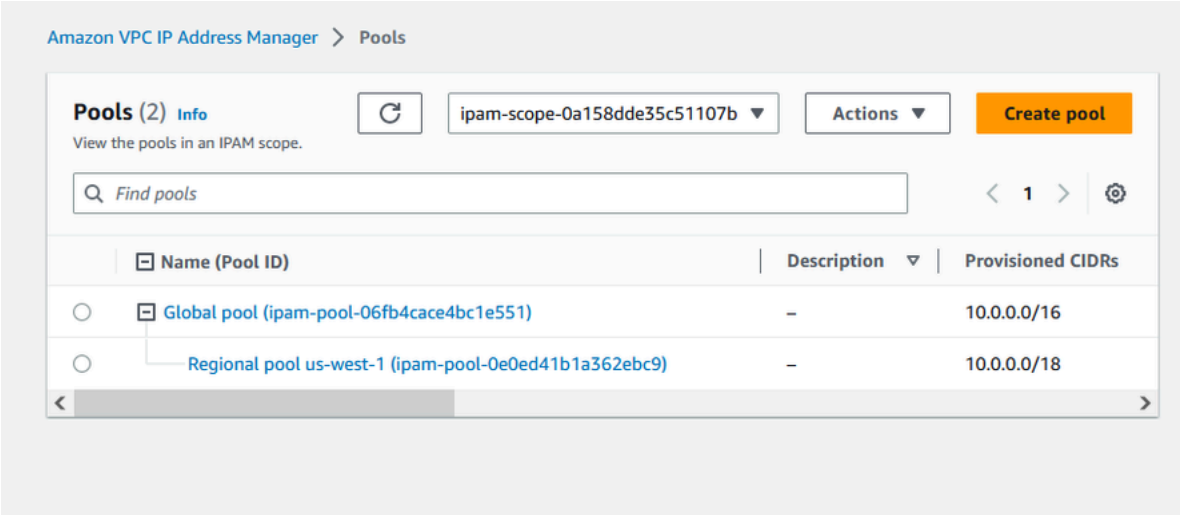
8. Under **Resource planning**, leave **Plan IP space within the scope** selected. For more information about using this option to plan for subnet IP space within a VPC, see Tutorial: Plan VPC IP address space for subnet IP allocations.
9. Under **CIDRs to provision**, enter 10.0.0.0/18, which will give this pool around 16,000 available IP addresses.



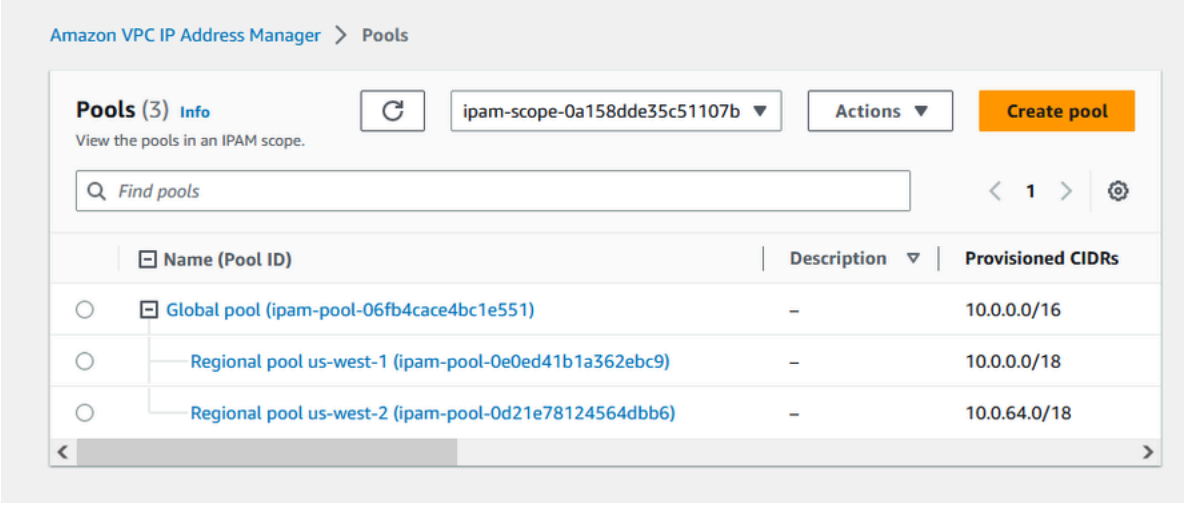
10. Leave **Configure this pool's allocation rule settings** disabled. You will not be allocating CIDRs to VPCs directly from this pool. Instead, you will allocate them from a sub-pool that you create from this pool.



11. Choose **Create pool**.
12. Return to the **Pools** view to see the hierarchy of IPAM pools that you've created.



13. Repeat the steps in this section and create a second Regional pool in **us-west-2** locale with the CIDR **10.0.64.0/18** provisioned to it. When you complete that process, you'll have three pools in a hierarchy similar to this one:

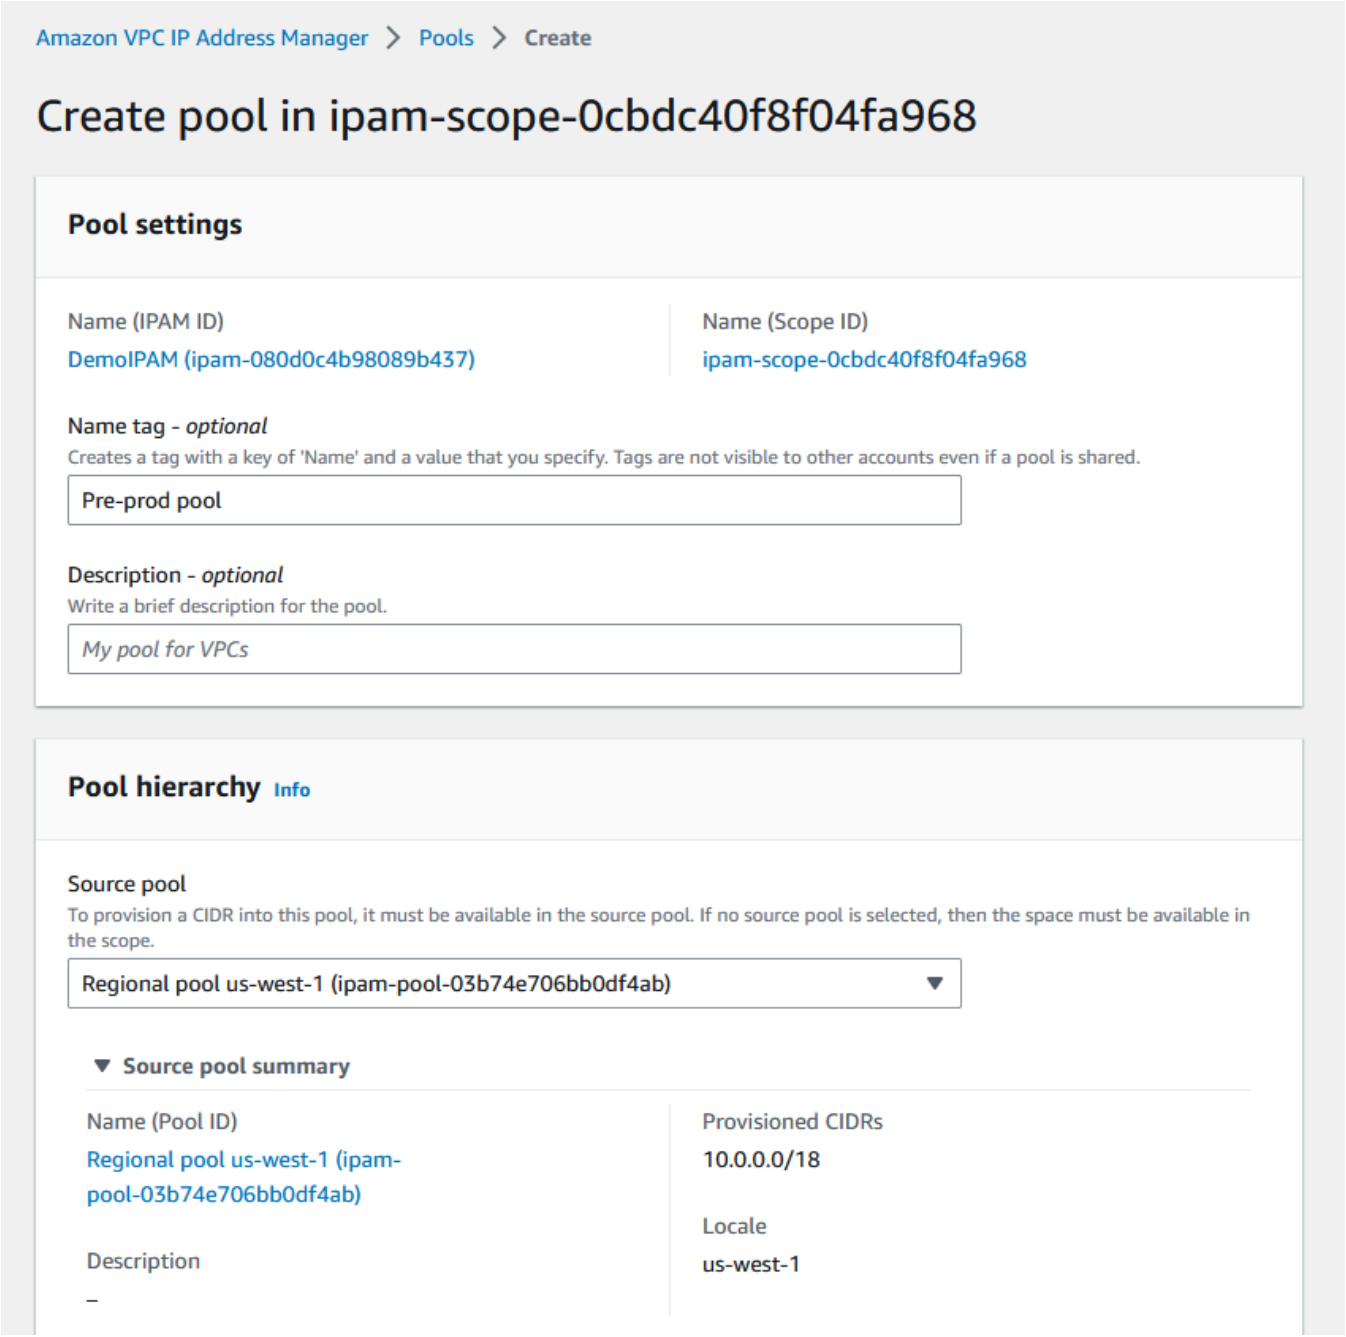


Step 5: Create a pre-production development pool

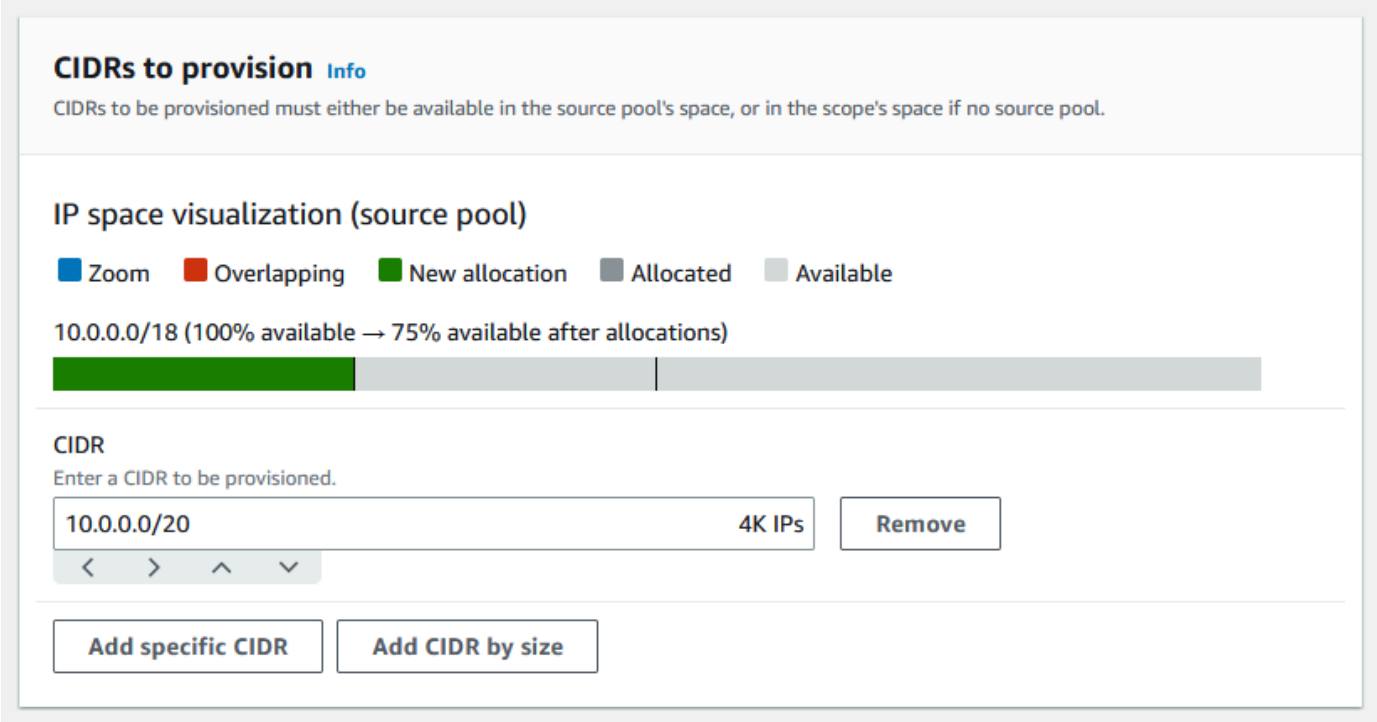
Follow the steps in this section to create a development pool for pre-production resources within one of your Regional pools.

To create a pre-production development pool

1. In the same way that you did in the previous section, using the IPAM admin account, create a pool called **Pre-prod pool**, but this time use **Regional pool us-west-1** as the source pool.

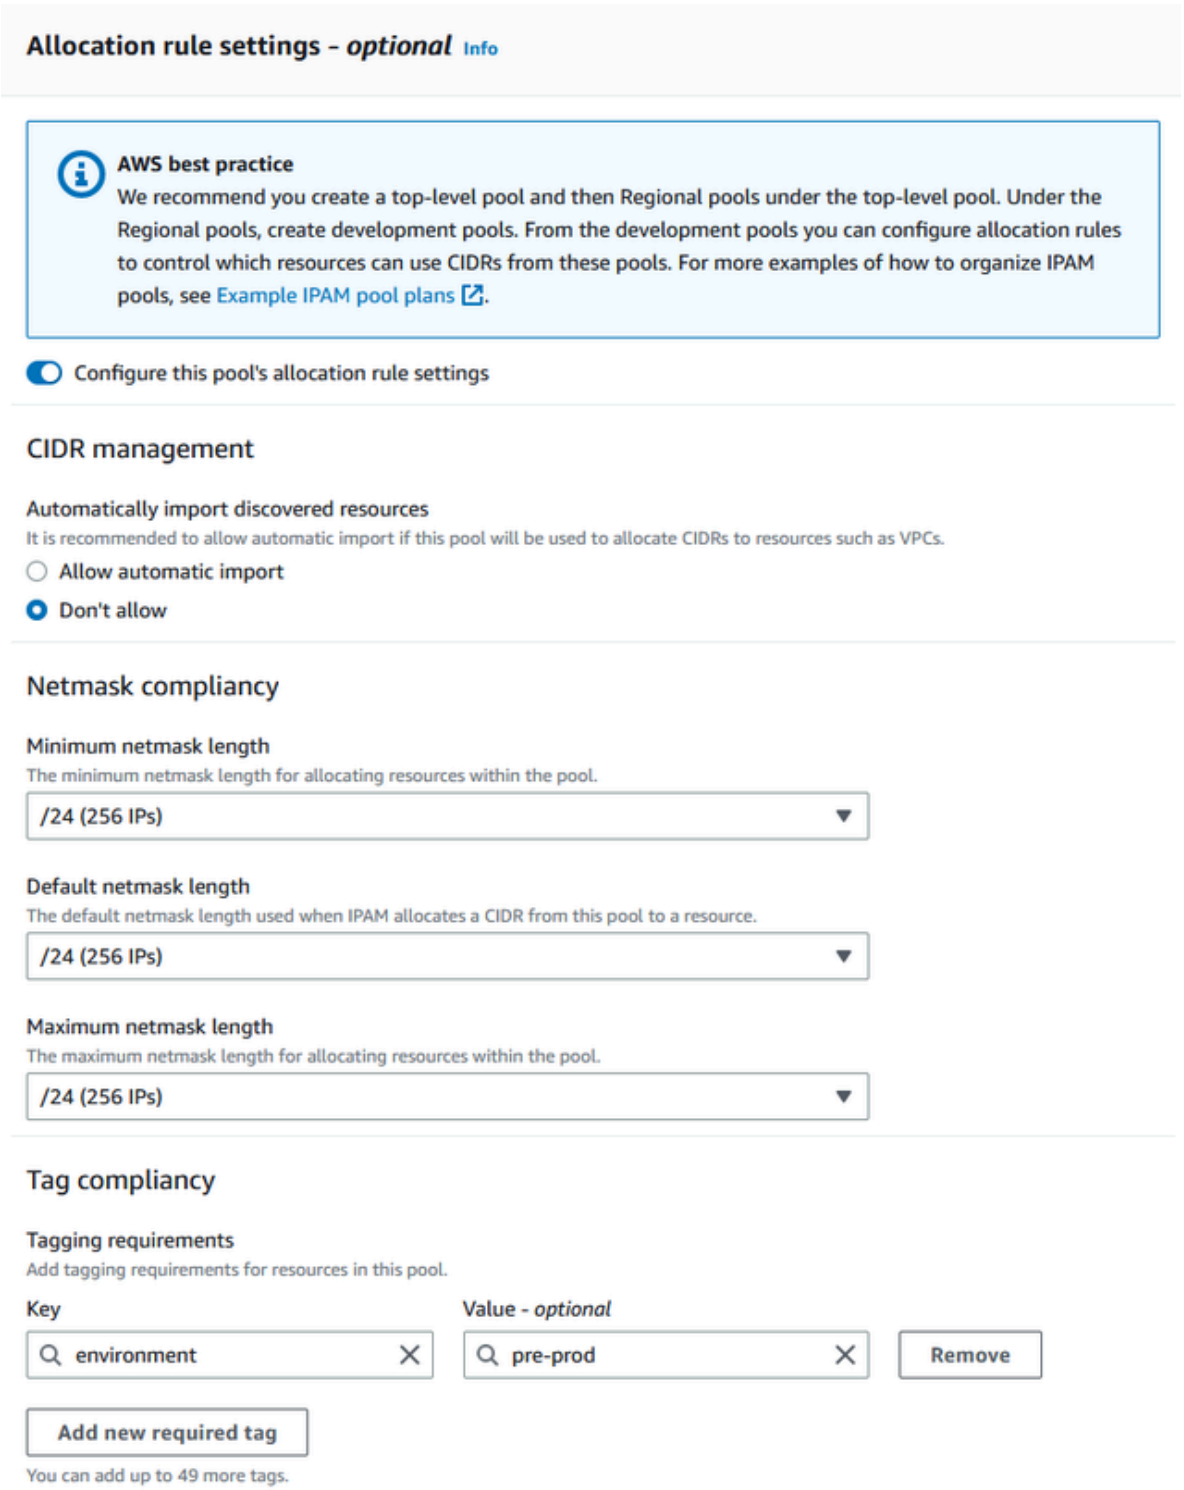


2. Specify a CIDR of 10.0.0.0/20 to provision, which will give this pool around 4,000 IP addresses.

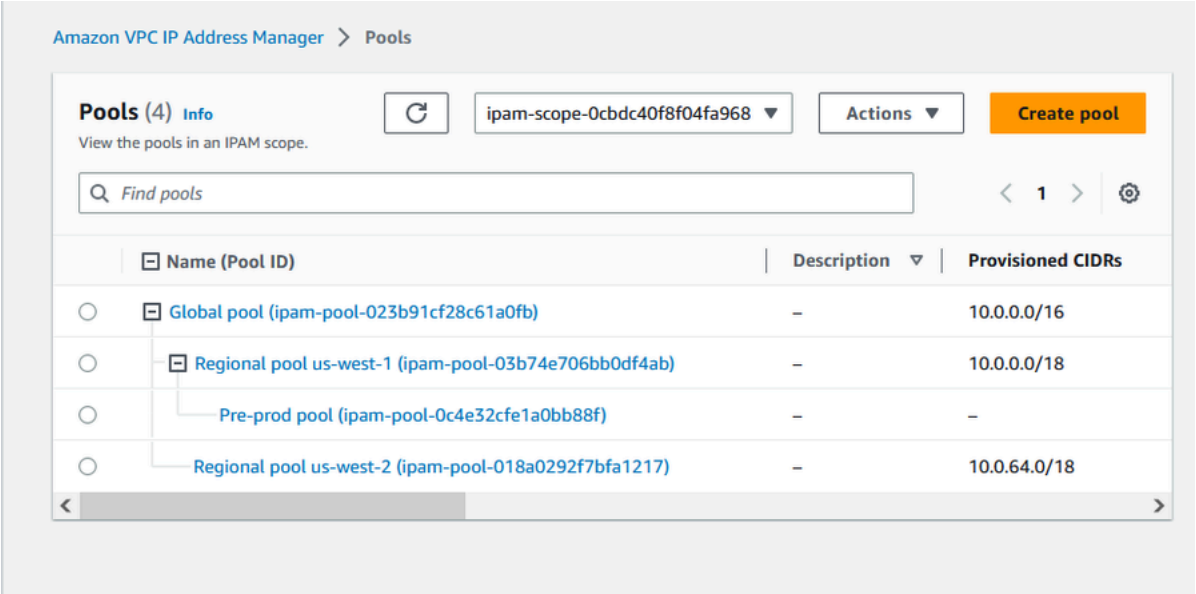


3. Toggle the option for **Configure this pool's allocation rule settings**. Do the following:

   1. Under **CIDR management**, for **Automatically import discovered resources**, leave the default **Don't allow** option selected. This option would enable IPAM to automatically import resource CIDRs it discovers in the pool's locale. A detailed description of this option is outside the scope of this tutorial, but you can read more about the option in Create a top-level IPv4 pool.
   2. Under **Netmask compliancy**, choose **/24** for the minimum, default, and maximum netmask length. A detailed description of this option is outside the scope of this tutorial, but you can read more about the option in Create a top-level IPv4 pool. What's important to note is that the VPC that you create later with a CIDR from this pool will be limited to /24 based on what we set here.
   3. Under **Tag compliance**, enter **environment/pre-prod**. This tag will be required for VPCs to allocate space from the pool. We will demonstrate later how this works.



4. Choose **Create pool**.
5. The pool hierarchy now includes an additional subpool under **Regional pool us-west-1**:



Now you're ready to share the IPAM pool with another member account in your organization and enable that account to allocate a CIDR from the pool to create a VPC.

Step 6: Share the IPAM pool

Follow the steps in this section to share the pre-production IPAM pool using AWS Resource Access Manager (RAM).

This section consists of two subsections:

- Step 6.1. Enable resource sharing in AWS RAM: This step must be done by the AWS Organizations management account.
- Step 6.2. Share an IPAM pool using AWS RAM: This step must be done by the IPAM admin.

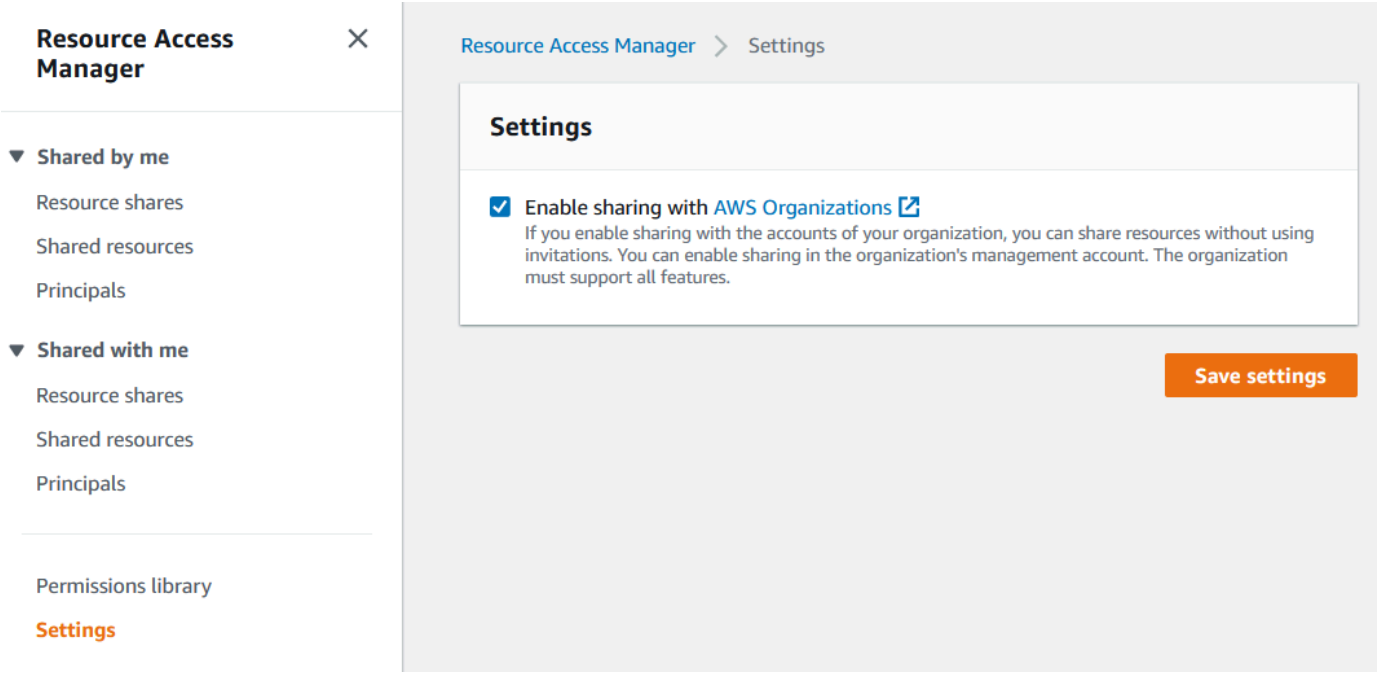
Step 6.1. Enable resource sharing in AWS RAM

After you create your IPAM, you'll want to share IP address pools with other accounts in your organization. Before you share an IPAM pool, complete the steps in this section to enable resource sharing with AWS RAM.

To enable resource sharing

1. Using the AWS Organizations management account, open the AWS RAM console at https://console.aws.amazon.com/ram/.

2. In the left navigation pane, choose **Settings**, choose **Enable sharing with AWS Organizations**, and then choose **Save settings**.



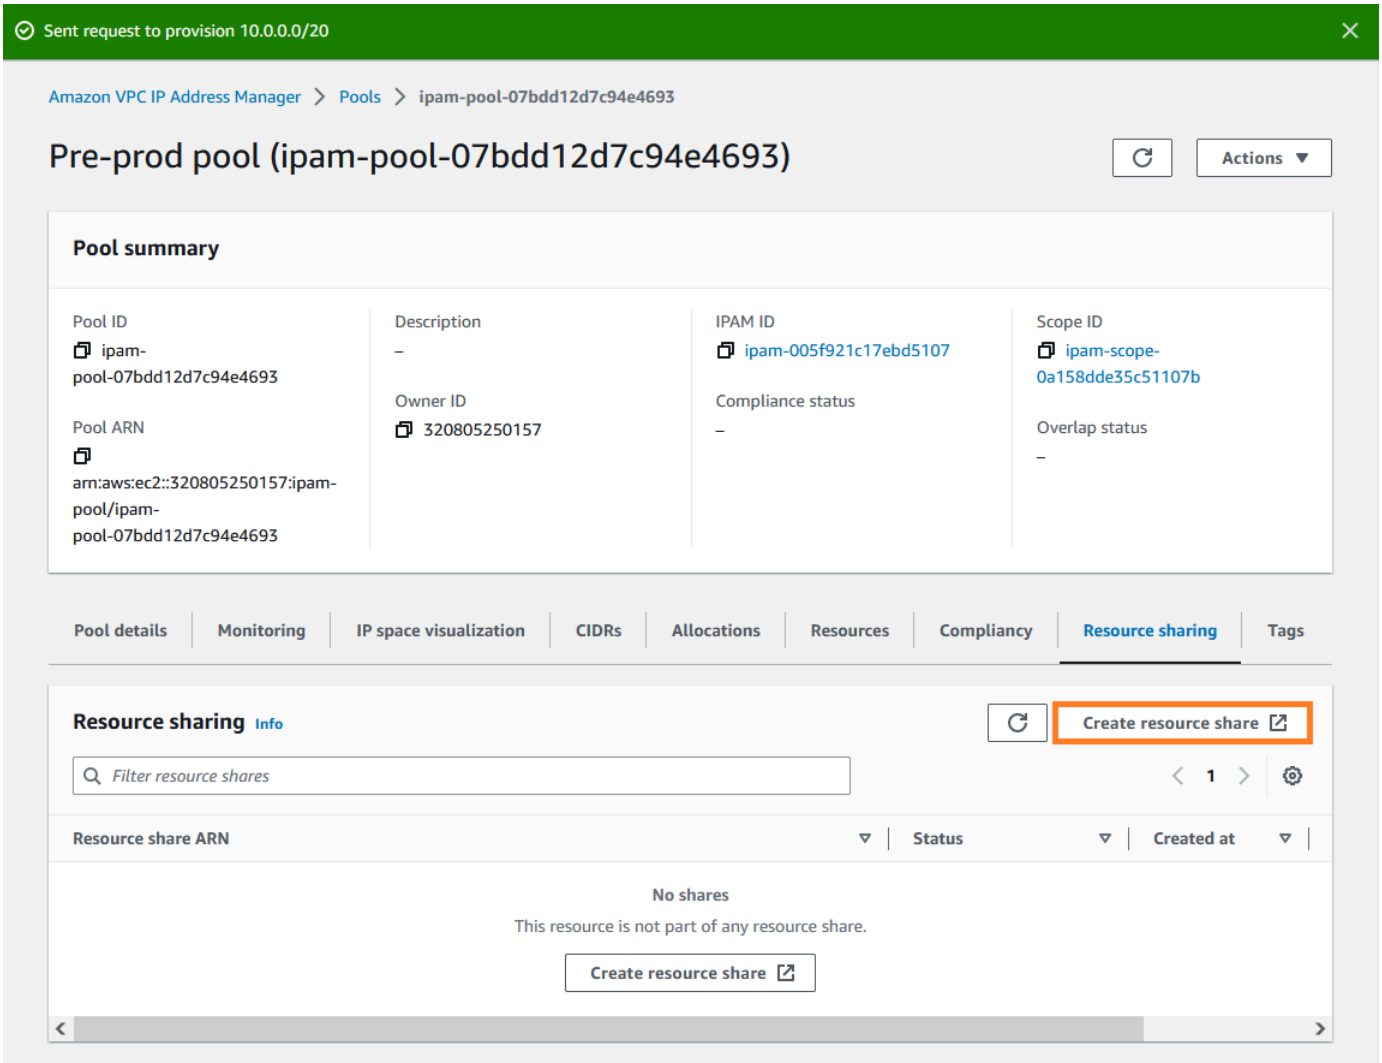
You can now share an IPAM pool with other members of the organization.

Step 6.2. Share an IPAM pool using AWS RAM

In this section you'll share the pre-production development pool with another AWS Organizations member account. For complete instructions on sharing IPAM pools, including information on the required IAM permissions, see Share an IPAM pool using AWS RAM.

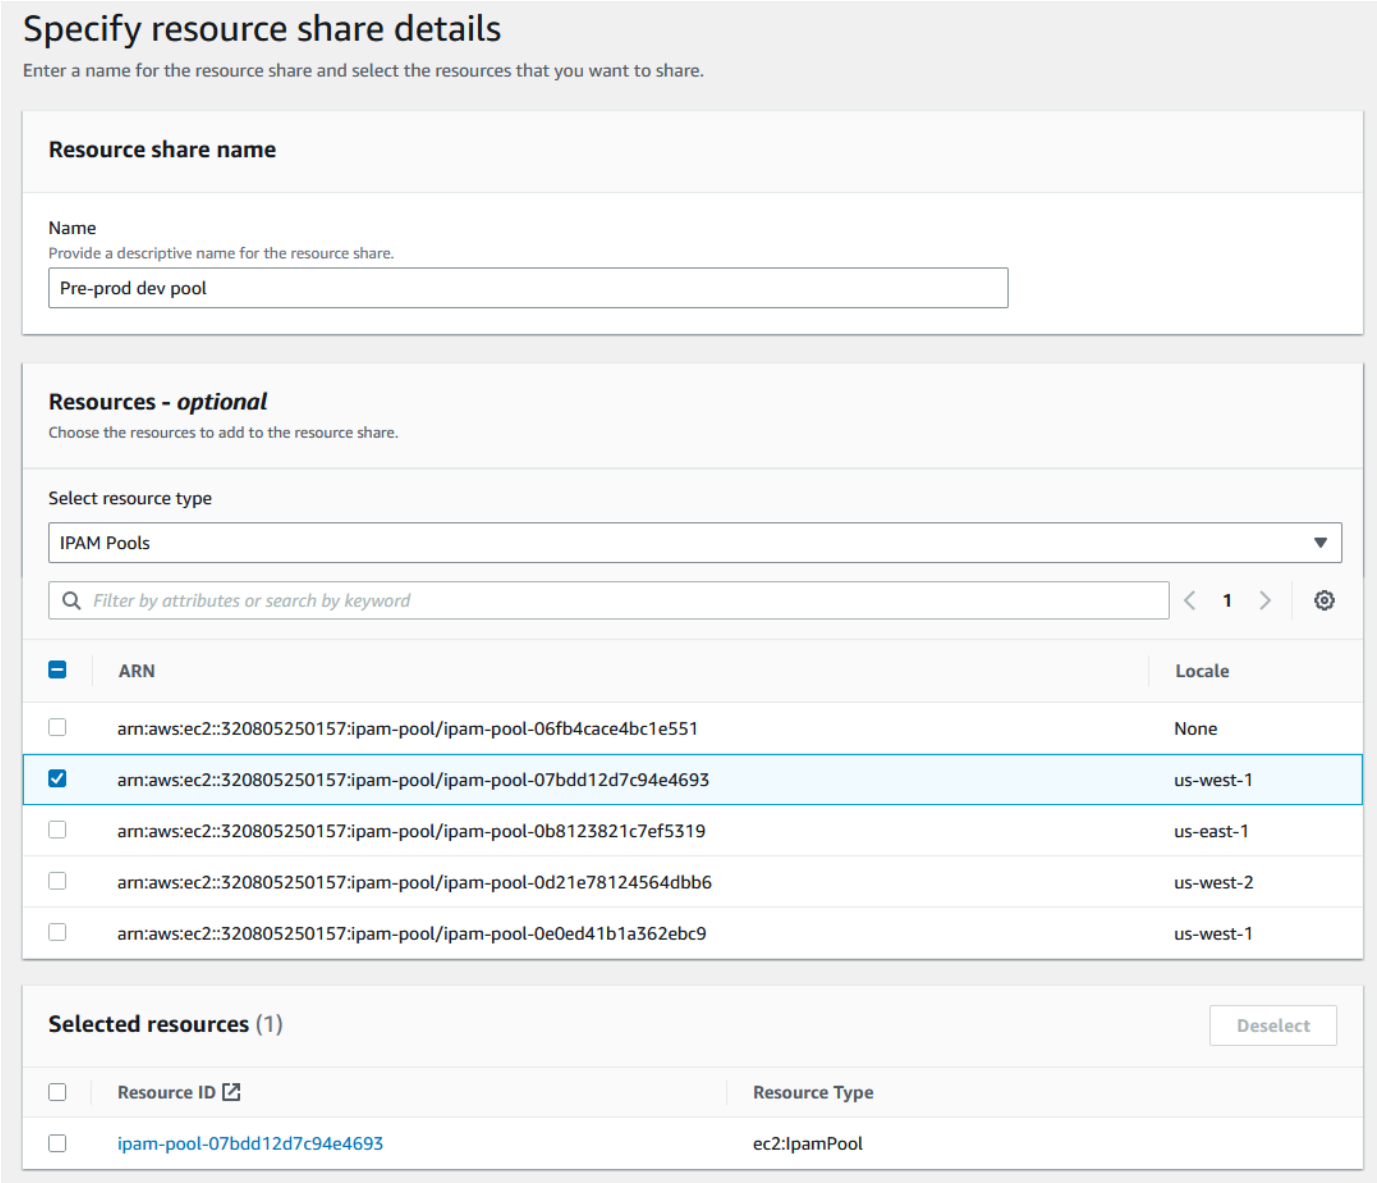
To share an IPAM pool using AWS RAM

1. Using the IPAM admin account, open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.
3. Choose the private scope, choose the pre-production IPAM pool, and choose **Actions** > **View details**.
4. Under **Resource sharing**, choose **Create resource share**. The AWS RAM console opens. You'll share the pool using AWS RAM.
5. Choose **Create a resource share**.

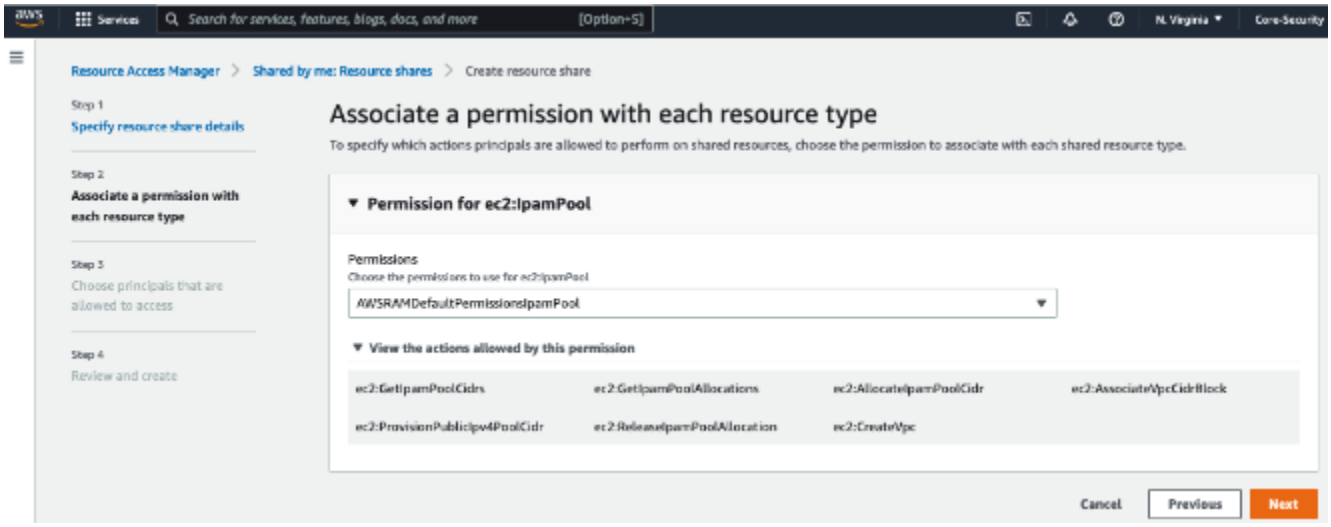


The AWS RAM console opens.

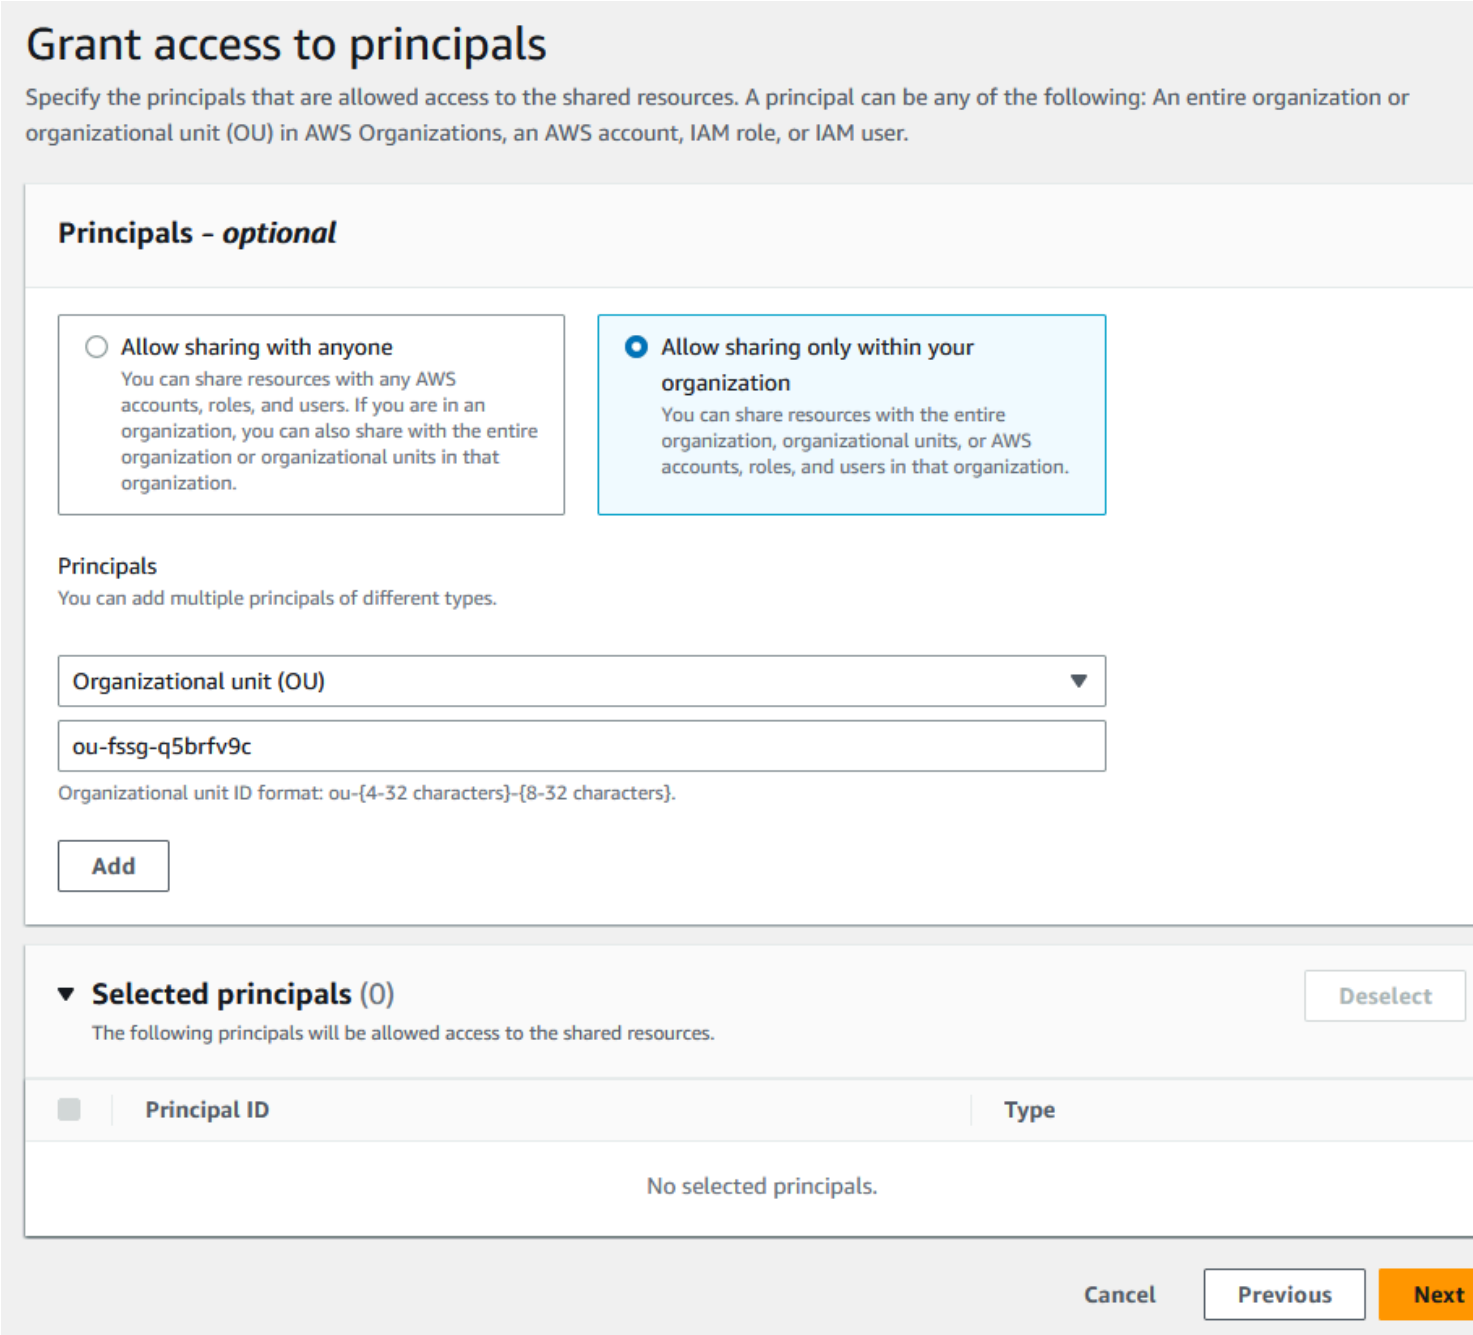
6. In the AWS RAM console, choose **Create a resource share** again.
7. Add a **Name** for the shared pool.
8. Under **Select resource type**, choose **IPAM pools,** and then choose the ARN of the pre-production development pool.



9. Choose **Next**.
10. Leave the default **AWSRAMDefaultPermissionsIpamPool** permission selected. The details of the permission options are out of scope for this tutorial, but you can find out more about these options in Share an IPAM pool using AWS RAM.



11. Choose **Next**.
12. Under **Principals**, choose **Allow sharing only within your organization.** Enter your AWS Organizations organization unit ID (as mentioned in How AWS Organizations integrates with IPAM, and then choose **Add** .



13. Choose **Next**.
14. Review the resource share options and the principals that you'll be sharing with, and then choose **Create**.

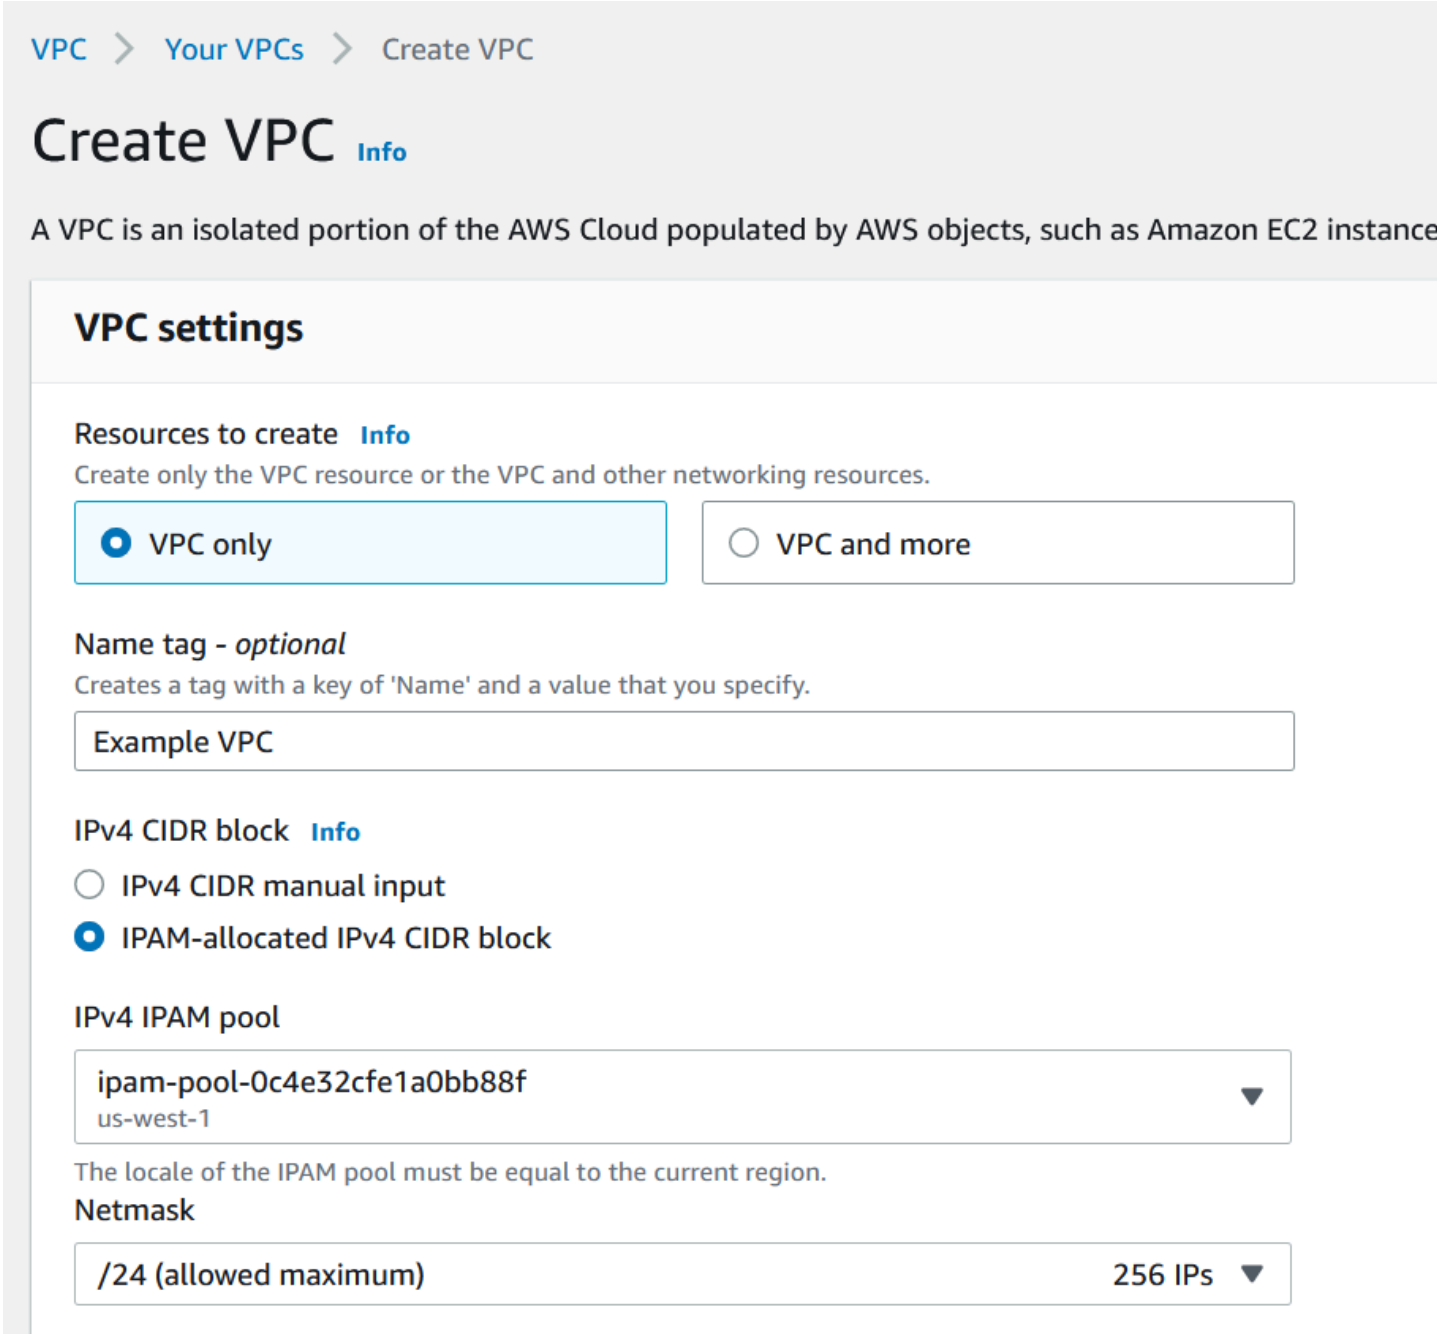
Now that the pool has been shared, go to the next step to create a VPC with a CIDR allocated from an IPAM pool.

Step 7: Create a VPC with a CIDR allocated from an IPAM pool

Follow the steps in this section to create a VPC with a CIDR allocated from the pre-production pool. This step should be completed by the member account in the OU that the IPAM pool was shared with in the previous section (called **example-member-account-2** in How AWS Organizations integrates with IPAM). For more information about the IAM permissions that are required to create VPCs, see Amazon VPC policy examples in the *Amazon VPC User Guide*.

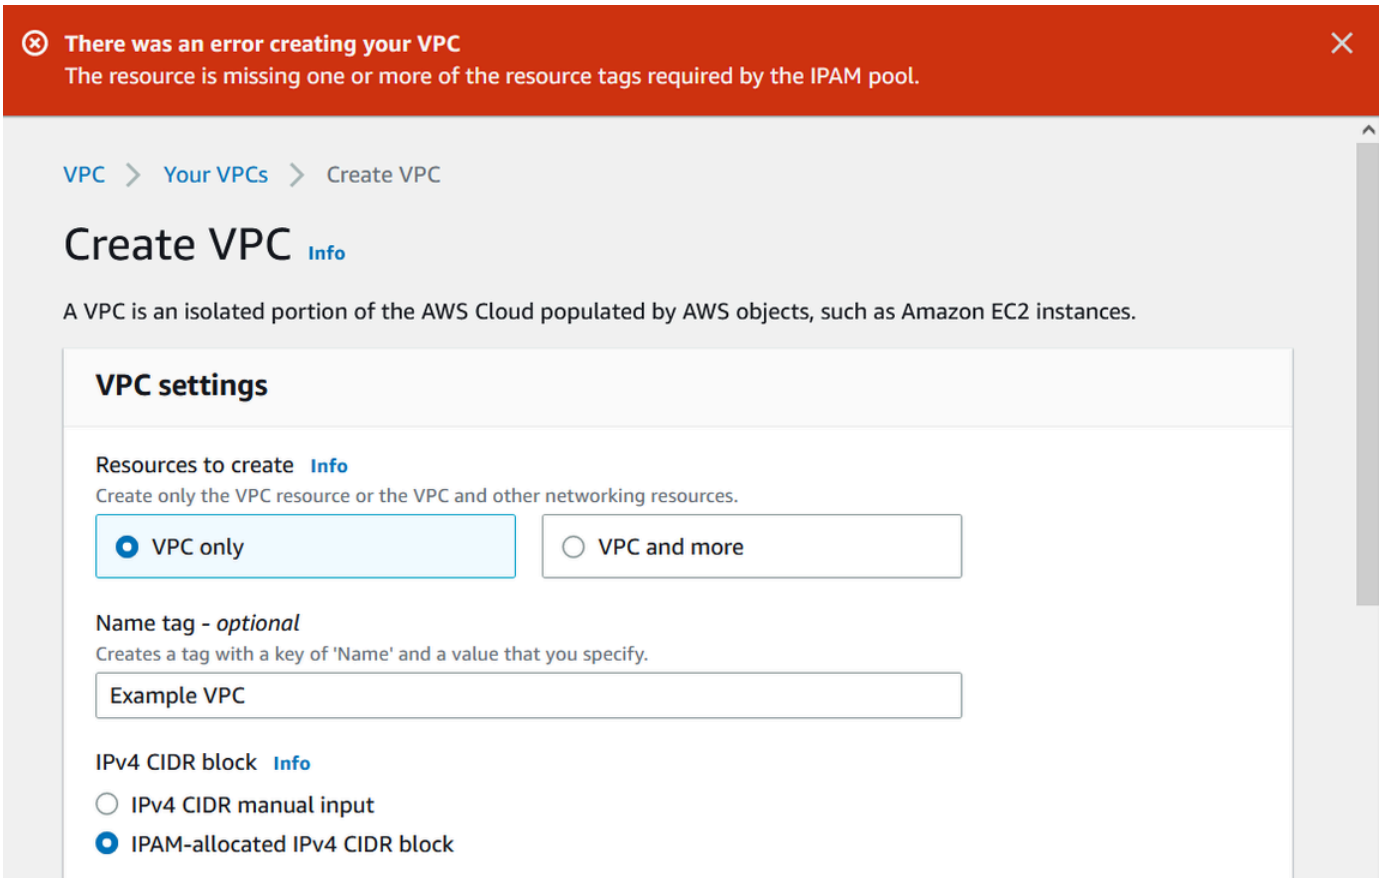
To create a VPC with a CIDR allocated from an IPAM pool

1. Using the member account, open the VPC console at https://console.aws.amazon.com/vpc/ as the member account that you'll use as the developer account.
2. Choose **Create VPC**.
3. Do the following:
    1. Enter a name, such as **Example VPC.**
    2. Choose **IPAM-allocated IPv4 CIDR block.**
    3. Under **IPv4 IPAM pool**, choose the ID of the pre-production pool.
    4. Choose a **Netmask** length. Because you limited the available netmask length for this pool to /24 (in Step 5: Create a pre-production development pool), the only netmask option available is /24.

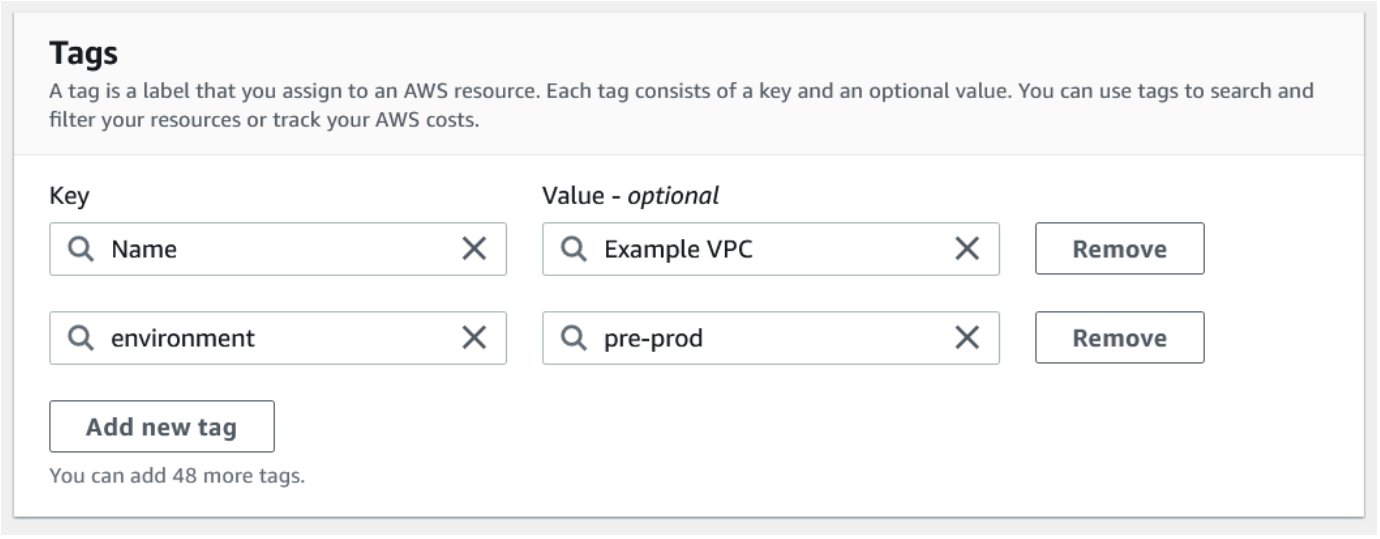


4. For demonstration purposes, under **Tags**, do not add any additional tags at this time. When you created the pre-prod pool (in Step 5: Create a pre-production development pool), you added an allocation rule that required any VPCs that are created with CIDRs from this pool to have an environment/pre-prod tag. Leave the environment/pre-prod tag off for now so that you can see that an error appears telling you that a required tag was not added.
5. Choose **Create VPC**.
6. An error appears telling you that a required tag was not added. The error appears because you set an allocation rule when you created the pre-prod pool (in Step 5: Create a pre-production

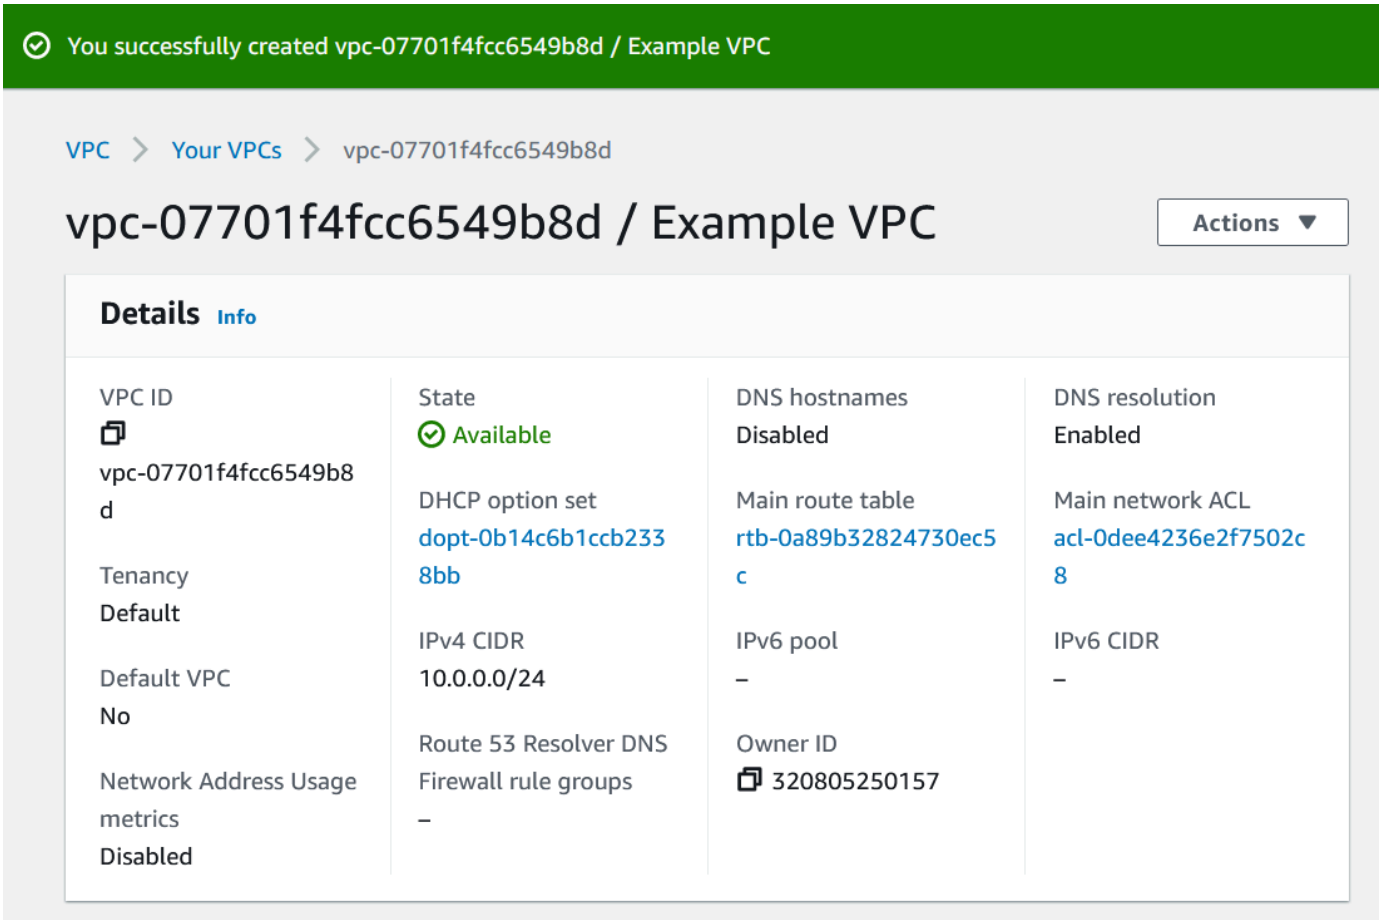
development pool). The allocation rule required any VPCs that are created with CIDRs from this pool to have an environment/pre-prod tag.



7. Now, under **Tags**, add the tag **environment/pre-prod** and choose **Create VPC** again.



8. The VPC is created successfully, and the VPC complies with the tag rule on the pre-production pool:



In the **Resources** pane of the IPAM console, the IPAM admin will be able to see and manage the VPC and its allocated CIDR. Note that it takes some time for the VPC to appear in the **Resources** pane.

Step 8: Cleanup

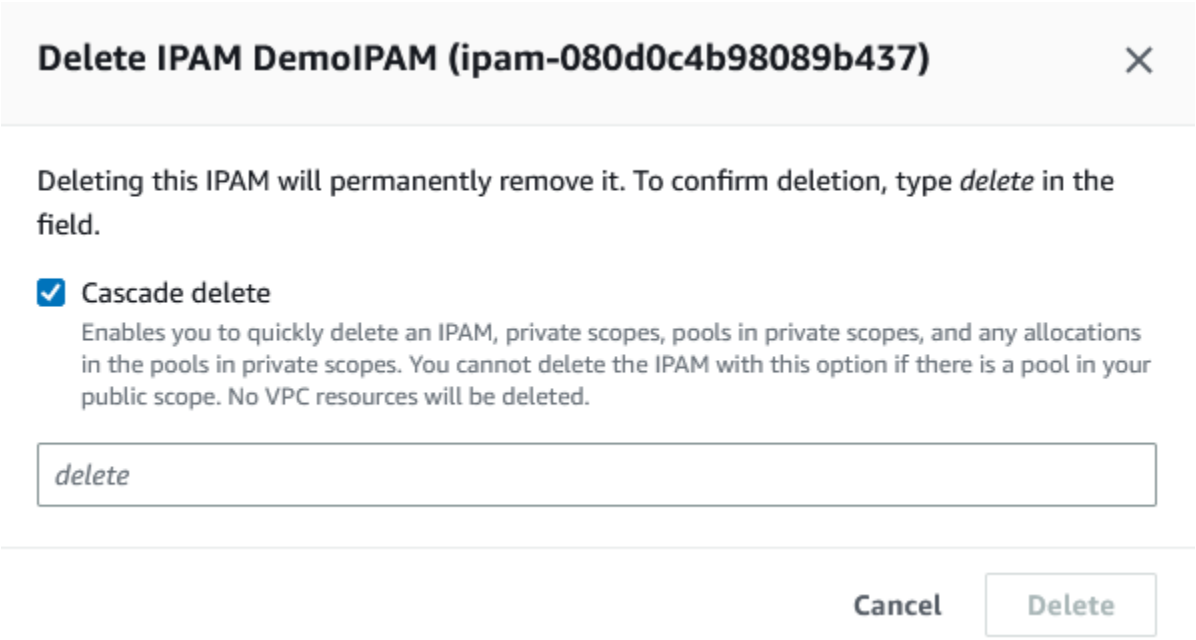
In this tutorial, you created an IPAM with a delegated admin, created multiple pools, and enabled a member account in your organization to allocate a VPC CIDR from a pool.

Follow the steps in this section to clean up the resources that you created in this tutorial.

To cleanup the resources created in this tutorial

1. Using the member account that created the example VPC, delete the VPC. For detailed instructions, see Delete your VPC in the *Amazon Virtual Private Cloud User Guide*.

2. Using the IPAM admin account, delete the example resource share in the AWS RAM console. For detailed instructions, see Deleting a resource share in AWSAWS RAM in the *AWS Resource Access Manager User Guide*.
3. Using the IPAM admin account, log into the RAM console and disable sharing with AWS Organizations that you enable in Step 6.1. Enable resource sharing in AWS RAM.
4. Using the IPAM admin account, delete the example IPAM by selecting the IPAM in the IPAM console and then choosing **Actions** > **Delete**. For detailed instructions, see Delete an IPAM.
5. When you're prompted to delete the IPAM, choose **Cascade delete**. This will delete all scopes and pools within the IPAM before deleting the IPAM.



6. Enter **delete** and then choose **Delete**.
7. Using the AWS Organizations management account, log into the IPAM console, choose **Settings**, and remove the delegated administrator account.
8. (Optional) When you integrate IPAM with AWS Organizations, IPAM automatically creates a service-linked role in each member account. Using each AWS Organizations member account, log into IAM and delete the **AWSServiceRoleForIPAM** service linked role in each member account.
9. Cleanup is complete.

Tutorial: Create an IPAM and pools using the AWS CLI

Follow the steps in this tutorial to use the AWS CLI to create an IPAM, create IP address pools, and allocate a VPC with a CIDR from an IPAM pool.

The following is an example hierarchy of the pool structure that you will create by following the steps in this section:

- IPAM operating in AWS Region 1, AWS Region 2
  - Private scope
    - Top-level pool
      - Regional pool in AWS Region 2
        - Development pool
          - Allocation for a VPC

> **Note**
>
> In this section, you'll create an IPAM. You can only create one IPAM per AWS Region. For more information, see Quotas for your IPAM. If you have already delegated an IPAM account and created an IPAM, you can skip steps 1 and 2.

Contents

Step 1: Enable IPAM in your organization

This step is optional. Complete this step to enable IPAM in your organization and configure your delegated IPAM using the AWS CLI. For more information about the role of the IPAM account, see Integrate IPAM with accounts in an AWS Organization.

This request must be made from an AWS Organizations management account. When you run the following command, ensure that you're using a role with an IAM policy that permits the following actions:

- `ec2:EnableIpamOrganizationAdminAccount`
- `organizations:EnableAwsServiceAccess`
- `organizations:RegisterDelegatedAdministrator`
- `iam:CreateServiceLinkedRole`

```
aws ec2 enable-ipam-organization-admin-account --region us-east-1 --delegated-admin-
account-id 11111111111
```

You should see the following output, indicating that enabling was successful.

```
{
    "Success": true
}
```

Step 2: Create an IPAM

Follow the steps in this section to create an IPAM and view additional information about the scopes that are created. You will use this IPAM when you create pools and provision IP address ranges for those pools in later steps.

> **Note**
>
> The operating Regions option determines which AWS Regions the IPAM pools can be used for. For more information about operating Regions, see Create an IPAM.

To create an IPAM using the AWS CLI

1. Run the following command to create the IPAM instance.

```
aws ec2 create-ipam --description my-ipam --region us-east-1 --operating-
regions RegionName=us-west-2
```

When you create an IPAM, AWS automatically does the following:

- Returns a globally unique resource ID (`IpamId`) for the IPAM.
- Creates a default public scope (`PublicDefaultScopeId`) and a default private scope (`PrivateDefaultScopeId`).

```
{

    "Ipam": {
        "OwnerId": "123456789012",
        "IpamId": "ipam-0de83dba6694560a9",
        "IpamArn": "arn:aws:ec2::123456789012:ipam/ipam-0de83dba6694560a9",
        "PublicDefaultScopeId": "ipam-scope-02a24107598e982c5",
        "PrivateDefaultScopeId": "ipam-scope-065e7dfe880df679c",
        "ScopeCount": 2,
        "Description": "my-ipam",
        "OperatingRegions": [
            {
                "RegionName": "us-west-2"
            },
            {
                "RegionName": "us-east-1"
            }
        ],
        "Tags": []
    }
}
```

2. Run the following command to view additional information related to the scopes. The public scope is intended for IP addresses that are going to be accessed through the public internet. The private scope is intended for IP addresses that are not going to be accessed through the public internet.

```
aws ec2 describe-ipam-scopes --region us-east-1
```

In the output, you see the available scopes. You'll use the private scope ID in the next step.

```
{
    "IpamScopes": [
        {
            "OwnerId": "123456789012",
            "IpamScopeId": "ipam-scope-02a24107598e982c5",
            "IpamScopeArn": "arn:aws:ec2::123456789012:ipam-scope/ipam-
scope-02a24107598e982c5",
            "IpamArn": "arn:aws:ec2::123456789012:ipam/ipam-0de83dba6694560a9",
            "IpamScopeType": "public",
            "IsDefault": true,
            "PoolCount": 0
        },
        {
            "OwnerId": "123456789012",
            "IpamScopeId": "ipam-scope-065e7dfe880df679c",
            "IpamScopeArn": "arn:aws:ec2::123456789012:ipam-scope/ipam-
scope-065e7dfe880df679c",
            "IpamArn": "arn:aws:ec2::123456789012:ipam/ipam-0de83dba6694560a9",
            "IpamScopeType": "private",
            "IsDefault": true,
            "PoolCount": 0
        }
    ]
}
```

Step 3: Create an IPv4 address pool

Follow the steps in this section to create an IPv4 address pool.

Important

You won't use the `--locale` option on this top-level pool. You will set the locale option later on the Regional pool. The locale is the AWS Region where you want a pool to be available for CIDR allocations. As a result of not setting the locale on the top-level pool, the locale will default to None. If a pool has a locale of None, the pool won't be available to

VPC resources in any AWS Region. You can only manually allocate IP address space in the pool to reserve space.

To create an IPv4 address pool for all of your AWS resources using the AWS CLI

1. Run the following command to create an IPv4 address pool. Use the ID of the private scope of the IPAM that you created in the previous step.

```
aws ec2 create-ipam-pool --ipam-scope-id ipam-scope-065e7dfe880df679c --
description "top-level-pool" --address-family ipv4
```

   In the output, you'll see a state of `create-in-progress` for the pool.

```
{
    "IpamPool": {
        "OwnerId": "123456789012",
        "IpamPoolId": "ipam-pool-0008f25d7187a08d9",
        "IpamPoolArn": "arn:aws:ec2::123456789012:ipam-pool/ipam-
pool-0008f25d7187a08d9",
        "IpamScopeArn": "arn:aws:ec2::123456789012:ipam-scope/ipam-
scope-065e7dfe880df679c",
        "IpamScopeType": "private",
        "IpamArn": "arn:aws:ec2::123456789012:ipam/ipam-0de83dba6694560a9",
        "Locale": "None",
        "PoolDepth": 1,
        "State": "create-in-progress",
        "Description": "top-level-pool",
        "AutoImport": false,
        "AddressFamily": "ipv4",
        "Tags": []
    }
}
```

2. Run the following command until you see a state of `create-complete` in the output.

```
aws ec2 describe-ipam-pools
```

   The following example output shows the correct state.

```
{
```

```
    "IpamPools": [
        {
            "OwnerId": "123456789012",
            "IpamPoolId": "ipam-pool-0008f25d7187a08d9",
            "IpamPoolArn": "arn:aws:ec2::123456789012:ipam-pool/ipam-
pool-0008f25d7187a08d9",
            "IpamScopeArn": "arn:aws:ec2::123456789012:ipam-scope/ipam-
scope-065e7dfe880df679c",
            "IpamScopeType": "private",
            "IpamArn": "arn:aws:ec2::123456789012:ipam/ipam-0de83dba6694560a9",
            "Locale": "None",
            "PoolDepth": 1,
            "State": "create-complete",
            "Description": "top-level-pool",
            "AutoImport": false,
            "AddressFamily": "ipv4"
        }
    ]
}
```

Step 4: Provision a CIDR to the top-level pool

Follow the steps in this section to provision a CIDR to the top-level pool, and then verify that the CIDR is provisioned. For more information, see Provision CIDRs to a pool.

To provision a CIDR block to the pool using the AWS CLI

1. Run the following command to provision the CIDR.

```
aws ec2 provision-ipam-pool-cidr --region us-east-1 --ipam-pool-id ipam-
pool-0008f25d7187a08d9 --cidr 10.0.0.0/8
```

   In the output, you can verify the state of the provisioning.

```
{
    "IpamPoolCidr": {
        "Cidr": "10.0.0.0/8",
        "State": "pending-provision"
    }
}
```

2. Run the following command until you see a state of `provisioned` in the output.

```
aws ec2 get-ipam-pool-cidrs --region us-east-1 --ipam-pool-id ipam-
pool-0008f25d7187a08d9
```

The following example output shows the correct state.

```
{
    "IpamPoolCidrs": [
        {
            "Cidr": "10.0.0.0/8",
            "State": "provisioned"
        }
    ]
}
```

Step 5. Create a Regional pool with CIDR sourced from the top-level pool

When you create an IPAM pool, the pool belongs to the AWS Region of the IPAM by default. When you create a VPC, the pool that the VPC draws from must be in the same Region as the VPC. You can use the `--locale` option when you create a pool to make the pool available to services in a Region other than the Region of the IPAM. Follow the steps in this section to create a Regional pool in another locale.

To create a pool with a CIDR sourced from the previous pool using the AWS CLI

1. Run the following command to create the pool and insert space with a known available CIDR from the previous pool.

```
aws ec2 create-ipam-pool --description "regional--pool" --region us-east-1 --ipam-
scope-id ipam-scope-065e7dfe880df679c --source-ipam-pool-id
ipam-pool-0008f25d7187a08d9 --locale us-west-2 --address-family ipv4
```

In the output, you'll see the ID of the pool that you created. You'll need this ID in the next step.

```
{
    "IpamPool": {
```

```
        "OwnerId": "123456789012",
        "IpamPoolId": "ipam-pool-0da89c821626f1e4b",
        "SourceIpamPoolId": "ipam-pool-0008f25d7187a08d9",
        "IpamPoolArn": "arn:aws:ec2::123456789012:ipam-pool/ipam-
pool-0da89c821626f1e4b",
        "IpamScopeArn": "arn:aws:ec2::123456789012:ipam-scope/ipam-
scope-065e7dfe880df679c",
        "IpamScopeType": "private",
        "IpamArn": "arn:aws:ec2::123456789012:ipam/ipam-0de83dba6694560a9",
        "Locale": "us-west-2",
        "PoolDepth": 2,
        "State": "create-in-progress",
        "Description": "regional--pool",
        "AutoImport": false,
        "AddressFamily": "ipv4",
        "Tags": []
    }
}
```

2. Run the following command until you see a state of `create-complete` in the output.

```
aws ec2 describe-ipam-pools
```

In the output, you see the pools that you have in your IPAM. In this tutorial, we created a top-level and a Regional pool, so you'll see them both.

```
{
    "IpamPools": [
        {
            "OwnerId": "123456789012",
            "IpamPoolId": "ipam-pool-0008f25d7187a08d9",
            "IpamPoolArn": "arn:aws:ec2::123456789012:ipam-pool/ipam-
pool-0008f25d7187a08d9",
            "IpamScopeArn": "arn:aws:ec2::123456789012:ipam-scope/ipam-
scope-065e7dfe880df679c",
            "IpamScopeType": "private",
            "IpamArn": "arn:aws:ec2::123456789012:ipam/ipam-0de83dba6694560a9",
            "Locale": "None",
            "PoolDepth": 1,
            "State": "create-complete",
            "Description": "top-level-pool",
            "AutoImport": false,
            "AddressFamily": "ipv4"
```

```
        },
        {
            "OwnerId": "123456789012",
            "IpamPoolId": "ipam-pool-0da89c821626f1e4b",
            "SourceIpamPoolId": "ipam-pool-0008f25d7187a08d9",
            "IpamPoolArn": "arn:aws:ec2::123456789012:ipam-pool/ipam-
pool-0da89c821626f1e4b",
            "IpamScopeArn": "arn:aws:ec2::123456789012:ipam-scope/ipam-
scope-065e7dfe880df679c",
            "IpamScopeType": "private",
            "IpamArn": "arn:aws:ec2::123456789012:ipam/ipam-0de83dba6694560a9",
            "Locale": "us-west-2",
            "PoolDepth": 2,
            "State": "create-complete",
            "Description": "regional--pool",
            "AutoImport": false,
            "AddressFamily": "ipv4"
        }
    ]
}
```

Step 6: Provision a CIDR to the Regional pool

Follow the steps in this section to assign a CIDR block to the pool, and validate that it's been successfully provisioned.

To assign a CIDR block to the Regional pool using the AWS CLI

1. Run the following command to provision the CIDR.

```
aws ec2 provision-ipam-pool-cidr --region us-east-1 --ipam-pool-id ipam-
pool-0da89c821626f1e4b --cidr 10.0.0.0/16
```

   In the output, you see the state of the pool.

```
{
    "IpamPoolCidr": {
        "Cidr": "10.0.0.0/16",
        "State": "pending-provision"
    }
}
```

2. Run the following command until you see the state of `provisioned` in the output.

```
aws ec2 get-ipam-pool-cidrs --region us-east-1 --ipam-pool-id ipam-
pool-0da89c821626f1e4b
```

The following example output shows the correct state.

```
{
    "IpamPoolCidrs": [
        {
            "Cidr": "10.0.0.0/16",
            "State": "provisioned"
        }
    ]
}
```

3. Run the following command to query the top-level pool to view the allocations. The Regional pool is considered an allocation within the top-level pool.

```
aws ec2 get-ipam-pool-allocations --region us-east-1 --ipam-pool-id ipam-
pool-0008f25d7187a08d9
```

In the output, you see the Regional pool as an allocation in the top-level pool.

```
{
    "IpamPoolAllocations": [
        {
            "Cidr": "10.0.0.0/16",
            "IpamPoolAllocationId": "ipam-pool-alloc-
fbd525f6c2bf4e77a75690fc2d93479a",
            "ResourceId": "ipam-pool-0da89c821626f1e4b",
            "ResourceType": "ipam-pool",
            "ResourceOwner": "123456789012"
        }
    ]
}
```

Step 7. Create a RAM share for enabling IP assignments across accounts

This step is optional. You can complete this step only if you completed Integrate IPAM with accounts in an AWS Organization.

When you create an IPAM pool AWS RAM share, it enables IP assignments across accounts. RAM sharing is only available in your home AWS Region. Note that you create this share in the same Region as the IPAM, not in the local Region for the pool. All administrative operations on IPAM resources are made through the home Region of your IPAM. The example in this tutorial creates a single share for a single pool, but you can add multiple pools to a single share. For more information, including an explanation of the options that you must enter, see Share an IPAM pool using AWS RAM.

Run the following command to create a resource share.

```
aws ram create-resource-share --region us-east-1 --name pool_share --resource-
arns arn:aws:ec2::123456789012:ipam-pool/ipam-pool-0dec9695bca83e606 --
principals 123456
```

The output shows that the pool was created.

```
{
    "resourceShare": {
        "resourceShareArn": "arn:aws:ram:us-west-2:123456789012:resource-
share/3ab63985-99d9-1cd2-7d24-75e93EXAMPLE",
        "name": "pool_share",
        "owningAccountId": "123456789012",
        "allowExternalPrincipals": false,
        "status": "ACTIVE",
        "creationTime": 1565295733.282,
        "lastUpdatedTime": 1565295733.282
    }
}
```

Step 8. Create a VPC

Run the following command to create a VPC and assign a CIDR block to the VPC from the pool in your newly created IPAM.

```
aws ec2 create-vpc --region us-east-1 --ipv4-ipam-pool-id ipam-pool-04111dca0d960186e
 --cidr-block 10.0.0.0/24
```

The output shows that the VPC was created.

```
{
    "Vpc": {
        "CidrBlock": "10.0.0.0/24",
        "DhcpOptionsId": "dopt-19edf471",
        "State": "pending",
        "VpcId": "vpc-0983f3c454f3d8be5",
        "OwnerId": "123456789012",
        "InstanceTenancy": "default",
        "Ipv6CidrBlockAssociationSet": [],
        "CidrBlockAssociationSet": [
            {
                "AssociationId": "vpc-cidr-assoc-00b24cc1c2EXAMPLE",
                "CidrBlock": "10.0.0.0/24",
                "CidrBlockState": {
                    "State": "associated"
                }
            }
        ],
        "IsDefault": false
    }
}
```

Step 9. Cleanup

Follow the steps in this section to delete the IPAM resources you've created in this tutorial.

1. Delete the VPC.

   ```
   aws ec2 delete-vpc --vpc-id vpc-0983f3c454f3d8be5
   ```

2. Delete the IPAM pool RAM share.

   ```
   aws ram delete-resource-share --resource-share-arn arn:aws:ram:us-
   west-2:123456789012:resource-share/3ab63985-99d9-1cd2-7d24-75e93EXAMPLE
   ```

3. Deprovision pool CIDR from the Regional pool.

```
 aws ec2 deprovision-ipam-pool-cidr --ipam-pool-id ipam-pool-0da89c821626f1e4b --
region us-east-1
```

4. Deprovision pool CIDR from the top-level pool.

```
 aws ec2 deprovision-ipam-pool-cidr --ipam-pool-id ipam-pool-0008f25d7187a08d9 --
region us-east-1
```

5. Delete the IPAM

```
aws ec2 delete-ipam --region us-east-1
```

Tutorial: View IP address history using the AWS CLI

The scenarios in this section show you how to analyze and audit IP address usage using the AWS CLI. For general information about using the AWS CLI, see Using the AWS CLI in the *AWS Command Line Interface User Guide*.

Contents

Overview

IPAM automatically retains your IP address monitoring data for up to three years. You can use the historical data to analyze and audit your network security and routing policies. You can search for historical insights for the following types of resources:

- VPCs
- VPC subnets
- Elastic IP addresses
- EC2 instances that are running
- EC2 network interfaces attached to instances

Important

Although IPAM doesn't monitor Amazon EC2 instances or EC2 network interfaces attached to instances, you can use the Search IP history feature to search for historical data on EC2 instance and network interface CIDRs.

Note

- The commands in this tutorial must be run using the account that owns the IPAM and the AWS Region that hosts the IPAM.
- Records of changes to CIDRs are picked up in periodic snapshots, which means that it can take some time for records to appear or be updated, and the values for SampledStartTime and SampledEndTime can differ from the actual times they occurred.

Scenarios

The scenarios in this section show you how to analyze and audit IP address usage using the AWS CLI. For more information about the values mentioned in this tutorial like sampled end time and start time, see View IP address history.

Scenario 1: Which resources were associated with `10.2.1.155/32` between 1:00 AM and 9:00 PM on December 27, 2021 (UTC)?

1. Run the following command:

```
aws ec2 get-ipam-address-history --region us-east-1 --cidr 10.2.1.155/32 --ipam-scope-id ipam-scope-05b579a1909c5fc7a --start-time 2021-12-20T01:00:00.000Z --end-time 2021-12-27T21:00:00.000Z
```

2. View the results of the analysis. In the example below, the CIDR was allocated to a network interface and EC2 instance over the course of the time period. Note that no **SampledEndTime** value means the record is still active. For more information about the values shown in the following output, see View IP address history.

```
{
    "HistoryRecords": [
```

```
        {
            "ResourceOwnerId": "123456789012",
            "ResourceRegion": "us-east-1",
            "ResourceType": "network-interface",
            "ResourceId": "eni-0b4e53eb1733aba16",
            "ResourceCidr": "10.2.1.155/32",
            "VpcId": "vpc-0f5ee7e1ba908a378",
            "SampledStartTime": "2021-12-27T20:08:46.672000+00:00"
        },
        {
            "ResourceOwnerId": "123456789012",
            "ResourceRegion": "us-east-1",
            "ResourceType": "instance",
            "ResourceId": "i-064da1f79baed14f3",
            "ResourceCidr": "10.2.1.155/32",
            "VpcId": "vpc-0f5ee7e1ba908a378",
            "SampledStartTime": "2021-12-27T20:08:46.672000+00:00"
        }
    ]
}
```

If the owner ID of the instance to which a network interface is attached differs from the owner ID of the network interface (as is the case for NAT gateways, Lambda network interfaces in VPCs, and other AWS services), the `ResourceOwnerId` is `amazon-aws` rather than the account ID of the owner of the network interface. The following example shows the record for a CIDR associated with a NAT gateway:

```
{
    "HistoryRecords": [
        {
            "ResourceOwnerId": "123456789012",
            "ResourceRegion": "us-east-1",
            "ResourceType": "network-interface",
            "ResourceId": "eni-0b4e53eb1733aba16",
            "ResourceCidr": "10.0.0.176/32",
            "VpcId": "vpc-0f5ee7e1ba908a378",
            "SampledStartTime": "2021-12-27T20:08:46.672000+00:00"
        },
        {
            "ResourceOwnerId": "amazon-aws",
            "ResourceRegion": "us-east-1",
            "ResourceType": "instance",
```

```
            "ResourceCidr": "10.0.0.176/32",
            "VpcId": "vpc-0f5ee7e1ba908a378",
            "SampledStartTime": "2021-12-27T20:08:46.672000+00:00"
        }
    ]
}
```

Scenario 2: Which resources were associated with `10.2.1.0/24` from December 1, 2021 to December 27, 2021 (UTC)?

1. Run the following command:

```
aws ec2 get-ipam-address-history --region us-east-1 --cidr 10.2.1.0/24 --ipam-scope-id ipam-scope-05b579a1909c5fc7a --start-time 2021-12-01T00:00:00.000Z --end-time 2021-12-27T23:59:59.000Z
```

2. View the results of the analysis. In the example below, the CIDR was allocated to a subnet and VPC over the course of the time period. Note that no **SampledEndTime** value means the record is still active. For more information about the values shown in the following output, see View IP address history.

```
{
    "HistoryRecords": [
        {
            "ResourceOwnerId": "123456789012",
            "ResourceRegion": "us-east-1",
            "ResourceType": "subnet",
            "ResourceId": "subnet-0864c82a42f5bffed",
            "ResourceCidr": "10.2.1.0/24",
            "VpcId": "vpc-0f5ee7e1ba908a378",
            "SampledStartTime": "2021-12-27T20:08:46.672000+00:00"
        },
        {
            "ResourceOwnerId": "123456789012",
            "ResourceRegion": "us-east-1",
            "ResourceType": "vpc",
            "ResourceId": "vpc-0f5ee7e1ba908a378",
            "ResourceCidr": "10.2.1.0/24",
            "ResourceComplianceStatus": "compliant",
            "ResourceOverlapStatus": "nonoverlapping",
            "VpcId": "vpc-0f5ee7e1ba908a378",
```

```
            "SampledStartTime": "2021-12-27T20:08:46.672000+00:00"
        }
    ]
}
```

Scenario 3: Which resources were associated with 2605:9cc0:409::/56 from December 1, 2021 to December 27, 2021 (UTC)?

1. Run the following command, where --region is the IPAM home Region:

```
aws ec2 get-ipam-address-history --region us-east-1 --cidr 2605:9cc0:409::/56 --
ipam-scope-id ipam-scope-07cb485c8b4a4d7cc --start-time 2021-12-01T01:00:00.000Z --
end-time 2021-12-27T23:59:59.000Z
```

2. View the results of the analysis. In the example below, the CIDR was allocated to two different VPCs over the course of the time period in a Region outside the IPAM home Region. Note that no **SampledEndTime** value means the record is still active. For more information about the values shown in the following output, see View IP address history.

```
{
    "HistoryRecords": [
        {
            "ResourceOwnerId": "123456789012",
            "ResourceRegion": "us-east-2",
            "ResourceType": "vpc",
            "ResourceId": "vpc-01d967bf3b923f72c",
            "ResourceCidr": "2605:9cc0:409::/56",
            "ResourceName": "First example VPC",
            "ResourceComplianceStatus": "compliant",
            "ResourceOverlapStatus": "nonoverlapping",
            "VpcId": "vpc-01d967bf3b923f72c",
            "SampledStartTime": "2021-12-23T20:02:00.701000+00:00",
            "SampledEndTime": "2021-12-23T20:12:59.848000+00:00"
        },
        {
            "ResourceOwnerId": "123456789012",
            "ResourceRegion": "us-east-2",
            "ResourceType": "vpc",
            "ResourceId": "vpc-03e62c7eca81cb652",
            "ResourceCidr": "2605:9cc0:409::/56",
            "ResourceName": "Second example VPC",
```

```
            "ResourceComplianceStatus": "compliant",
            "ResourceOverlapStatus": "nonoverlapping",
            "VpcId": "vpc-03e62c7eca81cb652",
            "SampledStartTime": "2021-12-27T15:11:00.046000+00:00"
        }
    ]
}
```

Scenario 4: Which resources were associated with `10.0.0.0/24` in the last 24 hours (assuming the current time is midnight on December 27, 2021 (UTC))?

1. Run the following command:

```
aws ec2 get-ipam-address-history --region us-east-1 --cidr 10.0.0.0/24 --ipam-
scope-id ipam-scope-05b579a1909c5fc7a --start-time 2021-12-27T00:00:00.000Z
```

2. View the results of the analysis. In the example below, the CIDR has been allocated to numerous subnets and VPCs over the time period. Note that no **SampledEndTime** value means the record is still active. For more information about the values shown in the following output, see View IP address history.

```
{
    "HistoryRecords": [
        {
            "ResourceOwnerId": "123456789012",
            "ResourceRegion": "us-east-2",
            "ResourceType": "subnet",
            "ResourceId": "subnet-0d1b8f899725aa72d",
            "ResourceCidr": "10.0.0.0/24",
            "ResourceName": "Example name",
            "VpcId": "vpc-042b8a44f64267d67",
            "SampledStartTime": "2021-12-11T16:35:59.074000+00:00",
            "SampledEndTime": "2021-12-28T15:34:00.017000+00:00"
        },
        {
            "ResourceOwnerId": "123456789012",
            "ResourceRegion": "us-east-2",
            "ResourceType": "vpc",
            "ResourceId": "vpc-09754dfd85911abec",
            "ResourceCidr": "10.0.0.0/24",
            "ResourceName": "Example name",
```

```
            "ResourceComplianceStatus": "unmanaged",
            "ResourceOverlapStatus": "overlapping",
            "VpcId": "vpc-09754dfd85911abec",
            "SampledStartTime": "2021-12-27T20:07:59.947000+00:00",
            "SampledEndTime": "2021-12-28T15:34:00.017000+00:00"
        },
        {
            "ResourceOwnerId": "123456789012",
            "ResourceRegion": "us-west-2",
            "ResourceType": "vpc",
            "ResourceId": "vpc-0a8347f594bea5901",
            "ResourceCidr": "10.0.0.0/24",
            "ResourceName": "Example name",
            "ResourceComplianceStatus": "unmanaged",
            "ResourceOverlapStatus": "overlapping",
            "VpcId": "vpc-0a8347f594bea5901",
            "SampledStartTime": "2021-12-11T16:35:59.318000+00:00"
        },
        {
            "ResourceOwnerId": "123456789012",
            "ResourceRegion": "us-east-1",
            "ResourceType": "subnet",
            "ResourceId": "subnet-0af7eadb0798e9148",
            "ResourceCidr": "10.0.0.0/24",
            "ResourceName": "Example name",
            "VpcId": "vpc-03298ba16756a8736",
            "SampledStartTime": "2021-12-14T21:07:22.357000+00:00"
        }
    ]
}
```

Scenario 5: Which resources are currently associated with `10.2.1.155/32`?

1. Run the following command:

```
aws ec2 get-ipam-address-history --region us-east-1 --cidr 10.2.1.155/32 --ipam-
scope-id ipam-scope-05b579a1909c5fc7a
```

2. View the results of the analysis. In the example below, the CIDR was allocated to a network interface and EC2 instance over the time period. Note that no **SampledEndTime** value means the record is still active. For more information about the values shown in the following output, see View IP address history.

```
{
    "HistoryRecords": [
        {
            "ResourceOwnerId": "123456789012",
            "ResourceRegion": "us-east-1",
            "ResourceType": "network-interface",
            "ResourceId": "eni-0b4e53eb1733aba16",
            "ResourceCidr": "10.2.1.155/32",
            "VpcId": "vpc-0f5ee7e1ba908a378",
            "SampledStartTime": "2021-12-27T20:08:46.672000+00:00"
        },
        {
            "ResourceOwnerId": "123456789012",
            "ResourceRegion": "us-east-1",
            "ResourceType": "instance",
            "ResourceId": "i-064da1f79baed14f3",
            "ResourceCidr": "10.2.1.155/32",
            "VpcId": "vpc-0f5ee7e1ba908a378",
            "SampledStartTime": "2021-12-27T20:08:46.672000+00:00"
        }
    ]
}
```

Scenario 6: Which resources are currently associated with `10.2.1.0/24`?

1. Run the following command:

```
aws ec2 get-ipam-address-history --region us-east-1 --cidr 10.2.1.0/24 --ipam-scope-id ipam-scope-05b579a1909c5fc7a
```

2. View the results of the analysis. In the example below, the CIDR was allocated to a VPC and subnet over the time period. Only the results that match this exact /24 CIDR are returned, not all /32 within the /24 CIDR. Note that no **SampledEndTime** value means the record is still active. For more information about the values shown in the following output, see View IP address history.

```
{
    "HistoryRecords": [
        {
            "ResourceOwnerId": "123456789012",
```

```
            "ResourceRegion": "us-east-1",
            "ResourceType": "subnet",
            "ResourceId": "subnet-0864c82a42f5bffed",
            "ResourceCidr": "10.2.1.0/24",
            "VpcId": "vpc-0f5ee7e1ba908a378",
            "SampledStartTime": "2021-12-27T20:08:46.672000+00:00"
        },
        {
            "ResourceOwnerId": "123456789012",
            "ResourceRegion": "us-east-1",
            "ResourceType": "vpc",
            "ResourceId": "vpc-0f5ee7e1ba908a378",
            "ResourceCidr": "10.2.1.0/24",
            "ResourceComplianceStatus": "compliant",
            "ResourceOverlapStatus": "nonoverlapping",
            "VpcId": "vpc-0f5ee7e1ba908a378",
            "SampledStartTime": "2021-12-27T20:08:46.672000+00:00"
        }
    ]
}
```

Scenario 7: Which resources are currently associated with 54.0.0.9/32?

In this example, 54.0.0.9/32 is assigned to an Elastic IP address that is not part of the AWS Organization integrated with your IPAM.

1. Run the following command:

```
aws ec2 get-ipam-address-history --region us-east-1 --cidr 54.0.0.9/32 --ipam-
scope-id ipam-scope-05b579a1909c5fc7a
```

2. Since 54.0.0.9/32 is assigned to an Elastic IP address that is not part of the AWS Organization integrated with the IPAM in this example, no records are returned.

```
{
    "HistoryRecords": []
}
```

Tutorial: Bring your ASN to IPAM

If your applications use trusted IP addresses and Autonomous System Numbers (ASNs) that your partners or customers have allow listed in their network, you can run these applications in AWS. Your partners or customers do not need to change their allow lists.

An Autonomous System Number (ASN) is a globally unique number which enables a group of networks to be identified over the internet and exchange routing data with other networks dynamically using Border Gateway Protocol. Internet service providers (ISPs), for example, use ASNs to identify the network traffic source. Not all organizations purchase their own ASNs, but for organizations which do, they can bring their ASN to AWS.

Bring your own autonomous system number (BYOASN) enables you to advertise the IPv4 or IPv6 addresses that you bring to AWS with your own public ASN instead of the AWS ASN. When you use BYOASN, the traffic originating from your IP address carries your ASN instead of the AWS ASN, and your workloads are reachable by customers or partners that have allow listed traffic based on your IP address and ASN.

Important

- Complete this tutorial using the IPAM admin account in your IPAM's home Region.
- This tutorial assumes you own the public ASN you'd like to bring to IPAM and that you've already brought a BYOIP CIDR to AWS and provisioned it to a pool in your public scope. You can bring an ASN to IPAM at any time, but to use it, you have to associate with a CIDR that you've brought to your AWS account. This tutorial assumes that you have already done that. For more information, see Tutorial: Bring your IP addresses to IPAM.
- You can change between your advertising your own ASN or an AWS ASN without delay, but you are limited to changing from an AWS ASN to your own ASN once per hour.
- If your BYOIP CIDR is currently advertised, you do not have to withdraw it from advertising to associate with your ASN.

Onboarding prerequisites for your ASN

You will need the following to complete this tutorial:

- Your public 2-byte or 4-byte ASN.

- If you've already brought an IP address range to AWS with Tutorial: Bring your IP addresses to IPAM, you need the IP address CIDR range. You'll also need a private key. You can use the private key that you created when you brought the IP address CIDR range to AWS or you can create a new private key as described in Create a private key and generate an X.509 certificate in the *Amazon EC2 User Guide*.
- When you bring an IPv4 or IPv6 address range to AWS with Tutorial: Bring your IP addresses to IPAM, you create an X.509 certificate and upload the X.509 certificate to the RDAP record in your Regional Internet Registry (RIR). You must upload the same certificate you created to the RDAP record in your RIR for the ASN. Be sure to include the `-----BEGIN CERTIFICATE-----` and `-----END CERTIFICATE-----` strings before and after the encoded portion. All of this content must be on a single, long line. The procedure for updating RDAP depends on your RIR:
  - For ARIN, use the Account Manager portal to add the certificate in the "Public Comments" section for the "Network Information" object representing your ASN by using the "Modify ASN" option. Do not add it to the comments section for your organization.
  - For RIPE, add the certificate as a new "descr" field to the "aut-num" object representing your ASN. These can usually be found in the "My Resources" section of the

    RIPE Database portal . Do not add it to the comments section for your organization or the "remarks" field of the "aut-num" object.
  - For APNIC, email the certificate to helpdesk@apnic.net to manually add it to the "remarks" field for your ASN. Send the email using the APNIC authorized contact for the ASN.
- When you bring an IP address range to IPAM, you create a ROA to verify that you control the IP address space that you are bringing to IPAM. In addition to that ROA, you must have a second ROA in your RIR with the ASN that you are bringing to IPAM. If you don't have this second ROA for the ASN in your RIR, complete 3. Create a ROA object in your RIR. Ignore the other steps.
- We recommend that you publish an Autonomous System Provider Authorization (ASPA) object for your ASN in your RIR. The ASPA object authorizes AWS to readvertise route announcements that originate from your ASN. Include the Amazon ASNs 16509 and 14618. For the AWS GovCloud (US) Regions, use ASN 8987. For the AWS European Sovereign Cloud, use ASNs 16509 and 214101. If an ASPA object already exists for your ASN, you must add these Amazon ASNs to it. Otherwise, routes that AWS readvertises from your ASN fail ASPA validation.

Tutorial steps

Complete the steps below using the AWS console or the AWS CLI.

AWS Management Console

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the left navigation pane, choose **IPAMs**.
3. Choose your IPAM.
4. Choose the **BYOASNs** tab and choose **Provision BYOASNs**.
5. Enter the **ASN**. As a result, the **Message** field is automatically populated with the message you will need to sign in the next step.

   - The format of the message is as follows, where ACCOUNT is your AWS account number, ASN is the ASN you are bringing to IPAM, and YYYYMMDD is the expiry date of the message (which defaults to the last day of the next month). Example:

   ```
   text_message="1|aws|ACCOUNT|ASN|YYYYMMDD|SHA256|RSAPSS"
   ```

6. Copy the message and replace the expiry date with your own value if you want to.
7. Sign the message using the private key. Example:

   ```
   signed_message=$( echo -n $text_message | openssl dgst -sha256 -sigopt
    rsa_padding_mode:pss -sigopt rsa_pss_saltlen:-1 -sign private-key.pem -keyform
    PEM | openssl base64 | tr -- '+=/' '-_~' | tr -d "\n")
   ```

8. Under **Signature**, enter the signature.
9. (Optional) To provision another ASN, choose **Provision another ASN**. You can provision up to 5 ASNs. To increase this quota, see Quotas for your IPAM.
10. Choose **Provision**.
11. View the provisioning process in the **BYOASNs** tab. Wait for the **State** to change from *Pending-provision* to *Provisioned*. BYOASNs in a *Failed-provision* state are automatically removed after 7 days. Once the ASN is successfully provisioned, you can associate it with a BYOIP CIDR.
12. In the left navigation pane, choose **Pools**.
13. Choose your public scope. For more information about scopes, see How IPAM works.
14. Choose a regional pool that has a BYOIP CIDR provisioned to it. The pool must have **Service** set to **EC2** and must have a locale chosen.
15. Choose the **CIDRs** tab and select a BYOIP CIDR.
16. Choose **Actions** > **Manage BYOASN associations**.

17. Under **Associated BYOASNs**, choose the ASN you brought to AWS. If you have multiple ASNs, you can associate multiple ASNs to the BYOIP CIDR. You can associate as many ASNs as you can bring to IPAM. Note that you can bring up to 5 ASNs to IPAM by default. For more information, see Quotas for your IPAM.
18. Choose **Associate**.
19. Wait for the ASN association to complete. Once the ASN is successfully associated with the BYOIP CIDR, you can advertise the BYOIP CIDR again.
20. Choose the pool **CIDRs** tab.
21. Select the BYOIP CIDR and choose **Actions** > **Advertise**. As a result, your ASN options are displayed: the Amazon ASN and any ASNs you've brought to IPAM.
22. Select the ASN you brought to IPAM and choose **Advertise CIDR**. As a result, the BYOIP CIDR is advertised and the value in the **Advertising** column changes from Withdrawn to Advertised. The **Autonomous System Number** column displays the ASN associated with the CIDR.
23. (optional) If you decide that you want to change the ASN association back to the Amazon ASN, select the BYOIP CIDR and choose **Actions** > **Advertise** again. This time, choose the Amazon ASN. You can swap back to the Amazon ASN at any time, but you can only change to a custom ASN once every hour.

The tutorial is complete.

Cleanup

1. Disassociate the ASN from the BYOIP CIDR
   - To withdraw the BYOIP CIDR from advertising, in your pool in the public scope, choose the BYOIP CIDR and choose **Actions** > **Withdraw from advertising**.
   - To disassociate the ASN from the CIDR, choose **Actions** > **Manage BYOASN associations**.
2. Deprovision the ASN
   - To deprovision the ASN, in the BYOASNs tab, choose the ASN and choose **Deprovision ASN**. As a result, the ASN is deprovisioned. BYOASNs in a *Deprovisioned* state are automatically removed after 7 days.

Cleanup is complete.

Command line

1. Provision your ASN by including your ASN and authorization message. The signature is the message signed with your private key.

```
aws ec2 provision-ipam-byoasn --ipam-id $ipam_id --asn 12345 --asn-
authorization-context Message="$text_message",Signature="$signed_message"
```

2. Describe your ASN to track the provisioning process. If the request succeeds, you should see the *ProvisionStatus* set to *provisioned* after a few minutes.

```
aws ec2 describe-ipam-byoasn
```

3. Associate your ASN with your BYOIP CIDR. Any custom ASN you wish to advertise from must first be associated with your CIDR.

```
aws ec2 associate-ipam-byoasn --asn 12345 --cidr xxx.xxx.xxx.xxx/n
```

4. Describe your CIDR to track the association process.

```
aws ec2 describe-byoip-cidrs --max-results 10
```

5. Advertise your CIDR with your ASN. If the CIDR is already advertised, this will swap the origin ASN from Amazon's to yours.

```
aws ec2 advertise-byoip-cidr --asn 12345 --cidr xxx.xxx.xxx.xxx/n
```

6. Describe your CIDR to see the ASN state change from *associated* to *advertised*.

```
aws ec2 describe-byoip-cidrs --max-results 10
```

The tutorial is complete.

Cleanup

1. Do one of the following:

   - To withdraw just your ASN advertisement and go back to using the Amazon ASNs while keeping the CIDR advertised you must call advertise-byoip-cidr with the special AWS

value for the asn parameter. You can swap back to the Amazon ASN at any time, but you can only change to a custom ASN once every hour.

```
aws ec2 advertise-byoip-cidr --asn AWS --cidr xxx.xxx.xxx.xxx/n
```

- To withdraw your CIDR and ASN advertisement simultaneously, you can call withdraw-byoip-cidr.

```
aws ec2 withdraw-byoip-cidr --cidr xxx.xxx.xxx.xxx/n
```

2. To clean up your ASN, you must first disassociate it from your BYOIP CIDR.

```
aws ec2 disassociate-ipam-byoasn --asn 12345 --cidr xxx.xxx.xxx.xxx/n
```

3. Once your ASN is disassociated from all the BYOIP CIDRs with which you associated it, you can deprovision it.

```
aws ec2 deprovision-ipam-byoasn --ipam-id $ipam_id --asn 12345
```

4. The BYOIP CIDR can also be deprovisioned once all ASN associations are removed.

```
aws ec2 deprovision-ipam-pool-cidr --ipam-pool-id ipam-pool-1234567890abcdef0 --
cidr xxx.xxx.xxx.xxx/n
```

5. Confirm the deprovisioning.

```
aws ec2 get-ipam-pool-cidrs --ipam-pool-id ipam-pool-1234567890abcdef0
```

Cleanup is complete.

Next steps

To automate ROA management for your ASN and IP prefixes, see Monitor BGP route protection.

Tutorial: Bring your IP addresses to IPAM

The tutorials in this section walk you through the process of bringing public IP address space to AWS and managing the space with IPAM.

Managing public IP address space with IPAM has the following benefits:

- **Improves public IP addresses utilization across your organization**: You can use IPAM to share IP address space across AWS accounts. Without using IPAM, you cannot share your public IP space across AWS Organizations accounts.
- **Simplifies the process of bringing public IP space to AWS**: You can use IPAM to onboard public IP address space once, and then use IPAM to distribute your public IPs across Regions to resources like EC2 instances and application load balancers. Without IPAM, you have to onboard your public IPs for each AWS Region.

> **Note**
>
> To monitor RPKI validity, detect route overlaps, and automate ROA management for your BYOIP prefixes, see Monitor BGP route protection and Tutorial: Set up delegated RPKI for BYOIP prefixes.

Contents

Verify domain control

Before you bring an IP address range to AWS, you have to use one of the options described in this section to verify that you control the IP address space. This applies to both IPv4 and IPv6 address ranges. Later, when you bring the IP address range to AWS, AWS validates that you control the IP address range. This validation ensures that customers cannot use IP ranges belonging to others, preventing routing and security issues.

There are two methods that you can use to verify that you control the range:

- **X.509 certificate**: If your IP address range is registered with an Internet Registry that supports RDAP (such as ARIN, RIPE and APNIC), you can use an X.509 certificate to verify ownership of your domain.

- **DNS TXT record**: Regardless of whether your Internet Registry supports RDAP, you can use a verification token and a DNS TXT record to verify ownership of your domain.

Contents

Verify your domain with an X.509 certificate

This section describes how to verify your domain with an X.509 certificate before you bring your IP address range to IPAM.

To verify your domain with an X.509 certificate

1. Complete the three steps in Prerequisites for BYOIP in Amazon EC2 in the *Amazon EC2 User Guide*.

   > **Note**
   >
   > When you create the ROAs, for IPv4 CIDRs you must set the maximum length of an IP address prefix to `/24`. For IPv6 CIDRs, if you are adding them to an advertisable pool, the maximum length of an IP address prefix must be `/48`. This ensures that you have full flexibility to divide your public IP address across AWS Regions. IPAM enforces the maximum length you set. The maximum length is the smallest prefix length announcement you will allow for this route. For example, if you bring a `/20` CIDR block to AWS, by setting the maximum length to `/24`, you can divide the larger block any way you like (such as with `/21`, `/22`, or `/24`) and distribute those smaller CIDR blocks to any Region. If you were to set the maximum length to `/23`, you would not be able to divide and advertise a `/24` from the larger block. Also, note that `/24` is the smallest IPv4 block and `/48` is the smallest IPv6 block you can advertise from a Region to the internet.

2. Complete steps 1 and 2 only under Provision a publicly advertisable address range in AWS in the *Amazon EC2 User Guide*, **and don't provision the address range (step 3) yet**. Save the `text_message` and `signed_message`. You'll need them later in this process.

When you've completed these steps, continue with Bring your own IP to IPAM using both the AWS Management Console and the AWS CLI or Bring your own IP CIDR to IPAM using only the AWS CLI.

Verify your domain with a DNS TXT record

Complete the steps in this section to verify your domain with a DNS TXT record before you bring your IP address range to IPAM.

You can use DNS TXT records to validate that you control a public IP address range. DNS TXT records are a type of DNS record that contain information about your domain name. This feature enables you to bring IP addresses registered with any internet registry (such as JPNIC, LACNIC, and AFRINIC), not just those that support RDAP (Registration Data Access Protocol) record-based validations (such as ARIN, RIPE and APNIC).

> **Important**
>
> Before you can continue, you must have already created an IPAM in the Free or Advanced Tier. If you don't have an IPAM, complete Create an IPAM first.

Contents

Step 1: Create a ROA if you don't have one

You must have a Route Origin Authorization (ROA) in your Regional Internet Registry (RIR) for IP address ranges you wish to advertise. If you don't have a ROA in your RIR, complete 3. Create a ROA object in your RIR in the *Amazon EC2 User Guide*. Ignore the other steps.

The most specific IPv4 address range that you can bring is /24. The most specific IPv6 address range that you can bring is /48 for CIDRs that are publicly advertisable and /60 for CIDRs that are not publicly advertisable.

Step 2. Create a verification token

A verification token is an AWS-generated random value that you can use to prove control of an external resource. For example, you can use a verification token to validate that you control a public IP address range when you bring an IP address range to AWS (BYOIP).

Complete the steps in this section to create a verification token which you'll need in a later step in this tutorial to bring your IP address range to IPAM. Use the instructions below for either the AWS console or the AWS CLI.

AWS Management Console

To create a verification token

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the AWS Management Console, choose the AWS Region where you created your IPAM.
3. In the left navigation pane, choose **IPAMs**.
4. Choose your IPAM and then choose the **Verification tokens tab**.
5. Select **Create verification token**.
6. After you create the token, leave this browser tab open. You'll need the **Token value**, **Token name** in the next step and the **Token ID** in a later step.

Note the following:

- Once you create a verification token, you can reuse the token for multiple BYOIP CIDRs that you provision from your IPAM within 72 hours. If you want to provision more CIDRs after 72 hours, you need a new token.
- You can create up to 100 tokens. If you reach the limit, delete expired tokens.

Command line

- Request that IPAM creates a verification token that you will use for the DNS configuration with create-ipam-external-resource-verification-token:

```
aws ec2 create-ipam-external-resource-verification-token --ipam-id ipam-id
```

This will return an IpamExternalResourceVerificationTokenId and token with `TokenName` and `TokenValue`, and the expiration time (`NotAfter`) of the token.

```
{
    "IpamExternalResourceVerificationToken": {
        "IpamExternalResourceVerificationTokenId": "ipam-ext-res-ver-
token-0309ce7f67a768cf0",
        "IpamId": "ipam-0f9e8725ac3ae5754",
        "TokenValue": "a34597c3-5317-4238-9ce7-50da5b6e6dc8",
        "TokenName": "86950620",
        "NotAfter": "2024-05-19T14:28:15.927000+00:00",
        "Status": "valid",
        "Tags": [],
        "State": "create-in-progress" }
}
```

Note the following:

- Once you create a verification token, you can reuse the token for multiple BYOIP CIDRs that you provision from your IPAM within 72 hours. If you want to provision more CIDRs after 72 hours, you need a new token.
- You can view your tokens using describe-ipam-external-resource-verification-tokens.
- You can create up to 100 tokens. If you reach the limit, you can delete expired tokens using delete-ipam-external-resource-verification-token.

Step 3. Set up the DNS zone and TXT record

Complete the steps in this section to set up the DNS zone and TXT record. If you are not using Route53 as your DNS, then follow the documentation provided by your DNS provider to set up a DNS Zone and add a TXT record.

If you are using Route53, note the following:

- To create a Reverse Lookup Zone in the AWS console, see Creating a public hosted zone in the *Amazon Route 53 Developer Guide* or use the AWS CLI command create-hosted-zone.
- To create a record in the Reverse Lookup Zone in the AWS console, see Creating records by using the Amazon Route 53 console in the *Amazon Route 53 Developer Guide* or use the AWS CLI command change-resource-record-sets.

- After you are done creating your hosted zone, delegate the hosted zone from your RIR to the name servers provided by Route53 (such as for LACNIC or APNIC).

Whether you are using another DNS provider or Route53, when you set up the TXT record, note the following:

- Record name should be your token name.
- Record type should be TXT.
- ResourceRecord Value should be the token value.

Example:

- **Name**: `86950620.113.0.203.in-addr.arpa`
- **Type**: TXT
- **ResourceRecords Value**: `a34597c3-5317-4238-9ce7-50da5b6e6dc8`

Where:

- `86950620` is the verification token name.
- `113.0.203.in-addr.arpa` is the Reverse Lookup Zone name.
- TXT is the record type.
- `a34597c3-5317-4238-9ce7-50da5b6e6dc8` is the verification token value.

Note

Depending on the size of the prefix to be brought to IPAM with BYOIP, one or more authentication records must be created in the DNS. These authentication records are of the record type TXT and must be placed into the reverse zone of the prefix itself or its parent prefix.

- For IPv4, authentication records need to align to ranges at an octet boundary that make up the prefix.
  - **Examples**
  - For 198.18.123.0/24, which is already aligned at an octet boundary, you would need to create a single authentication record at:

- *token-name*.123.18.198.in-addr.arpa. IN TXT "*token-value*"

- For 198.18.12.0/22, which itself is not aligned to octet boundary, you would need to create four authentication records. These records must cover the subnets 198.18.12.0/24, 198.18.13.0/24, 198.18.14.0/24, and 198.18.15.0/24 which are aligned at an octet boundary. The corresponding DNS entries must be:
  - *token-name*.12.18.198.in-addr.arpa. IN TXT "*token-value*"
  - *token-name*.13.18.198.in-addr.arpa. IN TXT "*token-value*"
  - *token-name*.14.18.198.in-addr.arpa. IN TXT "*token-value*"
  - *token-name*.15.18.198.in-addr.arpa. IN TXT "*token-value*"
- For 198.18.0.0/16, which is already aligned at an octet boundary, you need to create a single authentication record:
  - *token-name*.18.198.in-addr.arpa. IN TXT "*token-value*"

- For IPv6, authentication records need to align to ranges at nibble boundary that make up the prefix. Valid nibble values are e.g. 32, 36, 40, 44, 48, 52, 56, and 60.
  - **Examples**
    - For 2001:0db8::/40, which is already aligned at nibble boundary, you need to create a single authentication record:
      - *token-name*.0.0.8.b.d.0.1.0.0.2.ip6.arpa TXT "*token-value*"
    - For 2001:0db8:80::/42, which is itself not aligned at nibble boundary, you need to create four authentication records. These records must cover the subnets 2001:db8:80::/44, 2001:db8:90::/44, 2001:db8:a0::/44, and 2001:db8:b0::/44 which are aligned at a nibble boundary. The corresponding DNS entries must be:
      - *token-name*.8.0.0.8.b.d.0.1.0.0.2.ip6.arpa TXT "*token-value*"
      - *token-name*.9.0.0.8.b.d.0.1.0.0.2.ip6.arpa TXT "*token-value*"
      - *token-name*.a.0.0.8.b.d.0.1.0.0.2.ip6.arpa IN TXT "*token-value*"
      - *token-name*.b.0.0.8.b.d.0.1.0.0.2.ip6.arpa IN TXT "*token-value*"
    - For the non-advertised range 2001:db8:0:1000::/54, which is itself not aligned at a nibble boundary, you need to create four authentication records. These records must cover the subnets 2001:db8:0:1000::/56, 2001:db8:0:1100::/56, 2001:db8:0:1200::/56, and 2001:db8:0:1300::/56 which are aligned at a nibble boundary. The corresponding DNS entries must be:
      - *token-name*.0.1.0.0.0.0.8.b.d.0.1.0.0.2.ip6.arpa IN TXT "*token-value*"

- *token-name*.1.1.0.0.0.0.8.b.d.0.1.0.0.2.ip6.arpa IN TXT "*token-value*"
- *token-name*.2.1.0.0.0.0.8.b.d.0.1.0.0.2.ip6.arpa IN TXT "*token-value*"
- *token-name*.3.1.0.0.0.0.8.b.d.0.1.0.0.2.ip6.arpa IN TXT "*token-value*"

- To validate the correct number of hexadecimal numbers between the *token-name* and the "ip6.arpa" string, multiply the number by four. The result should match the prefix length. For example, for a /56 prefix you should have 14 hexadecimal digits.

When you've completed these steps, continue with Bring your own IP to IPAM using both the AWS Management Console and the AWS CLI or Bring your own IP CIDR to IPAM using only the AWS CLI.

Bring your own IP to IPAM using both the AWS Management Console and the AWS CLI

Bringing Your Own IP (BYOIP) to IPAM allows you to use your organization's existing IPv4 and IPv6 address ranges in AWS. This enables you to maintain consistent branding, improve network performance, enhance security, and simplify management by unifying on-premises and cloud environments under your own IP address space.

Follow these steps to bring an IPv4 or IPv6 CIDR to IPAM using both the AWS Management Console and the AWS CLI.

Note

Before you begin, you must have first verified domain control.

Once you bring an IPv4 address range to AWS, you can use all of the IP addresses in the range, including the first address (the network address) and the last address (the broadcast address).

Contents

Bring your own IPv4 CIDR to IPAM using both the AWS Management Console and the AWS CLI

Follow these steps to bring an IPv4 CIDR to IPAM and allocate an Elastic IP address (EIP) using both the AWS Management Console and the AWS CLI.

Important

- This tutorial assumes you have already completed the steps in the following sections:
  - Integrate IPAM with accounts in an AWS Organization.
  - Create an IPAM.
- Each step of this tutorial must be done by one of three AWS Organizations accounts:
  - The management account.
  - The member account configured to be your IPAM administrator in Integrate IPAM with accounts in an AWS Organization. In this tutorial, this account will be called the IPAM account.
  - The member account in your organization which will allocate CIDRs from an IPAM pool. In this tutorial, this account will be called the member account.

Contents

Step 1: Create AWS CLI named profiles and IAM roles

To complete this tutorial as a single AWS user, you can use AWS CLI named profiles to switch from one IAM role to another. Named profiles are collections of settings and credentials that you refer to when using the `--profile` option with the AWS CLI. For more information about how to create IAM roles and named profiles for AWS accounts, see Using an IAM role in the AWS CLI.

Create one role and one named profile for each of the three AWS accounts you will use in this tutorial:

- A profile called `management-account` for the AWS Organizations management account.
- A profile called `ipam-account` for the AWS Organizations member account that is configured to be your IPAM administrator.
- A profile called `member-account` for the AWS Organizations member account in your organization which will allocate CIDRs from an IPAM pool.

After you have created the IAM roles and named profiles, return to this page and go to the next step. You will notice throughout the rest of this tutorial that the sample AWS CLI commands use the `--profile` option with one of the named profiles to indicate which account must run the command.

Step 2: Create a top-level IPAM pool

Complete the steps in this section to create a top-level IPAM pool.

This step must be done by the IPAM account.

To create a pool

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.
3. By default, when you create a pool, the default private scope is selected. Choose the public scope. For more information about scopes, see How IPAM works.
4. Choose **Create pool**.
5. (Optional) Add a **Name tag** for the pool and a **Description** for the pool.
6. Under **Source**, choose **IPAM scope**.
7. Under **Address family**, choose **IPv4**.

8. Under **Resource planning**, leave **Plan IP space within the scope** selected. For more information about using this option to plan for subnet IP space within a VPC, see Tutorial: Plan VPC IP address space for subnet IP allocations.
9. Under **Locale**, choose **None**.

   The IPAM integration with BYOIP requires that the locale is set on whichever pool will be used for the BYOIP CIDR. Since we are going to create a top-level IPAM pool with a Regional pool within it, and we're going to allocate space to an Elastic IP address from the Regional pool. You set the locale on the Regional pool, not the top-level pool. You'll add the locale to the Regional pool when you create the Regional pool in a later step.

   > **Note**
   >
   > If you are creating a single pool only and not a top-level pool with Regional pools within it, you would want to choose a Locale for this pool so that the pool is available for allocations.

10. Under **Public IP source**, choose **BYOIP**.
11. Under **CIDRs to provision**, do one of the following:

    - If you verified your domain control with an X.509 certificate, you must include the CIDR and the BYOIP message and certificate signature that you created in that step so we can verify that you control the public space.
    - If you verified your domain control with a DNS TXT record, you must include the CIDR and IPAM verification token that you created in that step so we can verify that you control the public space.

    Note that when provisioning an IPv4 CIDR to a pool within the top-level pool, the minimum IPv4 CIDR you can provision is /24; more specific CIDRs (such as /25) are not permitted.

    > **Important**
    >
    > While most provisioning will be completed within two hours, it may take up to one week to complete the provisioning process for publicly advertisable ranges.

12. Leave **Configure this pool's allocation rule settings** unselected.
13. (Optional) Choose **Tags** for the pool.

14. Choose **Create pool**.

Ensure that this CIDR has been provisioned before you continue. You can see the state of provisioning in the **CIDRs** tab in the pool details page.

Step 3. Create a Regional pool within the top-level pool

Create a Regional pool within the top-level pool. The IPAM integration with BYOIP requires that the locale is set on whichever pool will be used for the BYOIP CIDR. You'll add the locale to the Regional pool when you create the Regional pool in this section. The `Locale` must be part of one of the operating Regions you configured when you created the IPAM. For example, a locale of *us-east-1* means that *us-east-1* must be an operating Region for the IPAM. A locale of *us-east-1-scl-1* (a network border group used for Local Zones) means that the IPAM must have an operating Region of *us-east-1*.

This step must be done by the IPAM account.

To create a Regional pool within a top-level pool

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.
3. By default, when you create a pool, the default private scope is selected. If you don't want to use the default private scope, from the dropdown menu at the top of the content pane, choose the scope you want to use. For more information about scopes, see How IPAM works.
4. Choose **Create pool**.
5. (Optional) Add a **Name tag** for the pool and a **Description** for the pool.
6. Under **Source**, choose the top-level pool that you created in the previous section.
7. Under **Resource planning**, leave **Plan IP space within the scope** selected. For more information about using this option to plan for subnet IP space within a VPC, see Tutorial: Plan VPC IP address space for subnet IP allocations.
8. Under **Locale**, choose the locale for the pool. In this tutorial, we'll use `us-east-2` as the locale for the Regional pool. The available options come from the operating Regions that you chose when you created your IPAM.

   The locale for the pool should be one of the following:

   - An AWS Region where you want this IPAM pool to be available for allocations.

- The network border group for an AWS Local Zone where you want this IPAM pool to be available for allocations (supported Local Zones). This option is only available for IPAM IPv4 pools in the public scope.
- An AWS Dedicated Local Zone. To create a pool within an AWS Dedicated Local Zone, enter the AWS Dedicated Local Zone in the selector input.
- `Global` when you want to use IP addresses globally across all AWS Regions, such as CloudFront locations. The `Global` locale is only available for public IPv4 pools.

For example, you can only allocate a CIDR for a VPC from an IPAM pool that shares a locale with the VPC's Region. Note that when you have chosen a locale for a pool, you cannot modify it. If the home Region of the IPAM is unavailable due to an outage and the pool has a locale different than the home Region of the IPAM, the pool can still be used to allocate IP addresses.

Choosing a locale ensures there are no cross-region dependencies between your pool and the resources allocating from it.

9. Under **Service**, choose **EC2 (EIP/VPC)**. The service you select determines the AWS service where the CIDR will be advertisable. Currently, the only option is **EC2 (EIP/VPC)**, which means that the CIDRs allocated from this pool will be advertisable for the Amazon EC2 service (for Elastic IP addresses) and the Amazon VPC service (for CIDRs associated with VPCs).
10. Under **CIDRs to provision**, choose a CIDR to provision for the pool.

> **Note**
>
> When provisioning a CIDR to a Regional pool within the top-level pool, the most specific IPv4 CIDR you can provision is /24; more specific CIDRs (such as /25) are not permitted. After you create the Regional pool, you can create smaller pools (such as /25) within the same Regional pool. Note that if you share the Regional pool or pools within it, these pools can only be used in the locale set on the same Regional pool.

11. Enable **Configure this pool's allocation rule settings**. You have the same allocation rule options here as you did when you created the top-level pool. See Create a top-level IPv4 pool for an explanation of the options that are available when you create pools. The allocation rules for the Regional pool are not inherited from the top-level pool. If you do not apply any rules here, there will be no allocation rules set for the pool.
12. (Optional) Choose **Tags** for the pool.

13. When you've finished configuring your pool, choose **Create pool**.

Ensure that this CIDR has been provisioned before you continue. You can see the state of provisioning in the **CIDRs** tab in the pool details page.

Step 4: Advertise the CIDR

The steps in this section must be done by the IPAM account. Once you associate the Elastic IP address (EIP) with an instance or Elastic Load Balancer, you can then start advertising the CIDR you brought to AWS that is in pool that has the **Service EC2 (EIP/VPC)** configured. In this tutorial, that's your Regional pool. By default the CIDR is not advertised, which means it's not publicly accessible over the internet.

This step must be done by the IPAM account.

> **Note**
>
> The advertisement status doesn't not restrict your ability to allocate Elastic IP addresses. Even if your BYOIPv4 CIDR is not advertised, you can still can create EIPs from the IPAM pool.

To advertise the CIDR

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.
3. By default, when you create a pool, the default private scope is selected. Choose the public scope. For more information about scopes, see How IPAM works.
4. Choose the Regional pool you created in this tutorial.
5. Choose the **CIDRs** tab.
6. Select the BYOIP CIDR and choose **Actions** > **Advertise**.
7. Choose **Advertise CIDR**.

As a result, the BYOIP CIDR is advertised and the value in the **Advertising** column changes from **Withdrawn** to **Advertised**.

Step 5. Share the Regional pool

Follow the steps in this section to share the IPAM pool using AWS Resource Access Manager (RAM).

Enable resource sharing in AWS RAM

After you create your IPAM, you'll want to share the regional pool with other accounts in your organization. Before you share an IPAM pool, complete the steps in this section to enable resource sharing with AWS RAM. If you are using the AWS CLI to enable resource sharing, use the `--profile` **`management-account`** option.

To enable resource sharing

1. Using the AWS Organizations management account, open the AWS RAM console at https://console.aws.amazon.com/ram/.
2. In the left navigation pane, choose **Settings**, choose **Enable sharing with AWS Organizations**, and then choose **Save settings**.

You can now share an IPAM pool with other members of the organization.

Share an IPAM pool using AWS RAM

In this section you'll share the regional pool with another AWS Organizations member account. For complete instructions on sharing IPAM pools, including information on the required IAM permissions, see Share an IPAM pool using AWS RAM. If you are using the AWS CLI to enable resource sharing, use the `--profile` **`ipam-account`** option.

To share an IPAM pool using AWS RAM

1. Using the IPAM admin account, open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.
3. Choose the private scope, choose the IPAM pool, and choose **Actions** > **View details**.
4. Under **Resource sharing**, choose **Create resource share**. The AWS RAM console opens. You share the pool using AWS RAM.
5. Choose **Create a resource share**.
6. In the AWS RAM console, choose **Create a resource share** again.
7. Add a **Name** for the shared pool.

8. Under **Select resource type**, choose **IPAM pools,** and then choose the ARN of the pool you want to share.
9. Choose **Next**.
10. Choose the **AWSRAMPermissionIpamPoolByoipCidrImport** permission. The details of the permission options are out of scope for this tutorial, but you can find out more about these options in Share an IPAM pool using AWS RAM.
11. Choose **Next**.
12. Under **Principals** > **Select principal type**, choose **AWS account** and enter the account ID of the account that will be bringing an IP address range to IPAM and choose **Add** .
13. Choose **Next**.
14. Review the resource share options and the principals that you'll be sharing with, and then choose **Create**.
15. To allow the **`member-account`** account to allocate IP address CIDRS from the IPAM pool, create a second resource share with `AWSRAMDefaultPermissionsIpamPool`. The value for `--resource-arns` is the ARN of the IPAM pool that you created in the previous section. The value for `--principals` is the account ID of the **`member-account`**. The value for `--permission-arns` is the ARN of the `AWSRAMDefaultPermissionsIpamPool` permission.

Step 6: Allocate an Elastic IP address from the pool

Complete the steps in this section to allocate an Elastic IP address from the pool. Note that if you are using public IPv4 pools to allocate Elastic IP addresses, you can use the alternative steps in Alternative to Step 6 rather than the steps in this section.

> **Important**
>
> If you see an error related to not having permissions to call ec2:AllocateAddress, the managed permission currently assigned to the IPAM pool that was shared with you needs to be updated. Contact the person who created the resource share and ask them to update the managed permission `AWSRAMPermissionIpamResourceDiscovery` to the default version. For more information, see Update a resource share in the *AWS RAM User Guide* .

AWS Management Console

Follow the steps in Allocate an Elastic IP address in the *Amazon EC2 User Guide* to allocate the address, but note the following:

- This step must be done by the member account.
- Ensure that the AWS Region you are in in the EC2 console matches the Locale option you chose when you created the Regional pool.
- When you choose the address pool, choose the option to **Allocate using an IPv4 IPAM pool** and choose the Regional pool you created.

Command line

Allocate an address from the pool with the allocate-address command. The `--region` you use must match the `-locale` option you chose when you created the pool in Step 2. Include the ID of the IPAM pool you created in Step 2 in `--ipam-pool-id`. Optionally, you can also choose a specific `/32` in your IPAM pool by using the `--address` option.

```
aws ec2 allocate-address --region us-east-1 --ipam-pool-id ipam-
pool-07ccc86aa41bef7ce
```

Example response:

```
{
    "PublicIp": "18.97.0.41",
    "AllocationId": "eipalloc-056cdd6019c0f4b46",
    "PublicIpv4Pool": "ipam-pool-07ccc86aa41bef7ce",
    "NetworkBorderGroup": "us-east-1",
    "Domain": "vpc"
}
```

For more information, see Allocate an Elastic IP address in the *Amazon EC2 User Guide*.

Step 7: Associate the Elastic IP address with an EC2 instance

Complete the steps in this section to associate the Elastic IP address with an EC2 instance.

AWS Management Console

Follow the steps in Associate an Elastic IP address in the *Amazon EC2 User Guide* to allocate an Elastic IP address from the IPAM pool, but note the following: When you use AWS Management Console option, the AWS Region you associate the Elastic IP address in must match the Locale option you chose when you created the Regional pool.

This step must be done by the member account.

Command line

This step must be done by the member account. Use the `--profile` **`member-account`** option.

Associate the Elastic IP address with an instance with the associate-address command. The `--region` you associate the Elastic IP address in must match the `--locale` option you chose when you created the Regional pool.

```
aws ec2 associate-address --region us-east-1 --instance-id i-07459a6fca5b35823 --
public-ip 18.97.0.41
```

Example response:

```
{
    "AssociationId": "eipassoc-06aa85073d3936e0e"
}
```

For more information, see Associate an Elastic IP address with an instance or network interface in the *Amazon EC2 User Guide*.

Step 8: Cleanup

Follow the steps in this section to clean up the resources you've provisioned and created in this tutorial.

Step 1: Withdraw the CIDR from advertising

This step must be done by the IPAM account.

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.

2. In the navigation pane, choose **Pools**.
3. By default, when you create a pool, the default private scope is selected. Choose the public scope.
4. Choose the Regional pool you created in this tutorial.
5. Choose the **CIDRs** tab.
6. Select the BYOIP CIDR and choose **Actions** > **Withdraw from advertising**.
7. Choose **Withdraw CIDR**.

As a result, the BYOIP CIDR is no longer advertised and the value in the **Advertising** column changes from **Advertised** to **Withdrawn**.

Step 2: Disassociate the Elastic IP address

This step must be done by the member account. If you are using the AWS CLI, use the `--profile` **`member-account`** option.

- Complete the steps in Disassociate an Elastic IP address in the *Amazon EC2 User Guide* to disassociate the EIP. When you open EC2 in the AWS Management console, the AWS Region you disassociate the EIP in must match the `Locale` option you chose when you created the pool that will be used for the BYOIP CIDR. In this tutorial, that pool is the Regional pool.

Step 3: Release the Elastic IP address

This step must be done by the member account. If you are using the AWS CLI, use the `--profile` **`member-account`** option.

- Complete the steps in Release an Elastic IP address in the *Amazon EC2 User Guide* to release an Elastic IP address (EIP) from the public IPv4 pool. When you open EC2 in the AWS Management console, the AWS Region you allocate the EIP in must match the `Locale` option you chose when you created the pool that will be used for the BYOIP CIDR.

Step 4: Delete any RAM shares and disable RAM integration with AWS Organizations

This step must be done by the IPAM account and management account respectively. If you are using the AWS CLI to delete the RAM shares and disable RAM integration, use the `--profile` **`ipam-account`** and `--profile` **`management-account`** options.

- Complete the steps in Deleting a resource share in AWS RAM and Disabling resource sharing with AWS Organizations in the *AWS RAM User Guide*, in that order, to delete the RAM shares and disable RAM integration with AWS Organizations.

Step 5: Deprovision the CIDRs from the Regional pool and top-level pool

This step must be done by the IPAM account. If you are using the AWS CLI to share the pool, use the `--profile` **`ipam-account`** option.

- Complete the steps in Deprovision CIDRs from a pool to deprovision the CIDRs from the Regional pool and then the top-level pool, in that order.

Step 6: Delete the Regional pool and top-level pool

This step must be done by the IPAM account. If you are using the AWS CLI to share the pool, use the `--profile` **`ipam-account`** option.

- Complete the steps in Delete a pool to delete the Regional pool and then the top-level pool, in that order.

Alternative to Step 6

If you are using public IPv4 pools to allocate Elastic IP addresses, you can use the steps in this section rather than the steps in Step 6: Allocate an Elastic IP address from the pool.

Contents

Step 1: Create a public IPv4 pool

This step should be done by the member account that will provision an Elastic IP address.

Note

- This step must be done by the member account using the AWS CLI.
- Public IPv4 pools and IPAM pools are managed by distinct resources in AWS. Public IPv4 pools are single account resources that enable you to convert your publicly-owned CIDRs to Elastic IP addresses. IPAM pools can be used to allocate your public space to public IPv4 pools.

To create a public IPv4 pool using the AWS CLI

- Run the following command to provision the CIDR. When you run the command in this section, the value for `--region` must match the `Locale` option you chose when you created the pool that will be used for the BYOIP CIDR.

```
aws ec2 create-public-ipv4-pool --region us-east-2 --profile member-account
```

In the output, you'll see the public IPv4 pool ID. You will need this ID in the next step.

```
{
    "PoolId": "ipv4pool-ec2-09037ce61cf068f9a"
}
```

Step 2: Provision the public IPv4 CIDR to your public IPv4 pool

Provision the public IPv4 CIDR to your public IPv4 pool. The value for `--region` must match the `Locale` value you chose when you created the pool that will be used for the BYOIP CIDR. The `--netmask-length` is the amount of space out of the IPAM pool that you want to bring to your public pool. The value cannot be larger than the netmask length of the IPAM pool. The least specific `--netmask-length` you can define is 24.

Note

- If you are bringing a /24 CIDR range to IPAM to share across an AWS Organization, you can provision smaller prefixes to multiple IPAM pools, say /27 (using `-- netmask-`

length 27), rather than provisioning the entire /24 CIDR (using -- netmask-length 24) as is shown in this tutorial.

- This step must be done by the member account using the AWS CLI.

To create a public IPv4 pool using the AWS CLI

1. Run the following command to provision the CIDR.

```
aws ec2 provision-public-ipv4-pool-cidr --region us-east-2 --ipam-pool-id ipam-
pool-04d8e2d9670eeab21 --pool-id ipv4pool-ec2-09037ce61cf068f9a --netmask-length 24
 --profile member-account
```

   In the output, you'll see the provisioned CIDR.

```
{
    "PoolId": "ipv4pool-ec2-09037ce61cf068f9a",
    "PoolAddressRange": {
        "FirstAddress": "130.137.245.0",
        "LastAddress": "130.137.245.255",
        "AddressCount": 256,
        "AvailableAddressCount": 256
    }
}
```

2. Run the following command to view the CIDR provisioned in the public IPv4 pool.

```
aws ec2 describe-public-ipv4-pools --region us-east-2 --max-results 10 --
profile member-account
```

   In the output, you'll see the provisioned CIDR. By default the CIDR is not advertised, which means it's not publicly accessible over the internet. You will have the chance to set this CIDR to advertised in the last step of this tutorial.

```
{
    "PublicIpv4Pools": [
        {
            "PoolId": "ipv4pool-ec2-09037ce61cf068f9a",
            "Description": "",
            "PoolAddressRanges": [
```

```
                {
                    "FirstAddress": "130.137.245.0",
                    "LastAddress": "130.137.245.255",
                    "AddressCount": 256,
                    "AvailableAddressCount": 255
                }
            ],
            "TotalAddressCount": 256,
            "TotalAvailableAddressCount": 255,
            "NetworkBorderGroup": "us-east-2",
            "Tags": []
        }
    ]
}
```

Once you create the public IPv4 pool, to view the public IPv4 pool allocated in the IPAM Regional pool, open the IPAM console and view the allocation in the Regional pool under **Allocations** or **Resources**.

Step 3: Allocate an Elastic IP address from the public IPv4 pool

Complete the steps in Allocate an Elastic IP address in the *Amazon EC2 User Guide* to allocate an EIP from the public IPv4 pool. When you open EC2 in the AWS Management console, the AWS Region you allocate the EIP in must match the `Locale` option you chose when you created the pool that will be used for the BYOIP CIDR.

This step must be done by the member account. If you are using the AWS CLI, use the `--profile` **`member-account`** option.

Once you've completed these three steps, return to Step 7: Associate the Elastic IP address with an EC2 instance and continue until you complete the tutorial.

Alternative to Step 6 cleanup

Complete these steps to clean up public IPv4 pools created with the alternative to Step 9. You should complete these steps after you release the Elastic IP address during the standard cleanup process in Step 8: Cleanup.

Step 1: Deprovision the public IPv4 CIDR from your public IPv4 pool

> **Important**
>
> This step must be done by the member account using the AWS CLI.

1. View your BYOIP CIDRs.

```
aws ec2 describe-public-ipv4-pools --region us-east-2 --profile member-account
```

In the output, you'll see the IP addresses in your BYOIP CIDR.

```
{
    "PublicIpv4Pools": [
        {
            "PoolId": "ipv4pool-ec2-09037ce61cf068f9a",
            "Description": "",
            "PoolAddressRanges": [
                {
                    "FirstAddress": "130.137.245.0",
                    "LastAddress": "130.137.245.255",
                    "AddressCount": 256,
                    "AvailableAddressCount": 256
                }
            ],
            "TotalAddressCount": 256,
            "TotalAvailableAddressCount": 256,
            "NetworkBorderGroup": "us-east-2",
            "Tags": []
        }
    ]
}
```

2. Run the following command to release the CIDR from the public IPv4 pool.

```
aws ec2 deprovision-public-ipv4-pool-cidr --region us-east-2 --pool-id ipv4pool-
ec2-09037ce61cf068f9a --cidr 130.137.245.0/24 --profile member-account
```

3. View your BYOIP CIDRs again and ensure there are no more provisioned addresses. When you run the command in this section, the value for `--region` must match the Region of your IPAM.

```
aws ec2 describe-public-ipv4-pools --region us-east-2 --profile member-account
```

In the output, you'll see the IP addresses count in your public IPv4 pool.

```
{
    "PublicIpv4Pools": [
        {
            "PoolId": "ipv4pool-ec2-09037ce61cf068f9a",
            "Description": "",
            "PoolAddressRanges": [],
            "TotalAddressCount": 0,
            "TotalAvailableAddressCount": 0,
            "NetworkBorderGroup": "us-east-2",
            "Tags": []
        }
    ]
}
```

Note

It can take some time for IPAM to discover that public IPv4 pool allocations have been removed. You cannot continue to clean up and deprovision the IPAM pool CIDR until you see that the allocation has been removed from IPAM.

Step 2: Delete the public IPv4 pool

This step must be done by the member account.

- Run the following command to delete the public IPv4 pool the CIDR. When you run the command in this section, the value for `--region` must match the `Locale` option you chose when you created the pool that will be used for the BYOIP CIDR. In this tutorial, that pool is the Regional pool. This step must be done using the AWS CLI.

```
aws ec2 delete-public-ipv4-pool --region us-east-2 --pool-id ipv4pool-
ec2-09037ce61cf068f9a --profile member-account
```

In the output, you'll see the return value **true**.

```
{
"ReturnValue": true
}
```

Once you delete the pool, to view the allocation unmanaged by IPAM, open the IPAM console and view the details of the Regional pool under **Allocations**.

Bring your own IPv6 CIDR to IPAM using the AWS Management Console

Follow the steps in this tutorial to bring an IPv6 CIDR to IPAM and allocate a VPC with the CIDR using both the AWS Management Console and the AWS CLI.

If you do not need to advertise your IPv6 addresses over the Internet, you can provision a private GUA IPv6 address to an IPAM. For more information, see Enable provisioning private IPv6 GUA CIDRs.

Important

- This tutorial assumes you have already completed the steps in the following sections:
  - Integrate IPAM with accounts in an AWS Organization.
  - Create an IPAM.
- Each step of this tutorial must be done by one of three AWS Organizations accounts:
  - The management account.
  - The member account configured to be your IPAM administrator in Integrate IPAM with accounts in an AWS Organization. In this tutorial, this account will be called the IPAM account.
  - The member account in your organization which will allocate CIDRs from an IPAM pool. In this tutorial, this account will be called the member account.

Contents

Step 1: Create a top-level IPAM pool

Since you are going to create a top-level IPAM pool with a Regional pool within it, and we're going to allocate space to a resource from the Regional pool. You set the locale on the Regional pool, not the top-level pool. You'll add the locale to the Regional pool when you create the Regional pool in a later step. The IPAM integration with BYOIP requires that the locale is set on whichever pool will be used for the BYOIP CIDR.

This step must be done by the IPAM account.

To create a pool

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.
3. By default, when you create a pool, the default private scope is selected. Choose the public scope. For more information about scopes, see How IPAM works.
4. Choose **Create pool**.
5. (Optional) Add a **Name tag** for the pool and a **Description** for the pool.
6. Under **Source**, choose **IPAM scope**.
7. Under **Address family**, choose **IPv6**.
8. Under **Resource planning**, leave **Plan IP space within the scope** selected. For more information about using this option to plan for subnet IP space within a VPC, see Tutorial: Plan VPC IP address space for subnet IP allocations.
9. Under **Locale**, choose **None**. You will set the locale on the Regional pool.

   The locale is the AWS Region where you want this IPAM pool to be available for allocations. For example, you can only allocate a CIDR for a VPC from an IPAM pool that shares a locale

with the VPC's Region. Note that when you have chosen a locale for a pool, you cannot modify it. If the home Region of the IPAM is unavailable due to an outage and the pool has a locale different than the home Region of the IPAM, the pool can still be used to allocate IP addresses.

> **Note**
>
> If you are creating a single pool only and not a top-level pool with Regional pools within it, you would want to choose a Locale for this pool so that the pool is available for allocations.

10. Under **Public IP source**, **BYOIP** is selected by default.
11. Under **CIDRs to provision**, do one of the following:

    - If you verified your domain control with an X.509 certificate, you must include the CIDR and the BYOIP message and certificate signature that you created in that step so we can verify that you control the public space.
    - If you verified your domain control with a DNS TXT record, you must include the CIDR and IPAM verification token that you created in that step so we can verify that you control the public space.

    Note that when provisioning an IPv6 CIDR to a pool within the top-level pool, the most specific IPv6 address range that you can bring is /48 for CIDRs that are publicly advertisable and /60 for CIDRs that are not publicly advertisable.

> **Important**
>
> While most provisioning will be completed within two hours, it may take up to one week to complete the provisioning process for publicly advertisable ranges.

12. Leave **Configure this pool's allocation rule settings** unselected.
13. (Optional) Choose **Tags** for the pool.
14. Choose **Create pool**.

Ensure that this CIDR has been provisioned before you continue. You can see the state of provisioning in the **CIDRs** tab in the pool details page.

Step 2. Create a Regional pool within the top-level pool

Create a Regional pool within the top-level pool. A Locale is required on the pool and it must be one of the operating Regions you configured when you created the IPAM.

This step must be done by the IPAM account.

To create a Regional pool within a top-level pool

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.
3. By default, when you create a pool, the default private scope is selected. If you don't want to use the default private scope, from the dropdown menu at the top of the content pane, choose the scope you want to use. For more information about scopes, see How IPAM works.
4. Choose **Create pool**.
5. (Optional) Add a **Name tag** for the pool and a description for the pool.
6. Under **Source**, choose the top-level pool that you created in the previous section.
7. Under **Resource planning**, leave **Plan IP space within the scope** selected. For more information about using this option to plan for subnet IP space within a VPC, see Tutorial: Plan VPC IP address space for subnet IP allocations.
8. Choose the locale for the pool. Choosing a locale ensures there are no cross-region dependencies between your pool and the resources allocating from it. The available options come from the operating Regions that you chose when you created your IPAM. In this tutorial, we'll use `us-east-2` as the locale for the Regional pool.

   The locale is the AWS Region where you want this IPAM pool to be available for allocations. For example, you can only allocate a CIDR for a VPC from an IPAM pool that shares a locale with the VPC's Region. Note that when you have chosen a locale for a pool, you cannot modify it. If the home Region of the IPAM is unavailable due to an outage and the pool has a locale different than the home Region of the IPAM, the pool can still be used to allocate IP addresses.
9. Under **Service**, choose **EC2 (EIP/VPC)**. The service you select determines the AWS service where the CIDR will be advertisable. Currently, the only option is **EC2 (EIP/VPC)**, which means that the CIDRs allocated from this pool will be advertisable for the Amazon EC2 service and the Amazon VPC service (for CIDRs associated with VPCs).
10. Under **CIDRs to provision**, choose a CIDR to provision for the pool. Note that when provisioning an IPv6 CIDR to a pool within the top-level pool, the most specific IPv6 address

range that you can bring is /48 for CIDRs that are publicly advertisable and /60 for CIDRs that are not publicly advertisable.

11. Enable **Configure this pool's allocation rule settings** and choose optional allocation rules for this pool:

    - **Automatically import discovered resources**: This option is not available if the **Locale** is set to **None**. If selected, IPAM will continuously look for resources within the CIDR range of this pool and automatically import them as allocations into your IPAM. Note the following:
      - The CIDRs that will be allocated for these resources must not already be allocated to other resources in order for the import to succeed.
      - IPAM will import a CIDR regardless of its compliance with the pool's allocation rules, so a resource might be imported and subsequently marked as noncompliant.
      - If IPAM discovers multiple CIDRs that overlap, IPAM will import the largest CIDR only.
      - If IPAM discovers multiple CIDRs with matching CIDRs, IPAM will randomly import one of them only.
    - **Minimum netmask length**: The minimum netmask length required for CIDR allocations in this IPAM pool to be compliant and the largest size CIDR block that can be allocated from the pool. The minimum netmask length must be less than the maximum netmask length. Possible netmask lengths for IPv4 addresses are `0` - `32`. Possible netmask lengths for IPv6 addresses are `0` - `128`.
    - **Default netmask length**: A default netmask length for allocations added to this pool.
    - **Maximum netmask length**: The maximum netmask length that will be required for CIDR allocations in this pool. This value dictates the smallest size CIDR block that can be allocated from the pool. Ensure that this value is minimum **/48**.
    - **Tagging requirements**: The tags that are required for resources to allocate space from the pool. If the resources have their tags changed after they have allocated space or if the allocation tagging rules are changed on the pool, the resource may be marked as noncompliant.
    - **Locale**: The locale that will be required for resources that use CIDRs from this pool. Automatically imported resources that do not have this locale will be marked noncompliant. Resources that are not automatically imported into the pool will not be allowed to allocate space from the pool unless they are in this locale.
12. (Optional) Choose **Tags** for the pool.
13. When you've finished configuring your pool, choose **Create pool**.

Ensure that this CIDR has been provisioned before you continue. You can see the state of provisioning in the **CIDRs** tab in the pool details page.

Step 3. Share the Regional pool

Follow the steps in this section to share the IPAM pool using AWS Resource Access Manager (RAM).

Enable resource sharing in AWS RAM

After you create your IPAM, you'll want to share the regional pool with other accounts in your organization. Before you share an IPAM pool, complete the steps in this section to enable resource sharing with AWS RAM. If you are using the AWS CLI to enable resource sharing, use the `--profile` **`management-account`** option.

To enable resource sharing

1. Using the AWS Organizations management account, open the AWS RAM console at https://console.aws.amazon.com/ram/.
2. In the left navigation pane, choose **Settings**, choose **Enable sharing with AWS Organizations**, and then choose **Save settings**.

You can now share an IPAM pool with other members of the organization.

Share an IPAM pool using AWS RAM

In this section you'll share the regional pool with another AWS Organizations member account. For complete instructions on sharing IPAM pools, including information on the required IAM permissions, see Share an IPAM pool using AWS RAM. If you are using the AWS CLI to enable resource sharing, use the `--profile` **`ipam-account`** option.

To share an IPAM pool using AWS RAM

1. Using the IPAM admin account, open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.
3. Choose the private scope, choose the IPAM pool, and choose **Actions** > **View details**.
4. Under **Resource sharing**, choose **Create resource share**. The AWS RAM console opens. You share the pool using AWS RAM.

5. Choose **Create a resource share**.
6. In the AWS RAM console, choose **Create a resource share** again.
7. Add a **Name** for the shared pool.
8. Under **Select resource type**, choose **IPAM pools,** and then choose the ARN of the pool you want to share.
9. Choose **Next**.
10. Choose the **AWSRAMPermissionIpamPoolByoipCidrImport** permission. The details of the permission options are out of scope for this tutorial, but you can find out more about these options in Share an IPAM pool using AWS RAM.
11. Choose **Next**.
12. Under **Principals** > **Select principal type**, choose **AWS account** and enter the account ID of the account that will be bringing an IP address range to IPAM and choose **Add** .
13. Choose **Next**.
14. Review the resource share options and the principals that you'll be sharing with, and then choose **Create**.
15. To allow the **`member-account`** account to allocate IP address CIDRS from the IPAM pool, create a second resource share with `AWSRAMDefaultPermissionsIpamPool`. The value for `--resource-arns` is the ARN of the IPAM pool that you created in the previous section. The value for `--principals` is the account ID of the **`member-account`**. The value for `--permission-arns` is the ARN of the `AWSRAMDefaultPermissionsIpamPool` permission.

Step 4: Create a VPC

Complete the steps in Create a VPC in the *Amazon VPC User Guide*.

This step must be done by the member account.

> **Note**
>
> - When you open VPC in the AWS Management console, the AWS Region you create the VPC in must match the `Locale` option you chose when you created the pool that will be used for the BYOIP CIDR.
> - When you reach the step to choose a CIDR for the VPC, you will have an option to use a CIDR from an IPAM pool. Choose the Regional pool you created in this tutorial.

When you create the VPC, AWS allocates a CIDR in the IPAM pool to the VPC. You can view the allocation in IPAM by choosing a pool in the content pane of the IPAM console and viewing the **Allocations** tab for the pool.

Step 5: Advertise the CIDR

The steps in this section must be done by the IPAM account. Once you create the VPC, you can then start advertising the CIDR you brought to AWS that is in the pool that has the **Service EC2 (EIP/VPC)** configured. In this tutorial, that's your Regional pool. By default the CIDR is not advertised, which means it's not publicly accessible over the internet.

This step must be done by the IPAM account.

To advertise the CIDR

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.
3. By default, when you create a pool, the default private scope is selected. Choose the public scope. For more information about scopes, see How IPAM works.
4. Choose the Regional pool you created in this tutorial.
5. Choose the **CIDRs** tab.
6. Select the BYOIP CIDR and choose **Actions** > **Advertise**.
7. Choose **Advertise CIDR**.

As a result, the BYOIP CIDR is advertised and the value in the **Advertising** column changes from **Withdrawn** to **Advertised**.

Step 6: Cleanup

Follow the steps in this section to clean up the resources you've provisioned and created in this tutorial.

Step 1: Withdraw the CIDR from advertising

This step must be done by the IPAM account.

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.

3. By default, when you create a pool, the default private scope is selected. Choose the public scope.
4. Choose the Regional pool you created in this tutorial.
5. Choose the **CIDRs** tab.
6. Select the BYOIP CIDR and choose **Actions** > **Withdraw from advertising**.
7. Choose **Withdraw CIDR**.

As a result, the BYOIP CIDR is no longer advertised and the value in the **Advertising** column changes from **Advertised** to **Withdrawn**.

Step 2: Delete the VPC

This step must be done by the member account.

- Complete the steps in Delete a VPC in the *Amazon VPC User Guide* to delete the VPC. When you open VPC in the AWS Management console, the AWS Region delete the VPC from must match the `Locale` option you chose when you created the pool that will be used for the BYOIP CIDR. In this tutorial, that pool is the Regional pool.

  When you delete the VPC, it takes time for IPAM to discover that the resource has been deleted and to deallocate the CIDR allocated to the VPC. You cannot continue to the next step in the cleanup until you see that IPAM has removed the allocation from the pool in the pool details **Allocations** tab.

Step 3: Delete the RAM shares and disable RAM integration with AWS Organizations

This step must be done by the IPAM account and management account respectively.

- Complete the steps in Deleting a resource share in AWS RAM and Disabling resource sharing with AWS Organizations in the *AWS RAM User Guide*, in that order, to delete the RAM shares and disable RAM integration with AWS Organizations.

Step 4: Deprovision the CIDRs from the Regional pool and top-level pool

This step must be done by the IPAM account.

- Complete the steps in Deprovision CIDRs from a pool to deprovision the CIDRs from the Regional pool and then the top-level pool, in that order.

Step 5: Delete the Regional pool and top-level pool

This step must be done by the IPAM account.

- Complete the steps in Delete a pool to delete the Regional pool and then the top-level pool, in that order.

Bring your own IP CIDR to IPAM using only the AWS CLI

Bringing Your Own IP (BYOIP) to IPAM allows you to use your organization's existing IPv4 and IPv6 address ranges in AWS. This enables you to maintain consistent branding, improve network performance, enhance security, and simplify management by unifying on-premises and cloud environments under your own IP address space.

Follow these steps to bring an IPv4 or IPv6 CIDR to IPAM using only the AWS CLI.

> **Note**
>
> Before you begin, you must have first verified domain control.

Once you bring an IPv4 address range to AWS, you can use all of the IP addresses in the range, including the first address (the network address) and the last address (the broadcast address).

Contents

Bring your own public IPv4 CIDR to IPAM using only the AWS CLI

Follow these steps to bring an IPv4 CIDR to IPAM and allocate an Elastic IP address (EIP) with the CIDR using only the AWS CLI.

> **Important**
>
> - This tutorial assumes you have already completed the steps in the following sections:
>   - Integrate IPAM with accounts in an AWS Organization.
>   - Create an IPAM.

- Each step of this tutorial must be done by one of three AWS Organizations accounts:
  - The management account.
  - The member account configured to be your IPAM administrator in Integrate IPAM with accounts in an AWS Organization. In this tutorial, this account will be called the IPAM account.
  - The member account in your organization which will allocate CIDRs from an IPAM pool. In this tutorial, this account will be called the member account.

Contents

Step 1: Create AWS CLI named profiles and IAM roles

To complete this tutorial as a single AWS user, you can use AWS CLI named profiles to switch from one IAM role to another. Named profiles are collections of settings and credentials that you refer to when using the `--profile` option with the AWS CLI. For more information about how to create IAM roles and named profiles for AWS accounts, see Using an IAM role in the AWS CLI.

Create one role and one named profile for each of the three AWS accounts you will use in this tutorial:

- A profile called `management-account` for the AWS Organizations management account.

- A profile called `ipam-account` for the AWS Organizations member account that is configured to be your IPAM administrator.
- A profile called `member-account` for the AWS Organizations member account in your organization which will allocate CIDRs from an IPAM pool.

After you have created the IAM roles and named profiles, return to this page and go to the next step. You will notice throughout the rest of this tutorial that the sample AWS CLI commands use the `--profile` option with one of the named profiles to indicate which account must run the command.

Step 2: Create an IPAM

This step is optional. If you already have an IPAM created with operating Regions of `us-east-1` and `us-west-2` created, you can skip this step. Create an IPAM and specify an operating region of `us-east-1` and `us-west-2` . You must select an operating region so that you can use the locale option when you create your IPAM pool. The IPAM integration with BYOIP requires that the locale is set on whichever pool will be used for the BYOIP CIDR.

This step must be done by the IPAM account.

Run the following command:

```
aws ec2 create-ipam --description my-ipam --region us-east-1 --operating-
regions RegionName=us-west-2 --profile ipam-account
```

In the output, you'll see the IPAM you've created. Note the value for `PublicDefaultScopeId`. You will need your public scope ID in the next step. You are using the public scope because BYOIP CIDRs are public IP addresses, which is what the public scope is meant for.

```
{
 "Ipam": {
        "OwnerId": "123456789012",
        "IpamId": "ipam-090e48e75758de279",
        "IpamArn": "arn:aws:ec2::123456789012:ipam/ipam-090e48e75758de279",
        "PublicDefaultScopeId": "ipam-scope-0087d83896280b594",
        "PrivateDefaultScopeId": "ipam-scope-08b70b04fbd524f8d",
        "ScopeCount": 2,
        "Description": "my-ipam",
        "OperatingRegions": [
            {
```

```
                "RegionName": "us-east-1"
            },
            {
                "RegionName": "us-west-2"
            }
        ],
        "Tags": []
    }
}
```

Step 3: Create a top-level IPAM pool

Complete the steps in this section to create a top-level IPAM pool.

This step must be done by the IPAM account.

To create an IPv4 address pool for all of your AWS resources using the AWS CLI

1. Run the following command to create an IPAM pool. Use the ID of the public scope of the IPAM that you created in the previous step.

   This step must be done by the IPAM account.

   ```
   aws ec2 create-ipam-pool --region us-east-1 --ipam-scope-id ipam-
   scope-0087d83896280b594 --description "top-level-IPv4-pool" --address-family ipv4
    --profile ipam-account
   ```

   In the output, you'll see `create-in-progress`, which indicates that pool creation is in progress.

   ```
   {
       "IpamPool": {
           "OwnerId": "123456789012",
           "IpamPoolId": "ipam-pool-0a03d430ca3f5c035",
           "IpamPoolArn": "arn:aws:ec2::123456789012:ipam-pool/ipam-
   pool-0a03d430ca3f5c035",
           "IpamScopeArn": "arn:aws:ec2::123456789012:ipam-scope/ipam-
   scope-0087d83896280b594",
           "IpamScopeType": "public",
           "IpamArn": "arn:aws:ec2::123456789012:ipam/ipam-090e48e75758de279",
           "Locale": "None",
           "PoolDepth": 1,
   ```

```
        "State": "create-in-progress",
        "Description": "top-level-pool",
        "AutoImport": false,
        "AddressFamily": "ipv4",
        "Tags": []
    }
}
```

2. Run the following command until you see a state of `create-complete` in the output.

```
aws ec2 describe-ipam-pools --region us-east-1 --profile ipam-account
```

The following example output shows the state of the pool.

```
{
    "IpamPools": [
        {
            "OwnerId": "123456789012",
            "IpamPoolId": "ipam-pool-0a03d430ca3f5c035",
            "IpamPoolArn": "arn:aws:ec2::123456789012:ipam-pool/ipam-
pool-0a03d430ca3f5c035",
            "IpamScopeArn": "arn:aws:ec2::123456789012:ipam-scope/ipam-
scope-0087d83896280b594",
            "IpamScopeType": "public",
            "IpamArn": "arn:aws:ec2::123456789012:ipam/ipam-090e48e75758de279",
            "Locale": "None",
            "PoolDepth": 1,
            "State": "create-complete",
            "Description": "top-level-IPV4-pool",
            "AutoImport": false,
            "AddressFamily": "ipv4",
            "Tags": []
        }
    ]
}
```

Step 4: Provision a CIDR to the top-level pool

Provision a CIDR block to the top-level pool. Note that when provisioning an IPv4 CIDR to a pool within the top-level pool, the minimum IPv4 CIDR you can provision is /24; more specific CIDRs (such as /25) are not permitted.

Note

- If you verified your domain control with an X.509 certificate, you must include the CIDR and the BYOIP message and certificate signature that you created in that step so we can verify that you control the public space.
- If you verified your domain control with a DNS TXT record, you must include the CIDR and IPAM verification token that you created in that step so we can verify that you control the public space.

You only need to verify domain control when you provision the BYOIP CIDR to the top-level pool. For the Regional pool within the top-level pool, you can omit the domain ownership verification option.

This step must be done by the IPAM account.

Important

You only need to verify domain control when you provision the BYOIP CIDR to the top-level pool. For the Regional pool within the top-level pool, you can omit the domain control option. Once you onboard your BYOIP to IPAM, you are not required to perform ownership validation when you divide the BYOIP across Regions and accounts.

To provision a CIDR block to the pool using the AWS CLI

1. To provision the CIDR with certificate information, use the following command example. In addition to replacing the values as needed in the example, ensure that you replace `Message` and `Signature` values with the `text_message` and `signed_message` values that you got in Verify your domain with an X.509 certificate.

```
aws ec2 provision-ipam-pool-cidr --region us-east-1 --ipam-
pool-id ipam-pool-0a03d430ca3f5c035 --cidr 130.137.245.0/24 --
verification-method remarks-x509 --cidr-authorization-context
 Message="1|aws|470889052444|130.137.245.0/24|20250101|SHA256|
RSAPSS",Signature="W3gdQ9PZHLjPmrnGM~cvGx~KCIsMaU0P7ENO7VRnfSuf9NuJU5RUveQzus~QmF~Nx42j3z7d
hApR89Kt6GxRYOdRaNx8yt-uoZWzxct2yIhWngy-
du9pnEHBOX6WhoGYjWszPw0iV4cmaAX9DuMs8ASR83K127VvcBcRXElT5URr3gWEB1CQe3rmuyQk~gAdbXiDN-94-
```

```
oS9AZlafBbrFxRjFWRCTJhc7Cg3ASbRO-VWNci-
C~bWAPczbX3wPQSjtWGV3k1bGuD26ohUc02o8oJZQyYXRpgqcWGVJdQ__" --profile ipam-account
```

To provision the CIDR with verification token information, use the following command example. In addition to replacing the values as needed in the example, ensure that you replace `ipam-ext-res-ver-token-0309ce7f67a768cf0` with the `IpamExternalResourceVerificationTokenId` token ID that you got in Verify your domain with a DNS TXT record.

```
aws ec2 provision-ipam-pool-cidr --region us-east-1 --ipam-pool-id ipam-
pool-0a03d430ca3f5c035 --cidr 130.137.245.0/24 --verification-method dns-
token --ipam-external-resource-verification-token-id ipam-ext-res-ver-
token-0309ce7f67a768cf0 --profile ipam-account
```

In the output, you'll see the CIDR pending provision.

```
{
    "IpamPoolCidr": {

        "Cidr": "130.137.245.0/24",

        "State": "pending-provision"

    }

}
```

2. Ensure that this CIDR has been provisioned before you continue.

> **Important**
>
> While most provisioning will be completed within two hours, it may take up to one week to complete the provisioning process for publicly advertisable ranges.

Run the following command until you see a state of `provisioned` in the output.

```
aws ec2 get-ipam-pool-cidrs --region us-east-1 --ipam-pool-id ipam-
pool-0a03d430ca3f5c035 --profile ipam-account
```

The following example output shows the state.

```
{
    "IpamPoolCidrs": [
        {
            "Cidr": "130.137.245.0/24",
            "State": "provisioned"
        }
    ]
}
```

Step 5: Create a Regional pool within the top-level pool

Create a Regional pool within the top-level pool.

The locale for the pool should be one of the following:

- An AWS Region where you want this IPAM pool to be available for allocations.
- The network border group for an AWS Local Zone where you want this IPAM pool to be available for allocations (supported Local Zones). This option is only available for IPAM IPv4 pools in the public scope.
- An AWS Dedicated Local Zone. To create a pool within an AWS Dedicated Local Zone, enter the AWS Dedicated Local Zone in the selector input.
- `Global` when you want to use IP addresses globally across all AWS Regions, such as CloudFront locations. The `Global` locale is only available for public IPv4 pools.

For example, you can only allocate a CIDR for a VPC from an IPAM pool that shares a locale with the VPC's Region. Note that when you have chosen a locale for a pool, you cannot modify it. If the home Region of the IPAM is unavailable due to an outage and the pool has a locale different than the home Region of the IPAM, the pool can still be used to allocate IP addresses.

When you run the commands in this section, the value for `--region` must include the `--locale` option you entered when you created the pool that will be used for the BYOIP CIDR. For example, if you created the BYOIP pool with a locale of *us-east-1*, the `--region` should be *us-east-1*. If you created the BYOIP pool with a locale of *us-east-1-scl-1* (a network border group used for Local Zones), the `--region` should be *us-east-1* because that Region manages the locale *us-east-1-scl-1*.

This step must be done by the IPAM account.

Choosing a locale ensures there are no cross-region dependencies between your pool and the resources allocating from it. The available options come from the operating Regions that you chose when you created your IPAM. In this tutorial, we'll use `us-west-2` as the locale for the Regional pool.

> **Important**
>
> When you create the pool, you must include `--aws-service ec2`. The service you select determines the AWS service where the CIDR will be advertisable. Currently, the only option is `ec2`, which means that the CIDRs allocated from this pool will be advertisable for the Amazon EC2 service (for Elastic IP addresses) and the Amazon VPC service (for CIDRs associated with VPCs).

To create a Regional pool using the AWS CLI

1. Run the following command to create the pool.

```
aws ec2 create-ipam-pool --description "Regional-IPv4-pool" --region us-east-1
 --ipam-scope-id ipam-scope-0087d83896280b594 --source-ipam-pool-id ipam-
pool-0a03d430ca3f5c035 --locale us-west-2 --address-family ipv4 --aws-service ec2
 --profile ipam-account
```

   In the output, you'll see IPAM creating the pool.

```
{
     "IpamPool": {
        "OwnerId": "123456789012",
        "IpamPoolId": "ipam-pool-0d8f3646b61ca5987",
        "SourceIpamPoolId": "ipam-pool-0a03d430ca3f5c035",
        "IpamPoolArn": "arn:aws:ec2::123456789012:ipam-pool/ipam-
pool-0d8f3646b61ca5987",
        "IpamScopeArn": "arn:aws:ec2::123456789012:ipam-scope/ipam-
scope-0087d83896280b594",
        "IpamScopeType": "public",
        "IpamArn": "arn:aws:ec2::123456789012:ipam/ipam-090e48e75758de279",
        "Locale": "us-west-2",
        "PoolDepth": 2,
        "State": "create-in-progress",
        "Description": "Regional--pool",
        "AutoImport": false,
```

```
        "AddressFamily": "ipv4",
        "Tags": [],
        "ServiceType": "ec2"
    }
}
```

2. Run the following command until you see a state of `create-complete` in the output.

```
aws ec2 describe-ipam-pools --region us-east-1 --profile ipam-account
```

In the output, you see the pools that you have in your IPAM. In this tutorial, we created a top-level and a Regional pool, so you'll see them both.

Step 6: Provision a CIDR to the Regional pool

Provision a CIDR block to the Regional pool.

> **Note**
>
> When provisioning a CIDR to a Regional pool within the top-level pool, the most specific IPv4 CIDR you can provision is /24; more specific CIDRs (such as /25) are not permitted. After you create the Regional pool, you can create smaller pools (such as /25) within the same Regional pool. Note that if you share the Regional pool or pools within it, these pools can only be used in the locale set on the same Regional pool.

This step must be done by the IPAM account.

To assign a CIDR block to the Regional pool using the AWS CLI

1. Run the following command to provision the CIDR.

```
aws ec2 provision-ipam-pool-cidr --region us-east-1 --ipam-pool-id ipam-
pool-0d8f3646b61ca5987 --cidr 130.137.245.0/24 --profile ipam-account
```

In the output, you'll see the CIDR pending provision.

```
{
    "IpamPoolCidr": {
```

```
        "Cidr": "130.137.245.0/24",

        "State": "pending-provision"

    }

}
```

2. Run the following command until you see the state of `provisioned` in the output.

```
aws ec2 get-ipam-pool-cidrs --region us-east-1 --ipam-pool-id ipam-
pool-0d8f3646b61ca5987 --profile ipam-account
```

The following example output shows the correct state.

```
{
    "IpamPoolCidrs": [
        {
            "Cidr": "130.137.245.0/24",
            "State": "provisioned"
        }
    ]
}
```

Step 7: Advertise the CIDR

The steps in this section must be done by the IPAM account. Once you associate the Elastic IP address (EIP) with an instance or Elastic Load Balancer, you can then start advertising the CIDR you brought to AWS that is in pool that has `--aws-service ec2` defined. In this tutorial, that's your Regional pool. By default the CIDR is not advertised, which means it's not publicly accessible over the internet. When you run the command in this section, the value for `--region` must match the `--locale` option you entered when you created the pool that will be used for the BYOIP CIDR.

This step must be done by the IPAM account.

> **Note**
>
> The advertisement status doesn't not restrict your ability to allocate Elastic IP addresses. Even if your BYOIPv4 CIDR is not advertised, you can still can create EIPs from the IPAM pool.

Start advertising the CIDR using the AWS CLI

- Run the following command to advertise the CIDR.

```
aws ec2 advertise-byoip-cidr --region us-west-2 --cidr 130.137.245.0/24 --
profile ipam-account
```

In the output, you'll see the CIDR is advertised.

```
{
    "ByoipCidr": {
        "Cidr": "130.137.245.0/24",
        "State": "advertised"
    }
}
```

Step 8: Share the Regional pool

Follow the steps in this section to share the IPAM pool using AWS Resource Access Manager (RAM).

Enable resource sharing in AWS RAM

After you create your IPAM, you'll want to share the regional pool with other accounts in your organization. Before you share an IPAM pool, complete the steps in this section to enable resource sharing with AWS RAM. If you are using the AWS CLI to enable resource sharing, use the `--profile management-account` option.

To enable resource sharing

1. Using the AWS Organizations management account, open the AWS RAM console at https://console.aws.amazon.com/ram/.

2. In the left navigation pane, choose **Settings**, choose **Enable sharing with AWS Organizations**, and then choose **Save settings**.

You can now share an IPAM pool with other members of the organization.

Share an IPAM pool using AWS RAM

In this section you'll share the regional pool with another AWS Organizations member account. For complete instructions on sharing IPAM pools, including information on the required IAM permissions, see Share an IPAM pool using AWS RAM. If you are using the AWS CLI to enable resource sharing, use the `--profile` **`ipam-account`** option.

To share an IPAM pool using AWS RAM

1. Using the IPAM admin account, open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.
3. Choose the private scope, choose the IPAM pool, and choose **Actions** > **View details**.
4. Under **Resource sharing**, choose **Create resource share**. The AWS RAM console opens. You share the pool using AWS RAM.
5. Choose **Create a resource share**.
6. In the AWS RAM console, choose **Create a resource share** again.
7. Add a **Name** for the shared pool.
8. Under **Select resource type**, choose **IPAM pools,** and then choose the ARN of the pool you want to share.
9. Choose **Next**.
10. Choose the **AWSRAMPermissionIpamPoolByoipCidrImport** permission. The details of the permission options are out of scope for this tutorial, but you can find out more about these options in Share an IPAM pool using AWS RAM.
11. Choose **Next**.
12. Under **Principals** > **Select principal type**, choose **AWS account** and enter the account ID of the account that will be bringing an IP address range to IPAM and choose **Add** .
13. Choose **Next**.
14. Review the resource share options and the principals that you'll be sharing with, and then choose **Create**.

15. To allow the **`member-account`** account to allocate IP address CIDRS from the IPAM pool, create a second resource share with `AWSRAMDefaultPermissionsIpamPool`. The value for `--resource-arns` is the ARN of the IPAM pool that you created in the previous section. The value for `--principals` is the account ID of the **`member-account`**. The value for `--permission-arns` is the ARN of the `AWSRAMDefaultPermissionsIpamPool` permission.

Step 9: Allocate an Elastic IP address from the pool

Complete the steps in this section to allocate an Elastic IP address from the pool. Note that if you are using public IPv4 pools to allocate Elastic IP addresses, you can use the alternative steps in Alternative to Step 9 rather than the steps in this section.

> **Important**
>
> If you see an error related to not having permissions to call ec2:AllocateAddress, the managed permission currently assigned to the IPAM pool that was shared with you needs to be updated. Contact the person who created the resource share and ask them to update the managed permission `AWSRAMPermissionIpamResourceDiscovery` to the default version. For more information, see Update a resource share in the *AWS RAM User Guide* .

AWS Management Console

Follow the steps in Allocate an Elastic IP address in the *Amazon EC2 User Guide* to allocate the address, but note the following:

- This step must be done by the member account.
- Ensure that the AWS Region you are in in the EC2 console matches the Locale option you chose when you created the Regional pool.
- When you choose the address pool, choose the option to **Allocate using an IPv4 IPAM pool** and choose the Regional pool you created.

Command line

Allocate an address from the pool with the allocate-address command. The `--region` you use must match the `-locale` option you chose when you created the pool in Step 2. Include the ID of the IPAM pool you created in Step 2 in `--ipam-pool-id`. Optionally, you can also choose a specific `/32` in your IPAM pool by using the `--address` option.

```
aws ec2 allocate-address --region us-east-1 --ipam-pool-id ipam-
pool-07ccc86aa41bef7ce
```

Example response:

```
{
    "PublicIp": "18.97.0.41",
    "AllocationId": "eipalloc-056cdd6019c0f4b46",
    "PublicIpv4Pool": "ipam-pool-07ccc86aa41bef7ce",
    "NetworkBorderGroup": "us-east-1",
    "Domain": "vpc"
}
```

For more information, see Allocate an Elastic IP address in the *Amazon EC2 User Guide*.

Step 10: Associate the Elastic IP address with an EC2 instance

Complete the steps in this section to associate the Elastic IP address with an EC2 instance.

AWS Management Console

Follow the steps in Associate an Elastic IP address in the *Amazon EC2 User Guide* to allocate an Elastic IP address from the IPAM pool, but note the following: When you use AWS Management Console option, the AWS Region you associate the Elastic IP address in must match the Locale option you chose when you created the Regional pool.

This step must be done by the member account.

Command line

This step must be done by the member account. Use the `--profile` **`member-account`** option.

Associate the Elastic IP address with an instance with the associate-address command. The `--region` you associate the Elastic IP address in must match the `--locale` option you chose when you created the Regional pool.

```
aws ec2 associate-address --region us-east-1 --instance-id i-07459a6fca5b35823 --
public-ip 18.97.0.41
```

Example response:

```
{
    "AssociationId": "eipassoc-06aa85073d3936e0e"
}
```

For more information, see Associate an Elastic IP address with an instance or network interface in the *Amazon EC2 User Guide*.

Step 11: Cleanup

Follow the steps in this section to clean up the resources you've provisioned and created in this tutorial. When you run the commands in this section, the value for `--region` must include the `--locale` option you entered when you created the pool that will be used for the BYOIP CIDR.

Clean up using the AWS CLI

1. View the EIP allocation managed in IPAM.

   This step must be done by the IPAM account.

   ```
   aws ec2 get-ipam-pool-allocations --region us-west-2 --ipam-pool-id ipam-
   pool-0d8f3646b61ca5987 --profile ipam-account
   ```

   The output shows the allocation in IPAM.

   ```
   {
       "IpamPoolAllocations": [
           {
               "Cidr": "130.137.245.0/24",
               "IpamPoolAllocationId": "ipam-pool-
   alloc-5dedc8e7937c4261b56dc3e3eb53dc45",
               "ResourceId": "ipv4pool-ec2-0019eed22a684e0b2",
               "ResourceType": "ec2-public-ipv4-pool",
               "ResourceOwner": "123456789012"
           }
       ]
   }
   ```

2. Stop advertising the IPv4 CIDR.

   This step must be done by the IPAM account.

```
aws ec2 withdraw-byoip-cidr --region us-west-2 --cidr 130.137.245.0/24 --
profile ipam-account
```

In the output, you'll see the CIDR State has changed from **advertised** to **provisioned**.

```
{
    "ByoipCidr": {
        "Cidr": "130.137.245.0/24",
        "State": "provisioned"
    }
}
```

3. Release the Elastic IP address.

   This step must be done by the member account.

   ```
   aws ec2 release-address --region us-west-2 --allocation-
   id eipalloc-0db3405026756dbf6 --profile member-account
   ```

   You will not see any output when you run this command.

4. View the EIP allocation is no longer managed in IPAM. It can take some time for IPAM to discover that the Elastic IP address has been removed. You cannot continue to clean up and deprovision the IPAM pool CIDR until you see that the allocation has been removed from IPAM. When you run the command in this section, the value for `--region` must include the `--locale` option you entered when you created the pool that will be used for the BYOIP CIDR.

   This step must be done by the IPAM account.

   ```
   aws ec2 get-ipam-pool-allocations --region us-west-2 --ipam-pool-id ipam-
   pool-0d8f3646b61ca5987 --profile ipam-account
   ```

   The output shows the allocation in IPAM.

   ```
   {
       "IpamPoolAllocations": []
   }
   ```

5. Deprovision the Regional pool CIDR. When you run the commands in this step, the value for `--region` must match the Region of your IPAM.

This step must be done by the IPAM account.

```
aws ec2 deprovision-ipam-pool-cidr --region us-east-1 --ipam-pool-id ipam-
pool-0d8f3646b61ca5987 --cidr 130.137.245.0/24 --profile ipam-account
```

In the output, you'll see the CIDR pending deprovision.

```
{
    "IpamPoolCidr": {

        "Cidr": "130.137.245.0/24",

        "State": "pending-deprovision"

    }

}
```

Deprovisioning takes time to complete. Check the status of deprovisioning.

```
aws ec2 get-ipam-pool-cidrs --region us-east-1 --ipam-pool-id ipam-
pool-0d8f3646b61ca5987 --profile ipam-account
```

Wait until you see **deprovisioned** before you continue to the next step.

```
{
    "IpamPoolCidr": {

        "Cidr": "130.137.245.0/24",

        "State": "deprovisioned"

    }

}
```

6. Delete the RAM shares and disable RAM integration with AWS Organizations. Complete the steps in Deleting a resource share in AWS RAM and Disabling resource sharing with AWS Organizations in the *AWS RAM User Guide*, in that order, to delete the RAM shares and disable RAM integration with AWS Organizations.

This step must be done by the IPAM account and management account respectively. If you are using the AWS CLI to delete the RAM shares and disable RAM integration, use the `--profile` **`ipam-account`** and `--profile` **`management-account`** options.

7. Delete the Regional pool. When you run the command in this step, the value for `--region` must match the Region of your IPAM.

   This step must be done by the IPAM account.

```
aws ec2 delete-ipam-pool --region us-east-1 --ipam-pool-id ipam-
pool-0d8f3646b61ca5987 --profile ipam-account
```

   In the output, you can see the delete state.

```
{
   "IpamPool": {
        "OwnerId": "123456789012",
        "IpamPoolId": "ipam-pool-0d8f3646b61ca5987",
        "SourceIpamPoolId": "ipam-pool-0a03d430ca3f5c035",
        "IpamPoolArn": "arn:aws:ec2::123456789012:ipam-pool/ipam-
pool-0d8f3646b61ca5987",
        "IpamScopeArn": "arn:aws:ec2::123456789012:ipam-scope/ipam-
scope-0087d83896280b594",
        "IpamScopeType": "public",
        "IpamArn": "arn:aws:ec2::123456789012:ipam/ipam-090e48e75758de279",
        "Locale": "us-east-1",
        "PoolDepth": 2,
        "State": "delete-in-progress",
        "Description": "reg-ipv4-pool",
        "AutoImport": false,
        "Advertisable": true,
        "AddressFamily": "ipv4"
    }
}
```

8. Deprovision the top-level pool CIDR. When you run the commands in this step, the value for `--region` must match the Region of your IPAM.

   This step must be done by the IPAM account.

```
aws ec2 deprovision-ipam-pool-cidr --region us-east-1 --ipam-pool-id ipam-
pool-0a03d430ca3f5c035 --cidr 130.137.245.0/24 --profile ipam-account
```

In the output, you'll see the CIDR pending deprovision.

```
{
    "IpamPoolCidr": {

        "Cidr": "130.137.245.0/24",

        "State": "pending-deprovision"

    }

}
```

Deprovisioning takes time to complete. Run the following command to check the status of deprovisioning.

```
aws ec2 get-ipam-pool-cidrs --region us-east-1 --ipam-pool-id ipam-
pool-0a03d430ca3f5c035 --profile ipam-account
```

Wait until you see **deprovisioned** before you continue to the next step.

```
{
    "IpamPoolCidr": {

        "Cidr": "130.137.245.0/24",

        "State": "deprovisioned"

    }

}
```

9. Delete the top-level pool. When you run the command in this step, the value for `--region` must match the Region of your IPAM.

   This step must be done by the IPAM account.

```
aws ec2 delete-ipam-pool --region us-east-1 --ipam-pool-id ipam-
pool-0a03d430ca3f5c035 --profile ipam-account
```

In the output, you can see the delete state.

```
{
  "IpamPool": {
        "OwnerId": "123456789012",
        "IpamPoolId": "ipam-pool-0a03d430ca3f5c035",
        "IpamPoolArn": "arn:aws:ec2::123456789012:ipam-pool/ipam-
pool-0a03d430ca3f5c035",
        "IpamScopeArn": "arn:aws:ec2::123456789012:ipam-scope/ipam-
scope-0087d83896280b594",
        "IpamScopeType": "public",
        "IpamArn": "arn:aws:ec2::123456789012:ipam/ipam-090e48e75758de279",
        "Locale": "us-east-1",
        "PoolDepth": 2,
        "State": "delete-in-progress",
        "Description": "top-level-pool",
        "AutoImport": false,
        "Advertisable": true,
        "AddressFamily": "ipv4"
    }
}
```

10. Delete the IPAM. When you run the command in this step, the value for `--region` must match the Region of your IPAM.

    This step must be done by the IPAM account.

```
aws ec2 delete-ipam --region us-east-1 --ipam-id ipam-090e48e75758de279 --
profile ipam-account
```

In the output, you'll see the IPAM response. This means that the IPAM was deleted.

```
{
    "Ipam": {
        "OwnerId": "123456789012",
        "IpamId": "ipam-090e48e75758de279",

        "IpamArn": "arn:aws:ec2::123456789012:ipam/ipam-090e48e75758de279",
```

```
        "PublicDefaultScopeId": "ipam-scope-0087d83896280b594",

        "PrivateDefaultScopeId": "ipam-scope-08b70b04fbd524f8d",

        "ScopeCount": 2,

        "OperatingRegions": [

            {

                "RegionName": "us-east-1"

            },
            {
                "RegionName": "us-west-2"
            }
        ],
    }
}
```

Alternative to Step 9

If you are using public IPv4 pools to allocate Elastic IP addresses, you can use the steps in this section rather than the steps in Step 9: Allocate an Elastic IP address from the pool.

Contents

Step 1: Create a public IPv4 pool

This step would typically be done by a different AWS account which wants to provision an Elastic IP address, such as the member account.

> **Important**
>
> Public IPv4 pools and IPAM pools are managed by distinct resources in AWS. Public IPv4 pools are single account resources that enable you to convert your publicly-owned CIDRs to Elastic IP addresses. IPAM pools can be used to allocate your public space to public IPv4 pools.

To create a public IPv4 pool using the AWS CLI

- Run the following command to provision the CIDR. When you run the command in this section, the value for `--region` must match the `--locale` option you entered when you created the pool that will be used for the BYOIP CIDR.

```
aws ec2 create-public-ipv4-pool --region us-west-2 --profile member-account
```

  In the output, you'll see the public IPv4 pool ID. You will need this ID in the next step.

```
{
    "PoolId": "ipv4pool-ec2-0019eed22a684e0b2"
}
```

Step 2: Provision the public IPv4 CIDR to your public IPv4 pool

Provision the public IPv4 CIDR to your public IPv4 pool. The value for `--region` must match the `--locale` value you entered when you created the pool that will be used for the BYOIP CIDR. The least specific `--netmask-length` you can define is 24.

This step must be done by the member account.

To create a public IPv4 pool using the AWS CLI

1. Run the following command to provision the CIDR.

```
aws ec2 provision-public-ipv4-pool-cidr --region us-west-2 --ipam-pool-id ipam-
pool-0d8f3646b61ca5987 --pool-id ipv4pool-ec2-0019eed22a684e0b2 --netmask-length 24
 --profile member-account
```

   In the output, you'll see the provisioned CIDR.

```
{
    "PoolId": "ipv4pool-ec2-0019eed22a684e0b2",
    "PoolAddressRange": {
        "FirstAddress": "130.137.245.0",
        "LastAddress": "130.137.245.255",
        "AddressCount": 256,
        "AvailableAddressCount": 256
    }
}
```

2. Run the following command to view the CIDR provisioned in the public IPv4 pool.

```
aws ec2 describe-byoip-cidrs --region us-west-2 --max-results 10 --profile member-account
```

In the output, you'll see the provisioned CIDR. By default the CIDR is not advertised, which means it's not publicly accessible over the internet. You will have the chance to set this CIDR to advertised in the last step of this tutorial.

```
{
    "ByoipCidrs": [
        {
            "Cidr": "130.137.245.0/24",
            "StatusMessage": "Cidr successfully provisioned",
            "State": "provisioned"
        }
    ]
}
```

Step 3: Create an Elastic IP address from the public IPv4 pool

Create an Elastic IP address (EIP) from the public IPv4 pool. When you run the commands in this section, the value for `--region` must match the `--locale` option you entered when you created the pool that will be used for the BYOIP CIDR.

This step must be done by the member account.

To create an EIP from the public IPv4 pool using the AWS CLI

1. Run the following command to create the EIP.

```
aws ec2 allocate-address  --region us-west-2 --public-ipv4-pool ipv4pool-
ec2-0019eed22a684e0b2 --profile member-account
```

In the output, you'll see the allocation.

```
{
    "PublicIp": "130.137.245.100",
    "AllocationId": "eipalloc-0db3405026756dbf6",
    "PublicIpv4Pool": "ipv4pool-ec2-0019eed22a684e0b2",
    "NetworkBorderGroup": "us-east-1",
    "Domain": "vpc"
}
```

2. Run the following command to view the EIP allocation managed in IPAM.

   This step must be done by the IPAM account.

```
aws ec2 get-ipam-pool-allocations --region us-west-2 --ipam-pool-id ipam-
pool-0d8f3646b61ca5987 --profile ipam-account
```

   The output shows the allocation in IPAM.

```
{
    "IpamPoolAllocations": [
        {
            "Cidr": "130.137.245.0/24",
            "IpamPoolAllocationId": "ipam-pool-
alloc-5dedc8e7937c4261b56dc3e3eb53dc45",
            "ResourceId": "ipv4pool-ec2-0019eed22a684e0b2",
            "ResourceType": "ec2-public-ipv4-pool",
            "ResourceOwner": "123456789012"
        }
    ]
}
```

Alternative to Step 9 cleanup

Complete these steps to clean up public IPv4 pools created with the alternative to Step 9. You should complete these steps after you release the Elastic IP address during the standard cleanup process in Step 10: Cleanup.

1. View your BYOIP CIDRs.

   This step must be done by the member account.

   ```
   aws ec2 describe-public-ipv4-pools --region us-west-2 --profile member-account
   ```

   In the output, you'll see the IP addresses in your BYOIP CIDR.

   ```
   {
       "PublicIpv4Pools": [
           {
               "PoolId": "ipv4pool-ec2-0019eed22a684e0b2",
               "Description": "",
               "PoolAddressRanges": [
                   {
                       "FirstAddress": "130.137.245.0",
                       "LastAddress": "130.137.245.255",
                       "AddressCount": 256,
                       "AvailableAddressCount": 256
                   }
               ],
               "TotalAddressCount": 256,
               "TotalAvailableAddressCount": 256,
               "NetworkBorderGroup": "us-east-1",
               "Tags": []
           }
       ]
   }
   ```

2. Release the CIDR from the public IPv4 pool. When you run the command in this section, the value for `--region` must match the Region of your IPAM.

   This step must be done by the member account.

```
aws ec2 deprovision-public-ipv4-pool-cidr --region us-east-1 --pool-id ipv4pool-
ec2-0019eed22a684e0b2 --cidr 130.137.245.0/24 --profile member-account
```

3. View your BYOIP CIDRs again and ensure there are no more provisioned addresses. When you run the command in this section, the value for `--region` must match the Region of your IPAM.

   This step must be done by the member account.

   ```
   aws ec2 describe-public-ipv4-pools --region us-east-1 --profile member-account
   ```

   In the output, you'll see the IP addresses count in your public IPv4 pool.

   ```
   {
       "PublicIpv4Pools": [
           {
               "PoolId": "ipv4pool-ec2-0019eed22a684e0b2",
               "Description": "",
               "PoolAddressRanges": [],
               "TotalAddressCount": 0,
               "TotalAvailableAddressCount": 0,
               "NetworkBorderGroup": "us-east-1",
               "Tags": []
           }
       ]
   }
   ```

Bring your own IPv6 CIDR to IPAM using only the AWS CLI

Follow these steps to bring an IPv6 CIDR to IPAM and allocate a VPC using only the AWS CLI.

If you do not need to advertise your IPv6 addresses over the Internet, you can provision a private GUA IPv6 address to an IPAM. For more information, see Enable provisioning private IPv6 GUA CIDRs.

Important

- This tutorial assumes you have already completed the steps in the following sections:

- Integrate IPAM with accounts in an AWS Organization.
- Create an IPAM.

- Each step of this tutorial must be done by one of three AWS Organizations accounts:
  - The management account.
  - The member account configured to be your IPAM administrator in Integrate IPAM with accounts in an AWS Organization. In this tutorial, this account will be called the IPAM account.
  - The member account in your organization which will allocate CIDRs from an IPAM pool. In this tutorial, this account will be called the member account.

Contents

Step 1: Create AWS CLI named profiles and IAM roles

To complete this tutorial as a single AWS user, you can use AWS CLI named profiles to switch from one IAM role to another. Named profiles are collections of settings and credentials that you refer to when using the `--profile` option with the AWS CLI. For more information about how to create IAM roles and named profiles for AWS accounts, see Using an IAM role in the AWS CLI.

Create one role and one named profile for each of the three AWS accounts you will use in this tutorial:

- A profile called `management-account` for the AWS Organizations management account.

- A profile called `ipam-account` for the AWS Organizations member account that is configured to be your IPAM administrator.
- A profile called `member-account` for the AWS Organizations member account in your organization which will allocate CIDRs from an IPAM pool.

After you have created the IAM roles and named profiles, return to this page and go to the next step. You will notice throughout the rest of this tutorial that the sample AWS CLI commands use the `--profile` option with one of the named profiles to indicate which account must run the command.

Step 2: Create an IPAM

This step is optional. If you already have an IPAM created with operating Regions of `us-east-1` and `us-west-2` created, you can skip this step. Create an IPAM and specify an operating region of `us-east-1` and `us-west-2` . You must select an operating region so that you can use the locale option when you create your IPAM pool. The IPAM integration with BYOIP requires that the locale is set on whichever pool will be used for the BYOIP CIDR.

This step must be done by the IPAM account.

Run the following command:

```
aws ec2 create-ipam --description my-ipam --region us-east-1 --operating-
regions RegionName=us-west-2 --profile ipam-account
```

In the output, you'll see the IPAM you've created. Note the value for `PublicDefaultScopeId`. You will need your public scope ID in the next step.

```
{
 "Ipam": {
        "OwnerId": "123456789012",
        "IpamId": "ipam-090e48e75758de279",
        "IpamArn": "arn:aws:ec2::123456789012:ipam/ipam-090e48e75758de279",
        "PublicDefaultScopeId": "ipam-scope-0087d83896280b594",
        "PrivateDefaultScopeId": "ipam-scope-08b70b04fbd524f8d",
        "ScopeCount": 2,
        "Description": "my-ipam",
        "OperatingRegions": [
            {
                "RegionName": "us-east-1"
```

```
            },
            {
                "RegionName": "us-west-2"
            }
        ],
        "Tags": []
    }
}
```

Step 3: Create an IPAM pool

Since you are going to create a top-level IPAM pool with a Regional pool within it, and we're going to allocate space to a resource (a VPC) from the Regional pool, you will set the locale on the Regional pool and not the top-level pool. You'll add the locale to the Regional pool when you create the Regional pool in a later step. The IPAM integration with BYOIP requires that the locale is set on whichever pool will be used for the BYOIP CIDR.

This step must be done by the IPAM account.

Choose if you want this IPAM pool CIDR to be advertisable by AWS over the public internet (`--publicly-advertisable` or `--no-publicly-advertisable`).

> **Note**
>
> Note that the scope ID must be the ID for the public scope and the address family must be `ipv6`.

To create an IPv6 address pool for all of your AWS resources using the AWS CLI

1. Run the following command to create an IPAM pool. Use the ID of the public scope of the IPAM that you created in the previous step.

   ```
   aws ec2 create-ipam-pool --region us-east-1 --ipam-scope-id ipam-
   scope-0087d83896280b594 --description "top-level-IPv6-pool" --address-
   family ipv6 --publicly-advertisable --profile ipam-account
   ```

   In the output, you'll see `create-in-progress`, which indicates that pool creation is in progress.

   ```
   {
   ```

```
    "IpamPool": {

        "OwnerId": "123456789012",
        "IpamPoolId": "ipam-pool-07f2466c7158b50c4",

        "IpamPoolArn": "arn:aws:ec2::123456789012:ipam-pool/ipam-
pool-07f2466c7158b50c4",
        "IpamScopeArn": "arn:aws:ec2::123456789012:ipam-scope/ipam-
scope-0087d83896280b594",
        "IpamScopeType": "public",

        "IpamArn": "arn:aws:ec2::123456789012:ipam/ipam-090e48e75758de279",

        "Locale": "None",

        "PoolDepth": 1,

        "State": "create-in-progress",

        "Description": "top-level-Ipv6-pool",

        "AutoImport": false,

        "Advertisable": true,

        "AddressFamily": "ipv6",

        "Tags": []

    }

}
```

2. Run the following command until you see a state of `create-complete` in the output.

```
aws ec2 describe-ipam-pools --region us-east-1 --profile ipam-account
```

The following example output shows the state of the pool.

```
{
    "IpamPool": {

        "OwnerId": "123456789012",
```

```
        "IpamPoolId": "ipam-pool-07f2466c7158b50c4",

        "IpamPoolArn": "arn:aws:ec2::123456789012:ipam-pool/ipam-
pool-07f2466c7158b50c4",
        "IpamScopeArn": "arn:aws:ec2::123456789012:ipam-scope/ipam-
scope-0087d83896280b594",
        "IpamScopeType": "public",

        "IpamArn": "arn:aws:ec2::123456789012:ipam/ipam-090e48e75758de279",

        "Locale": "None",

        "PoolDepth": 1,

        "State": "create-complete",

        "Description": "top-level-Ipv6-pool",

        "AutoImport": false,

        "Advertisable": true,

        "AddressFamily": "ipv6",

        "Tags": []

    }

}
```

Step 4: Provision a CIDR to the top-level pool

Provision a CIDR block to the top-level pool. Note that when provisioning an IPv6 CIDR to a pool within the top-level pool, the most specific IPv6 address range that you can bring is /48 for CIDRs that are publicly advertisable and /60 for CIDRs that are not publicly advertisable.

Note

- If you verified your domain control with an X.509 certificate, you must include the CIDR and the BYOIP message and certificate signature that you created in that step so we can verify that you control the public space.

- If you verified your domain control with a DNS TXT record, you must include the CIDR and IPAM verification token that you created in that step so we can verify that you control the public space.

You only need to verify domain control when you provision the BYOIP CIDR to the top-level pool. For the Regional pool within the top-level pool, you can omit the domain ownership option.

This step must be done by the IPAM account.

To provision a CIDR block to the pool using the AWS CLI

1. To provision the CIDR with certificate information, use the following command example. In addition to replacing the values as needed in the example, ensure that you replace `Message` and `Signature` values with the `text_message` and `signed_message` values that you got in Verify your domain with an X.509 certificate.

```
aws ec2 provision-ipam-pool-cidr --region us-east-1 --ipam-pool-id ipam-
pool-07f2466c7158b50c4 --cidr 2605:9cc0:409::/48 --verification-method remarks-
x509 --cidr-authorization-context Message="1|aws|470889052444|2605:9cc0:409::/48|
20250101|SHA256|RSAPSS",Signature="FU26~vRG~NUGXa~akxd6dvdcCfvL88g8d~YAuai-
CR7HqMwzcgdS9RlpBGtfIdsRGyr77LmWyWqU9Xp1g2R1kSkfD00NiLKLcv9F63k6wdEkyFxNp7RAJDvF1mBwxmSgH~C
Vp6LON3yOOXMp4JENB9uM7sMlu6oeoutGyyhXFeYPzlGSRdcdfKNKaimvPCqVsxGN5AwSilKQ8byNqoa~G3dvs8ueSa
wispI~r69fq515UR19TA~fmmxBDh1huQ8DkM1rqcwveWow__" --profile ipam-account
```

To provision the CIDR with verification token information, use the following command example. In addition to replacing the values as needed in the example, ensure that you replace `ipam-ext-res-ver-token-0309ce7f67a768cf0` with the `IpamExternalResourceVerificationTokenId` token ID that you got in Verify your domain with a DNS TXT record.

```
aws ec2 provision-ipam-pool-cidr --region us-east-1 --ipam-pool-id ipam-
pool-07f2466c7158b50c4 --cidr 2605:9cc0:409::/48 --verification-method
 dns-token --ipam-external-resource-verification-token-id ipam-ext-res-ver-
token-0309ce7f67a768cf0 --profile ipam-account
```

In the output, you'll see the CIDR pending provision.

```
{
```

```
    "IpamPoolCidr": {

        "Cidr": "2605:9cc0:409::/48",

        "State": "pending-provision"

    }

}
```

2. Ensure that this CIDR has been provisioned before you continue.

> **Important**
>
> While most provisioning will be completed within two hours, it may take up to one week to complete the provisioning process for publicly advertisable ranges.

Run the following command until you see a state of `provisioned` in the output.

```
aws ec2 get-ipam-pool-cidrs --region us-east-1 --ipam-pool-id ipam-
pool-07f2466c7158b50c4 --profile ipam-account
```

The following example output shows the state.

```
{
    "IpamPoolCidrs": [
        {
            "Cidr": "2605:9cc0:409::/48",
            "State": "provisioned"
        }
    ]
}
```

Step 5: Create a Regional pool within the top-level pool

Create a Regional pool within the top-level pool. `--locale` is required on the pool and it must be one of the operating Regions you configured when you created the IPAM.

This step must be done by the IPAM account.

> **Important**
>
> When you create the pool, you must include `--aws-service ec2`. The service you select determines the AWS service where the CIDR will be advertisable. Currently, the only option is `ec2`, which means that the CIDRs allocated from this pool will be advertisable for the Amazon EC2 service and the Amazon VPC service (for CIDRs associated with VPCs).

To create a Regional pool using the AWS CLI

1. Run the following command to create the pool.

```
aws ec2 create-ipam-pool --description "Regional-IPv6-pool" --region us-east-1
 --ipam-scope-id ipam-scope-0087d83896280b594 --source-ipam-pool-id ipam-
pool-07f2466c7158b50c4 --locale us-west-2 --address-family ipv6 --aws-service ec2
 --profile ipam-account
```

   In the output, you'll see IPAM creating the pool.

```
{
    "IpamPool": {
        "OwnerId": "123456789012",
        "IpamPoolId": "ipam-pool-0053b7d2b4fc3f730",
        "SourceIpamPoolId": "ipam-pool-07f2466c7158b50c4",
        "IpamPoolArn": "arn:aws:ec2::123456789012:ipam-pool/ipam-
pool-0053b7d2b4fc3f730",
        "IpamScopeArn": "arn:aws:ec2::123456789012:ipam-scope/ipam-
scope-0087d83896280b594",
        "IpamScopeType": "public",
        "IpamArn": "arn:aws:ec2::123456789012:ipam/ipam-090e48e75758de279",
        "Locale": "us-west-2",
        "PoolDepth": 2,
        "State": "create-in-progress",
        "Description": "reg-ipv6-pool",
        "AutoImport": false,
        "Advertisable": true,
        "AddressFamily": "ipv6",
        "Tags": [],
        "ServiceType": "ec2"
    }
}
```

2. Run the following command until you see a state of `create-complete` in the output.

```
aws ec2 describe-ipam-pools --region us-east-1 --profile ipam-account
```

In the output, you see the pools that you have in your IPAM. In this tutorial, we created a top-level and a Regional pool, so you'll see them both.

Step 6: Provision a CIDR to the Regional pool

Provision a CIDR block to the Regional pool. Note that when provisioning the CIDR to a pool within the top-level pool, the most specific IPv6 address range that you can bring is /48 for CIDRs that are publicly advertisable and /60 for CIDRs that are not publicly advertisable.

This step must be done by the IPAM account.

To assign a CIDR block to the Regional pool using the AWS CLI

1. Run the following command to provision the CIDR.

```
aws ec2 provision-ipam-pool-cidr --region us-east-1 --ipam-pool-id ipam-
pool-0053b7d2b4fc3f730 --cidr 2605:9cc0:409::/48 --profile ipam-account
```

In the output, you'll see the CIDR pending provision.

```
{
    "IpamPoolCidr": {
        "Cidr": "2605:9cc0:409::/48",
        "State": "pending-provision"
    }
}
```

2. Run the following command until you see the state of `provisioned` in the output.

```
aws ec2 get-ipam-pool-cidrs --region us-east-1 --ipam-pool-id ipam-
pool-0053b7d2b4fc3f730 --profile ipam-account
```

The following example output shows the correct state.

```
{
    "IpamPoolCidrs": [
```

```
        {
            "Cidr": "2605:9cc0:409::/48",
            "State": "provisioned"
        }
    ]
}
```

Step 7. Share the Regional pool

Follow the steps in this section to share the IPAM pool using AWS Resource Access Manager (RAM).

Enable resource sharing in AWS RAM

After you create your IPAM, you'll want to share the regional pool with other accounts in your organization. Before you share an IPAM pool, complete the steps in this section to enable resource sharing with AWS RAM. If you are using the AWS CLI to enable resource sharing, use the `--profile` **`management-account`** option.

To enable resource sharing

1. Using the AWS Organizations management account, open the AWS RAM console at https://console.aws.amazon.com/ram/.
2. In the left navigation pane, choose **Settings**, choose **Enable sharing with AWS Organizations**, and then choose **Save settings**.

You can now share an IPAM pool with other members of the organization.

Share an IPAM pool using AWS RAM

In this section you'll share the regional pool with another AWS Organizations member account. For complete instructions on sharing IPAM pools, including information on the required IAM permissions, see Share an IPAM pool using AWS RAM. If you are using the AWS CLI to enable resource sharing, use the `--profile` **`ipam-account`** option.

To share an IPAM pool using AWS RAM

1. Using the IPAM admin account, open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.

3. Choose the private scope, choose the IPAM pool, and choose **Actions** > **View details**.
4. Under **Resource sharing**, choose **Create resource share**. The AWS RAM console opens. You share the pool using AWS RAM.
5. Choose **Create a resource share**.
6. In the AWS RAM console, choose **Create a resource share** again.
7. Add a **Name** for the shared pool.
8. Under **Select resource type**, choose **IPAM pools,** and then choose the ARN of the pool you want to share.
9. Choose **Next**.
10. Choose the **AWSRAMPermissionIpamPoolByoipCidrImport** permission. The details of the permission options are out of scope for this tutorial, but you can find out more about these options in Share an IPAM pool using AWS RAM.
11. Choose **Next**.
12. Under **Principals** > **Select principal type**, choose **AWS account** and enter the account ID of the account that will be bringing an IP address range to IPAM and choose **Add** .
13. Choose **Next**.
14. Review the resource share options and the principals that you'll be sharing with, and then choose **Create**.
15. To allow the **`member-account`** account to allocate IP address CIDRS from the IPAM pool, create a second resource share with `AWSRAMDefaultPermissionsIpamPool`. The value for `--resource-arns` is the ARN of the IPAM pool that you created in the previous section. The value for `--principals` is the account ID of the **`member-account`**. The value for `--permission-arns` is the ARN of the `AWSRAMDefaultPermissionsIpamPool` permission.

Step 8: Create a VPC using the IPv6 CIDR

Create a VPC using the IPAM pool ID. You must associate an IPv4 CIDR block to the VPC as well using the `--cidr-block` option or the request will fail. When you run the command in this section, the value for `--region` must match the `--locale` option you entered when you created the pool that will be used for the BYOIP CIDR.

This step must be done by the member account.

To create a VPC with the IPv6 CIDR using the AWS CLI

1. Run the following command to provision the CIDR.

```
aws ec2 create-vpc --region us-west-2 --ipv6-ipam-pool-id ipam-
pool-0053b7d2b4fc3f730 --cidr-block 10.0.0.0/16 --ipv6-netmask-length 56 --
profile member-account
```

   In the output, you'll see the VPC being created.

```
{
    "Vpc": {
        "CidrBlock": "10.0.0.0/16",
        "DhcpOptionsId": "dopt-2afccf50",
        "State": "pending",
        "VpcId": "vpc-00b5573ffc3b31a29",
        "OwnerId": "123456789012",
        "InstanceTenancy": "default",
        "Ipv6CidrBlockAssociationSet": [
            {
                "AssociationId": "vpc-cidr-assoc-01b5703d6cc695b5b",
                "Ipv6CidrBlock": "2605:9cc0:409::/56",
                "Ipv6CidrBlockState": {
                    "State": "associating"
                },
                "NetworkBorderGroup": "us-east-1",
                "Ipv6Pool": "ipam-pool-0053b7d2b4fc3f730"
            }
        ],
        "CidrBlockAssociationSet": [
            {
                "AssociationId": "vpc-cidr-assoc-09cccb07d4e9a0e0e",
                "CidrBlock": "10.0.0.0/16",
                "CidrBlockState": {
                    "State": "associated"
                }
            }
        ],
        "IsDefault": false
    }
}
```

2. View the VPC allocation in IPAM.

```
aws ec2 get-ipam-pool-allocations --region us-west-2 --ipam-pool-id ipam-
pool-0053b7d2b4fc3f730 --profile ipam-account
```

In the output, you'll see allocation in IPAM.

```
{
    "IpamPoolAllocations": [
        {
            "Cidr": "2605:9cc0:409::/56",
            "IpamPoolAllocationId": "ipam-pool-
alloc-5f8db726fb9e4ff0a33836e649283a52",
            "ResourceId": "vpc-00b5573ffc3b31a29",
            "ResourceType": "vpc",
            "ResourceOwner": "123456789012"
        }
    ]
}
```

Step 9: Advertise the CIDR

Once you create the VPC with CIDR allocated in IPAM, you can then start advertising the CIDR you brought to AWS that is in pool that has `--aws-service ec2` defined. In this tutorial, that's your Regional pool. By default the CIDR is not advertised, which means it's not publicly accessible over the internet. When you run the command in this section, the value for `--region` must match the `--locale` option you entered when you created the Regional pool that will be used for the BYOIP CIDR.

This step must be done by the IPAM account.

Start advertising the CIDR using the AWS CLI

- Run the following command to advertise the CIDR.

```
aws ec2 advertise-byoip-cidr --region us-west-2 --cidr 2605:9cc0:409::/48 --
profile ipam-account
```

In the output, you'll see the CIDR is advertised.

```
{
```

```
    "ByoipCidr": {
        "Cidr": "2605:9cc0:409::/48",
        "State": "advertised"
    }
}
```

Step 10: Cleanup

Follow the steps in this section to clean up the resources you've provisioned and created in this tutorial. When you run the commands in this section, the value for `--region` must match the `--locale` option you entered when you created the Regional pool that will be used for the BYOIP CIDR.

Clean up using the AWS CLI

1. Run the following command to view the VPC allocation managed in IPAM.

   This step must be done by the IPAM account.

   ```
   aws ec2 get-ipam-pool-allocations --region us-west-2 --ipam-pool-id ipam-
   pool-0053b7d2b4fc3f730 --profile ipam-account
   ```

   The output shows the allocation in IPAM.

   ```
   {
       "IpamPoolAllocations": [
           {
               "Cidr": "2605:9cc0:409::/56",
               "IpamPoolAllocationId": "ipam-pool-
   alloc-5f8db726fb9e4ff0a33836e649283a52",
               "ResourceId": "vpc-00b5573ffc3b31a29",
               "ResourceType": "vpc",
               "ResourceOwner": "123456789012"
           }
       ]
   }
   ```

2. Run the following command to stop advertising the CIDR. When you run the command in this step, the value for `--region` must match the `--locale` option you entered when you created the Regional pool that will be used for the BYOIP CIDR.

This step must be done by the IPAM account.

```
aws ec2 withdraw-byoip-cidr --region us-west-2 --cidr 2605:9cc0:409::/48 --
profile ipam-account
```

In the output, you'll see the CIDR State has changed from **advertised** to **provisioned**.

```
{
    "ByoipCidr": {
        "Cidr": "2605:9cc0:409::/48",
        "State": "provisioned"
    }
}
```

3. Run the following command to delete the VPC. When you run the command in this section, the value for `--region` must match the `--locale` option you entered when you created the Regional pool that will be used for the BYOIP CIDR.

   This step must be done by the member account.

   ```
   aws ec2 delete-vpc --region us-west-2 --vpc-id vpc-00b5573ffc3b31a29 --
   profile member-account
   ```

   You will not see any output when you run this command.

4. Run the following command to view the VPC allocation in IPAM. It can take some time for IPAM to discover that the VPC has been deleted and remove this allocation. When you run the commands in this section, the value for `--region` must match the `--locale` option you entered when you created the Regional pool that will be used for the BYOIP CIDR.

   This step must be done by the IPAM account.

   ```
   aws ec2 get-ipam-pool-allocations --region us-west-2 --ipam-pool-id ipam-
   pool-0053b7d2b4fc3f730 --profile ipam-account
   ```

   The output shows the allocation in IPAM.

   ```
   {
      "IpamPoolAllocations": [
   ```

```
        {

            "Cidr": "2605:9cc0:409::/56",

            "IpamPoolAllocationId": "ipam-pool-
alloc-5f8db726fb9e4ff0a33836e649283a52",
            "ResourceId": "vpc-00b5573ffc3b31a29",

            "ResourceType": "vpc",

            "ResourceOwner": "123456789012"

        }

    ]

}
```

Rerun the command and look for the allocation to be removed. You cannot continue to clean up and deprovision the IPAM pool CIDR until you see that the allocation has been removed from IPAM.

```
aws ec2 get-ipam-pool-allocations --region us-west-2 --ipam-pool-id ipam-
pool-0053b7d2b4fc3f730 --profile ipam-account
```

The output shows the allocation removed from IPAM.

```
{
    "IpamPoolAllocations": []
}
```

5. Delete the RAM shares and disable RAM integration with AWS Organizations. Complete the steps in Deleting a resource share in AWS RAM and Disabling resource sharing with AWS Organizations in the *AWS RAM User Guide*, in that order, to delete the RAM shares and disable RAM integration with AWS Organizations.

   This step must be done by the IPAM account and management account respectively. If you are using the AWS CLI to delete the RAM shares and disable RAM integration, use the `--profile` **`ipam-account`** and `--profile` **`management-account`** options.

6. Run the following command to deprovision the Regional pool CIDR.

This step must be done by the IPAM account.

```
aws ec2 deprovision-ipam-pool-cidr --region us-east-1 --ipam-pool-id ipam-
pool-0053b7d2b4fc3f730 --cidr 2605:9cc0:409::/48 --profile ipam-account
```

In the output, you'll see the CIDR pending deprovision.

```
{
    "IpamPoolCidr": {
        "Cidr": "2605:9cc0:409::/48",
        "State": "pending-deprovision"
    }
}
```

Deprovisioning takes time to complete. Continue to run the command until you see the CIDR state **deprovisioned**.

```
aws ec2 get-ipam-pool-cidrs --region us-east-1 --ipam-pool-id ipam-
pool-0053b7d2b4fc3f730 --cidr 2605:9cc0:409::/48 --profile ipam-account
```

In the output, you'll see the CIDR pending deprovision.

```
{
    "IpamPoolCidr": {
        "Cidr": "2605:9cc0:409::/48",
        "State": "deprovisioned"
    }
}
```

7. Run the following command to delete the Regional pool.

   This step must be done by the IPAM account.

   ```
   aws ec2 delete-ipam-pool --region us-east-1 --ipam-pool-id ipam-
   pool-0053b7d2b4fc3f730 --profile ipam-account
   ```

   In the output, you can see the delete state.

   ```
   {
   ```

```
    "IpamPool": {
        "OwnerId": "123456789012",
        "IpamPoolId": "ipam-pool-0053b7d2b4fc3f730",
        "SourceIpamPoolId": "ipam-pool-07f2466c7158b50c4",
        "IpamPoolArn": "arn:aws:ec2::123456789012:ipam-pool/ipam-
pool-0053b7d2b4fc3f730",
        "IpamScopeArn": "arn:aws:ec2::123456789012:ipam-scope/ipam-
scope-0087d83896280b594",
        "IpamScopeType": "public",
        "IpamArn": "arn:aws:ec2::123456789012:ipam/ipam-090e48e75758de279",
        "Locale": "us-east-1",
        "PoolDepth": 2,
        "State": "delete-in-progress",
        "Description": "reg-ipv6-pool",
        "AutoImport": false,
        "Advertisable": true,
        "AddressFamily": "ipv6"
    }
}
```

8. Run the following command to deprovision the top-level pool CIDR.

   This step must be done by the IPAM account.

```
aws ec2 deprovision-ipam-pool-cidr --region us-east-1 --ipam-pool-id ipam-
pool-07f2466c7158b50c4 --cidr 2605:9cc0:409::/48 --profile ipam-account
```

   In the output, you'll see the CIDR pending deprovision.

```
{
    "IpamPoolCidr": {
        "Cidr": "2605:9cc0:409::/48",
        "State": "pending-deprovision"
    }
}
```

   Deprovisioning takes time to complete. Run the following command to check the status of deprovisioning.

```
aws ec2 get-ipam-pool-cidrs --region us-east-1 --ipam-pool-id ipam-
pool-07f2466c7158b50c4 --profile ipam-account
```

Wait until you see **deprovisioned** before you continue to the next step.

```
{
    "IpamPoolCidr": {

        "Cidr": "2605:9cc0:409::/48",

        "State": "deprovisioned"

    }

}
```

9. Run the following command to delete the top-level pool.

   This step must be done by the IPAM account.

```
aws ec2 delete-ipam-pool --region us-east-1 --ipam-pool-id ipam-
pool-07f2466c7158b50c4 --profile ipam-account
```

   In the output, you can see the delete state.

```
{
    "IpamPool": {
        "OwnerId": "123456789012",
        "IpamPoolId": "ipam-pool-0053b7d2b4fc3f730",
        "SourceIpamPoolId": "ipam-pool-07f2466c7158b50c4",
        "IpamPoolArn": "arn:aws:ec2::123456789012:ipam-pool/ipam-
pool-0053b7d2b4fc3f730",
        "IpamScopeArn": "arn:aws:ec2::123456789012:ipam-scope/ipam-
scope-0087d83896280b594",
        "IpamScopeType": "public",
        "IpamArn": "arn:aws:ec2::123456789012:ipam/ipam-090e48e75758de279",
        "Locale": "us-east-1",
        "PoolDepth": 2,
        "State": "delete-in-progress",
        "Description": "reg-ipv6-pool",
        "AutoImport": false,
        "Advertisable": true,
        "AddressFamily": "ipv6"
    }
```

```
}
```

10. Run the following command to delete the IPAM.

    This step must be done by the IPAM account.

```
aws ec2 delete-ipam --region us-east-1 --ipam-id ipam-090e48e75758de279 --
profile ipam-account
```

    In the output, you'll see the IPAM response. This means that the IPAM was deleted.

```
{
    "Ipam": {
        "OwnerId": "123456789012",
        "IpamId": "ipam-090e48e75758de279",
        "IpamArn": "arn:aws:ec2::123456789012:ipam/ipam-090e48e75758de279",
        "PublicDefaultScopeId": "ipam-scope-0087d83896280b594",
        "PrivateDefaultScopeId": "ipam-scope-08b70b04fbd524f8d",
        "ScopeCount": 2,
        "OperatingRegions": [
            {

                "RegionName": "us-east-1"

            },
            {
                "RegionName": "us-west-2"
            }
        ]
    }
}
```

Bring your own IP to CloudFront using IPAM (supports IPv4 and IPv6)

IPAM's BYOIP for global services lets you use your own IPv4 and IPv6 addresses with AWS global services like CloudFront. Unlike regional BYOIP, your IP addresses are advertised from multiple edge locations simultaneously through anycast routing.

This tutorial covers:

- Creating global IPAM pools for IPv4 (/24) and/or IPv6 (/48) address ranges

- Provisioning Anycast Static IP lists with your own IP addresses
- Advertising your CIDRs globally through CloudFront edge locations
- Dual-stack configurations using separate IPv4 and IPv6 IPAM pools

Why use this feature?

- **Maintain IP allowlisting** – Use existing approved IP addresses instead of updating firewall configurations
- **Simplify migrations** – Migrate from other CDNs without changing IP infrastructure
- **Consistent branding** – Keep your existing IP address space when moving to AWS
- **IPv6 readiness** – Support modern dual-stack architectures with both IPv4 and IPv6

Who should use this feature?

Organizations that need their own IP addresses with global content delivery:

- Large enterprises with IP allowlisting requirements
- Companies migrating from other CDNs with existing IP addresses
- Organizations with strict security policies requiring specific IP ranges
- Enterprises requiring dual-stack (IPv4/IPv6) configurations for global reach

When to use this feature?

Use BYOIP for global services when you need to:

- Maintain existing IP allowlisting with partners/clients
- Migrate from another CDN using your IP addresses
- Meet compliance requirements for specific IP ranges
- Deploy dual-stack architectures supporting both IPv4 and IPv6 clients

> **Note**
>
> Requires /24 CIDR blocks for IPv4. Dual-stack (IPv4 and IPv6) requires /24 IPv4 and /48 IPv6 CIDR blocks. Currently available for CloudFront only.

Prerequisites

Complete these steps before starting:

- **IPAM setup** – Integrate IPAM with accounts in an AWS Organization and Create an IPAM
- **Domain verification** – Verify domain control
- **Create top-level pool(s)** – Follow steps 1-2 in Bring your own IPv4 CIDR to IPAM and/or Bring your own IPv6 CIDR to IPAM
- **ROA (Route Origin Authorization)** – Ensure ROAs are configured for both IPv4 (/24) and IPv6 (/48) prefixes if deploying dual-stack

Global service configuration steps

The following steps differ from the standard regional BYOIP process and establish the pattern for global services. For dual-stack deployments, you'll create separate pools for IPv4 and IPv6, then provision both to CloudFront.

Step 1: Create global pool(s) for anycast services

Instead of creating a regional pool, create a global pool for anycast services:

Console

To create a global pool using the console:

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**
3. Choose **Create pool**
4. **Source**: Choose your top-level BYOIP pool
5. **Locale**: Choose **Global**
6. **Service**: Choose **Global services** (appears when Global is selected)
7. **Public IP source**: Choose **BYOIP**
8. **CIDRs to provision**: Specify your /24 CIDR range (for IPv4) or /48 CIDR range (for IPv6)
9. Choose **Create pool**

CLI

For IPv4:

```
aws ec2 create-ipam-pool \
  --ipam-scope-id scope-id \
  --locale None \
  --address-family ipv4 \
  --source-ipam-pool-id top-level-pool-id

aws ec2 provision-ipam-pool-cidr \
  --ipam-pool-id global-pool-id \
  --cidr your-ipv4-/24
```

For IPv6:

```
aws ec2 create-ipam-pool \
  --ipam-scope-id scope-id \
  --locale None \
  --address-family ipv6 \
  --source-ipam-pool-id top-level-pool-id

aws ec2 provision-ipam-pool-cidr \
  --ipam-pool-id global-pool-id \
  --cidr your-ipv6-/48
```

⚠ Important

- For IPv4: You must allocate the full /24 block to this pool. You can provision more specific ranges within this block for different uses.
- For IPv6: You must allocate the full /48 block to this pool. You can provision more specific ranges within this block for different uses.

Step 2: Create service-specific resources

For CloudFront, create an anycast IP list that uses your IPAM pool. For detailed instructions, see Bring your own IP to CloudFront using IPAM in the *Amazon CloudFront Developer Guide*.

Key parameters for IPAM integration:

- **IP address type** – Choose **BYOIP**

- **IPAM pool** – Select your global pool from Step 1 (IPv4 or IPv6)
- **IP count** – Enter **3** (required for CloudFront)

Step 3: Associate with service resources

Associate your Anycast Static IP list with a CloudFront distribution. For detailed instructions, see Bring your own IP to CloudFront using IPAM in the *Amazon CloudFront Developer Guide*.

Key configuration:

- In distribution settings, select your Anycast IP List from Step 2

Step 4: Prepare for migration

- **Lower DNS TTL** – Set DNS TTL for your records to 60 seconds or lower
- **Wait for propagation** – Allow time for the new TTL to take effect across the internet

Step 5: Advertise CIDR globally

Use the IPAM global advertisement command:

Console

To advertise the CIDR using the console:

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**
3. Select your global pool
4. Choose the **CIDRs** tab
5. Select your CIDR and choose **Actions** > **Advertise CIDR**
6. Confirm the advertisement

CLI

For IPv4:

```
aws ec2 advertise-byoip-cidr \
  --cidr your-ipv4-/24
```

For IPv6:

```
aws ec2 advertise-byoip-cidr \
  --cidr your-ipv6-/48
```

Important

- Withdraw advertisement from your previous provider before running this command
- Update DNS records to point to CloudFront to complete the migration (A records for IPv4, AAAA records for IPv6)

Cleanup

To clean up resources created in this tutorial:

- **Delete CloudFront resources** – Follow the cleanup instructions in Bring your own IP to CloudFront using IPAM in the *Amazon CloudFront Developer Guide*
- **Withdraw CIDR and delete IPAM pools** – Follow the standard cleanup process in Step 8: Cleanup

Important

Delete CloudFront resources first, then proceed with IPAM cleanup to avoid service disruptions.

Tutorial: Set up delegated RPKI for BYOIP prefixes

This tutorial walks through all BGP route protection capabilities end to end. You can stop after any step and use what you've set up so far. Steps 1 and 2 require no RIR interaction. Steps 3 and later require a one-time setup with your RIR. For background on BGP route protection concepts, tier requirements, and supported RIRs, see Monitor BGP route protection.

Prerequisites

- An IPAM created in the Advanced Tier.

- One or more BYOIP prefixes provisioned to IPAM pools.
- Access to your Regional Internet Registry account (ARIN, RIPE, APNIC, or LACNIC).

Step 1: View your BGP routes

Once you have BYOIP prefixes provisioned to IPAM, view all advertised routes in the centralized dashboard.

AWS Management Console

To view your BGP routes

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **IPAM**, and then choose your IPAM.
3. Under **Monitoring**, choose **Route monitoring**.

The dashboard displays all BYOIP routes with prefix, locale, advertisement status, ASN, RPKI validity, ROA strength, and route overlaps.

Command line

Use get-ipam-discovered-routes to view discovered routes. This command is available to both Free Tier and Advanced Tier customers.

```
aws ec2 get-ipam-discovered-routes \
    --ipam-resource-discovery-id ipam-res-disco-0365d2977fc1672fe \
    --resource-region us-west-2
```

The following is example output.

```
{
    "IpamDiscoveredRoutes": [
        {
            "IpamResourceDiscoveryId": "ipam-res-disco-0365d2977fc1672fe",
            "ResourceRegion": "us-west-2",
            "ResourceOwnerId": "123456789012",
            "Cidr": "203.0.113.0/24",
            "Asn": "64512",
            "State": "advertised",
```

```
            "AdvertisementType": "regional",
            "NetworkBorderGroup": "us-west-2",
            "PoolId": "ipv4pool-ec2-0a1b2c3d4e5f6g7h8",
            "IpamPoolId": "ipam-pool-0da89c821626f1e4b",
            "SampleTime": "2026-03-10T15:30:00+00:00"
        }
    ]
}
```

Step 2: Review route protection findings

For Advanced Tier customers, IPAM evaluates routes against published ROA data and surfaces findings with get-ipam-route-protection-findings.

> **Note**
>
> get-ipam-route-protection-findings requires the Advanced Tier. Free Tier customers receive an `UnsupportedOperation` error.

1. List all findings.

```
aws ec2 get-ipam-route-protection-findings \
    --ipam-id ipam-0a1b2c3d4e5f6g7h8
```

2. Filter for invalid or missing ROAs.

```
aws ec2 get-ipam-route-protection-findings \
    --ipam-id ipam-0a1b2c3d4e5f6g7h8 \
    --filters "Name=rpki-status,Values=invalid,unknown"
```

3. Filter by status in a specific Region.

```
aws ec2 get-ipam-route-protection-findings \
    --ipam-id ipam-0a1b2c3d4e5f6g7h8 \
    --filters "Name=rpki-status,Values=invalid" "Name=resource-region,Values=us-
west-2"
```

The following is example output.

```
{
    "IpamId": "ipam-0a1b2c3d4e5f6g7h8",
    "RouteProtectionFindings": [
        {
            "ResourceOwnerId": "123456789012",
            "ResourceRegion": "us-west-2",
            "IpamPoolId": "ipam-pool-0da89c821626f1e4b",
            "Cidr": "203.0.113.0/24",
            "State": "advertised",
            "AdvertisementType": "regional",
            "NetworkBorderGroup": "us-west-2",
            "PoolId": "ipv4pool-ec2-0a1b2c3d4e5f6g7h8",
            "Asn": "64512",
            "RpkiStatus": "valid",
            "RpkiStrength": "strict",
            "Roas": [
                {
                    "Asn": "64512",
                    "Prefix": "203.0.113.0/24",
                    "MaxLength": 24,
                    "Match": true,
                    "Expiration": "2027-06-15T00:00:00Z"
                }
            ],
            "RouteOverlaps": [
                {
                    "Prefix": "203.0.113.128/25",
                    "Asn": "64513",
                    "DetectedAt": "2026-03-10T15:45:00+00:00"
                }
            ],
            "SampleTime": "2026-03-10T15:30:00+00:00",
            "RoaSampleTime": "2026-03-10T16:00:00+00:00"
        }
    ]
}
```

Valid filter names are `cidr`, `account-id`, `resource-region`, `byoip-cidr-state`, `advertisement-type`, `network-border-group`, `ipam-pool-id`, `rpki-status`, and `asn`. These EC2-style filter names don't always match the returned fields. For example, you filter on `account-id` but the response returns `ResourceOwnerId`, and you filter on `byoip-cidr-state` but the field is `State`. ROA strength is not filterable.

Step 3: Set up delegated RPKI

Delegated RPKI lets you authorize AWS to manage ROAs on your behalf.

1. **Create the Internet Registry Association.**

```
aws ec2 create-ipam-internet-registry-association --region us-east-1 \
    --ipam-id ipam-0de83dba6694560a9 \
    --rir ARIN --org-handle my-arin-org
```

The following is example output.

```
{
    "IpamInternetRegistryAssociation": {
        "IpamInternetRegistryAssociationId": "ipam-internet-registry-
assoc-036486dfa6af58ee0",
        "State": "create-in-progress"
    }
}
```

Run the following command until the state reaches `pending-enable`.

```
aws ec2 describe-ipam-internet-registry-associations --region us-east-1 \
    --ipam-internet-registry-association-ids ipam-internet-registry-
assoc-036486dfa6af58ee0
```

Once the state is `pending-enable`, the ChildRequestXml is ready to submit to your RIR. IPAM stages ROAs based on public VRP (Validated ROA Payload) data. They're pending and will be activated once the Internet Registry Association is enabled.

2. **Review the staged ROAs.**

```
aws ec2 get-ipam-route-origin-authorizations --region us-east-1 \
    --ipam-internet-registry-association-id ipam-internet-registry-
assoc-036486dfa6af58ee0
```

The following is example output.

```
{
    "Roas": [
```

```
        {
            "prefix": "18.96.0.0/14",
            "asn": "77221",
            "maxLength": "24",
            "state": "pending-activate"
        }
    ]
}
```

3. **Enable the Internet Registry Association.**

   Take the ChildRequestXml to your RIR portal and submit the delegation request. The RIR returns a parent response XML. Extract the following fields from that response: RpkiVersion, ServiceUri, ChildHandle, ParentHandle, and ParentBpkiTa. Then call the following command.

```
aws ec2 enable-ipam-internet-registry-association --region us-east-1 \
    --ipam-internet-registry-association-id ipam-internet-registry-
assoc-036486dfa6af58ee0 \
    --rpki-version "..." \
    --service-uri "..." \
    --child-handle "..." \
    --parent-handle "..." \
    --parent-bpki-ta "..."
```

   The following is example output.

```
{
    "IpamInternetRegistryAssociation": {
        "IpamInternetRegistryAssociationId": "ipam-internet-registry-
assoc-036486dfa6af58ee0",
        "State": "enable-in-progress"
    }
}
```

   Run the following command until the state reaches `enable-complete`.

```
aws ec2 describe-ipam-internet-registry-associations --region us-east-1 \
    --ipam-internet-registry-association-ids ipam-internet-registry-
assoc-036486dfa6af58ee0
```

Once the state is `enable-complete`, staged ROAs transition to `create-complete`. AWS now manages the ROA lifecycle for all CIDRs under this association.

4. **View associated CIDRs.**

```
aws ec2 get-ipam-internet-registry-association-cidrs --region us-east-1 \
    --ipam-internet-registry-association-id ipam-internet-registry-
assoc-036486dfa6af58ee0
```

The following is example output.

```
{
    "IpamInternetRegistryAssociationCidrs": [
        {
            "Cidr": "18.96.0.0/14",
            "LastObservedAt": "2026-07-30T18:00:00.000Z"
        }
    ]
}
```

5. **View associated ASNs.**

```
aws ec2 get-ipam-internet-registry-association-asns --region us-east-1 \
    --ipam-internet-registry-association-id ipam-internet-registry-
assoc-036486dfa6af58ee0
```

The following is example output.

```
{
    "IpamInternetRegistryAssociationAsns": [
        {
            "Asn": "77221",
            "LastObservedAt": "2026-07-30T18:00:00.000Z"
        }
    ]
}
```

Step 4: Provision BYOIP with automated ROA creation

With delegated RPKI active, provisioning is simplified.

Before (without delegated RPKI)	After (with delegated RPKI)
Must provide `--cidr-authorization-context`	Still pass `--cidr-authorization-context` , but with `Message="CoveredBy InternetRegistryAssociation",Signature=""` — no signed message is required
Must validate via WHOIS or DNS TXT record	Not required — IPAM verifies against associati on CIDRs
Must manually create ROAs at RIR before advertising	ROAs auto-created on provisioning
Must manually renew ROAs before expiration	AWS auto-renews — no action needed

```
aws ec2 provision-ipam-pool-cidr \
    --cidr 18.97.16.0/24 \
    --ipam-pool-id ipam-pool-0da89c821626f1e4b \
    --cidr-authorization-context
 Message="CoveredByInternetRegistryAssociation",Signature="" \
    --region us-east-1
```

IPAM validates ownership through the Internet Registry Association and creates strict ROAs matching the pool's locale and ASN. There is no manual ROA step.

Step 5: Manage ROAs for on-premises prefixes

For IP space that is not brought to AWS, use routing policy registrations (RPRs).

1. **Create an RPR.**

```
aws ec2 create-ipam-routing-policy-registration --region us-east-1 \
    --ipam-id ipam-0de83dba6694560a9 \
    --ipam-internet-registry-association-id ipam-internet-registry-
assoc-036486dfa6af58ee0 \
    --cidr 18.96.0.0/14 --asns 77221,13446 \
    --permit-more-specific-announcements
```

The following is example output.

```
{
    "deltaId": "0130c368-1f8c-4283-8f16-66e67e633086",
    "state": "PENDING"
}
```

2. **Check delta status.** If the change would invalidate existing routes, it fails with an error. Use `--force` to override.

```
aws ec2 get-ipam-routing-policy-registration-deltas --region us-east-1 \
    --ipam-id ipam-0de83dba6694560a9 \
    --ipam-internet-registry-association-id ipam-internet-registry-
assoc-036486dfa6af58ee0 \
    --delta-id 0130c368-1f8c-4283-8f16-66e67e633086
```

3. **Batch update (atomic).** Batch updates succeed or fail atomically. There is no partial application.

```
aws ec2 batch-modify-ipam-routing-policy-registrations --region us-east-1 \
    --ipam-id ipam-0de83dba6694560a9 \
    --ipam-internet-registry-association-id ipam-internet-registry-
assoc-036486dfa6af58ee0 \
    --delta-json file://delta.json
```

Where `delta.json` contains the following.

```
{
    "Add": [
        {
            "prefix": "18.96.0.0/14",
            "asns": ["77221", "13446"],
            "permit-more-specific-announcements": "false"
        }
    ],
    "Delete": [
        {
            "prefix": "18.97.16.0/24",
            "asns": ["77221", "13446"],
            "permit-more-specific-announcements": "false"
        }
```

```
    ]
}
```

4. **View all registrations for an association.**

```
aws ec2 get-ipam-routing-policy-registrations --region us-east-1 \
    --ipam-internet-registry-association-id ipam-internet-registry-
assoc-036486dfa6af58ee0
```

The following is example output.

```
{
    "IpamRoutingPolicyRegistrations": [
        {
            "Cidr": "18.96.0.0/14",
            "Asns": ["77221", "13446"],
            "PermitMoreSpecificAnnouncements": false,
            "MaxLength": 14,
            "LatestDeltaId": "0130c368-1f8c-4283-8f16-66e67e633086",
            "State": "create-complete"
        },
        {
            "Cidr": "18.97.16.0/24",
            "Asns": ["77221", "13446"],
            "PermitMoreSpecificAnnouncements": false,
            "MaxLength": 24,
            "LatestDeltaId": "0130c368-1f8c-4283-8f16-66e67e633086",
            "State": "create-complete"
        }
    ]
}
```

5. **Filter to a specific prefix.**

```
aws ec2 get-ipam-routing-policy-registrations --region us-east-1 \
    --ipam-internet-registry-association-id ipam-internet-registry-
assoc-036486dfa6af58ee0 \
    --cidr 18.96.0.0/14
```

Step 6: Set up CloudWatch alarms for route anomalies

IPAM publishes CloudWatch metrics for each BYOIP route to the global IPAM account. The `RoaExpiration` metric is published to the `AWS/IPAM` namespace with the dimensions `Cidr`, `RoaPrefix`, `Asn`, and `MaxLength`.

Type	Name	Description
Metric	RoaExpiration	Number of days until the ROA expires
Dimension	Asn	ASN for the prefix
Dimension	Cidr	CIDR brought via BYOIP
Dimension	MaxLength	MaxLength from the ROA
Dimension	RoaPrefix	Prefix from the ROA

Because `RoaExpiration` reports the number of days remaining until the ROA expires, alarm when the value drops to or below your threshold. Specify all four dimensions to target a single ROA. Create the alarm in the same account and Region where the metrics are published.

```
aws cloudwatch put-metric-alarm --region us-east-1 \
    --alarm-name "IPAM-RoaExpiration-203.0.113.0-24" \
    --alarm-description "Alert when the ROA for 203.0.113.0/24 is within 30 days of
 expiration" \
    --namespace "AWS/IPAM" \
    --metric-name RoaExpiration \
    --dimensions Name=Cidr,Value=203.0.113.0/24 Name=RoaPrefix,Value=203.0.113.0/24
 Name=Asn,Value=64512 Name=MaxLength,Value=24 \
    --statistic Minimum \
    --period 86400 \
    --evaluation-periods 1 \
    --threshold 30 \
    --comparison-operator LessThanOrEqualToThreshold \
    --treat-missing-data notBreaching \
    --alarm-actions arn:aws:sns:us-east-1:123456789012:roa-expiry-notifications
```

Cleanup

To remove delegated RPKI resources:

1. Delete all routing policy registrations.
2. Disassociate the Internet Registry Association.
3. (Optional) Remove the authorization at your RIR portal.

> **Important**
>
> Deleting an Internet Registry Association removes all AWS-managed ROAs for that association. Make sure your routes have alternative ROA coverage before you disassociate.

- Monitor IPAM with Amazon CloudWatch

Tutorial: Transfer a BYOIP IPv4 CIDR to IPAM

Follow these steps to transfer an existing IPv4 CIDR to IPAM. If you already have an IPv4 BYOIP CIDR with AWS, you can move the CIDR to IPAM from a public IPv4 pool. You cannot move an IPv6 CIDR to IPAM.

This tutorial assumes you have already successfully brought an IP address range to AWS using the process described in Bring your own IP addresses (BYOIP) in Amazon EC2 and now you want to transfer that IP address range to IPAM. If you are bringing a new IP address to AWS for the first time, complete the steps in Tutorial: Bring your IP addresses to IPAM.

If you transfer a public IPv4 pool to IPAM, there is no impact on existing allocations. Once you transfer a public IPv4 pool to IPAM, depending on the resource type, you may be able to monitor the existing allocations. For more information, see Monitor CIDR usage by resource.

Note

- This tutorial assumes you have already completed the steps in Create an IPAM.
- Each step of this tutorial must be done by one of two AWS accounts:
  - The account for the IPAM administrator. In this tutorial, this account will be called the IPAM account.
  - The account in your organization which owns the BYOIP CIDR. In this tutorial, this account will be called the BYOIP CIDR owner account.

Contents

Step 1: Create AWS CLI named profiles and IAM roles

To complete this tutorial as a single AWS user, you can use AWS CLI named profiles to switch from one IAM role to another. Named profiles are collections of settings and credentials that you refer to when using the `--profile` option with the AWS CLI. For more information about how to create IAM roles and named profiles for AWS accounts, see Using an IAM role in the AWS CLI.

Create one role and one named profile for each of the three AWS accounts you will use in this tutorial:

- A profile called `ipam-account` for the AWS account that is the IPAM administrator.
- A profile called `byoip-owner-account` for the AWS account in your organization which owns the BYOIP CIDR.

After you have created the IAM roles and named profiles, return to this page and go to the next step. You will notice throughout the rest of this tutorial that the sample AWS CLI commands use the `--profile` option with one of the named profiles to indicate which account must run the command.

Step 2: Get your IPAM's public scope ID

Follow the steps in this section to get your IPAM's public scope ID. This step should be performed by the **`ipam-account`** account.

Run the following command to get your public scope ID.

```
aws ec2 describe-ipams --region us-east-1 --profile ipam-account
```

In the output, you'll see your public scope ID. Note the values for `PublicDefaultScopeId`. You will need it in the next step.

```
{
 "Ipams": [
        {
            "OwnerId": "123456789012",
            "IpamId": "ipam-090e48e75758de279",
            "IpamArn": "arn:aws:ec2::123456789012:ipam/ipam-090e48e75758de279",
            "PublicDefaultScopeId": "ipam-scope-0087d83896280b594",
            "PrivateDefaultScopeId": "ipam-scope-08b70b04fbd524f8d",
            "ScopeCount": 2,
            "Description": "my-ipam",
            "OperatingRegions": [
                {
                    "RegionName": "us-east-1"
                },
                {
                    "RegionName": "us-west-2"
                }
            ],
            "Tags": []
        }
    ]
}
```

Step 3: Create an IPAM pool

Follow the steps in this section to create an IPAM pool. This step should be performed by the **`ipam-account`** account. The IPAM pool you create must be a top-level pool with the `--locale` option matching the BYOIP CIDR AWS Region. You can only transfer a BYOIP to a top-level IPAM pool.

> **Important**
>
> When you create the pool, you must include `--aws-service ec2`. The service you select determines the AWS service where the CIDR will be advertisable. Currently, the only option is `ec2`, which means that the CIDRs allocated from this pool will be advertisable for the Amazon EC2 service (for Elastic IP addresses) and the Amazon VPC service (for CIDRs associated with VPCs).

To create an IPv4 address pool for the transferred BYOIP CIDR using the AWS CLI

1. Run the following command to create an IPAM pool. Use the ID of the public scope of the IPAM that you retrieved in the previous step.

```
aws ec2 create-ipam-pool --region us-east-1 --profile ipam-account --ipam-scope-
id ipam-scope-0087d83896280b594 --description "top-level-pool" --locale us-west-2
 --aws-service ec2 --address-family ipv4
```

   In the output, you'll see `create-in-progress`, which indicates that pool creation is in progress.

```
{
    "IpamPool": {
        "OwnerId": "123456789012",
        "IpamPoolId": "ipam-pool-0a03d430ca3f5c035",
        "IpamPoolArn": "arn:aws:ec2::123456789012:ipam-pool/ipam-
pool-0a03d430ca3f5c035",
        "IpamScopeArn": "arn:aws:ec2::123456789012:ipam-scope/ipam-
scope-0087d83896280b594",
        "IpamScopeType": "public",
        "IpamArn": "arn:aws:ec2::123456789012:ipam/ipam-090e48e75758de279",
        "Locale": "us-west-2",
        "PoolDepth": 1,
```

```
        "State": "create-in-progress",
        "Description": "top-level-pool",
        "AutoImport": false,
        "AddressFamily": "ipv4",
        "Tags": [],
        "AwsService": "ec2"
    }
}
```

2. Run the following command until you see a state of `create-complete` in the output.

```
aws ec2 describe-ipam-pools --region us-east-1 --profile ipam-account
```

The following example output shows the state of the pool. You will need the **OwnerId** in the next step.

```
{
    "IpamPools": [
        {
            "OwnerId": "123456789012",
            "IpamPoolId": "ipam-pool-0a03d430ca3f5c035",
            "IpamPoolArn": "arn:aws:ec2::123456789012:ipam-pool/ipam-
pool-0a03d430ca3f5c035",
            "IpamScopeArn": "arn:aws:ec2::123456789012:ipam-scope/ipam-
scope-0087d83896280b594",
            "IpamScopeType": "public",
            "IpamArn": "arn:aws:ec2::123456789012:ipam/ipam-090e48e75758de279",
            "Locale": "us-west-2",
            "PoolDepth": 1,
            "State": "create-complete",
            "Description": "top-level-pool",
            "AutoImport": false,
            "AddressFamily": "ipv4",
            "Tags": [],
            "AwsService": "ec2"
        }
    ]
}
```

Step 4: Share the IPAM pool using AWS RAM

Follow the steps in this section to share an IPAM pool using AWS RAM so that another AWS account can transfer an existing BYOIP IPV4 CIDR to the IPAM pool and use the IPAM pool. This step should be performed by the **`ipam-account`** account.

To share an IPv4 address pool using the AWS CLI

1. View the AWS RAM permissions available for IPAM pools. You need both ARNs to complete the steps in this section.

```
aws ram list-permissions --region us-east-1 --profile ipam-account --resource-type
 ec2:IpamPool
```

```
{
    "permissions": [
        {
           "arn": "arn:aws:ram::aws:permission/AWSRAMDefaultPermissionsIpamPool",
           "version": "1",
           "defaultVersion": true,
           "name": "AWSRAMDefaultPermissionsIpamPool",
           "resourceType": "ec2:IpamPool",
           "status": "ATTACHABLE",
           "creationTime": "2022-06-30T13:04:29.335000-07:00",
           "lastUpdatedTime": "2022-06-30T13:04:29.335000-07:00",
           "isResourceTypeDefault": true
        },
        {
            "arn": "arn:aws:ram::aws:permission/
AWSRAMPermissionIpamPoolByoipCidrImport",
            "version": "1",
            "defaultVersion": true,
            "name": "AWSRAMPermissionIpamPoolByoipCidrImport",
            "resourceType": "ec2:IpamPool",
            "status": "ATTACHABLE",
            "creationTime": "2022-06-30T13:03:55.032000-07:00",
            "lastUpdatedTime": "2022-06-30T13:03:55.032000-07:00",
            "isResourceTypeDefault": false
        }
    ]
}
```

2. Create a resource share to enable the **byoip-owner-account** account to import BYOIP CIDRs to IPAM. The value for `--resource-arns` is the ARN of the IPAM pool that you created in the previous section. The value for `--principals` is the account ID of the BYOIP CIDR owner account. The value for `--permission-arns` is the ARN of the `AWSRAMPermissionIpamPoolByoipCidrImport` permission.

```
aws ram create-resource-share --region us-east-1 --profile ipam-account
 --name PoolShare2 --resource-arns arn:aws:ec2::123456789012:ipam-pool/
ipam-pool-0a03d430ca3f5c035 --principals 111122223333 --permission-arns
 arn:aws:ram::aws:permission/AWSRAMPermissionIpamPoolByoipCidrImport
```

```
{

    "resourceShare": {

        "resourceShareArn": "arn:aws:ram:us-east-1:123456789012:resource-
share/7993758c-a4ea-43ad-be12-b3abaffe361a",
        "name": "PoolShare2",

        "owningAccountId": "123456789012",

        "allowExternalPrincipals": true,

        "status": "ACTIVE",

        "creationTime": "2023-04-28T07:32:25.536000-07:00",

        "lastUpdatedTime": "2023-04-28T07:32:25.536000-07:00"

        }

}
```

3. (Optional) If you want to allow the **byoip-owner-account** account to allocate IP address CIDRS from the IPAM pool to public IPv4 pools after the transfer is complete, copy the ARN for `AWSRAMDefaultPermissionsIpamPool` and create a second resource share. The value for `--resource-arns` is the ARN of the IPAM pool that you created in the previous section. The value for `--principals` is the account ID of the BYOIP CIDR owner account. The value for `--permission-arns` is the ARN of the `AWSRAMDefaultPermissionsIpamPool` permission.

```
aws ram create-resource-share --region us-east-1 --profile ipam-account
 --name PoolShare1 --resource-arns arn:aws:ec2::123456789012:ipam-pool/
ipam-pool-0a03d430ca3f5c035 --principals 111122223333 --permission-arns
 arn:aws:ram::aws:permission/AWSRAMDefaultPermissionsIpamPool
```

```
{

    "resourceShare": {

        "resourceShareArn": "arn:aws:ram:us-east-1:123456789012:resource-
share/8d1e229b-2830-4cf4-8b10-19c889235a2f",
        "name": "PoolShare1",

        "owningAccountId": "123456789012",

        "allowExternalPrincipals": true,

        "status": "ACTIVE",

        "creationTime": "2023-04-28T07:31:25.536000-07:00",

        "lastUpdatedTime": "2023-04-28T07:31:25.536000-07:00"

        }

}
```

As a result of creating the resource share in RAM, the byoip-owner-account account can now move CIDRs to IPAM.

Step 5: Transfer an existing BYOIP IPV4 CIDR to IPAM

Follow the steps in this section to transfer an existing BYOIP IPV4 CIDR to IPAM. This step should be performed by the **`byoip-owner-account`** account.

Important

Once you bring an IPv4 address range to AWS, you can use all of the IP addresses in the range, including the first address (the network address) and the last address (the broadcast address).

To transfer the BYOIP CIDR to IPAM, the BYOIP CIDR owner must have these permissions in their IAM policy:

- `ec2:MoveByoipCidrToIpam`
- `ec2:ImportByoipCidrToIpam`

Note

You can use either the AWS Management Console or the AWS CLI for this step.

AWS Management Console

To transfer a BYOIP CIDR to the IPAM pool:

1. Open the IPAM console at https://console.aws.amazon.com/ipam/ as the **`byoip-owner-account`** account.
2. In the navigation pane, choose **Pools**.
3. Choose the top-level pool created and shared in this tutorial.
4. Choose **Actions** > **Transfer BYOIP CIDR**.
5. Choose **Transfer BYOIP CIDR**.
6. Choose your BYOIP CIDR.
7. Choose **Provision**.

Command line

Use the following AWS CLI commands transfer a BYOIP CIDR to the IPAM pool using the AWS CLI:

1. Run the following command to transfer the CIDR. Ensure that the `--region` value is the AWS Region of the BYOIP CIDR.

```
aws ec2 move-byoip-cidr-to-ipam --region us-west-2 --profile byoip-owner-account
 --ipam-pool-id ipam-pool-0a03d430ca3f5c035 --ipam-pool-owner 123456789012 --
cidr 130.137.249.0/24
```

   In the output, you'll see the CIDR pending provision.

```
{
    "ByoipCidr": {

        "Cidr": "130.137.249.0/24",

        "State": "pending-transfer"

    }

}
```

2. Ensure that the CIDR has been transferred. Run the following command until you see a state of `complete-transfer` in the output.

```
aws ec2 move-byoip-cidr-to-ipam --region us-west-2  --profile byoip-
owner-account --ipam-pool-id ipam-pool-0a03d430ca3f5c035 --ipam-pool-
owner 123456789012 --cidr 130.137.249.0/24
```

   The following example output shows the state.

```
{
    "ByoipCidr": {

        "Cidr": "130.137.249.0/24",

        "State": "complete-transfer"

    }

}
```

Step 6: View the CIDR in IPAM

Follow the steps in this section to view the CIDR in IPAM. This step should be performed by the **`ipam-account`** account.

To view the transferred BYOIP CIDR in IPAM pool using the AWS CLI

- Run the following command to view the allocation managed in IPAM. Ensure that the `--region` value is the AWS Region of the BYOIP CIDR.

```
aws ec2 get-ipam-pool-allocations --region us-west-2  --profile ipam-account --
ipam-pool-id ipam-pool-0d8f3646b61ca5987
```

  The output shows the allocation in IPAM.

```
{
    "IpamPoolAllocations": [
        {
            "Cidr": "130.137.249.0/24",
            "IpamPoolAllocationId": "ipam-pool-
alloc-5dedc8e7937c4261b56dc3e3eb53dc46",
            "ResourceId": "ipv4pool-ec2-0019eed22a684e0b3",
            "ResourceType": "ec2-public-ipv4-pool",
            "ResourceOwner": "111122223333"
        }
    ]
}
```

Step 7: Cleanup

Follow the steps in this section to remove the resources you created in this tutorial. This step should be performed by the **`ipam-account`** account.

To cleanup the resources created in this tutorial using the AWS CLI

1. To delete the IPAM pool shared resource, run the following command to get the first resource share ARN:

```
aws ram get-resource-shares --region us-east-1 --profile ipam-account --
name PoolShare1 --resource-owner SELF
```

```
{
    "resourceShares": [
        {
            "resourceShareArn": "arn:aws:ram:us-east-1:123456789012:resource-
share/8d1e229b-2830-4cf4-8b10-19c889235a2f",
            "name": "PoolShare1",
            "owningAccountId": "123456789012",
            "allowExternalPrincipals": true,
            "status": "ACTIVE",
            "creationTime": "2023-04-28T07:31:25.536000-07:00",
            "lastUpdatedTime": "2023-04-28T07:31:25.536000-07:00",
            "featureSet": "STANDARD"
        }
    ]
}
```

2. Copy the resource share ARN and use it to delete the IPAM pool resource share.

```
aws ram delete-resource-share --region us-east-1 --profile ipam-account
 --resource-share-arn arn:aws:ram:us-east-1:123456789012:resource-
share/8d1e229b-2830-4cf4-8b10-19c889235a2f
```

```
{
    "returnValue": true
}
```

3. If you created an additional resource share in Step 4: Share the IPAM pool using AWS RAM, repeat the previous two steps to get the second resource share ARN for `PoolShare2` and delete the second resource share.

4. Run the following command to get the allocation ID for the BYOIP CIDR. Ensure that the `--region` value matches the AWS Region of the BYOIP CIDR.

```
aws ec2 get-ipam-pool-allocations --region us-west-2  --profile ipam-account --
ipam-pool-id ipam-pool-0d8f3646b61ca5987
```

The output shows the allocation in IPAM.

```
{
    "IpamPoolAllocations": [
        {
            "Cidr": "130.137.249.0/24",
            "IpamPoolAllocationId": "ipam-pool-
alloc-5dedc8e7937c4261b56dc3e3eb53dc46",
            "ResourceId": "ipv4pool-ec2-0019eed22a684e0b3",
            "ResourceType": "ec2-public-ipv4-pool",
            "ResourceOwner": "111122223333"
        }
    ]
}
```

5. Release the CIDR from the public IPv4 pool. When you run the command in this section, the value for `--region` must match the Region of your IPAM.

   This step must be done by the **`byoip-owner-account`** account.

```
aws ec2 deprovision-public-ipv4-pool-cidr --region us-east-1  --profile byoip-
owner-account --pool-id ipv4pool-ec2-0019eed22a684e0b3 --cidr 130.137.249.0/24
```

6. View your BYOIP CIDRs again and ensure there are no more provisioned addresses. When you run the command in this section, the value for `--region` must match the Region of your IPAM.

   This step must be done by the **`byoip-owner-account`** account.

```
aws ec2 describe-public-ipv4-pools --region us-east-1 --profile byoip-owner-account
```

   In the output, you'll see the IP addresses count in your public IPv4 pool.

```
{
    "PublicIpv4Pools": [
        {
            "PoolId": "ipv4pool-ec2-0019eed22a684e0b3",
            "Description": "",
            "PoolAddressRanges": [],
            "TotalAddressCount": 0,
            "TotalAvailableAddressCount": 0,
            "NetworkBorderGroup": "us-east-1",
            "Tags": []
```

```
        }
    ]
}
```

7. Run the following command to delete the top-level pool.

```
aws ec2 delete-ipam-pool --region us-east-1  --profile ipam-account --ipam-pool-
id ipam-pool-0a03d430ca3f5c035
```

In the output, you can see the delete state.

```
{
    "IpamPool": {
        "OwnerId": "123456789012",
        "IpamPoolId": "ipam-pool-0a03d430ca3f5c035",
        "IpamPoolArn": "arn:aws:ec2::123456789012:ipam-pool/ipam-
pool-0a03d430ca3f5c035",
        "IpamScopeArn": "arn:aws:ec2::123456789012:ipam-scope/ipam-
scope-0087d83896280b594",
        "IpamScopeType": "public",
        "IpamArn": "arn:aws:ec2::123456789012:ipam/ipam-090e48e75758de279",
        "Locale": "us-east-1",
        "PoolDepth": 2,
        "State": "delete-in-progress",
        "Description": "top-level-pool",
        "AutoImport": false,
        "Advertisable": true,
        "AddressFamily": "ipv4",
        "AwsService": "ec2"
    }
}
```

Tutorial: Plan VPC IP address space for subnet IP allocations

Complete this tutorial to plan the VPC IP address space for allocating IP addresses to VPC subnets and monitor IP address-related metrics at the subnet and VPC level.

Note

This tutorial covers allocating private IPv4 address space in a private IPAM scope to VPCs and subnets. You can also complete this tutorial using an IPv6 CIDR range by creating the VPC with an Amazon-provided IPv6 CIDR block option on the VPC console.

Planning VPC IP address space for subnets enables you to do the following:

- **Plan and organize your VPC's IP addresses for allocation to subnets**: You can divide VPC IP address space into smaller CIDR blocks and provision those CIDR blocks to subnets with different business needs, such as if you're running workloads in development or production subnets.
- **Simplify IP address allocations for VPC subnets**: Once your VPC's address space is planned and organized, you can choose a netmask length rather than manually inputting a CIDR. For example, if a developer is creating a subnet for hosting development workloads, they need to choose a pool and a netmask length for the subnet and IPAM will automatically allocate the CIDR block to your subnet.

The following example shows the hierarchy of the pool and resource structure that you will create with this tutorial:

- Private scope
  - Resource planning pool (10.0.0.0/20)
    - Dev subnet pool (10.0.0.0/24)
      - Dev subnet (10.0.0.0/28)
    - Prod subnet pool (10.0.0.1/24)
      - Prod subnet (10.0.0.16/28)

Important

- The resource planning pool can be used to allocate CIDRs to subnets or it can be used as a source pool in which you can create other pools. In this tutorial, we use the resource planning pool as a source pool for subnet pools.
- You can create multiple resource planning pools using the same VPC if the VPC has more than one CIDR provisioned to it. For example, if a VPC has two CIDRs assigned to it, you

can create two resource planning pools, one from each CIDR. Each CIDR can be assigned to one pool at a time.

Step 1: Create a VPC

Complete the steps in this section to create a VPC to be used for subnet IP address planning. For more information about the IAM permissions that are required to create VPCs, see Amazon VPC policy examples in the *Amazon VPC User Guide*.

> **Note**
>
> You can use an existing VPC rather than creating a new one, but this tutorial focuses on the scenario where the VPC is configured with a manually-allocated CIDR block, not an IPAM-allocated automatically CIDR block.

To create a VPC

1. Using the IPAM admin account, open the VPC console at https://console.aws.amazon.com/vpc/.
2. Choose **Create VPC**.
3. Enter a name for the VPC, such as tutorial-vpc.
4. Choose **IPv4 CIDR manual input** and enter an IPv4 CIDR block. In this tutorial, we use 10.0.0.0/20.
5. Skip the option to add an IPv6 CIDR block.
6. Choose **Create VPC**.
7. Using the IPAM admin account, open the IPAM console at https://console.aws.amazon.com/ipam/.
8. Choose **Resources** in the left navigation pane.
9. Wait for the VPC that you created to appear. This takes some time to happen and you may need to refresh the window to see it appear. The VPC must be discovered by IPAM before you continue to the next step.

Step 2: Create a resource planning pool

Complete the steps in this section to create a resource planning pool.

To create a resource planning pool

1. Using the IPAM admin account, open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.
3. Choose the private scope.
4. Choose **Create pool**.
5. Under **IPAM scope**, leave the private scope selected.
6. (Optional) Add a **Name tag** for the pool, such as "Resource-planning-pool".
7. Under **Source**, choose **IPAM scope**.
8. Under **Resource planning**, choose **Plan IP space within a VPC** and choose the VPC you created in the previous step. The VPC is the resource used to provision CIDRs to the resource planning pool.
9. Under **CIDRs to provision**, choose the VPC CIDR to provision for the resource pool. The CIDR you provision to the resource planning pool must match the CIDR provisioned to the VPC. In this tutorial, we use 10.0.0.0/20.
10. Choose **Create pool**.
11. Once the pool is created, choose the **CIDR** tab to see the state of the provisioned CIDR. Refresh the page and wait for the CIDR state to change from *Pending-provision* to *Provisioned* before you go to the next step.

Step 3: Create subnet pools

Complete the steps in this section to create two subnet pools that will be used for allocating IP space to subnets.

To create subnet pools

1. Using the IPAM admin account, open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.

3. Choose the private scope.
4. Choose **Create pool**.
5. Under **IPAM scope**, leave the private scope selected.
6. (Optional) Add a **Name tag** for the pool, such as "dev-subnet-pool".
7. Under **Source**, choose **IPAM pool** and select the resource planning pool you created in Step 3. The address family, Resource planning configuration, and Locale are automatically inherited from the source pool.
8. Under **CIDRs to provision**, choose the CIDR to provision for the subnet pool. In this tutorial, we use 10.0.0.0/24.
9. Choose **Create pool**.
10. Once the pool is created, choose the **CIDR tab** to see the state of the provisioned CIDR. Refresh the page and wait for the CIDR state to change from *Pending-provision* to *Provisioned* before you go to the next step.
11. Repeat this process to create another subnet called "prod-subnet-pool".

At this point, if you want to make this subnet pool available to other AWS accounts, you can share the subnet pool. For instructions on how to do that, see Share an IPAM pool using AWS RAM. Then return here to complete the tutorial.

Step 4: Create subnets

Complete these steps to create two subnets.

To create subnets

1. Using the appropriate account, open the VPC console at https://console.aws.amazon.com/vpc/.
2. Choose **Subnets** > **Create subnet**.
3. Choose the VPC you created at the start of this tutorial.
4. Enter a name for the subnet, such as "tutorial-subnet".
5. (optional) Choose an **Availability Zone**.
6. Under **IPv4 CIDR block**, choose **IPAM-allocated IPV4 CIDR block** and choose the dev subnet pool and a /28 netmask.
7. Choose **Create subnet**.

8. Repeat this process to create another subnet. This time choose the prod subnet pool and a /28 netmask.
9. Return to the IPAM console and choose **Resources** in the left navigation pane.
10. Look for the subnet pools you created and wait for the subnets that you created to appear beneath it. This takes some time to happen and you may need to refresh the window to see it appear.

The tutorial is complete. You can create additional subnet pools as needed or you can launch in EC2 instance into one of the subnets.

IPAM publishes metrics related to IP address usage in subnets. You can set CloudWatch alarms on the SubnetIPUsage metric, thereby allowing you to take action when IP utilization thresholds are breached. If, for example, you have a /24 CIDR (256 IP addresses) assigned to a subnet and you want to be notified when 80% of the IPs have been utilized, you can set up a CloudWatch alarm to alert you when this threshold is reached. For more information on creating an alarm for subnet IP usage, see Quick tip for creating alarms.

Step 5: Cleanup

Complete these steps to delete the resources you created with this tutorial.

To clean up the resources

1. Using the IPAM admin account, open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.
3. Choose the private scope.
4. Choose the resource planning pool and choose **Action** > **Delete**.
5. Select **Cascade delete**. The resource planning pool and the subnet pools will be deleted. This will not delete the subnets themselves. They will stay with CIDRs provisioned to them, though the CIDRs will no longer be from an IPAM pool.
6. Choose **Delete**.
7. Delete the subnets.
8. Delete the VPC.

Cleanup is complete.

Allocate sequential Elastic IP addresses from an IPAM pool

IPAM enables you to provision Amazon-owned public IPv4 blocks to IPAM pools and allocate sequential Elastic IP addresses from those pools to AWS resources.

Contiguously-allocated Elastic IP addresses are public IPv4 addresses that are allocated sequentially. For example, if Amazon provides you a public IPv4 CIDR block of `192.0.2.0/30` and you allocate the four available public IPv4 addresses from that CIDR block, an example of four sequential Elastic IP addresses is `192.0.2.0`, `192.0.2.1`, `192.0.2.2`, and `192.0.2.3`.

Contiguously-allocated Elastic IP addresses enable you to simplify your security and networking rules in the following ways:

- **Security administration**: Using sequential IPv4 addresses reduces your firewall management overhead. You can add an entire prefix with a single rule and associate IPs from the same prefix as you scale, saving time and effort.
- **Enterprise access**: You can simplify the address space shared with your clients by using an entire CIDR block instead of a long list of individual public IPv4 addresses. This avoids the need to constantly communicate IP changes as your application scales on AWS.
- **Simplified IP management**: Using sequential IPv4 addresses simplifies public IP management for your central networking team, as it reduces the need to track individual public IPs and instead allows them to focus on a limited number of IP prefixes.

In this tutorial, you'll go through the steps required to allocate sequential Elastic IP addresses from an IPAM pool. You'll create an IPAM pool with an Amazon-provided contiguous public IPv4 CIDR block, allocate Elastic IP addresses from the pool, and learn how to monitor IPAM pool allocations.

Note

- There are charges associated with provisioning Amazon-owned public IPv4 CIDR blocks. For more information, see the **Amazon-provided contiguous IPv4 block** tab on the Amazon VPC pricing page.
- This tutorial assumes you want to create an IPAM using IPAM with a single account. If you want to share Amazon-owned contiguous public IPv4 blocks across accounts, first Integrate IPAM with accounts in an AWS Organization and then Share an IPAM pool using AWS RAM. If you integrate with AWS Organizations, you have the option to create a

service control policy to prevent deprovisioning of the contig IPv4 blocks assigned to the pool.

- You cannot transfer sequential Elastic IP addresses allocated from an IPAM pool to other AWS accounts. Instead, IPAM allows you to share IPAM pools across AWS accounts by integrating IPAM with AWS Organizations (as mentioned above).
- There are limits on the number of Amazon-owned public IPv4 CIDR blocks you can provision and their size. For more information, see Quotas for your IPAM.

Contents

Step 1: Create an IPAM

Complete the steps in this section to create an IPAM.

AWS Management Console

To create an IPAM

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the AWS Management Console, choose the AWS Region in which you want to create the IPAM. Create the IPAM in your main Region of operations.
3. On the service home page, choose **Create IPAM**.
4. Select **Allow Amazon VPC IP Address Manager to replicate data from source account(s) into the IPAM delegate account**. If you do not select this option, you cannot create an IPAM.
5. Choose an **IPAM tier**. For more information about the features available in each tier and the costs associated with the tiers, see the IPAM tab on the Amazon VPC pricing page.

6. Under **Operating regions**, select the AWS Regions in which this IPAM can manage and discover resources. The AWS Region in which you are creating your IPAM is selected as one of the operating Regions by default. For example, if you're creating this IPAM in AWS Region `us-east-1` but you want to create Regional IPAM pools later that provide CIDRs to VPCs in `us-west-2`, select `us-west-2` here. If you forget an operating Region, you can return at a later time and edit your IPAM settings.

   > **Note**
   >
   > If you are creating an IPAM in the Free Tier, you can select multiple operating Regions for your IPAM, but the only IPAM feature that will be available across operating Regions is Public IP insights. You cannot use other features in the Free Tier, like BYOIP, across the IPAM's operating Regions. You can only use them in the IPAM's home Region. To use all IPAM features across operating Regions, create an IPAM in the Advanced Tier.

7. Choose **Create IPAM**.

Command line

The commands in this section link to the AWS CLI Reference documentation. The documentation provides detailed descriptions of the options that you can use when you run the commands.

Create the IPAM with the create-ipam command:

```
aws ec2 create-ipam --region us-east-1
```

Example response:

```
{
    "Ipam": {
        "OwnerId": "320805250157",
        "IpamId": "ipam-0755477df834ea06b",
        "IpamArn": "arn:aws:ec2::320805250157:ipam/ipam-0755477df834ea06b",
        "IpamRegion": "us-east-1",
        "PublicDefaultScopeId": "ipam-scope-01bc7290e4a9202f9",
        "PrivateDefaultScopeId": "ipam-scope-0a50983b97a7a583a",
        "ScopeCount": 2,
        "OperatingRegions": [
```

```
            {
                "RegionName": "us-east-1"
            }
        ],
        "State": "create-in-progress",
        "Tags": [],
        "DefaultResourceDiscoveryId": "ipam-res-disco-02cc5b34cc3f04f09",
        "DefaultResourceDiscoveryAssociationId": "ipam-res-disco-
assoc-06b3a4dccfc81f7c1",
        "ResourceDiscoveryAssociationCount": 1,
        "Tier": "advanced"
    }
}
```

You'll need the PublicDefaultScopeId in the next step. For more information about scopes, see How IPAM works.

Step 2: Create an IPAM pool and provision a CIDR

Complete the steps in this section to create an IPAM pool from which you'll allocate the Elastic IP addresses.

AWS Management Console

To create a pool

1. Open the IPAM console at https://console.aws.amazon.com/ipam/.
2. In the navigation pane, choose **Pools**.
3. Choose the public scope. For more information about scopes, see How IPAM works.
4. Choose **Create pool**.
5. (Optional) Add a **Name tag** for the pool and a **Description** for the pool.
6. Under **Source**, choose **IPAM scope**.
7. Under **Address family**, choose **IPv4**.
8. Under **Resource planning**, leave **Plan IP space within the scope** selected.
9. Under **Locale**, choose the locale for the pool. The locale is the AWS Region where you want this IPAM pool to be available for allocations. The available options come from the operating Regions that you chose when you created your IPAM.

10. Under **Service**, choose **EC2 (EIP/VPC)**. The service you select determines the AWS service where the CIDR will advertised. Currently, the only option is **EC2 (EIP/VPC)**, which means that the CIDRs allocated from this pool will be advertised for the Amazon EC2 service (for Elastic IP addresses).
11. Under **Public IP source**, choose **Amazon-owned**.
12. Under **CIDR to provision**, choose **Add Amazon-owned public CIDR**. Choose a **Netmask** length between `/28` (16 IP addresses) and `/30` (4 IP addresses). You can add up to 2 CIDRs by default. For information about increasing the limits on Amazon-provided contiguous public IPv4 CIDRs, see Quotas for your IPAM.
13. Leave **Configure this pool's allocation rule settings** unselected.
14. (Optional) Choose **Tags** for the pool.
15. Choose **Create pool**.

Ensure that this CIDR has been provisioned before you continue. You can see the state of provisioning in the **CIDRs** tab in the pool details page.

Command line

To create a pool

1. Create an IPAM pool with the create-ipam-pool command. The locale is the AWS Region where you want this IPAM pool to be available for allocations. The available options come from the operating Regions that you chose when you created your IPAM.

```
aws ec2 create-ipam-pool --region us-east-1 --ipam-scope-id ipam-
scope-01bc7290e4a9202f9 --address-family ipv4 --locale us-east-1 --aws-service
 ec2 --public-ip-source amazon
```

Example response with state `create-in-progress`:

```
{

    "IpamPool": {

        "OwnerId": "320805250157",

        "IpamPoolId": "ipam-pool-07ccc86aa41bef7ce",
```

```
        "IpamPoolArn": "arn:aws:ec2::320805250157:ipam-pool/ipam-
pool-07ccc86aa41bef7ce",
        "IpamScopeArn": "arn:aws:ec2::320805250157:ipam-scope/ipam-
scope-01bc7290e4a9202f9",
        "IpamScopeType": "public",

        "IpamArn": "arn:aws:ec2::320805250157:ipam/ipam-0755477df834ea06b",

        "IpamRegion": "us-east-1",

        "Locale": "us-east-1",

        "PoolDepth": 1,

        "State": "create-in-progress",

        "AutoImport": false,

        "AddressFamily": "ipv4",

        "Tags": [],

        "AwsService": "ec2",

        "PublicIpSource": "amazon"

    }

}
```

2. Check that the pool was created successfully with the describe-ipam-pools command.

```
aws ec2 describe-ipam-pools --region us-east-1 --ipam-pool-ids ipam-
pool-07ccc86aa41bef7ce
```

Example response with state `create-complete`:

```
{

    "IpamPools": [
        {
            "OwnerId": "320805250157",
            "IpamPoolId": "ipam-pool-07ccc86aa41bef7ce",
```

```
            "IpamPoolArn": "arn:aws:ec2::320805250157:ipam-pool/ipam-
pool-07ccc86aa41bef7ce",
            "IpamScopeArn": "arn:aws:ec2::320805250157:ipam-scope/ipam-
scope-01bc7290e4a9202f9",
            "IpamScopeType": "public",
            "IpamArn": "arn:aws:ec2::320805250157:ipam/ipam-0755477df834ea06b",
            "IpamRegion": "us-east-1",
            "Locale": "us-east-1",
            "PoolDepth": 1,
            "State": "create-complete",
            "AutoImport": false,
            "AddressFamily": "ipv4",
            "Tags": [],
            "AwsService": "ec2",
            "PublicIpSource": "amazon"
        }
    ]
}
```

3. Provision a CIDR to the pool with the provision-ipam-pool-cidr command. Choose a `--netmask-length` between `/28` (16 IP addresses) and `/30` (4 IP addresses). You can add up to 2 CIDRs by default. For information about increasing the limits on Amazon-provided contiguous public IPv4 CIDRs, see Quotas for your IPAM.

```
aws ec2 provision-ipam-pool-cidr --region us-east-1 --ipam-pool-id ipam-
pool-07ccc86aa41bef7ce --netmask-length 29
```

Example response with state `pending-provision`:

```
{

    "IpamPoolCidr": {
        "State": "pending-provision",
        "IpamPoolCidrId": "ipam-pool-cidr-01856e43994df4913b7bc6aac47adf983",
        "NetmaskLength": 29
    }
}
```

4. Ensure that this CIDR has been provisioned before you continue. You can view the state of provisioning using the get-ipam-pool-cidrs command.

```
aws ec2 get-ipam-pool-cidrs --region us-east-1 --ipam-pool-id ipam-
pool-07ccc86aa41bef7ce
```

Example response with state `provisioned`:

```
{

    "IpamPoolCidrs": [
        {
            "Cidr": "18.97.0.40/29",
            "State": "provisioned",
            "IpamPoolCidrId": "ipam-pool-
cidr-01856e43994df4913b7bc6aac47adf983",
            "NetmaskLength": 29
        }
    ]
}
```

Step 3: Allocate an Elastic IP address from the pool

Complete the steps in this section to allocate an Elastic IP address from the pool.

AWS Management Console

Follow the steps in Allocate an Elastic IP address in the *Amazon EC2 User Guide* to allocate the address, but note the following:

- Ensure that the AWS Region you are in in the EC2 console matches the Locale option you chose when you created the pool in Step 2.
- When you choose the address pool, choose the option to **Allocate using an IPv4 IPAM pool** and choose the pool you created in Step 1.

Command line

Allocate an address from the pool with the allocate-address command. The `--region` you use must match the `-locale` option you chose when you created the pool in Step 2. Include the ID of the IPAM pool you created in Step 2 in `--ipam-pool-id`.

```
aws ec2 allocate-address --region us-east-1 --ipam-pool-id ipam-
pool-07ccc86aa41bef7ce
```

Example response:

```
{
    "PublicIp": "18.97.0.41",
    "AllocationId": "eipalloc-056cdd6019c0f4b46",
    "PublicIpv4Pool": "ipam-pool-07ccc86aa41bef7ce",
    "NetworkBorderGroup": "us-east-1",
    "Domain": "vpc"
}
```

Optionally, you can also choose a specific `/32` in your IPAM pool by using the `--address` option.

```
aws ec2 allocate-address --region us-east-1 --ipam-pool-id ipam-
pool-07ccc86aa41bef7ce --address 18.97.0.41
```

Example response:

```
{
    "PublicIp": "18.97.0.41",
    "AllocationId": "eipalloc-056cdd6019c0f4b46",
    "PublicIpv4Pool": "ipam-pool-07ccc86aa41bef7ce",
    "NetworkBorderGroup": "us-east-1",
    "Domain": "vpc"
}
```

For more information, see Allocate an Elastic IP address in the *Amazon EC2 User Guide*.

Step 4: Associate the Elastic IP address with an EC2 instance

Complete the steps in this section to associate the Elastic IP address with an EC2 instance.

AWS Management Console

Follow the steps in Associate an Elastic IP address in the *Amazon EC2 User Guide* to allocate an Elastic IP address from the IPAM pool, but note the following: When you use AWS Management

Console option, the AWS Region you associate the Elastic IP address in must match the Locale option you chose when you created the pool in Step 2.

Command line

Associate the Elastic IP address with an instance with the associate-address command. The `--region` you associate the Elastic IP address in must match the `--locale` option you chose when you created the pool in Step 2.

```
aws ec2 associate-address --region us-east-1 --instance-id i-07459a6fca5b35823 --
public-ip 18.97.0.41
```

Example response:

```
{
    "AssociationId": "eipassoc-06aa85073d3936e0e"
}
```

For more information, see Associate an Elastic IP address with an instance or network interface in the *Amazon EC2 User Guide*.

Step 5: Track and monitor pool usage

Once you've allocated Elastic IP addresses from the IPAM pool, you can track and monitor IPAM pool allocations.

AWS Management Console

- View the IPAM pool details **Allocations** tab in the IPAM console. Any Elastic IP addresses allocated from the IPAM pool have a **Resource Type** of **EIP**.
- Use Public IP insights:
  - Under **Public IP types**, filter by **Amazon-owned EIPs**. This shows the total number of public IPv4 addresses allocated to Amazon-owned Elastic IP addresses. If you filter by this measure and scroll to **Public IP addresses** at the bottom of the page, you'll see the Elastic IP addresses you've allocated.
  - Under **EIP usage**, filter by **Associated Amazon-owned EIPs** or **Unassociated Amazon-owned EIPs**. This shows the total number of Elastic IP addresses that you have allocated in

your AWS account and that you have or have not associated with an EC2 instance, network interface, or AWS resource. If you filter by this measure and scroll to **Public IP addresses** at the bottom of the page, you'll see details about the filtered resources.

- Under **Amazon-owned IPv4 contiguous IPs usage**, monitor sequential public IPv4 address usage over time and related Amazon-owned IPv4 IPAM pools.

- Use Amazon CloudWatch to track and monitor metrics related to Amazon-provided contiguous public IPv4 blocks that have been provisioned to IPAM pools. For the available metrics specific to contiguous IPv4 blocks, see **Public IP Metrics** under IPAM metrics. In addition to viewing metrics, you can create alarms in Amazon CloudWatch to notify you when thresholds are reached. Creating alarms and setting up notifications with Amazon CloudWatch is outside the scope of this tutorial. For more information, see Using Amazon CloudWatch alarms in the *Amazon CloudWatch User Guide*.

Command line

- View the IPAM pool allocations with the get-ipam-pool-allocations command. Any Elastic IP addresses allocated from the IPAM pool have a **Resource Type** of **eip**.

```
aws ec2 get-ipam-pool-allocations --region us-east-1 --ipam-pool-id ipam-
pool-07ccc86aa41bef7ce
```

Example response:

```
{
     "IpamPoolAllocations": [
        {
            "Cidr": "18.97.0.40/32",
            "IpamPoolAllocationId": "ipam-pool-
alloc-0bd07df786e8148aba2763e2b6c1c44bd",
            "ResourceId": "eipalloc-0c9decaa541d89aa9",
            "ResourceType": "eip",
            "ResourceRegion": "us-east-1",
            "ResourceOwner": "320805250157"
        }
    ]
}
```

- Use Amazon CloudWatch to track and monitor metrics related to Amazon-provided contiguous public IPv4 blocks that have been provisioned to IPAM pools. For the available

metrics specific to contiguous IPv4 blocks, see **Public IP Metrics** under IPAM metrics. In addition to viewing metrics, you can create alarms in Amazon CloudWatch to notify you when thresholds are reached. Creating alarms and setting up notifications with Amazon CloudWatch is outside the scope of this tutorial. For more information, see Using Amazon CloudWatch alarms in the *Amazon CloudWatch User Guide*.

The tutorial is now complete. You've created an IPAM pool with an Amazon-provided contiguous public IPv4 CIDR block, allocated Elastic IP addresses from the pool, and learned how to monitor IPAM pool allocations. Continue to the next section to delete the resources you've created in this tutorial.

Cleanup

Follow the steps in this section to clean up the resources you've created in this tutorial.

Step 1: Disassociate the Elastic IP address

Complete the steps in Disassociate an Elastic IP address in the *Amazon EC2 User Guide* to disassociate the Elastic IP address.

Step 2: Release the Elastic IP address

Complete the steps in Release an Elastic IP address in the *Amazon EC2 User Guide* to release an Elastic IP address from the public IPv4 pool.

Step 3: Deprovision the CIDR from the IPAM pool

Complete the steps in Deprovision CIDRs from a pool to deprovision the Amazon-owned public CIDR from the IPAM pool. This step is required for pool deletion. You will be billed for the Amazon-provided contiguous IPv4 block until this step is complete.

Step 4: Delete the IPAM pool

Complete the steps in Delete a pool to delete the IPAM pool.

Step 5: Delete the IPAM

Complete the steps in Delete an IPAM to delete the IPAM.

The tutorial cleanup is complete.

Identity and access management in IPAM

AWS uses security credentials to identify you and to grant you access to your AWS resources. You can use features of AWS Identity and Access Management (IAM) to allow other users, services, and applications to use your AWS resources fully or in a limited way, without sharing your security credentials.

This section describes the AWS service-linked roles that are created specifically for IPAM and the managed policies attached to the IPAM service-linked roles. For more information about AWS IAM roles and policies, see Roles terms and concepts in the *IAM User Guide*.

For more information about identity and access management for VPC, see Identity and access management for Amazon VPC in the *Amazon VPC User Guide*.

Contents

Service-linked roles for IPAM

IPAM uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role. Service-linked roles are predefined by IPAM and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up IPAM easier because you don't have to manually add the necessary permissions. IPAM defines the permissions of its service-linked roles, and unless defined otherwise, only IPAM can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

Service-linked role permissions

IPAM uses the **AWSServiceRoleForIPAM** service-linked role to call the actions in the attached **AWSIPAMServiceRolePolicy** managed policy. For more information on the allowed actions in that policy, see AWS managed policies for IPAM.

Also attached to the service-linked role is an IAM trust policy that allows the `ipam.amazonaws.com` service to assume the service-linked role.

Create the service-linked role

IPAM monitors the IP address usage in one or more accounts by assuming the service-linked role in an account, discovering the resources and their CIDRs, and integrating the resources with IPAM.

The service-linked role is created in one of two ways:

- **When you integrate with AWS Organizations**

  If you Integrate IPAM with accounts in an AWS Organization using the IPAM console or using the `enable-ipam-organization-admin-account` AWS CLI command, the **AWSServiceRoleForIPAM** service-linked role is automatically created in each of your AWS Organizations member accounts. As a result, the resources within all member accounts are discoverable by IPAM.

  > **Important**
  >
  > For IPAM to create the service-linked role on your behalf:
  >
  > - The AWS Organizations management account that enables IPAM integration with AWS Organizations must have an IAM policy attached to it that permits the following actions:
  >   - `ec2:EnableIpamOrganizationAdminAccount`
  >   - `organizations:EnableAwsServiceAccess`
  >   - `organizations:RegisterDelegatedAdministrator`
  >   - `iam:CreateServiceLinkedRole`
  > - The IPAM account must have an IAM policy attached to it that permits the `iam:CreateServiceLinkedRole` action.

- **When you create an IPAM using a single AWS account**

  If you Use IPAM with a single account, the **AWSServiceRoleForIPAM** service-linked role is automatically created when you create an IPAM as that account.

  > **Important**
  >
  > If you use IPAM with a single AWS account, before you create an IPAM, you must ensure that the AWS account you are using has an IAM policy attached to it that permits the `iam:CreateServiceLinkedRole` action. When you create the IPAM, you automatically

create the **AWSServiceRoleForIPAM** service-linked role. For more information on managing IAM policies, see Editing a service-linked role description in the *IAM User Guide*.

Edit the service-linked role

You can't edit the **AWSServiceRoleForIPAM** service-linked role.

Delete the service-linked role

If you no longer need to use IPAM, we recommend that you delete the **AWSServiceRoleForIPAM** service-linked role.

> **Note**
>
> You can delete the service-linked role only after you delete all IPAM resources in your AWS account. This ensures that you can't inadvertently remove the monitoring capability of IPAM.

Follow these steps to delete the service-linked role using the AWS CLI:

1. Delete your IPAM resources using deprovision-ipam-pool-cidr and delete-ipam. For more information, see Deprovision CIDRs from a pool and Delete an IPAM.
2. Disable the IPAM account with disable-ipam-organization-admin-account.
3. Disable the IPAM service with disable-aws-service-access using the `--service-principal ipam.amazonaws.com` option.
4. Delete the service-linked role: delete-service-linked-role. When you delete the service-linked role, the IPAM managed policy is also deleted. For more information, see Deleting a service-linked role in the *IAM User Guide*.

AWS managed policies for IPAM

If you are using IPAM with a single AWS account and you create an IPAM, the **AWSIPAMServiceRolePolicy** managed policy is automatically created in your IAM account and attached to the **AWSServiceRoleForIPAM** service-linked role.

If you enable IPAM integration with AWS Organizations, the **AWSIPAMServiceRolePolicy** managed policy is automatically created in your IAM account and in each of your AWS Organizations member accounts, and the managed policy is attached to the **AWSServiceRoleForIPAM** service-linked role.

This managed policy enables IPAM to do the following:

- Monitor CIDRs associated with networking resources across all members of your AWS Organization.
- Store metrics related to IPAM in Amazon CloudWatch, such as the IP address space available in your IPAM pools and the number of resource CIDRs that comply with allocation rules.
- Modify and read managed prefix lists.

The following example shows the details of the managed policy that's created.

                "ec2:DescribeSecurityGroupRules",
                "ec2:DescribeSubnets",
                "ec2:DescribeVpcs",
                "ec2:DescribeVpnConnections",
                "ec2:GetIpamDiscoveredAccounts",
                "ec2:GetIpamDiscoveredPublicAddresses",
                "ec2:GetIpamDiscoveredResourceCidrs",
                "ec2:GetManagedPrefixListEntries",
                "ec2:ModifyManagedPrefixList",
```

```
                "globalaccelerator:ListAccelerators",
                "globalaccelerator:ListByoipCidrs",
                "organizations:DescribeAccount",
                "organizations:DescribeOrganization",
                "organizations:ListAccounts",
                "organizations:ListDelegatedAdministrators",
                "organizations:ListChildren",
                "organizations:ListParents",
                "organizations:DescribeOrganizationalUnit"
            ],
            "Resource": "*"
        },
        {
            "Sid": "CloudWatchMetricsPublishActions",
            "Effect": "Allow",
            "Action": "cloudwatch:PutMetricData",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "cloudwatch:namespace": "AWS/IPAM"
                }
            }
        }
    ]
}
```

The first statement in the preceding example enables IPAM to monitor the CIDRs used by your single AWS account or by the members of your AWS Organization.

The second statement in the preceding example uses the `cloudwatch:PutMetricData` condition key to allow IPAM to store IPAM metrics in your `AWS/IPAM` Amazon CloudWatch namespace. These metrics are used by the AWS Management Console to display data about the allocations in your IPAM pools and scopes. For more information, see Monitor CIDR usage with the IPAM dashboard.

Updates to the AWS managed policy

View details about updates to AWS managed policies for IPAM since this service began tracking these changes.

Change	Description	Date
AWSIPAMServiceRolePolicy	Actions added to the AWSIPAMServiceRolePolicy managed policy (ec2:ModifyManagedPrefixList, ec2:DescribeManagedPrefixLists, and ec2:GetManagedPrefixListEntries) to enable IPAM to modify and read managed prefix lists.	October 31, 2025
AWSIPAMServiceRolePolicy	Actions added to the AWSIPAMServiceRolePolicy managed policy (`organizations:ListChildren` ,`organizations:ListParents` , and `organizations:DescribeOrganizationalUnit`) to enable IPAM to get the details of Organizational Units (OUs) in AWS Organizations so that customers can use IPAM at the OU level.	November 21, 2024
AWSIPAMServiceRolePolicy	Action added to the AWSIPAMServiceRolePolicy managed policy (`ec2:GetIpamDiscoveredPublicAddresses`) to enable IPAM to get public IP addresses during resource discovery.	November 13, 2023
AWSIPAMServiceRolePolicy	Actions added to the AWSIPAMServiceRole	November 1, 2023

Change	Description	Date
	Policy managed policy (`ec2:DescribeAccountAttributes`, `ec2:DescribeNetworkInterfaces`, `ec2:DescribeSecurityGroups`, `ec2:DescribeSecurityGroupRules`, `ec2:DescribeVpnConnections`, `globalaccelerator:ListAccelerators`, and `globalaccelerator:ListByoipCidrs`) to enable IPAM to get public IP addresses during resource discovery.	
AWSIPAMServiceRolePolicy	Two actions added to the AWSIPAMServiceRolePolicy managed policy (`ec2:GetIpamDiscoveredAccounts` and `ec2:GetIpamDiscoveredResourceCidrs`) to enable IPAM to get the AWS accounts and resource CIDRs being monitored during resource discovery.	January 25, 2023
IPAM started tracking changes	IPAM started tracking changes for its AWS managed policies.	December 2, 2021

Example policy

The example policy in this section contains all the relevant AWS Identity and Access Management (IAM) actions for full IPAM usage. Depending on how you are using IPAM, you may not need to include all of the IAM actions. For a full experience using the IPAM console, you may need to include additional IAM actions for services such as AWS Organizations, AWS Resource Access Manager (AWS RAM), and Amazon CloudWatch.

```

Quotas for your IPAM

This section lists the quotas related to IPAM. The Service Quotas console also provides information about IPAM quotas. You can use the Service Quotas console to view default quotas and request quota increases for adjustable quotas. For more information, see Requesting a quota increase in the *Service Quotas User Guide*.

Name	Default	Adjustable
Amazon-provided contiguous public IPv4 CIDR blocks	2	Yes. Contact the AWS Support Center as described in AWS service quotas in the *AWS General Reference*.
Amazon-provided contiguous public IPv4 CIDR block netmask length	/28	Acceptable size is between /28 and /30. To request an increase, contact the AWS Support Center as described in AWS service quotas in the *AWS General Reference*.
Amazon-provided IPv6 CIDR block netmask length	/52	Yes. Contact the AWS Support Center as described in AWS service quotas in the *AWS General Reference*.
Amazon-provided IPv6 CIDR blocks per Regional pool	1	Yes. Contact the AWS Support Center as described in AWS service quotas in

Name	Default	Adjustable
		the *AWS General Reference*.
Autonomous System Numbers (ASNs) that you can bring to IPAM	5	Yes. Contact the AWS Support Center as described in AWS service quotas in the *AWS General Reference*.
CIDRs per pool	50	Yes
Enabled targets per IPAM policy	100	Yes. To request an adjustment to the quota, contact the AWS Support Center as described in AWS service quotas in the *AWS General Reference*.
IPAM administrators per organization	1	No
IPAMs per Region	1	No
IPAM policies per IPAM	10	Yes. To request an adjustment to the quota, contact the AWS Support Center as described in AWS service quotas in the *AWS General Reference*.

Name	Default	Adjustable
IPAM policy allocation rules per resource-locale pair*	10	Yes. To request an adjustment to the quota, contact the AWS Support Center as described in AWS service quotas in the *AWS General Reference*.
Organizational unit exclusions per resource discovery	10	Yes. Contact the AWS Support Center as described in AWS service quotas in the *AWS General Reference*.
Pool depth (the number of pools within pools)	10	Yes
Pools per scope	50	Yes
Prefix list resolvers per IPAM	10	Yes
Prefix list resolver targets per prefix list resolver	50	Yes. Contact the AWS Support Center as described in AWS service quotas in the *AWS General Reference*.
Rules per prefix list resolver	100	Yes. Contact the AWS Support Center as described in AWS service quotas in the *AWS General Reference*.

Name	Default	Adjustable
CIDR entries per prefix list resolver version	1000	Yes. Contact the AWS Support Center as described in AWS service quotas in the *AWS General Reference*.
Resource discovery associations per IPAM	5	Yes
Resource discoveries per Region	1	No
Resource utilization metrics	50	Yes. Contact the AWS Support Center as described in AWS service quotas in the *AWS General Reference*.
Scopes per IPAM	5	Yes. When you create an IPAM, a private and public default scope are created for you. If you want to create additiona l scopes, they will be private scopes. You cannot create additional public scopes.

* *Resource-locale pair:* When setting allocation rules, you must specify both a resource type (the AWS resource like EIPs, ALBs, or RDS clusters) and a locale (the AWS Region or Local Zone where the rule applies). Allocation rules are scoped to this resource type and locale combination. For example, if you're setting a policy for EIPs in us-east-1, you can set up to 10 rules for that specific resource-locale pair*.

Pricing for IPAM

Amazon VPC IP Address Manager (IPAM) is a service that helps you manage your IP address space across your AWS resources and on-premises networks. IPAM provides a centralized way to plan, monitor, and control the IP addresses used by your AWS and on-premises resources.

This section describes how to view pricing-related information and your current IPAM costs.

Contents

View pricing information

IPAM is offered in two tiers: Free and Advanced Tier. For more information about the features available in each tier and the costs associated with the tiers, see the **IPAM** tab on the Amazon VPC pricing page.

View your current costs and usage using AWS Cost Explorer

When you use the IPAM Advanced Tier, you pay an hourly price per active IP address managed by IPAM. If you want to view and analyze your IPAM costs and usage, you can use the AWS Cost Explorer.

1. Open the AWS Cost Management console at https://console.aws.amazon.com/cost-management/home.
2. Choose **Cost Explorer**.
3. Filter for IPAM usage by choosing **Usage type** and entering **`IPAddressManager`**.
4. Select one or more checkboxes. Each of them represents a different AWS Region.
5. Choose **Apply**.

If, for example, you select *USE1-IPAddressManager-IP-Hours(Hrs)* and us-east-1 is your IPAM home Region, you'll see the number of active IP hours billed by IPAM in all Regions and the cost. If, say, the usage in hours is 18, this means that you could have 1 active IP address for 18 hours, 3 IP

addresses in 3 different Regions each active for 6 hours, or any combination of these that add up to 18 hours.

For more information about AWS Cost Explorer, see Analyzing your costs with AWS Cost Explorer in the *AWS Cost Management User Guide*.

Related information

While the AWS technical documentation site is a comprehensive resource, there are many other places to find information about AWS services. AWS blogs, whitepapers, case studies, and community forums can provide valuable insights, real-world examples, and alternative perspectives beyond the official technical details. Exploring these diverse sources can give you a more well-rounded understanding of AWS offerings.

The following related resources can help you as you work with Amazon VPC IP Address Manager:

- Amazon VPC IP Address Manager Best Practices: An AWS blog on best practices for planning and creating a scalable address scheme with Amazon VPC IP Address Manager.
- Network Address Management and Auditing at Scale with Amazon VPC IP Address Manager: An AWS blog that introduces Amazon VPC IP Address Manager and shows you how to use the service in the AWS console.
- Configure fine-grained access to your resources shared using AWS Resource Access Manager: An AWS blog that explains how to share an IPAM pool with the accounts in an AWS Organizations organization unit.
- Visualize enterprise IP address management and planning with CIDR map: An AWS blog that explains how to visualize your entire IPv4 and IPv6 landscape using the IPAM CIDR map in the IPAM console.

Document history for IPAM

The following table describes the releases for IPAM.

Feature	Description	Release Date
Monitor BGP route protection and delegate RPKI for BYOIP prefixes	You can now monitor RPKI validity, ROA strength, and route overlaps for your BYOIP prefixes across accounts and Regions, and delegate ROA management to AWS with delegated RPKI. This feature requires IPAM Advanced Tier.	August 6, 2026
Bring your own IP to CloudFront using IPAM	Use IPAM to manage your BYOIP CIDRs for AWS global services, starting with CloudFront anycast services.	November 21, 2025
Define public IPv4 allocation strategy with IPAM policies	You can now use IPAM policies to define rules that map AWS services to specific IPAM pools, helping define public IPv4 allocation strategy.	November 19, 2025
Integrate IPAM with Infoblox infrastructure	You can now integrate IPAM with Infoblox infrastructure, enabling you to manage AWS IP addresses through your existing Infoblox workflows while gaining cloud-native AWS capabilities. This integration is available for private scopes and requires IPAM Advanced Tier.	November 7, 2025
Automate prefix list updates	You can now use IPAM prefix list resolvers to automate prefix list updates based on IPAM pool CIDRs.	October 31, 2025
Manage alarms from IPAM console	You can now create and manage Amazon CloudWatch alarms directly from the IPAM console. IPAM-related alarms will appear as	August 21, 2025

Feature	Description	Release Date
	warning bars and visual indicators when in INSUFFICIENT_DATA or ALARM states.	
Enable cost distribution	When you enable cost distribution, you distribute the charges for active IP addresses to the accounts using the IP addresses rather than to the IPAM owner. This is useful for large organizations where the delegated IPAM admin manages the IP addresses centrally using IPAM and each account is responsible for their own usage, eliminating the need for manual billing calculations.	May 1, 2025
Exclude organizational units from IPAM	If your IPAM is integrated with AWS Organizations, you can now exclude organizational units from IPAM. IPAM will not manage the IP addresses in accounts in organizational unit exclusions.	November 21, 2024
AWS managed policy updates - Update to an existing policy	Existing AWSIPAMServiceRolePolicy updated.	November 21, 2024
Allocate sequential Elastic IP addresses from an IPAM pool	IPAM now enables you to provision Amazon-owned public IPv4 blocks to IPAM pools and allocate sequential Elastic IP addresses from those pools to AWS resources. Sequential Elastic IP addresses enable you to simplify your networking and security allowlisting needs.	August 28, 2024
Private IPv6 GUA and ULAs	You can now provision private IPv6 GUA and ULA ranges to an IPAM pool in a private scope. Private IPv6 addresses are only available in IPAM. For more information about private IPv6 addressing, see Private IPv6 addresses in the *Amazon VPC User Guide*.	August 8, 2024

Feature	Description	Release Date
IPAM Free and Advanced Tiers	You can now choose between Free Tier and Advanced Tier for your IPAM.	November 17, 2023
Public IP insights	Previously, you could only view public IP insights in a single Region. You can now view public IP insights across Regions. In addition, you can now view public IP address insights in Amazon CloudWatch.	November 17, 2023
Plan VPC IP address space for subnet IP allocations	You can now use IPAM to plan for subnet IP space within a VPC and monitor IP address-related metrics at the subnet and VPC level.	November 17, 2023
Bring your own ASN (BYOASN)	You can now bring your own autonomous system number (ASN) to AWS.	November 17, 2023
AWS managed policy updates - Update to an existing policy	Existing AWSIPAMServiceRolePolicy updated.	November 17, 2023
AWS managed policy updates - Update to an existing policy	Existing AWSIPAMServiceRolePolicy updated.	November 1, 2023
Resource utilization metrics	IPAM now publishes IP utilization metrics for resources that the IPAM monitors to Amazon CloudWatch.	August 2, 2023
Public IP insights	Public IP insights shows you all public IPv4 addresses used by services in this Region in your account. You can use these insights to identify public IPv4 address usage and view recommendations to release unused Elastic IP addresses.	July 28, 2023

Feature	Description	Release Date
AWS managed policy updates - Update to an existing policy	Existing AWSIPAMServiceRolePolicy updated.	January 25, 2023
Integrate IPAM with accounts outside of your organization	You can now manage IP addresses outside of your organization from a single IPAM account and share IPAM pools with the accounts of other AWS Organizations.	January 25, 2023
Amazon-provided IPv6 contiguous CIDR block for IPAM pools	When you create an IPAM pool in the public scope, you can now provision an Amazon-provided IPv6 contiguous CIDR block to the pool. For more information, see Create IPv6 address pools in your IPAM.	January 25, 2023
Initial release	This release introduces Amazon VPC IP Address Manager.	December 2, 2021
